Ferroelectric thin films and superlattices with nanoscale dimensions exhibit a competition of energetic phenomena that produce configurations of the polarization that are distinct from bulk materials. These configurations have a profound effect on the equilibrium and driven dynamics of the nanoscale material. These dynamics are coupled to the structure of these layers and can be observed in synchrotron radiation or free-electron-laser structural studies. For example, the nanoscale polarization configuration of PtTiO3/SrTiO3 (PTO/STO) superlattices, for example, exhibits equilibrium fluctuations that arise from the existence of many configurations with nearly identical free energy. The optically driven dynamics of the PTO/STO superlattice include a picosecond-scale distortion of the polarization in response to the optically induced acoustic pulse and a change in the magnitude of the polarization of the PTO due to polarization screening. The effect of polarization screening is comparatively larger in a strongly BaTiO3/CaTiO3 (BTO/CTO) superlattice. In BTO/CTO superlattice screening effects following above-bandgap excitation lead to a reduction in the polarization of the CaTiO3 component. The characteristic timescale for the development of these effects is on the scale of several picoseconds to tens of picoseconds, set by the propagation of acoustic pulses through the system. Further picosecond-scale diffraction studies reveal that the nanoscale structure affects the longitudinal acoustic sound velocity. There are prospects to employ these effects to affect structural parameters such as the oxygen octahedral tilt that affect other properties of ferroelectrics as well as the magnetism of multiferroics.

Transferring Orbital Angular Momentum to an Electron Beam Reveals Toroidal and Chiral Order Kayla X. Nguyen1,2; 1University of Illinois at Urbana-Champaign, United States; 2University of Oregon, United States

Orbital angular momentum and torque transfer play central roles in a wide range of magnetic textures and devices including skyrmions and spin-torque electronics. Unlike magnetic toroidal order, electric toroidal order, found in analogous topological structures in ferroelectrics, do not couple directly to linear external fields. Instead, we show that the presence of an electric toroidal moment in a ferro-fluidal phase transfers a measurable torque and orbital angular momentum to a localized electron beam in the ballistic limit. We record these torque transfers from a high-energy electron beam using a momentum-resolved detector. This approach provides a high-sensitivity method to detect polarization fields and their more complex order parameters and topologies. In addition to toroidal order, we also demonstrate high-precision measurements of vorticity and chirality for polar vortex-like phases.[1]

Phase Transformations in 2D Van der Waals Trichlorides: Insights from Cryogenic Scanning Transmitting Electron Microscopy Miaofang Chi; Oak Ridge National Laboratory, United States

Two-dimensional (2D) van der Waals (vdW) materials and their heterostructures offer an exceptional platform for investigating intriguing physical phenomena and implementing diverse applications. While it is widely acknowledged that lattice structural transformations often coincide with changes in electronic and spin structures, leading to the emergence of exotic quantum phenomena, it remains uncertain what the same structural transformations observed in bulk materials also occur in thin flake samples. As a result, a comprehensive understanding of the structure-property relationship in multi-layered 2D vdW materials is often lacking. In our recent studies, we aim to unveil the thickness-dependent phase transformations and changes in excitation states in several model 2D vdW trichlorides. To achieve this, we employ state-of-the-art techniques such as cryogenic atomic-resolution scanning transmission electron microscopy (STEM) and monochromated electron energy loss spectroscopy (EELS). By analyzing these materials with different numbers of layers at the atomic level, our findings provide insights into the layer-number-dependency that are crucial for harnessing the unique quantum
characteristics of thin-layer 2D vdW materials in various device applications.

Differential Phase Contrast STEM Imaging of Topological Structures Naoya Shibata; The University of Tokyo, Japan

Differential phase contrast scanning transmission electron microscopy (DPC STEM) is a powerful technique for directly characterizing local electromagnetic field distribution inside materials and devices. In recent years, new magnetic objective lens systems have realized a magnetic field-free environment at the sample position and created new opportunities for magnetic imaging. In this talk, we will introduce our recent applications of using DPC STEM to image magnetic skyrmions, imaging ferroelectric domain walls, and topological spin structures.

The Dynamics of Magnetic Helices in an Amorphous Material with Coherent X-Rays Sophie Morley1, Amah Singh1, Ryan Tumbleson1,2, Emily Hollingsworth1; Ahmad Us Saleheen1, Margaret McCarter1, Peter Fischer1,2, Frances Hellman3, Stephen Kevan4, Sujoy Roy5; Lawrence Berkeley National Laboratory, United States; 2University of California, Berkeley, United States

Synchrotron x-rays are a powerful element-specific probe for the study of magnetic ordering of a material. We measure the diffraction from a magnetic helix of pitch ~ 80 nm in a structurally amorphous FeGe thin film through its magnetic phase transition. We select the coherent part of the x-ray beam to produce an interference pattern known as speckle. The speckle pattern acts as a fingerprint of the specific microscopic configuration of the helical domains and their disorder. Taking speckle patterns over time gives us a way to characterise the dynamics over ~ 10-micron field of view but with nanoscale spatial sensitivity and ms to hour time sensitivity. We identify static and dynamic parts of the speckle throughout the transition which follow a universal behavior over several compositions. We extract faster dynamics at temperatures much lower than the transition temperature which we attribute to the motion of topological defects and on increasing temperature we observe on average slower fluctuations but from a larger volume of the sample. We have also performed micromagnetic simulations to model these disordered helical spin structures in support of our experimental findings.

Behavior of Magnetic Skyrmions Lattices at the Nanoscale Observed using In Situ Lorentz Transmission Electron Microscopy Amanda K. Petford-Long1,2; Yue Li3, Arthur McCray2,1 and Charudatta Phatak1,2; 1Argonne National Laboratory, United States; 2University of California, Berkeley, United States

Understanding the behavior of nanoscale magnetic structures relies on being able to understand the complex interplay of the energy terms that control this behavior at a local scale. The relative contribution of these energy terms can be modified by parameters such as geometric confinement and interactions between adjacent magnetic nanostructures. In addition, it is important to be able to explore how a magnetic nanostructure responds to an external driving force, such as temperature, and electric or magnetic fields. We use Lorentz transmission electron microscopy (STEM) combined with in-situ magnetizing and cooling experiments to elucidate the micromagnetic behavior at the sub-micron scale in nanomagnetic structures. By comparing the experimental and simulated results we gain a detailed understanding of the way in which the various energy terms contribute to the behavior that we observe.

The focus of this presentation will be on thin films of van der Waals materials that host magnetic skyrmions and other topological spin structures in which we make use of cryoEM to explore the way in which order in the skyrmions lattices evolves, the origin of this behavior, and the energy terms that control the behavior as a function of temperature and applied field.

9:00 AM QT03.06.02
Observation of Magnetic Resonance Modes in Polar Skyrmion Material VOSeO4 Araki Tomomao1; Takashi Kurumaji2, Masahito Mochizuki2, Yoshinori Tokura1,4, Rina Takagi4 and Shinichiro Seki1,4; 1The University of Tokyo, Japan; 2Waseda University, Japan; 3Japan Science and Technology Agency (JST), Japan; 4RIKEN, Japan

The magnetic skyrmion is a vortex structure of electron spins that behaves as a stable particle protected by topology. VOSeO4 is a magnetic insulator with a polar crystal structure (space group P6cc) and is one of a few materials that have been confirmed to exhibit a Néel-type magnetic skyrmion lattice[1, 2]. In this study, we experimentally investigate the microwave response of VOSeO4 to clarify the magnetic resonance dynamics. As a function of temperature and magnetic field, this compound hosts a rich variety of magnetic phases, including the triangular skyrmion lattice (tri. SKL) and cycloidal spin states. In the tri. SKL phase, clockwise mode (CW), counterclockwise mode (CCW), and breathing mode (BR) have been identified. We also identified three
distinctive magnetic resonance modes in the cycloid spin state, which corresponds to the rotational oscillation of local magnetic moment around the x, y, and z axes, respectively. The observed magnetic resonance spectra are well reproduced by theoretical calculations based on the magnetic Hamiltonian considering the Dzyaloshinskii-Moriya interaction and uniaxial anisotropy. The present results will contribute to the general understanding of the coherent dynamics of skyrmion and helical spin states in polar magnetic systems.

9:15 AM QT03.06.03 Effects of Dirac Band Tilting on Thermomagnetic Properties in Weyl Semimetals Eleanor Scott1, Poulomi Chakraborty2, Satya Guin3,4, Brian Skinner2 and Sarah J. Watzman1; 1University of Cincinnati, United States; 2The Ohio State University, United States; 3Max Planck Institute for Chemical Physics of Solids, Germany; 4Birla Institute of Technology and Science, India

The topological and semimetallic effects of Weyl semimetals make them excellent candidates for magneto-thermoelectric transport. Previous work in the thermoelectric properties of Type I Weyl semimetals (WSMs) has found that this class of materials possess both a large magneto-Seebeck effect and Nernst effect simultaneously, is very sensitive to doping, and that magneto-thermoelectric effects are maximized when the temperature is comparable to the Fermi energy. [1, 2]. Here, we shift our focus to Type II WSMs, which possesses asymmetric Dirac bands, unlike the band symmetry assumed in Type I WSMs. Our candidate material is WTe2, and previous single-crystalline data observed an extremely large Nernst thermopower, exceeding 7,000 μV K⁻¹ at 11.3 K and 9 T [3]. However, literature does not include full magneto-thermo-transport data over a broad temperature range, which we present here in polycrystalline WTe2. Experimental results indicate that unlike the behavior observed in the Type I WSM [1], the magneto-Seebeck effect is significantly reduced and is not maximized in the same temperature range as the Nernst effect. Additionally, the Nernst thermopower of this Type II WSM did not exhibit an anomalous Nernst effect beyond cryogenic temperatures, while NbP, a Type I WSM, exhibited anomalous behavior over a broad temperature range.

Our experimental work is complemented by theoretical models of the thermoelectric behavior. Previous theoretical models created for the NbP work matched well with the transport behavior seen in the experimental results. This model is then altered to account for the tilted band structure and transport properties specific to WTe2. By comparing both the experimental and theoretical results of thermoelectric transport in NbP and WTe2, we can determine how the tilting of Dirac bands effects magneto-thermo-electric transport behavior in WSMs.

9:30 AM BREAK

10:00 AM QT03.06.04 Thin-Film Realization of an Improper Ferroelectric Quantum Spin Liquid Candidate Johanna Nordlander1,2, Harvard University, United States; 2Paul Drude Institute for Solid State Electronics, Germany

Magnetically frustrated materials offer a playground for realizing exotic magnetic ground states such as quantum spin ices and spin liquids that have been proposed as building blocks in quantum computing and as potential hosts for unconventional superconductivity. The ability to synthesize such materials in thin-film form is necessary for their integration into the proposed device architectures and also allows further tuning of the magnetic ground state with dimensionality and epitaxial strain. However, thin-film realizations of quantum spin liquid candidate materials remain scarce. Here, we use reactive oxide molecular beam epitaxy to synthesize the first thin films of hexagonal TbInO3, a magnetically frustrated rare-earth system that was recently proposed as a spin liquid candidate. In bulk, TbInO3 exhibits geometrically driven improper ferroelectricity similar to the multiferroic hexagonal manganites, and displays the same topologically protected vortex domain pattern. The underlying lattice distortion causing this domain pattern imposes a stuffed honeycomb geometry on the quasi-two-dimensional Tb³⁺ sublattice which harbors the magnetic frustration in TbInO3. Here, we investigate the ferroelectric distortion in our epitaxial TbInO3 thin films using in-situ RHEED and post-deposition HAADF-STEM. We furthermore use SQUID magnetometry and X-ray spectroscopy to investigate the low-temperature magnetic behavior. Our work constitutes one of the few thin-film realizations of a quantum spin liquid candidate, and opens up for the use of epitaxy to further manipulate the unusual coexistence of ferroelectricity and spin liquid physics in this thin-film system.

10:30 AM QT03.06.05 Large Anomalous Frequency Shift in Perpendicular Standing Spin Wave Modes in BiYIG Films Induced by Thin Metallic Overlayers Byunghun Lee, Takian Fakhru, Caroline A. Ross and Geoffrey Beach, Massachusetts Institute of Technology, United States

Interface-driven phenomena in magnetic insulators is gaining attention owing to the possibility to control magnetization dynamics and magnetic textures in low-dissipation materials. Pure spin signals can be transported in magnetic insulators through magnon excitations, and controlling the nature of these excitations may lead to new insights into magnetization dynamics and novel spin wave devices. [1]

In this work, the influence of metallic overlayers on the spin wave dynamics of thin Bi-substituted yttrium iron garnet films is studied using Brillouin light scattering spectroscopy. [2] It is found that the magneto-static Damon-Eschbach modes exhibit a significant frequency shift when Pt, Au, or Cu films are deposited upon them, which arises from an interfacial contribution to the effective magnetic anisotropy. In addition, there is an unexpectedly large shift in the perpendicular standing spin wave mode frequencies that cannot be explained by anisotropy-induced surface spin pinning. Rather, the experimental observations are consistent with an interface-induced decrease in the effective thickness within with the standing waves are confined, increasing the exchange contribution to the mode frequency. It is suggested that this additional confinement may result from spin pumping at the insulator/metal interfaces, which results in a locally-overdamped interface region. We propose a phenomenological model that can describe the observation in terms of an interfacial region where the spin-orbit coupling plays a crucial role and the local effective damping associated with spin-pumping torque is relatively large, which would qualitatively explain the anomalously-large metal-induced frequency shifts. [3] These results uncover a previously-unidentified interface-driven change in magnetization dynamics that may be exploited to locally control and modulate magnonic properties in extended films.

The CuOSeO₃ material system has gained a lot of interest over the last 10-15 years because it is the only multiferroic insulator known to host magnetic skyrmions. This material falls into a B20 class which has a non-centrosymmetric cubic crystal lattice and crystallises in a P2₁3 space group. Most materials in this class, such as MnSi, Fe₃Ge, and Fe₃CoSi, despite having different compositions, have been observed to host magnetic skyrmions. This suggests that the role of the crystal structure might influence the capability of the material to host skyrmions. The skyrmion formation is a result of the four different Cu²⁺ sites, which have a 3-down 1-up spin arrangement with Ferromagnetic (FM) and Antiferromagnetic (AFM) super-exchange interactions being present. The lack of inversion symmetry in the corner shared O-Cu₄ tetrahedra result in an appreciable Dzyaloshinskii–Moriya interaction (DMI) between Cu²⁺ sites; this competes with the super-exchange interactions leading to spin canting that underpins the formation of helical/conical spin textures (depending on temperature and applied magnetic field strength). However, due to these systems’ complex spin and charge interactions, the underlying quantum-mechanical processes behind these phenomena are still not fully understood. Further experiments are required; as such, this project aims to provide details on the roles played by the crystal structure that may enable the magnetic structures observed in different conditions.

For this project, the focus is on the relationship between the crystal structure and the magnetic structures observed in the CuOSeO₃ material system. By manipulating the magnetic Cu sites and non-magnetic Se sites, the spin interactions between the magnetic sites will change, resulting in changes to the interacting Heisenberg and Dzyaloshinskii-Moriya interactions that are known to form skyrmions. These interactions are highly localised by magnetic ions, which makes them sensitive to spatial changes. Non-magnetic doping of substituting Te into the Se sites results in chemical pressure and expansion of the unit cell, which can change the spacing between atoms and the subtle crystal distortions should have an impact on these interactions. While magnetic doping by substituting Co²⁺ into the Cu²⁺ sites should have a large impact on these magnetic interactions due to the Co²⁺ ion having a stronger moment than Cu²⁺. This, in turn, should change the nature of the formation of magnetic skyrmions in this material. Understanding the role that subtle distortion to the magnetic network plays on the formation and stability of topological spin structures will be vital in designing materials for spintronics. This might, in fact, provide a guide in developing ambient condition spintronics materials, in which their absences have hindered the technological application of these topological spin structures.

We will present data from high-resolution synchrotron powder XRD and neutron powder diffraction to present the effects of magnetic and non-magnetic doping on both the crystal and magnetic structure of the material. Along with small-angle neutron scattering to confirm the presence of the helical and skyrmion phases. While in-depth SQUID magnetometry measurements were carried out to see the effects of doping on magnetisation. This collection of data aims to build an understanding of how the crystal structure plays a more important in the formation of skyrmions than is currently believed in literature.

Recent research in the field of thermoelectrics (TEs) has been focused on transverse TE devices which surpass their traditional longitudinal counterparts in a few facets, including their elimination of complex n- and p-type legs in exchange for one material whose TE output scales with device size. However, transverse TE materials require a magnetic field for operation, which can increase the complexity of device design. Though ferromagnetic materials have been shown to exhibit anomalous thermoelectric transport in the absence of magnetic field, these materials often have a large magnetization which can negatively impact electronic components in device applications. Canted antiferromagnetic topological semimetals, such as YbMnBi₂ and YbMnSb₂, have been shown to exhibit these large anomalous effects with low magnetization and high mobility, thus making them reasonable candidates for transverse TE applications.

Previous research on single crystalline YbMnBi₂, a Weyl semimetal, reported a notably large anomalous Nernst conductivity of ~10 A m⁻² K⁻¹ near 80 K, owing to the contribution of Mn to a non-zero Berry curvature and the strong spin-orbit coupling associated with $\text{Bi}$ [1]. In addition to this large anomalous Nernst conductivity, YbMnBi₂ is highly anisotropic, which is beneficial in device applications as it allows for simultaneously low electrical resistivity and thermal conductivity in different crystallographic directions. While these results are intriguing, polycrystalline materials are more applicable to TE devices as single crystals can be challenging to synthesize. In this work, polycrystalline samples of YbMnBi₂ are synthesized, and their magneto-thermoelectric transport is characterized as a function of temperature and externally applied magnetic field. Transport data is analyzed with an emphasis on the anisotropy present in single-crystalline samples being removed in polycrystalline samples. YbMnSb₂, a similarly anisotropic, canted antiferromagnetic Weyl semimetal. Previous work has reported a large, longitudinal thermopower of ~160 mV/K near 300 K [2]. However, transverse thermoelectric transport has yet to characterized. In this work, the anomalous Nernst and magneto-Seebeck effects of YbMnSb₂ are characterized as functions of temperature and magnetic field. Special attention is given to crystallographic orientation as well, as Dirac bands are expected to dominate transport in the ab-plane while parabolic bands dominate parallel to the c-axis.

Dy-Doping of Zn/Al Substituted Nickel Ferrite for Non-Collinear Magnetic Order

Verena Ney¹, Celina Parzer¹, Fabrice Wilhelm², Andrei Rogalev² and Andreas Ney²; ¹Johannes Kepler University, Austria; ²European Synchrotron Radiation Facility, France

Zn/Al substituted nickel ferrite (NiZAF) has been reported to be a very promising ferrimagnetic insulator with a Curie temperature well above room-temperature which exhibits a very low intrinsic magnetic damping [1]. Thin films of this magnetic spinel can be prepared using pulsed laser ablation [1] or reactive magnetron sputtering from single targets [2] as well as co-sputtering to vary the individual constituents independently [3]. Element selective characterization allows to determine the incorporation of the cationic species [1,2] and correlate them with the desired magnetic properties [3]. Besides an intrinsic low magnetic damping also non-collinear spin textures such as skyrmions are of potential interest for spintronic or magnonic applications. For magnetic spinel such non-collinear magnetic textures have been reported to be generated either by structural effects in nanoparticles or ultrathin films, e.g. [5] or by doping with trivalent rare earth ions such as Dy [6]. In this work we will report on a systematic growth series of NiZAF films which were doped...
with Dy by means of co-sputtering. Due to its large ionic radius Dy distorts the crystal structure of the hosting spinel and the low coercive field as well as the low magnetic damping significantly increase. Nonetheless, the Curie temperature well-above room-temperature remains and the spinel structure is maintained on a local scale as evidenced by x-ray linear dichroism studies. Upon Dy doping a local minimum in the zero-field cooled M(T) curves develops which can be taken as a first indication for a non-collinear spin-arrangement which will be subject to further investigations and the latest results for the magnetic texture will be presented.

Formation and Structural Transition of Magnetic Skyrmion Lattices in a Centrosymmetric Metallic Magnet Rina Takagi1,2; The University of Tokyo, Japan; 2JST PRESTO, Japan

Topological objects in condensed matters have attracted attention as the source of rich electromagnetic phenomena. Magnetic skyrmions are topologically protected particle-like objects appearing as swirling spin texture in magnets and intensively studied as the potential candidate of high-density information carrier in magnetic memory [Y. Tokura and N. Kanazawa, Chem. Rev. 121, 2857 (2021)]. Magnetic skyrmions were originally observed in noncentrosymmetric magnets, in which a competition between the ferromagnetic exchange and Dzyaloshinskii-Moriya interactions stabilizes a triangular skyrmion lattice (SkL) state. Recently, on the other hand, SkL states are also found for centrosymmetric rare-earth intermetallic compounds, which commonly host nanoscale skyrmions, leading to relatively large topological Hall effect. In the latter systems, so far, the SkL always reflects the symmetry of underlying crystal lattice, and a different mechanism of skyrmion formation via itinerant electrons has been proposed.

Here we report the discovery of multiple topological magnetic phases in a centrosymmetric metallic magnet EuAl4 [R. Takagi et al., Nat. Commun. 13, 1472 (2022)]. By means of neutron and resonant X-ray scattering experiments, EuAl4 turns out to show multiple-step reorientation of the fundamental magnetic modulation vector as a function of external magnetic field, which leads to the appearance of two distinctive SkL states, i.e., square and rhombic lattices of skyrmions with a diameter of 3.5 nm. We also found several other double-$Q$ states in this compound, one of which corresponds to the superposition of four sinusoidal magnetic orders, suggesting the topological magnetic state with the skyrmion number of 2.

The appearance of such multiple SkL states is distinctive from the previously reported centrosymmetric rare-earth intermetallic compounds, where the magnetic modulation vector is always fixed along the one specific direction and the symmetry of the SkL reflects that of underlying crystal lattice. The present results demonstrate that various skyrmion orders can be realized even in simple centrosymmetric magnets, which highlights rare-earth intermetallic compounds as a promising platform to control the competition of multiple topological magnetic phases in a single material.

8:30 AM *QT03.07.02
Real-Space Control of Topological Skyrmions and Antiskyrmions Licong Peng; Peking University, China

Magnetic skyrmions, characterized as topological "particles", and antiskyrmions, their corresponding "antiparticles", which host opposing topological numbers, have become the focus of significant interest within the realms of fundamental physics and spintronics. The potential for driving and controlling their movements will open the door for a new generation of skyrmion/antiskyrmion-centric spintronic devices.

Here I will introduce the in-situ Lorentz TEM imaging of topological spin textures and their dynamical behaviors. First, I will show the manipulation of a single skyrmion at room temperature in the chiral-lattice magnet CoZnMn$_2$-based microdevice using nanosecond current pulses. We have directly observed the skyrmion translation and transverse Hall motion and a dynamic transition from the static pinned state to the linear flow motion via a creep event using Lorentz TEM. Furthermore, we have evaluated the intrinsic skyrmion Hall angle and the skyrmion velocity. Our experimental observations of skyrmion flow motion qualitatively coincide with numerical calculations, suggesting the pinning effect on the skyrmion dynamics [1]. In addition to skyrmions, I will also discuss the real-space control of room-temperature antiskyrmions in magnets exhibiting $D_{2h}$ [2] and $S_3$ [3-4] symmetries. By adjusting the external magnetic field, temperature, thickness, and sample geometries, we have induced topological transformations among the antiskyrmions, elliptical skyrmions, and non-topological bubbles. This was achieved through the creation, propagation, and annihilation of Bloch line pairs, accompanied by changes in their helicity, lattice form, and topological number.

Spin-Orbit Torques Induced by Topological Insulators of the Bi2Te3 Family of Materials
Thomas Guillet1, Regina Galceran1, J.F. Sierra1, Marius Costache1, Matthieu Jamet2, Frederic Bonell2 and Sergio O. Valenzuela3,1; 1Catalan Institute of Nanoscience and Nanotechnology, Spain; 2Université Grenoble Alpes, France; 3ICREA, Spain
Van der Waals (vdW) heterostructures, including those comprising topological insulators (TIs) of the Bi2Te3 family of materials, have disruptive potential for magnetic random-access memory applications [1]. The boundary states of a TI can generate a non-equilibrium spin density to control the magnetization of a ferromagnet (FM) by means of the spin-orbit torques (SOTs). Recent reports have demonstrated large SOT efficiencies with TIs, however, to identify the microscopic mechanisms at play, as well as to maximize the SOT, a deep understanding and control of the properties of the TI/FM interface is needed. In this talk, I will first introduce the potential advantages of vdW heterostructures and of TIs for non-volatile spintronics memories. I will then describe the relevance of their boundary states and of preserving the quality of the TI/FM interface. Finally, I will argue that the discovery of vdW FM, which can be grown as high-quality thin films [4,5], can further improve the TI/FM interface, as the weak vdW interaction between the TI and the vdW FM can limit chemical reactions, intermixing and electronic hybridization. Our recent results using Fe3GeTe2 demonstrate large SOTs and magnetization switching with currents densities of about 1010 A/m2 [6].

11:30 AM QT04.01.03
Topological Properties of Superconducting PdBiSe2
Ramakanta Chapai1, Gordon Peterson1, Matthew Smylie1,2, Xinglong Chen1, Jidong Samuel Jiang1, David Graf1, Wai-Kwong Kwok1, John F. Mitchell1 and Ulrich Welp1; 1Argonne National Laboratory, United States; 2ICREA, Spain
The Parkertite-type transition-metal chalcogenides PdBiSe2 is a superconductor with Tc ~ 0.8 K. Recently, a non-zero Z2 topological index has been predicted in PdBiSe2, and subsequently unusual magneto-transport attributed to two-dimensional fermions is reported. By measuring the field dependence of magnetic torque in bulk single crystalline PdBiSe2 we observe de Haas-van Alphen (dHvA) oscillations. Through the analysis of the dHvA oscillations with H \parallel c, three frequencies are identified: Fα = 150 T, Fβ = 471 T and Fγ = 979 T with the low frequency dominating the spectrum. The Lifshitz-Kosevich analysis yields a small effective mass (0.11 m0) and nontrivial Berry phase (−π) for the dominant orbit, indicating nontrivial topology. The presence of nontrivial topology in a superconducting system makes PdBiSe2 a promising candidate to explore topological superconductivity.

11:45 AM QT04.01.04
Artificial Graphene Nanoribbons with Tailored Topological States
Nathan Guisinger, Pierre T. Darancet and Saw Hla; Argonne National Laboratory, United States
Low-dimensional materials functioning at the nanoscale are a critical component for a variety of current and future technologies. From the optimization of light harvesting solar technologies to novel electronic and magnetic device architectures, key physical phenomena are occurring at the nanometer and
atomic length-scales and predominately at interfaces. In this presentation, I will discuss low-dimensional material research occurring in the Quantum and Energy Materials (QEM) group at the Center for Nanoscale Materials. Specifically, the synthesis of artificial graphene nanoribbons by positioning carbon monoxide molecules on a copper surface to confine its surface state electrons into artificial atoms positioned to emulate the low-energy electronic structure of graphene derivatives. We demonstrate that the dimensionality of artificial graphene can be reduced to one dimension with proper “edge” passivation, with the emergence of an effectively-gapped one-dimensional nanoribbon structure. Remarkably, these one-dimensional structures show evidence of topological effects analogous to graphene nanoribbons. Guided by first-principles calculations, we spatially explore robust, zero-dimensional topological states by altering the topological invariants of quasi-one-dimensional artificial graphene nanostructures. The robustness and flexibility of our platform allows us to toggle the topological invariants between trivial and non-trivial on the same nanostructure. Our atomic synthesis gives access to nanoribbon geometries beyond the current reach of synthetic chemistry, and thus provides an ideal platform for the design and study of novel topological and quantum states of matter.

2:30 PM DISCUSSION TIME

2:30 PM QT04.02.03
Synthesis of Transition Metal Ditellurides (TMTs) Nanosheets: MoTe2 and PtTe2 Through Simulation-Guided Tellurization Pinaka Pani Tummala1,2, Sara Ghomi1,4, Alessandro Molle1, Christian Martella1 and Alessio Lamperti1; 1Consiglio Nazionale delle Ricerche, Italy; 2KU Leuven, Belgium; 3Università Cattolica del Sacro Cuore, Italy; 4Politecnico di Milano, Italy

In the classification of Transition metal ditellurides (TMTs), Molybdenum ditelluride (MoTe2) received significant emphasis due to its multiple polymorphic states including semiconducting, metallic, and topological semimetal phases.[1] Specifically, MoTe2 is an ideal candidate for creating 2D hetero phase homojunctions due to its minimal energy barrier between the 2H and 1T’ phases, as well as the negligible difference between their moduli, making it effortless to switch between the two phases. The 1T’ phase, with an orthorhombic structure, is significant for accessing topological properties and has potential as a host for the quantum spin hall effect and type-II Weyl semi-metallic state while the 2H-phase is useful as a 2D layered material in nanotechnologies due to its semiconducting properties. As the thickness decreases, MoTe2 exhibits an indirect-to-direct bandgap transition with a relatively lower bandgap than other transition metal dichalcogenides (TMDs).[2][3] So far, countless efforts have been undertaken for developing MoTe2 which are essential for the fabrication of devices to be integrated in different applications from nano-electronics to thermoelectric and energy sectors. Among the proposed methods, chemical vapor deposition (CVD) is considered as one of the reliable deposition methods.[4] In this context, here we report on the simulation guided CVD synthesis for obtaining MoTe2 nanosheets with pure 1T’ and 2H phases on SiO2/Si substrates with extensive coverage of 4 cm × 1 cm. The CVD based tellurization process involves a vapor-solid reaction between the pre-deposited molybdenum film and tellurium vapor, and we have optimized this process to improve the quality and scalability of the MoTe2 nanosheets. We found that the MoTe2 growth and its phase are primarily determined by the growth kinetics, tellurium concentration, and the configuration of the CVD furnace.[5] Further, by precisely controlling the temperature, we have extended our simulation-based tellurization approach to produce other TMTs, including PtTe2 and NiTe2. In particular, we were able to produce PtTe2 with a sharp 1T phase from the tellurization of a pre-deposited Pt of varying thickness. The so-grown PtTe2 recasts as a topological type-II Dirac semimetal and as such, it is expected to be optically tunable in the THz spectral range [6]. In this respect, we reduced the flat PtTe2 film to an array of microscale stripes so as to fabricate PtTe2-based plasmonic gratings where to measure optical resonances in the THz range.

We believe this work may represent a substantial advance in facilitating the direct integration of TMTs in electronic and photonic applications where to test the intrinsic topological features.

References

Topological materials exhibit exotic electronic properties, which make them promising for non-conventional electronics and spintronics. For instance, integrating nanowires of topological insulators into devices could be used for dissipationless electronics, quantum switches, generating and braiding Majorana fermions and quantum computing. However, the assembly of nanowires with controlled orientation on surface remains one challenge preventing their integration into practical devices. A possible solution that was demonstrated in our group in the past few years is the guided growth of horizontal Majorana fermions and quantum computing. However, the assembly of nanowires with controlled orientation on surface remains one challenge preventing

In this work, we demonstrate the guided growth of Bi$_2$Se$_3$ nanowires on flat and faceted sapphire surfaces. Bi$_2$Se$_3$ is a layered material with weak VdW interaction between its layers. It is also a topological insulator with narrow band gap in the bulk and topologically protected conducting states on its surface, as well as a thermoelectric material. The growth direction of these nanowires and their crystallographic orientation are controlled by the relations with the sapphire substrate, allowing the growth of ordered nanowires without the need for post-growth processes. To the best of our knowledge, this is the first example of guided growth of nanowires made of layered materials, which demonstrates the generality of the guided growth approach.

Synthetic Tuneability of the 1T’ -1T Phases in TMDs Cecilia Mattevi; Imperial College London, United Kingdom

In this talk, I will present our recent work on the precise synthesis of different metastable 2D Transition Metal Dichalcogenides and their use in spintronics, electrocatalysis and energy storage. I will provide an overview of the tuneability between magnetic and topologically insulating phases (1T’ and 1T) and their corresponding 2H phases at the synthesis level, which we have demonstrated for different TMD materials. The synthesis precision is scalable and based on the kinetic versus the thermodynamic control of the nucleation process, which enable the determination of the crystal structure preferentially leading to either the thermodynamically stable 2H phase or the metastable 1T’ and 1T phases. The possible mechanisms of crystallization of metastable polymorphs will be discussed and liquid phase synthesis versus chemically vapour deposited materials approaches will be compared in the light of phase control. Ultimately, the functional properties of the 1T’ and 1T phases, such as magnetism and electrocatalysis will be discussed.

Epitaxy of Bi2Se3 Thin Film by Chemical Vapor Deposition Skye Williams, Edwin Fohtung and Jian Shi; Rensselaer Polytechnic Institute, United States

Spin-momentum locking materials present large prospects to the design of spintronic devices. One of the figures of merit of spintronic materials is the spin-charge conversion efficiency. Bi$_2$Se$_3$ is a topological insulator with an impressive spin-charge conversion efficiency on its conductive surface states. Epitaxial Bi$_2$Se$_3$ is highly demanded for optimized conversion efficiency. In this work we present a chemical vapor deposition approach to grow Bi$_2$Se$_3$ epitaxially that have grain sizes exceeding 200 micrometers. We identify the existence of sub-unit cell layers in the epitaxial crystal. We apply the spin pumping approach to characterize the spin-charge conversion efficiency and compare it with reported values of Bi$_2$Se$_3$ synthesized by approaches such as sputtering. The work suggests chemical vapor deposition is a viable approach for producing high-quality large-scale topological Bi$_2$Se$_3$.

Tuning Topology in 2D Materials Zeila Zanolli; Utrecht University, Netherlands

In a few years, the energy consumption for information processing will constitute more than 25% of the total electrical energy consumption. Topological materials allow for symmetry-protected dissipationless electron transport along the edges of 2D materials, which offers a possible solution to the sustainability issue of electronics. However, controlling the topological properties of a material is an open research question.

We use first-principles Density Functional Theory simulations to predict pathways to control topological properties in 2D materials and, possibly, induce or strengthen the topological phase transition. The different strategies include proximity interaction with a magnetic substrate [1, 2], van der Waals interaction with the substrate [3, 4], twisting 2D heterostructures [5], and using an external electric field to manipulate spins in a Quantum Spin Hall insulator [6]. Going further, we will discuss the role of dimensionality in going from a 3D topological insulator to the 2D limit [7].

Efficient Quantum Transduction using Magnetic Topological Insulators Haowei Xu, Paola Cappellaro and Ju Li; Massachusetts Institute of Technology, United States
Transduction of quantum information between distinct quantum systems is an essential step in various applications, including quantum networks and quantum computing. Efficient quantum transduction necessitates transducers that can strongly interact with photons with vastly different frequencies. In this work, we propose that solid-state magnetic topological insulators can potentially serve as highly effective transducers, thanks to their topologically enhanced optical responses, robust spin-orbit coupling, as well as substantial spin density. Using MnBi2Te4 as an example, we showcase that unit transduction fidelity can be achieved with modest experimental requirements, while the transduction bandwidth can reach the GHz range.

Choice of substrate is one of most important factors for thin film growth. An extensive interdiffusion or chemical reaction might happen between substrate and target materials. For oxide materials, Schlom et al. comprehensively investigate the thermodynamic stability of binary oxides for epitaxial growth on silicon (Si) substrates[1]. However, the thermodynamic stability does not include any crystal information such as lattice constants, orientation of crystal growth. In order to predict the orientation of crystal growth, molecular dynamics (MD) is employed to evaluate the stability of oxide crystal on Si substrates[2].

In this study, MD was used to select suitable substrates for graphene growth with flat surface. Supercell was consisted of carbon clusters placed on variety of substrates with vacuum slab. As carbon clusters, (1) C atom, (2) six-membered ring (6-ring) and (3) seven six-membered rings (nanographene) were placed on SrTiO, silicon and sapphire substrates. On the surface of sapphire substrate, carbon clusters were placed on either aluminum or oxygen atoms, and the absorption energy was estimated by using the density functional theory (DFT) with a semi-core pseudopotential. The generalized gradient approximation (GGA) method was used to obtain the electron density. Materials Studio and DMol3 were used for preparing and optimizing supercells, respectively[3].

The surface of substrate was optimized, and then the carbon clusters were placed on the candidate substrates. Although the absorption energies showed not large differences on various surfaces, 6-ring, for an example, stood vertically up on Si(001) substrate and covered flatly on SrTiO substrate. Only SrTiO surface was flatly covered by both 6-ring and nanographene after optimization by MD simulation. The SrTiO substrate was the first choice for flat forward van der Waals materials as a powerful platform to engineer artificial multiferroic order and electrically control exotic magnetic textures. Further show the emergence of a strong magnetoelectric coupling, which allows the electric generation and control of magnetic skyrmions. Our results put following the moiré. Among the stochiometric trihalides, our results show that twisted CrBr3 bilayers give rise to the strongest multiferroic order. We

Since CVD graphene usually grows with intrinsic contamination on graphene surface during film growth, a post annealing is required to obtain a flat graphene. Super flat graphene is prepared by chemical vapor deposition (CVD) with post annexing in carbon dioxide atmosphere. Amorphous carbon is selectively etched in carbon dioxide atmosphere[4]. In this study, carbon films were experimentally deposited on target substrates in carbon dioxide atmosphere by pulsed laser deposition (PLD), and super flat surface (~60 pm) was observed on only SrTiO substrate, which agreed with the results of MD simulation. Since CVD graphene usually grows with intrinsic contamination on graphene surface during film growth, a post annealing is required to obtain a flat surface. However PLD prepared as-grown flat surface in carbon dioxide atmosphere.

This study was supported in part by Amada Foundation under contract AF-2020227-B3, Tokyo Ohka Foundation for Promotion of Science and Technology 22117 and the Collaborative Research Project of the Institute of Fluid Science, Tohoku University. Special acknowledgment to the National Cheng Kung University 90 and beyond (NCKU’90).

Topological Textures in Artificial Van der Waals Multiferroics with Twisted Two-Dimensional Materials
Jose Lado; Aalto University, Finland

Twisted van der Waals materials have risen as a powerful platform to engineer artificial quantum matter. Artificial moire heterostructures, in general, display two length scales, the original lattice constant and the emergent moire length. Here we reveal a microscopic mechanism to engineer van der Waals multiferroics from the interplay of non-collinear magnetism and spin-orbit coupling, both in van der Waals monolayers[1] and twisted multilayers[2]. First, focusing on the recently isolated NiI2 multiferroic monolayer, we reveal the origin of the helimagnetic order and the critical role of helical spin-orbit coupling in driving a ferroelectric distortion. We demonstrate that the electronic reconstruction accounting for the ferroelectric order emerges from the interplay of such a non-collinear magnetism and spin-orbit coupling. Second, we show the emergence of multiferroic order in twisted chromium trihalide bilayers, an order fully driven by the moire pattern and absent in aligned multilayers. We show that a spin texture is generated in the moire supercell of the twisted system as a consequence of the competition between stacking-dependent interlayer magnetic exchange and magnetic anisotropy. An electric polarization arises associated with such a non-collinear magnetic state due to the spin-orbit coupling, leading to the emergence of a local ferroelectric order following the moiré. Among the stochiometric trihalides, our results show that twisted CrBr3 bilayers give rise to the strongest multiferroic order. We further show the emergence of a strong magnetoelectric coupling, which allows the electric generation and control of magnetic skyrmions. Our results put forward van der Waals materials as a powerful platform to engineer artificial multiferroic order and electrically control exotic magnetic textures.

First-Principles Transport Including Magnetic and Spin-Orbit Effects
Matthieu J. Verstraete1,2, 3University of Liège, Belgium; 4University of Utrecht, Netherlands

Topology is the next frontier in materials science, opening possibilities for ultra low power devices, exquisite sensing capabilities, and synergies with quantum computing through the protection of state coherence.

We will showcase recent advances in the theory and applications of first-principles transport calculations, to include magnetism and spin-orbit interactions,
and what will be needed to tackle the most complex topological materials, which contain both effects. Using spinor wave functions and SOI naturally incorporates spin-flip processes in electron-phonon scattering. Comparisons to experiments on "simple" 3d ferromagnetic metals require the inclusion of electron-magnon scattering, both in resistivity and in magnon drag.

As a next step into topology, we showcase the first-principles conductivity of Weyl semi-metals, in particular TaAs for which our calculations are in very good agreement with available experiments. Finally, magnetoelectrically-active 2D Nickel Iodide (NiI2) can host topological magnetic states, and we find that it shows strong sensitivity to pressure. Combining experimental characterization with first and second principles simulations, we determine the pressure dependency (up to 20 GPa) of the electronic band structure, magnetic phase transition, and spinwave dispersion.

11:00 AM QT04.03.06
Logic Gate Analysis for Quantum Phase Differences in Systems with Multiple Degenerate Points Tatsuki Togo and Kyozaburo Takeda; Waseda University, Japan

The field of quantum information has been extensively researched, and an important concept here is the phase difference between the two basis states (0\rangle and 1\rangle in a qubit, which is an important concept used to distinguish quantum logic from classical logic. Hence, manipulating this phase difference is a prerequisite for quantum arithmetic. Consequently, various methods for quantum (phase) operations have been proposed, and one such method uses the non-Abelian Berry phase [1]. Because the non-Abelian Berry phase has a characteristic structure, particularly at quasi-degenerate points (QDPs) in the parameter space, combining QDPs with quantum operations becomes important. However, a QDP exists alone in the parameter space, complicating its combination with quantum operations. Nevertheless, heavy-mass holes (HHs) in SiGe two-dimensional quantum wells, where Rashba and Dresselhaus spin–orbit interactions (SOIs) coexist, feature multiple spin QDPs near point \Gamma in the Brillouin zone (BZ) [2]. In the vicinity of these QDPs, a characteristic structure is observed in the non-Abelian Berry phase when the wave vectors are chosen as parameters. Because these QDPs lie close to each other, they can realize novel quantum operations.

Here, we focus on the HH with multiple QDPs in the BZ, and discuss the features of quantum operations based on the non-Abelian Berry phase near these QDPs. We choose the 0\rangle and 1\rangle states as the SOI-stabilized (+) and -destabilized (-) HH (HH+/-) states, respectively, including the dynamical phases, and discuss the change in hybridization and phase difference between the 0\rangle and 1\rangle states. A Bloch sphere is used to visualize the hybridization ratio and phase difference. Further, we construct a time-evolution operator that reproduces the motion on the Bloch sphere and decomposes it into quantum logic gates to interpret changes in the state vector as quantum operations. We assume that the wave vector moves under the energy conservation law and recreate this motion as "cyclotron motion" under a perpendicular weak magnetic field. The time evolution of the state and wave vectors is determined by the simultaneous rate equation and semi-classical equation of motion.

In addition to point \Gamma, an HH has the following QDPs: M1 and M2 (16 meV) along the [1-10] and [-110] directions and D1 and D2 (24 meV) along the [-1-10] and [110] directions, respectively. To discuss such QDP-induced modulation, we consider the lower-energy region away from M and D (10 meV), and just above M (16 meV) and D (24 meV). We set the initial states of the wave vector along the [100] direction and the state vector to the 0\rangle state (HH+).

At 10 meV, the state barely moves from the 0\rangle state (z direction on the Bloch sphere), and no operation is apparently performed. However, the rate-equation-based time-evolution operator is equivalent to the Rz gate, and its rotation angle is 2\pi. This rotation angle corresponds to the (Abelian) Berry phase difference of HH+/- at 10 meV (+/π). This Berry phase can be attributed to the QDP at point \Gamma. This implies that even in the region away from the QDP, the state vector is operated by the Berry phase by the QDP surrounded by the parameter (wave vector) trajectory. By contrast, at 16 meV (point M), the state flip-flops during the passage of M, and the states 0\rangle and 1\rangle change completely to 1\rangle and 0\rangle, respectively. Through logic gate decomposition, we obtain the Rz gate corresponding to M, whose rotation angle is \pi. At 24 meV, the Rz gate corresponding to D is also obtained. However, the rotation angle is less than \pi, and the state transition is incomplete. Therefore, the state is operated by the Rz gate when it passes just above the QDP, and the rotation angle depends on the QDP.

Designing Quantum States in Two Dimensional Heterostructures Orlando J. Silveira1, Mohammad Amini1, Liwei Jing2, Viliam Vano1, Yan Linghao3, Ondrej Krejci3, Somesh Ganguli2, Shawshien Kezlebesic2, Jose Laa2, Adam Foster2 and Peter Lijeroth2; 1Aalto University, Finland; 2Soochow University, Taiwan; 3Kanazawa University, Japan

Vertical heterostructures have emerged as a promising route for designing quantum materials with extraordinary properties. In particular, the interplay between magnetism and superconductivity has garnered significant attention, driven by the potential realisation of topological superconductivity [1]. This research notes remarkable progress in the synthesis and characterization of two-dimensional materials in ultra-high vacuum environments. By employing scanning tunneling microscopy (STM) and spectroscopy (STS), along with tight-binding (TB) and density functional theory (DFT) calculations, a comprehensive understanding of these materials has been achieved.

We propose a novel approach utilizing a heterostructure composed of a supramolecular complex (SMC) on a van der Waals (vdW) superconductor. Through our investigations, we demonstrate that the combination of a magnetic SMC with a quasi-2D superconductor, specifically NbSe2, leads to the emergence of Yu-Shiba-Rusinov (YSR) bands—a crucial element for realizing topological superconductivity. The presence of these bands, along with the exotic magnetic ground state of the SMC, is thoroughly examined using scanning tunneling microscopy (STM) and X-ray magnetic circular dichroism (XMCD), complemented by density-functional theory (DFT) calculations. Notably, our approach offers the advantage of employing diverse molecules, atoms, and substrates, enabling highly tunable YSR bands.

Furthermore, we investigate the electronic structure of a ferroelectric 001 SnTe grown on NbSe2. Our DFT calculations reveal a strong binding between Sn and Te atoms within the substrate, resulting in significant modifications to the overall electronic structure and its dependence on the number of atomic layers of SnTe. We also extend the study to SnTe deposited on other vdW layered materials such as TMDs by means of DFT calculations.

Overall, this research contributes to the understanding and advancement of quantum materials, demonstrating the synthesis and characterization of versatile heterostructures and providing insights into their unique properties.

Spin Transport Proximity Phenomena in Van der Waals Heterostructures
J.F. Sierra, Luis Antonio Benitez, Josef Svetlik, Williams Savero Torres, Lorenzo Camosi, Marius Costache and Sergio O. Valenzuela; Catalan Institute of Nanoscience and Nanotechnology, Spain

The vast collection of two-dimensional materials and their co-integration in van der Waals heterostructures enable innovative device engineering. Their atomically thin nature promotes the design of artificial quantum and topological materials by proximity-induced effects with physical properties not readily found in their single material forms [1]. Such a flexible design approach is especially compelling for the development of spintronic devices, which usually harness functionalities from thin layers of magnetic and non-magnetic materials and their interfaces. In this talk, I will summarize recent experimental progress toward investigating proximity-induced magnetic and AHE in hybrid graphene-transition metal dichalcogenides systems through spin transport dynamics [2,3] and charge-spin interconversion experiments [4]. I will focus on the relevance of crystal symmetries in the emergence of unconventional charge-spin conversion components and anisotropic spin dynamics [5,6].

Kramers Nodal Lines, Weyl Fermions and Large AHE in SmAlSi
Emilia Morosan and Ming Yi; Rice University, United States

Kramers nodal lines (KNLs) are special type of Weyl line degeneracy that connects time reversal invariant momenta. KNLs are robust to spin orbit coupling (SOC), and are inherent to all non-centrosymmetric achiral crystal structures. In this talk I will present magneto-transport and ARPES experimental data together with DFT calculation, pointing to the existence of novel KNLs in SmAlSi. SmAlSi is a non-centrosymmetric metal that develops incommensurate spin density wave AFM order at low temperatures. I will show evidence for the symmetry-protected KNLs, as well as Weyl fermions under the broken inversion symmetry in the paramagnetic phase of SmAlSi. In the AFM state, angle-dependent quantum oscillations (AQOs) provide evidence for the Weyl points, while large AHE is observed in both the AFM and the PM states. We propose a new mechanism to explain AHE in non-FM materials, based on magnetic field-induced Weyl-nodes evolution in non-centrosymmetric Weyl semimetals. The proposed mechanism qualitatively explains the temperature dependence of the anomalous Hall conductivity (AHC) in SmAlSi.

On-Surface Synthesis of Silicon Nanoribbons
Maria E. Davila; ICMM-CSIC, Spain

Abstract

In recent years, the scientific community has put a lot of efforts into trying to artificially grow new functional materials by reducing their dimensionality from 2D to 1D or even 0D. However, it is not a simple task, which includes synthetic methods that could go in both possible top-down or bottom-up approaches. However, is not a simple task, which includes synthetic methods that could go in both possible top-down or bottom-up approaches.

Our group, working on the bottom-up approach through on-surface synthesis has been able to develop unprecedented new 0D, 1D or 2D silicon nanoshapes[1,2]. Here, we demonstrate the on-surface synthesis of atomically precise silicon nanoribbons by utilizing the Ag(110) surface and also we have unmasked the unique 1D pentagonal silicon structures formed on it, which had been elusive for over 10 years. Further, we will see how the different single crystals substrates greatly affects the growth of silicon and the new structures that can be formed on it[3].

Promising applications of new silicon nanoforms range from nanoelectronics to transistors or embedded sensors; however, one of the important challenges that we have to overcome is the isolation, through the separation of the substrates, of these interesting nanofoms.

Keywords: Silicon nanoribbons, 1D-Silicon.

Magnetic and Charge Order in Transition Metal Dichalcogenide Heterostructures
Daniel K. Bediako; University of California, Berkeley, United States
Next-generation electronic devices will exploit correlated electronic phenomena in quantum materials to encode information for ultra-fast, ultra-low-power, and non-volatile storage and retrieval. Spin–spin correlations in exotic magnetic materials are one basis for this new paradigm of compact, energy-efficient electronic systems, but these will require a nanoscale control over long-range magnetic ordering. Conceptually, this may be realized by designing materials that are inherently two-dimensional in their atomic connectivity, or by harnessing nanoscale, non-collinear spin textures in three-dimensional crystals.

Likewise, electronic correlations that produce complex charge order can be manipulated to exhibit multi-state resistance phenomena, analogous to phase change materials, but without fatigue. This talk will describe how transition metal dichalcogenides (TMDs) intercalated with open-shell transition metals represent a family of materials allowing fine control over the chemical and electronic structure of a magnetic material to tailor the interplay between (anti)ferromagnetic exchange, magnetocrystalline anisotropy, and anisotropic exchange (Dzyaloshinskii–Moriya interactions) to bring about exotic magnetic orders in two-dimensional (2D) materials or bulk crystals. The talk will show how soft-chemical methods can be used to prepare the highly coercive 2D ferromagnetic intercalation compound, Fe₃TaS₂, and the use of angle-resolved photoemission spectroscopy to understand differences in chiral helimagnetic order in related 3D compounds, Cr₃NbxS₂ and CrₓTaS₂. The role of intercalant disorder on magnetic order will be explored in these chiral helimagnets as well as the intrinsically disordered Fe₀.₇/ZrSe₂. Finally, the talk will show how endotaxial polypeptide heterostructures of TaS₂ enable multistate resistivity and chirality switching of charge density wave phases.

4:00 PM QT04.04.05
Interplay between Magnetism and Topology: Large Topological Hall Effect in an Antiferromagnetic Topological Insulator, EuCu₃As Subhajit Roychowdhury¹, Kartik Samanta¹, Premakumar Yanda¹, Bernard Malaman², Mengyu Yao², Walter Schnelle³, Emmanuel Guilmneau⁴, Procopio Constantino⁵, Sushmita Chandra⁵, Horst Bormann⁵, Maia G. Vergnory¹, Vladimir Strekov⁵, Chandra Shekhar¹ and Claudia Felser¹; ¹Max-Planck-Institute for Chemical Physics of Solids, Germany; ²Institut Jean Lamour-Universite de Lorraine, Centre National de la Recherche Scientifique, France; ³CRISMAT, CNRS, Normandie University, ENSICAEN, UNICAEN, France; ⁴Paul Scherrer Institute, Switzerland

Magnetic interactions in combination with nontrivial band structures can give rise to several exotic physical properties such as a large anomalous Hall effect, the anomalous Nernst effect and the topological Hall effect (THE). Antiferromagnetic (AFM) materials exhibit THE due to the presence of nontrivial spin structures. EuCu₃As crystallizes in a hexagonal structure with an AFM ground state (Néel temperature ~16 K). In this work, we observe a large topological Hall resistivity of ~7.4 μΩ·cm at 13 K which is significantly higher than the giant topological Hall effect of Gd₂PbS₃ (~3 μΩ·cm). Neutron diffraction experiments reveal that the spins form a transverse conical structure during the metamagnetic transition, resulting in the large topological Hall effect. In addition, by controlling the magnetic ordering structure of EuCu₃As with an external magnetic field, several fascinating topological states such as Dirac and Weyl semimetals have been revealed. These results suggest the possibility of spintronic devices based on antiferromagnets with tailored noncoplanar spin configurations.¹

8:30 AM QT04.05.01
Nonlinear Transport Effects in Chiral Elemental Tellurium Albert Fert¹, Manuel Suárez-Rodríguez², F. Calavalle², Beatriz Martín-García², A. Johansson³, Diogo C. Vaz³, F. de Juan⁴, I. Sousa⁵, Andrey Chuvilin⁶, I. Mertig⁷, M. Gobbi⁵ and F. Casanova²; ¹Université Paris-Saclay, France; ²Max Planck Institute of Microstructure Physics, Germany; ³Donostia International Physics Center, Spain; ⁴University of the Basque Country, Spain; ⁵Martin Luther University Halle-Wittenberg, Germany

Chiral materials are an ideal playground for exploring the relation between symmetry, relativistic effects, and electronic transport [1]. Indeed, the role of low symmetry on electronic transport has been studied on chiral organic molecules, but their poor electronic conductivity limits their potential for applications. Conversely, chiral inorganic crystals, such as elemental Tellurium (Te), present excellent electrical conductivity and strong spin-orbit coupling [2]. Therefore, Te become a perfect material for studying the connection between nonlinear transport phenomena, such as unidirectional magnetoresistance (UMR) [3] or nonlinear Hall effect (NLHE) [4], and chirality. Here, we synthesized single crystalline Te nanowires (NWs) and flakes with both handedness. On one hand, we report a chirality-dependent and gate-tunable Edelstein effect in the naturally hole-doped Te NWs [5]. By recording a UMR dependent on the relative orientation of the electrical current and the external applied magnetic field, we link the direction of the spin polarization to the handedness of the crystal. The measured UMR is explained on the basis of a chirality-dependent Edelstein effect arising from the radial spin texture at the H-point of the valence band of Te, which dominates the transport in our hole-doped Te NWs. In addition, an electrostatic gating enables the tuning of the Edelstein effect, leading to a modulation of the UMR amplitude by a factor of 6. On the other hand, we explore the NLHE in Te flakes. The symmetry of the measured second harmonic voltage under zero field, which is a consequence of the inversion symmetry breaking in Te, follows strictly the constraints for Te point group and is different from any material reported before. Moreover, by measuring flakes with opposite handedness, we were able to explore experimentally the effect of an inversion symmetry operation [6]. The all-electrical generation, control, and detection of spin polarization and second-order voltage in chiral Te NWs open the path to exploit chirality in the design of solid-state spintronic and energy harvesting devices.

9:00 AM DISCUSSION TIME
Towards a Topology-Based Compact Neuromorphic Component

Pierre Seneor1, Julian Peiro1, Victor Zatko1, Hao Wei1, Frederic Brunnett1, Simon Dubois1, Marta Galibi2, Regina Galceran3, Malésis Piquemal-Banci4, Florian Godel1, Jean-Christophe Charlier1, Piran Ravichandran Kidambi5, Robert Weatherup6, Stephan Hofmann1, John Robertson1, Mauro Och6, Cecilia Mattevi7, Aymeric Vecchiola7, Karim Bouzehouane8, Sophie Collins1, Albert Fert1, Frédéric Petroff1, Marie-Blandine Martin1 and Bruno Dlubak1; 1Université Paris-Saclay, France; 2Université de Valence, Spain; 3Institute de Ciencia de Materiais, Spain; 4Université Catholique de Louvain, Belgium; 5Vanderbilt University, United States; 6University of Oxford, United Kingdom; 7University of Cambridge, United Kingdom; 8Imperial College London, United Kingdom

Spin-based electronics, recently highlighted as a leading candidate for highly efficient and ultrafast embedded memories (such as MRAMs) and post-CMOS unconventional electronics strategies (including spin logics, stochastic, neuromorphic and quantum computing), have enjoyed considerable growth. Beyond the fundamental spin transport properties of graphene, 2D materials have unleashed a multitude of previously untapped possibilities for spintronic devices in terms of functionality and performance, ranging from gate control to topology.

Indeed, 2D materials offer the unlimited possibility of exposing their electronic structure to manipulation by proximity effects. We will demonstrate that this could be harnessed to shape the properties of 2Ds and van der Waals heterostructures in quantum devices[1] and materials. We will more specifically focus on how this could be leveraged in devices such as 2D based Magnetic Tunnel Junctions (2D-MTJs)[2,3].

Relying mostly on large scale 2D materials, we will give examples of spin manipulation and new mechanisms ranging from almost perfect 2D spin-filtering with -98% spin polarization in graphene [4] and up to 500% MR in black-phosphorous, to 2D material proximity hybridization leading to insulator-to-metal transition (spinterface) [5]. We will finally focus on spin-manipulation, and moreover show how this proximity effect can also be pushed further to create an artificial 2D magnet [6] relying on proximity interaction of graphene with a ferromagnetic insulator, towards a fully gateable 2D-MTJ for spin logics.

2D Materials Prospects for Magnetic Tunnel Junctions

Pierre Seneor1, Julian Peiro1, Victor Zatko1, Hao Wei1, Frederic Brunnett1, Simon Dubois1, Marta Galibi2, Regina Galceran3, Malésis Piquemal-Banci4, Florian Godel1, Jean-Christophe Charlier1, Piran Ravichandran Kidambi5, Robert Weatherup6, Stephan Hofmann1, John Robertson1, Mauro Och6, Cecilia Mattevi7, Aymeric Vecchiola7, Karim Bouzehouane8, Sophie Collins1, Albert Fert1, Frédéric Petroff1, Marie-Blandine Martin1 and Bruno Dlubak1; 1Université Paris-Saclay, France; 2Université de Valence, Spain; 3Institute de Ciencia de Materiais, Spain; 4Université Catholique de Louvain, Belgium; 5Vanderbilt University, United States; 6University of Oxford, United Kingdom; 7University of Cambridge, United Kingdom; 8Imperial College London, United Kingdom

Spin-based electronics, recently highlighted as a leading candidate for highly efficient and ultrafast embedded memories (such as MRAMs) and post-CMOS unconventional electronics strategies (including spin logics, stochastic, neuromorphic and quantum computing), have enjoyed considerable growth. Beyond the fundamental spin transport properties of graphene, 2D materials have unleashed a multitude of previously untapped possibilities for spintronic devices in terms of functionality and performance, ranging from gate control to topology.

Indeed, 2D materials offer the unlimited possibility of exposing their electronic structure to manipulation by proximity effects. We will demonstrate that this could be harnessed to shape the properties of 2Ds and van der Waals heterostructures in quantum devices[1] and materials. We will more specifically focus on how this could be leveraged in devices such as 2D based Magnetic Tunnel Junctions (2D-MTJs)[2,3].

Relying mostly on large scale 2D materials, we will give examples of spin manipulation and new mechanisms ranging from almost perfect 2D spin-filtering with -98% spin polarization in graphene [4] and up to 500% MR in black-phosphorous, to 2D material proximity hybridization leading to insulator-to-metal transition (spinterface) [5]. We will finally focus on spin-manipulation, and moreover show how this proximity effect can also be pushed further to create an artificial 2D magnet [6] relying on proximity interaction of graphene with a ferromagnetic insulator, towards a fully gateable 2D-MTJ for spin logics.

Towards a Topology-Based Compact Neuromorphic Component

Marie-Blandine Martin1, Tristan da Câmara Santa Clara Gomes2, Yanis Sassli1, Sachin Krishna1, Dedalo Sanz-Hernandez1, Tanvi Bhattacharjee-Schöffmann, Dafine Ravelosona, Damien Querlioz1, Liza Herrera-Diez1, Bruno Dlubak1, Nicolas Reyren1, Pierre Seneor1, Julie Grollier1 and Vincent Cross1; 1Unite Mixte Physique CNRS/Thales, France; 2The Université catholique de Louvain, Belgium; 3University of Paris-Saclay, France

Thanks to their original properties, magnetic skyrmions have many promising applications, from sensors through data storage to non-conventional computing [1-3]. Among the main advantages of magnetic skyrmions are their sub-micronic size, their particle-like behavior, their stability and non-volatility at room temperature and the low energy requirement for their motion. It has been shown, most often separately, that magnetic skyrmions can be experimentally nucleated [4-7], moved [4,7], annihilated [6] and detected electrically using Anomalous Hall effect [8] in metallic multilayers.

In this talk, we will propose a neuromorphic device design using full-electrical manipulation and detection of skyrmions to perform basic operations required for neuromorphic computing. Indeed, the operating principle of an artificial neuromorphic component is to work by performing a simple operation: it multiplies various input signals with corresponding synaptic weights and sums them up [9]. Mathematically, this can be represented as y = \sum(wixi), where xi are the inputs and wi are the synaptic weights. All the building blocks necessary to achieve the demonstration of a weighted sum of skyrmions will be presented, from the nucleation and motion of a controlled number of magnetic skyrmions in multilayer tracks using electrical current pulse parameters to the electrical detection of a sum of skyrmions through anomalous hall effect.

The demonstrated skyrmion-based neuromorphic device paves the way to skyrmionic low-energy devices contributing to a global reduction of the environmental impact of AI applications.

2D Topological Insulators for New Generation Thermoelectrics: Technological Development

Paolo Bondavalli1, Pierre Legagneux1, Eva Desgu1, Olivier Bourgeois2, Dominique Carisetti1 and Yannick Fagot-Revurat1; 1Thales Research and Technology, France; 2Institut néel, France; 3Université de Lorraine, France

The implementation of 2D topological materials is a potential revolution in this domain. During the NEXTOP project, funded by French Research Agency, we are working on a new generation of 2D topological insulators to demonstrate a ZT larger than 7. Two major issues are to be overwhelmed: the growth of 2D topological insulators on different kinds of substrates (insulating and conducting ones) and their implementation for thermoelectric tests. We are developing a new technique for growing WTe2 using sort of steps with different widths that will allow controlling its crystallinity and number of layers. Thanks to that, we will be able to perform thermoelectric measurements on this topological insulator which is up to now the only 2D material whose topological features have been demonstrated. This will be the first time that measurements will be performed. Techniques for stanene growth will be also presented during the meeting. Bottlenecks for in-situ tests to identify band structures will be also presented.
We report the possibility of obtaining Majorana zero modes (MZMs) in straight, highly perfect, and massively aligned atom-thin penta-silicene nanoribbons (p-SiNRs) with a very high aspect ratio, purely composed of silicon pentagonal building blocks, and grown by molecular beam epitaxy on the (110) surface of a silver crystal template. They could constitute the experimental realization of the generic Kitaev toy model. The spinless and full spin p-SiNRs with p-wave superconducting pairing reveal the emergence of topologically protected MZMs at opposite ends of the p-SiNRs. Besides the first nearest-neighbor hopping term and p-wave superconducting pairing, we consider an external magnetic field perpendicularly applied to the nanoribbon plane and an intrinsic Rashba spin-orbit coupling. The dispersion relation profiles show the closing and reopening of the superconducting gap for only one spin component, suggesting a spin-polarized topological phase transition (TPT). Along with this TPT, the energy spectrum as a function of the p-SiNR chemical potential exhibits zero-energy states and preferential spin direction. It is associated with nonoverlapping wave functions well-localized at the opposite extremities of the superconducting p-SiNRs. Hence, we show theoretically that the p-SiNRs could constitute a tantalizing new platform for MZMs.

Band-Gap Landscape Engineering in Large-Scale 2D Semiconductor Van der Waals Heterostructures for Spintronics
Bruno Dlubak1, Victor Zatko1, Hao Wei1, Frederic Brunet1, Simon Dubois1,2, Julian Peiro1, Marta Galbiati1,3, Florian Godel1, Jean-Christophe Charlier2, Mauro Och4, Cecilia Mattevi4, Aymeric Vecchiola1, Karim Bouzehouane1, Sophie Collin1, Frederic Petroff1, Marie-Blandine Martin1 and Pierre Senier1; 1Université Paris-Saclay, France; 2Université Catholique de Louvain, Belgium; 3Universidad de Valencia, Spain; 4Imperial College London, United Kingdom

The discovery of graphene has opened novel exciting opportunities in terms of functionalities and performances for spintronics devices. This started a wide exploration of a large variety of 2D crystals for spintronics with the hope to exploit some of their unique topological properties. We will present here experimental results concerning integration of 2D materials in vertical Magnetic Tunnel Junctions (MTJ). We will in particular focus the discussion on a novel pulsed laser deposition (PLD) approach for the definition of complex van der Waals heterostructures of 2D materials in magnetic tunnel junctions. This PLD growth approach unlocks the association in heterostructure of wide families of multifunctional 2D materials, including the most delicate ones. The direct growth of the 2D layers prevents the oxidation of the ferromagnet, enabling the use of these van der Waals materials for spintronics devices. Overall, the presented experiments unveil promising approaches for the quantum engineering of multifunctional 2D materials heterostructures for spintronics.

Effect of Molecular Beam Epitaxy (MBE) Growth Conditions on the Structural and Magnetic Properties of High Curie Temperature (MnSb/Te1-x(Sb/Te)x) System: Magnetic Topological Insulators

Recently it has been shown that structural disorder in 3D Topological Insulators (TI) has considerable effects on the properties of the materials. The addition of magnetic ions like Mn breaks time reversal symmetry and opens a gap in the Dirac point.1 This addition also changes the crystal structure from the typical quintuple layer (QLs) structure of non-magnetic TIs to a septuple layer (SLs) structure.2 Furthermore, addition of a Mn flux during MBE growth results in self-assembled structures of mixed QLs and SLs.2 Previously we reported the MBE growth of self-assembled structures of (MnSb1-x(Se/Te)x)2-x magnetic topological materials,3 and showed that their Curie temperature (TC) is dependent on the composition x (or %SL).4 Samples with 0.7 < x < 0.85 exhibit very high Tc values. Additionally, it was observed that as the Mn beam equivalent pressure (BEP) ratio used was increased, there was a corresponding increase in TC. Decreasing the growth rate further increased Tc to >100 K, the highest values reported for this material system. An understanding of how the changes in growth conditions lead to the Tc enhancement is not well-established.

Here we investigate the structural properties of the materials as they relate to the growth conditions, specifically Mn flux ratio during growth and reduced growth rate (GR). Samples grown at slow GRs (0.4 – 0.6 nm/min) were compared to samples grown at fast GRs (0.8 – 1.0 nm/min). Samples were investigated using several characterization techniques including X-ray diffraction, Energy Dispersion X-Ray Spectroscopy (EDS), Hall effect and scanning transmission electron microscopy (STEM).

We found that for the same Mn BEP ratio, low GR yields similar composition, x, as fast GRs. On the other hand, EDS showed that for x > 0.7, there was increased intermixing between Sb and Mn in both the fast and the slow GR samples. Furthermore, the samples grown with slow GR showed much greater Mn and Sb intermixing, as well as Mn and Te intermixing, suggesting increased Mn incorporation at the slow GR, as well as more disorder. Cross sectional EDS studies reveal a high Mn content in the QLs, consistent with (Sb1-x(Se/Te)x)2-x alloy formation. Hall effect measurements show that GR does not significantly affect the electrical doping in (MnSb1-x(Se/Te)x)2-x, supporting the proposal that a super-exchange magnetic mechanism is likely at play. Other techniques, such as magnetic force microscopy (MFM), are being explored to better understand the magnetic mechanisms leading to high Tc values and Raman spectroscopy is being explored to understand the disorder in these materials. Our results provide insight as to how to achieve on-demand magnetic TIs with enhanced properties.

Poster Spotlight: π Quantization in the Berry Phase by the Multiple Degenerate Points

Fuka Watanabe, Keijiro Hirata, Tatsuki Tojo and Kyozaburo Takeda; Waseda University, Japan

Physicomathematics can create new frontiers in condensed-matter physics. The application of topology proposes a novel concept, topological materials, that can deepen our understanding regarding quantum phenomena, particularly those related to spin and spin–orbit interactions (SOIs), such as the spin current, spin Hall effects, and spin–Zeeman effect [1]. In these topological materials, the SOI around the degenerate point is key in inducing a characteristic effective magnetic field (EMF). The degenerate state determines its own orthogonal eigenvectors but is not unique because of the “phase” indefiniteness. The Dirac cone is a prime example and results in a topological singularity originating from degeneracy. Spatial asymmetry can generate singularities in the EMF distribution, such as vortices, sources, and sinks, via the SOI around the degenerate point; subsequently, the spin is polarized characteristically therein, particularly when the system exhibits bulk inversion asymmetry (BIA) and/or structure inversion asymmetry (SIA).

In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b. To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by ±k. We vary the locations of the degenerate points by appropriately substituting a value for k, and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the directional effective mass.

In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points (±k) are located in the <110> direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BIA system distributes the EMF hyperbolically around each degenerate point. The synthesis of these two hyperbolic distributions results in a new concentric EMF distribution at the middle position. These newborn singularities in the EMF distribution results in accidental degeneracy at the middle position. The sign of the Berry curvature around the newly generated point is opposite to that at the prepared degenerate points.

Finally, we discuss the energy dependence of the Berry phase based on the calculated Berry connection and curvature. Since each degenerate point results in the Berry phase of ±π/2, the multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

Transport of spin information over long distances is key for many applications in spintronics. Achieving spin transmission within superconducting devices should lead to reductions in Joule heating and massive improvements in device efficiency and performance. The Weyl semimetal Mn$_3$Ge [1, 2, 3, 4] with an antiferromagnetic or ferrimagnetic phase has recently emerged as a promising material for spin transmission studies in the superconducting [1] and normal [3, 4] states. In this poster, we report the fabrication of magnetron-sputtered thin-films of Mn$_3$Ge and superconducting heterostructures with sub-nanometer-thickness-control in order to investigate the interplay between superconductivity and spin transport in Mn$_3$Ge. The results build a framework for spin-transport control in the superconducting state.

SnTe is one of the attractive materials for a topological crystalline insulator (TCI). SnTe films have been grown directly on GaAs (100) substrates by molecular beam epitaxy, and single domain SnTe layers preferentially oriented to (100) were achieved by now. The (111) oriented SnTe domains and Te were easily included in the film. The crystallographic orientation control and surface smoothness improvement was mainly performed in this study. SnTe layers were grown on (100) and (111)B oriented GaAs substrates by molecular beam epitaxy (MBE). Most of structures were formed on (100) GaAs substrates with (100) oriented ZnTe buffer layers. Elemental sources were used and the molecular beam intensity ratio ($J_{\text{Te}}/J_{\text{Sn}}$) was varied between 4:1 and 10:1. The size of the plateau was increased by increasing the molecular beam intensity ratio up to 1.0.

Since the growth temperature was relatively low, the inclusion of the excess material was not negligible. According to the result of X-ray diffraction (XRD) measurement, a diffraction peaks originated from hexagonal Te was observed with SnTe peaks when samples were grown with Te rich ($J_{\text{Te}}/J_{\text{Sn}}$ was between 2.9 and 1.5) conditions. In the secondary electron microscopy measurements, featureless surface was confirmed when the XRD of the sample exhibited no Te peak while dotted materials were clearly observed on the surface when the hexagonal Te peak was observed. The distribution density of the dot was high when the Te diffraction peak signal intensity was strong. Those dotted materials are presumed to be the residual of Te.

The orientation of the material was affected by the growth temperature. When the substrate temperature was raised, (111) SnTe domains were started to appear. The XRD peak intensities of (100) and (111) domains were comparable when the substrate temperature was 250 °C. In order to eliminate the (111) domain inclusion, the substrate temperature needed to be maintained below 240 °C. In order to enhance the (111) domain formation, (111)B oriented GaAs substrates were employed. (100) domains could be mostly eliminated when the substrate temperature was raised to 270 °C.

A standard van der Pauw Hall measurement was performed to characterize the electrical property at room temperature. The (100) sample that didn’t include the Te residual exhibited the resistivity of about ohm*cm. The resistivity has increased as the presence of Te residual became noticeable. Based on the literature, the room temperature resistivity of SnTe and Te were about ohm*cm and 0.3 ohm*cm, respectively. The higher resistivity obtained for the grown film might be originated from the mixing of Te residual. Although the surface morphology was improved by the introduction of the ZnTe buffer layer, the electrical properties were not improved. Boundaries of plateau probably became the center of carrier scatterings.

Poster Spotlight: Near-Absolute Spin-Valve Effect at f-Orbital Magnet/Superconductor Interfaces with Controlled Orbital-To-Spin Moments Sijie Wang1, Karine Dumesnil2, Harry Bradshaw1, Nadia Stelmasken1 and Jason W. Robinson1, 1University of Cambridge, United Kingdom; 2Institut Jean Lamour, France

The proximity effect between a thin-film superconductor (S) and a ferromagnet (F) can lead to a spin-splitting of the quasiparticle density of states and suppression of the superconducting critical temperature ($T_c$) (1). At an S/F interface, the average magnitude of the spin-splitting in S can be tuned via the micromagnetic state of F with shifts in $T_c$ between magnetized ($T_{c,m}$) and de-magnetized ($T_{c,dm}$) ferromagnet states being dependent [1-3] on the ratio of the superconducting coherence length ($\xi$) to the domain wall width ($\delta_d$): $\frac{c,m}{c,dm} \propto \frac{T_{c,m}/T_{c,dm}}{\xi/\delta_d}$. For $\delta_d/\xi \ll 1$, the proximity effect is hard to achieve with $\Delta T_{c,dm}$/ $T_{c,dm}$ ratios tending to be a small fraction of $T_{c,dm}$, indicating physics beyond the standard picture of the S/F proximity effect. Here we report S/F bilayers and S/F spin-valves in which F is a film of a ferromagnet (HoGd) with a controlled composition to tune the ratio of the orbital to spin components of the magnetization. The results demonstrate that $\Delta T_{c,dm}$ can approach infinity for a large ratio of the orbital moment to spin moment, which enables a near-absolute spin-valve effect. Our results demonstrate that the band structure of the ferromagnet in conjunction with the $\delta_d/\xi$ can be tuned to enable high-performance superconducting memory for energy efficiency electronics. A first principle theory is required in order to understand the relationship between $\Delta T_{c}/T_{c,dm}$ and the ratio of the orbital to spin moment of the F metal.
Chiral molecules (CMs), such as alpha-helix polyalanine, exhibit chiral-induced spin-selectivity (CISS) characteristics, which means that a flow of electron charge across a layer of CMs can result in a spin-filtering effect and phase coherent transport [1, 2]. Recently, for example, we have demonstrated low temperature phase-coherent transport through thin-film wires of Au and Cu with absorbed CMs [2]. For Au, we also observed evidence for induced ferromagnetism associated with the thiol-Au bonding and for Au and Cu, we detected an enhanced spin-orbit coupling. Here, we systematically study charge transport and magnetic anisotropy in thin films and wires of Au and Au/EuS where EuS is a ferromagnetic semiconductor. The thickness of Au is varied in the 1-10 nm range in order to optimise magnetic hysteresis in Au and magnetic anisotropy modification in Au/EuS structures. The results provide a platform for detailed studies regarding quantum behaviour including magnetic control of phase coherence transport and potentially a quantum anomalous Hall effect.

In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points (±ki) are located in the <110> direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the Berry phase of ±ki demonstrates that this quantization can be understood by counting the number of degenerate points in the Brillouin zone (BZ) in addition to identifying the sign of the Berry curvature [2].

In this study, we investigate the manner by which multiple degenerate points in the Brillouin zone (BZ) modify the topological features. We focus on a semiconductor system with a two-dimensional quantum well structure and investigate topological modifications via numerical calculations of the EMF, Berry connection, and curvature. Next, we reveal the energy dependence of the Berry phase modulated by the interaction between the degenerate points. We employ the Hamiltonian, in which the spatial asymmetry of the SIA and/or BIA is considered [1]. The effect of the competition between the SIA and BIA is investigated using tunable parameters a and b. To provide multiple degenerate points in the BZ, we locate the degenerate state at point Γ and then transfer it to a peculiar direction by ±k. We vary the locations of the degenerate points by appropriately substituting a value for k and examine the directional dependence of the synthesized EMF distribution. We further introduce anisotropy by changing the direction of the effective mass.

In the SIA system, each degenerate point presents a SIA-like singularity and the concentric EMF distribution results. The synthesis of these two concentric distributions generates a source and a sink at the middle position between the two prepared degenerate points when the points (±ki) are located in the <110> direction. Accordingly, the EMF is distributed hyperbolically, and the BIA-like singularity newly results. By contrast, the topological singularity in the BZ system distributes the EMF hyperbolically around each degenerate point. The multiple degenerate points quantize the Berry phase by π and result in a plateau profile against energy. We further demonstrate that this π quantization can be understood by counting the number of degenerate points in the BZ in addition to identifying the sign of the Berry curvature [2].

The proximity effect between a thin-film superconductor (S) and a ferromagnet (F) can lead to a spin-splitting of the quasiclassical state of S and suppression of the superconducting critical temperature ($T_c$) (1). At an S/F interface, the average magnitude of the spin-splitting in S can be tuned via the micromagnetic state of F with shifts in Tc between magnetized ($T_{can}$) and de-magnetized ($T_{dmn}$) ferromagnet states being dependent on the superconducting coherence length ($\xi$) to the domain wall width ($d_{dmn}$) i.e., $T_{can} - T_{dmn} = \Delta T_c/T_{dmn} \ll \xi/d_{dmn}$ can theoretically be infinite for an appropriate combination of S and F thin films in which S is thinner than $\xi$. Experimentally, however, such an absolute spin-valve effect is hard to achieve with $T_{can}/T_{dmn}$ ratios tending to be a small fraction of $T_{can}/T_{dmn}$ with $\xi/d_{dmn}$ can be tuned to enable high-performance superconducting memory for energy efficiency electronics. A first principle theory is required in order to understand the relationship between $\Delta T_c / T_{can}$ and the ratio of the orbital to spin moment of the F metal.

WTe2 Topological Insulator: Synthesis, Characterizations and Applications
Dimitri Dimitrov1,2, Vera M. Gospodinova3, J.F. Sierra4 and Sergio Valenzuela5; 1Institute of Solid State Physics, Bulgarian Academy of Sciences, Bulgaria; 2Institute of Optical Materials and Technologies (IOMT), Bulgarian Academy of Sciences, Bulgaria; 3Catalan Institute of Nanoscience and Nanotechnology (ICN2), Spain

Since the discovery of a new material phase, topological quantum materials (TQMs), [1] tremendous effort has been made to explore a wide variety of novel and abundant physics appearing in topological insulators (TIs), topological superconductors (TSCs), and Weyl semimetals for creating novel electric and spintronics devices. WTe2 belongs to the family of transition-metal dichalcogenides (TMDs) and crystallizes naturally in a non-centrosymmetric orthorhombic structure (also known as the Td or distorted 1T phase, in which the tungsten atoms are octahedrally coordinated by the tellurium atoms) with polar space group Pmn21. The polar axis in WTe2 is oriented along the stacking direction of layers. Unlike other TMDs, WTe2 is a Weyl semimetal in its native crystal phase [2]. Among Weyl semimetals, Td-type WTe2 is a new class, a type-II Weyl semimetal, where the Weyl points appear at the crossing of the oblique conduction and valence bands due to the broken inversion symmetry and non-saturating giant positive magnetoresistance is a manifestation of the type-II Weyl character [3]. In this presentation the current status of the research and emerging applications of WTe2 are reviewed.

Low Secondary Electron Emission 2D Surfaces
Isabel Montero; CSIC. Insituto de Ciencia de Materiales de Madrid, Spain

The secondary electron emission is the feedback mechanism of the resonant avalanche of electrons or Multipactor discharge in high-power RF devices onboard satellites. The multipactor discharge is a severe problem which limits the maximum power of RF instrumentation in space missions, it can cause RF signal loss and distortion and it can increase the noise figure or bit-error-rater even total mission failure. The search for surfaces with a low secondary electron emission yield (SEY) is considered one of the main research areas to reduce the multipactor effect in high-power RF devices used in spacecraft and other important technological fields such as high-energy particle accelerators. In this study, RF devices were made using aluminum alloy AA6061. The RF insertion losses of the devices were improved, meaning they were reduced, when AA was silver-coated. However, the SEY of silver, although lower than that of AA, still needs to be reduced to prevent multipactor. The SEY of silver exposed to air is greater than 2. The aim of this study was to deposit a 2D MoS2 layer on silver coatings that are suitable for reducing SEY and preventing multipactor discharge. Prior to the deposition of the silver coating, the alloy layer of the RF devices was zinclated, followed by the deposition of intermediary layers of Ni and Cu. We used deep eutectic ionic liquids (2:1 ethylene glycol-choline chloride) instead of water to deposit these coatings. Finally, the MoS2 was deposited on the external silver coating using an optimized electroless process. As a result, we have developed an electroless plating process for growing 2D nanostructures with a high aspect ratio. The characterization was performed in an ultra-high vacuum (UHV) system composed of three interconnected chambers at a pressure of less than 10^-9 hPa, while the fast entry chamber remained at 2x10^-7 hPa. SEY is defined as the number of emitted electrons per incident electron, that is, SEY = Ie/Ip, where Ie is the emitted current and Ip is the primary or incident current. SEY was measured in the primary electron energy range from 0 to 1000 eV. The samples were also analyzed by x-ray photoemission spectroscopy (XPS) and field-emission scanning electron microscopy (FESEM).

In this study, we report an extremely low SEY of this multi-layer coating. The SEY as a function of primary electron energy curves show a maximum value close to 0.8. Furthermore, a linear translation of the SEY curve towards the region where SEY >1 for oxygen content >0.3% is observed. The energy distribution curves (EDC) or energy spectra of secondary electrons also exhibit a significant decrease in the signal for kinetic energies <50eV, which is consistent with the SEY results.

Low-Temperature Microwave Impedance Microscopy of Topological Materials
Monica Allen; University of California, San Diego, United States

Quantum-relativistic materials often host electronic phenomena with exotic spatial distributions. We employ microwave impedance microscopy (MIM), which characterizes the local complex conductivity of a material, to directly visualize chiral edge modes and phase transitions in a quantum anomalous Hall insulator. This near-field imaging technique detects the unique fingerprint of topological edge modes in the GHz regime and spatially disentangles them from trivial states in the bulk of the material. Motivated by these experimental findings, we model the microwave response of topological edge states in a Chern insulator and demonstrate an enhanced MIM response can appear at the crystal boundaries due to collective edge magnetoplasmon excitations. The resonance frequency of these plasmonic modes should depend quantitatively on the topological invariant of the Chern insulator state and on the sample’s circumference, which highlights their non-local, topological nature. Looking forward, we will also discuss progress on the construction of a new
milliKelvin MIM, which will support spatially-resolved detection of topological states at low temperatures.

SESSION QT04.10: Virtual Session

High-Mobility Two-Dimensional Carriers from Surface Fermi Arcs in Ferromagnetic Weyl Semimetal SrRuO3 Films
Yuki K. Wakabayashi1, Shingo Kaneta-Takada1, Yoshitaka Yamamoto1, Kousuke Takiguchi1, Shinobu Ohya2, Masaaki Tanaka1; 1NTT Basic Research Laboratories, Japan; 2The University of Tokyo, Japan

Leveraging two-dimensional quantum transport phenomena and exploiting them in topological and spin electronics require thorough investigation into magnetic Weyl semimetals. Two-dimensional charge/spin carriers arising from pairs of Weyl nodes are realized in the presence of surface Fermi arcs in topological semimetals. To demonstrate such topological quantum transport phenomena, high-quality epitaxial films of Weyl semimetals are vital. Prior to the present study, we recently demonstrated that ultra-high-quality thin films of SrRuO3 exhibit quantum transport phenomena specific to bulk three-dimensional Weyl fermions [1,2], implying that they serve as a promising platform also for investigating novel two-dimensional transport in a topological state.

Here we present our findings on the thickness- and angle-dependent magnetotransport properties of SrRuO3, a magnetic Weyl semimetal. Utilizing machine-learning-assisted molecular beam epitaxy [3], we grew SrRuO3 films with 10 nm and 63 nm thicknesses. Quantum oscillations in the 10-nm film demonstrate a high quantum mobility of 3.5×10^3 cm^2/Vs, a light cyclotron mass of 0.25m_e (m_e is the free electron mass in a vacuum), and two-dimensional angular dependence. The two-dimensional, angular transport dependence might be regarded within two scenarios: (1) the surface Fermi arcs, or (2) the quantum confinement of the three-dimensional Weyl fermions. The former is plausible as the identical angular dependence is also observed in the 63-nm film, which is too thick to observe the quantum confinement effect in it. In addition, the linear thickness dependence of the phase shift provides evidence of the non-trivial nature of the quantum oscillations mediated by the surface Fermi arcs. Furthermore, magnetoresistance (MR) measurements while applying magnetic field parallel to the film surface up to 52 T confirmed the saturation of negative MR in the quantum limit (chiral anomaly), assuring that the carriers arise from a pair of Weyl nodes. These results endorse SrRuO3 as a promising material for topological oxide electronics and for physics investigation of two-dimensional quantum transport phenomena in magnetic Weyl semimetals [4].

Optical Nonlinearities in Hexagonal and Triangular Graphene Quantum Dots
Suresh Gnawali and Vadym Apalkov; Georgia State University, United States

Graphene quantum dots (GQDs), the graphene nanoparticles of a few nanometers excited by an ultrafast optical pulse of a few femtoseconds, exhibit several optical nonlinearities, including residual population and high harmonic generation (HHG). By introducing dephasing, we addressed nonlinearity, namely HHG in GQDs placed in a short linearly polarized optical pulse. At short finite dephasing times, the ultrafast electron dynamics show significant irreversibility with a large residual population of the excited quantum dot levels. When dephasing time increases, intensities correspond to a low-frequency boost, while the cutoff energy decreases regarding the high harmonic spectra. The cutoff energy's dependence on the optical pulse's amplitude is also sensitive to the frequency of the pulse. This dependence in hexagonal GQDs is almost linear when the optical pulse frequency is much less than the quantum dot band gap. However, when the pulse frequency is comparable to the band gap, the cutoff energy shows saturation behavior at a large field amplitude, >0.4 V/A. In triangular graphene quantum dots with zigzag edges, the intensities of high harmonics show a strong dependence on the initial electron population of the edge states of the quantum dot. If a zigzag triangular quantum dot possesses an even number of edge states, then even high harmonics are strongly suppressed. In this scenario, the odd and even harmonics are of comparable intensities.

8:30 AM QT04.10.04
Probing the Quality of Bi2Se3 Films Grown by Molecular Beam Epitaxy In-Situ with Spectroscopic Ellipsometry
Aofeng Bai1, Maria Hlase2, Prasanna Patil3, Roman Engel-Herbert4 and Frank Peiris1; 1Kenyon College, United States; 2The Pennsylvania State University, United States, 3Southern Illinois University Carbondale, United States; 4Paul-Drude-Institut für Festkörperphysik, Germany

Quantum materials such as topological insulators (TI) like Bi2Se3 feature massless Dirac-like states due to their spin-momentum coupling and time reversal invariance. These massless topological surface states (TSS) enable the study of new quantum physics and with that allow access to a plethora of technological advancements and the realization of applications with new functionalities for more energy efficient and faster computation schemes. The key to exploiting the unique properties of TIs lies in high-quality materials synthesis. However, Bi2Se3 synthesis is plagued with a large number of unintentional carriers, shifting the Fermi level up into the band gap and masking the TSS. Methods like compensation doping, or cation/anion mixing are being pursued successfully to prevent the Fermi level drift out of the band gap, but the price paid is a substantial carrier mobility reduction in the film limiting TSS observation to very low temperatures. To date, best results for achieving low bulk carrier concentrations and high mobilities are reported for a meticulously designed buffer layer (BL) growth approach consisting of Bi2Se3, In5Se3, and (Bi1In0.5alse) heterostructures, we found that the observed SE measurable for Bi2Se3 depend sensitively on the sample heterostructure design. To gain deeper insights about the observed differences, we developed oscillator models for the dielectric functions of Bi2Se3, In5Se3, and (Bi1In0.5alse) heterostructure. In this talk, we elucidate how in-situ spectroscopic ellipsometry (SE) can be employed as a non-invasive, non-contact, real-time, ultra-fast probe of the electronic properties of Bi2Se3 during growth. Evaluating the in-situ SE data obtained before and after growth of each layer from differently designed Bi2Se3, In5Se3, and (Bi1In0.5alse) heterostructures, we found that the weighted average SE measurable for Bi2Se3 oscillators of films grown on a In5Se3, and (Bi1In0.5alse) heterostructure were 20 % smaller.
than those of films grown directly on Al₂O₃. Smaller broadening parameters are generally associated with the degree of momentum-conservation between electronic transitions due to less pronounced electron scattering. Our finding thus indicates that the Bi₂Se₃ grown on the In₄Se₃, (Bi₀.7In₀.3)₂Se₃ heterostructure has superior quality compared to films grown on bare Al₂O₃. This conclusion was corroborated by Hall mobility measurements conducted at room-temperature, which ranged highest for Bi₂Se₃ films grown on In₄Se₃, (Bi₀.7In₀.3)₂Se₃ heterostructures. Based on the presented data, in-situ SE has the potential to serve as an ultra-fast, real-time probe of the electronic properties of Bi₂Se₃, and is thus highly advantageous for speeding up the engineering process of high-quality TIs growth.

Analysis of the Moving Boundary Problem for Spinodal Transformations in Thin Films Rahul Bani¹,²; ¹VTU, India; ²Jawaharlal Nehru Technological University, India

The equations of Spinodal Decomposition as postulated by Cahn and Hilliard involve a fourth order pde which to date has not been solved analytically. In this article these equations are examined in their various versions, and solutions obtained for the steady state and transient forms using various methods. Then the moving boundary associated with transformation is examined using a heat transfer approach and a solution attempted using a series and a similarity transformation approach. The equation is postulated to have two contributions one from the usual Laplacian and Fickian contribution part for which Stefan solutions are known, and one with a Double Laplacian which has not been examined. The thin film approximation is applied to simplify some parts of the analysis and to try to get a numerical solution.

Silk-Based Technology to Boost Food Security Benedetto Marelli; Massachusetts Institute of Technology, United States

The infrastructure of agro-food systems is responsible for more than 25% of anthropogenic greenhouse gas emissions while facing pressure to support an increasing world population. For the first time in history, the availability of arable land has plateaued, and crop yields are threatened by stressors such as soil salinity and drought that are further exacerbated by climate change. Food security and food waste are twin crises; more than 800 million people are undernourished, and 30% of food is lost or wasted from farm to fork. As new technologies that are economically sustainable, scalable, and rapidly deployable to market are needed to address these challenges, an opportunity lies for biomaterials to lead innovation in the agro-food industry. Our laboratory strives to reinvent silk proteins as advanced materials for boosting food security. Here, we will highlight recent developments in the nanomanufacturing of silk to design: (i) physical unclonable functions for food traceability, (ii) packaging that is biodegradable yet possess good membrane proprieties, sense spoilage and mitigate biotic decay, (iii) microenvironments that boost seed germination in marginal land, and (iv) different solutions to precisely deliver payloads in planta. These examples will provide an opportunity to discuss how the establishment of a prolonged biointerface between biomaterials and plants tissues requires the development of basic scientific knowledge on material-plant host response, mechanics of disorder-to-order transitions in proteinaceous materials during condensation phenomena, fluid mechanics, and transport phenomena in plants vasculature, and swelling of porous materials exposed to plant fluids.
According to the United Nations - Food Agricultural Organization (UN-FAO), we will need 56% more food to feed the growing global population by 2050. In addition, with more than 800 million people who are affected by hunger today, we need solutions that can address food production and supply challenges in short order. One way to address these challenges is to reduce food waste and loss which is reported between 30 and 50% based on geography and product category by the UN-FAO. Beyond the challenge of continuing to feed a growing population, the environmental and economic impacts of food waste are staggering: 8% of greenhouse gas emissions globally and a total cost of $2.6 trillion dollars annually are due to food waste.

In this talk, we will address how Apeel Sciences, a start-up based in Santa Barbara, CA, is approaching tackling food waste and loss by developing new plant based technologies and products that 'work with nature'. The talk will review the process and the journey of an 'idea' to a product via a multidisciplinary approach inspired by Materials Science and Engineering principles to develop a plant based edible coating and other technologies utilizing data science and computer vision to make quantitative produce quality tools and shelf life prediction models to address food loss.

9:30 AM SB01.01.03
Metabolomics in a Circular Bioeconomy: A Case for Fruit/Vegetable Waste Material Residuals
Nancy A. Flenkjer1, Michael A. Ochsenkühn2, Shady A. Amin3, Matteo Chiesa3 and Lina F. Yousef4; 1Khalifa University of Science and Technology, United Arab Emirates; 2New York University Abu Dhabi, United Arab Emirates; 3UiT The Arctic University of Norway, Norway; 4DeL'Arta-Outdoor Living Laboratory, United Arab Emirates

Research is accelerating towards establishing a circular bioeconomy to achieve the United Nations Sustainable Development Goals (SDGs) and drive sustainable development. Here, we applied untargeted metabolomics as an assessment tool for homogenous food waste residuals, providing an assessment of their marketability in the circular bioeconomy. The circular bioeconomy involves the comprehensive conversion of biological resources into renewable biobased products, which contributes to climate action and environmental well-being. One strategy for embracing a circular bioeconomy is the discovery of vertical conversions of food and agricultural waste residues, transforming them into value-added commodities. This article applies an untargeted metabolomics approach to gain insights into the phytochemical profile of fruit and vegetable residual wastes (FVRs). Through this analysis, 472 known metabolites were identified, with their relative abundances determined. Among the most prevalent 50 annotated metabolites in FVRs, a significant proportion consisted of natural products or bioactive compounds (64–86%), functional foods (7–12%), fragrances (0–8%), pesticides (0–6%), and intriguingly, environmental contaminants (7–23%). Homogenous waste residuals resulting from fruit and vegetable processing emerge as a promising source of bioactive nutraceuticals, functional food derivatives, and biomaterials. This study proposes using untargeted metabolomics as a rapid method to evaluate extracts obtained from homogenous food waste residuals. This approach provides a pre-assessment of their potential market value within the context of the circular bioeconomy.
Nanozyme has recently expanded applications in the field of food and agricultural science, offering the potential to enhance food safety by detecting toxic molecules. However, most of the nanozymes are derived from conventional chemistry and material science such as MOF/metal-based NP. These nanozymes encounter challenges related to their intrinsic toxicity and low-cost effectiveness when applied in food and agriculture. Thus, novel nanozymes that are highly suitable for food and agriculture for future applications are desired.

To address this need, we have introduced a novel type of nanozyme, called OC nanozymes, which are food and agriculture friendly. These nanozymes are composed of polymer and organic compounds and exhibit decent peroxidase-like catalytic activity. The customized, chelation-driven self-assembled particle generation process was contrived to provide spherical-shaped nanozymes containing partially mimicked cofactor sites (e.g., Fe-N or Fe-O) of the natural enzyme without using the conventional engineering process, including pyrolysis, organic solvent, and ionic gelation. In contrast to conventional nanozymes, OC nanozymes exhibit decent eco-compatibility, and cost effectiveness with satisfactory catalytic performance (e.g., Km = at least 7.27 μM ), and toxic herbicide detection(LOD =10 pg mL−1) within 7 minutes. Additionally, some OC nanozymes are designed to degrade at a moderate temperature (around 45 Celsius) after use, which provides benefits for further waste management issues. We envision that OC nanozymes can be utilized in further practical food applications.

Took this need, we have introduced a novel type of nanozyme, called OC nanozymes, which are food and agriculture friendly. We envision that OC nanozymes can be utilized in further practical food applications.
while decreasing environmental impact. Towards this goal there is much progress, with cell and tissue biomanufacturing central to the approaches. Further, there remain many challenges and opportunities ahead, from cells, media, safety and scale up, to tuning nutrition, composition and overall food quality and health. These topics will be discussed in the context of this emerging food frontier, where the impact is potentially transformative.

The Development of High Protein Plant-Based Cheese

Alejandro G. Marangoni and Stacie Dobson; University of Guelph, Canada

Animal proteins and animal by-products, such as milk and cheese, generate the greatest amounts of greenhouse gas emissions in the food sector. This, coupled with the demonstrably worsening climate crisis, means that there needs to be a shift to more sustainable alternatives in the form of plant-based foods. In particular, the plant-based cheese industry is relevant, as the products lack critical functionalities and nutrition compared to their dairy-based counterparts. Waxy starch, plant-protein isolate, and coconut oil were combined to create a novel high-protein (18w/w) plant-based cheese. We determined that by using native waxy starch, we can enhance its existing viscoelastic properties by modulating gelatinization through the addition of plant protein and fat. Texture profile analysis indicated that the cheese analogues could reach hardness levels of 15-90N, which allowed samples to be tailored to a wider range of dairy products. We determined that plant proteins and fat can behave as particulate fillers and enhance network strength but also create strategic junction zones during starch retrogradation. The degree of melt and stretch of the high protein plant-based analogues were 2-3times greater than those observed for commercial plant-based cheeses and significantly more similar to dairy cheese. The rheological melting kinetics saw that the high protein plant-based cheese displayed more viscous properties with increasing temperature. Tan (G'/G'') at 80°C was used as an indicator for sample meltability, where, values indicate better melt and more viscous systems. The high protein plant-based cheese reached tan values upwards to 0.8, whereas commercial plant-based cheese only reached tan values around 0.1. Synchrotron micro-CT as well as synchrotron mid-IR imaging was utilized to characterize structure and interactions between components.

2:30 PM SB01.02.03

Generating Animal-Free Protein Scaffolds using Antisolvent Precipitation under Couette Flow

Patrick A. Sullivan, Ying Wang, Lasanthisumathiratne and Leila Deravi; Northeastern University, United States

A common feature of animal-based proteins is their ability to self-assemble into continuous protein fibers, as seen in muscle and connective tissues. Their fibrous nature has inspired research and development in the tissue engineering, textile, and synthetic meat industries, to find methods of replicating this aligned fiber structure in non-animal-based proteins. Zein is a nitrogen storage protein that is primarily found in corn, that has become popular due to its status of Generally Regarded As Safe (GRAS), its biocompatibility, its fabrication flexibility and its unique solubility, solvating in 60-90% mixtures of ethanol and water. This makes it a prime candidate for antisolvent precipitation and extrusion methods to produce zein fibers for food industry applications. However, extrusions methods produce a rapid but random generation of fibers in terms of diameter and alignment when utilizing this antisolvent precipitation, and the conclusion has been drawn that further antisolvent zein fiber formation should focus on fiber orientation as a next step in investigation. In this work we aimed to produce aligned fibrous microstructures on zein scaffolds like those found in animal-based proteins. We investigate how salt concentration and identity influence the aggregation patterns of zein as it precipitates into nanoparticles through its addition to an aqueous antisolvent. We then use the conclusions drawn from these findings in combination with a custom-built device to induce anti-solvent precipitation under Couette-flow to produce continuous fibrous scaffolds, demonstrating their use as scaffolds for future tissue engineering applications.

2:45 PM SB01.02.04

Cephalopod-Inspired Material Design for Potential Food Applications

Bianca C. Datta; Ronin Institute for Independent Scholarship, United States

As the global population rises alongside a worsening climate outlook, alternative proteins such as plant and cell-based meat provide exciting avenues for meeting the increasing demand for meat sourced from animals and have implications for planetary and human health. While food science is a well-established field with a rich history, inclusion of methods and research paradigms from the materials community can accelerate the development of promising food technologies. In this work, we review the complex and interesting structure and functionality of cephalopods, the landscape of existing materials advances towards replicating these creatures, and extensions towards food and edible materials. In doing so, we bridge the rich culinary traditions around cuttlefish, octopus, and squid with advancements in tissue engineering and bio-inspired design. Few creatures generate as much wonder and curiosity as cephalopods. Renowned for their protective and communicative capabilities (camouflage, texture and shape change), they also demonstrate fascinating behavioral and cognitive abilities. Researchers have looked to cephalopods for inspiration in designing systems as varied as displays, programmable coloration, self-healing coatings, mechanical windows, and bioelectronics. We now look to their unique structure and properties to inspire a new domain of compelling alternative food materials.

Understanding Structure in Methylcellulose Solutions using Machine Learning Enhanced Scattering Analysis (CREASE), Coarse-Grained, and Atomistic Molecular Dynamics Simulations

Audrey Collins, Zijie Wu and Arthi Jayaraman; University of Delaware, United States

Methylcellulose (MC) iscellulose derivative in which some of the hydroxyl groups are replaced by methoxy(-OCH3) groups. Aqueous solutions of MC exhibit unique phase behavior wherein at low temperatures MC chains are soluble in water and at high temperatures MC chains assemble into semi-flexible fibrils and fibrillar networks. Fibrillar networks exhibit mechanical and rheological properties that make them useful as food and pharmaceutical
experimental samples (WPI/AlgMA, WPI-MA/AlgMA). These solutions were then cast into circular molds and exposed to the green light (525 nm) for 10 minutes for crosslinking to occur. The crosslinked polymer solutions were characterized through proton nuclear magnetic resonance (1H-NMR), scanning...

**INTRODUCTION**

The rising global population and increasing prevalence of food insecurity highlights the need for alternative food sources. New developments in biotechnology have given rise to many alternative food and protein options, including the research and development of cultivated meat.

Cultivated meat is produced via *in vitro* animal cell culture and their incorporation into manufactured scaffolds. Plant-based, alginate scaffolds are a common material used during manufacturing, due to the tunability of their mechanical properties through modification of molecular weight, chemical composition, and structure; however, alginate does not have the necessary cell adhesion ligands. Whey protein isolate (WPI) is a bioprocess of the dairy processing industry, is a food additive, and has recently been shown in the literature to encourage cell adhesion in bone and cartilage tissue engineering. The objective of our study was to investigate the effect of WPI-based scaffolds on muscle cell adhesion and viability for the production of scaffolding for cultivated meat. **METHODS**

The AlgMA was synthesized by dissolving sodium alginate in deionized (DI) water at a 1% (w/v) and a 20-molar excess of methacyrylate anhydride. WPI was dissolved in 1x phosphate buffered saline (PBS) at 5.25% (w/v). After 24 hours, the solutions were diazoinized (MWCQ = 6-8 kDa) against chilled DI water for three days to remove any residual reactants. Polymer solutions were then frozen and lyophilized. With these dry polymers, 3% (w/v) AlgMA solutions were prepared in DI water at room temperature, to which WPI or WPI-MA, was added to bring the protein concentration to 10% (w/v). One mM esoin Y, 125 mM triethanolamine, and 20 mM 1-vinyl-2-pyrrolidone were mixed with the control (AlgMA) and experimental samples (WPI/AlgMA, WPI-MA/AlgMA). These solutions were then cast into circular molds and exposed to the green light (525 nm) for 10 minutes for crosslinking to occur. The crosslinked polymer solutions were characterized... **RESULTS AND DISCUSSION**

A 3D interconnected porous network was created, showing differences compared to an AlgMA control. WPI-based scaffolds exhibited more ordered structures compared to that of the AlgMA control. Pore sizes ranged between 50-200 µm. While moderate weight loss was experienced by the non-modified WPI, the WPI-MA and AlgMA hydrogels displayed minimal weight loss after a period of seven days. Under a compressive load, the WPI-MA/AlgMA scaffolds were more compliant compared to the AlgMA control, and the WPI-based scaffolds exhibited moduli that closely resembled the mechanical properties of native muscle tissue. WPI-based scaffolds were non-toxic to C2C12 cells, and increased cell density over the course of seven days compared to controls. WPI/AlgMA and WPI-MA/AlgMA materials were found to be non-toxic to murine C2C12 myoblasts and promoted increased adhesion and proliferation compared to the AlgMA control. The incorporation of non-modified and chemically modified WPI in alginate scaffolds shows encouraging data that supports the use of WPI-based scaffolds for engineering muscle tissues *in vitro*. Also, the tunability of composition and mechanical properties will allow these materials to be fine-tuned for other properties such as texture and flavor. **CONCLUSION**

Scaffolds were formulated using methacrylated alginate (AlgMA), WPI, and methacrylated WPI (WPI-MA). The resultant scaffold product was a photo-alginate scaffold showing encouraging data that supports the use of WPI-based scaffolds for engineering muscle tissue. Our work provides a holistic understanding of MC chains assembly in water and aids material development for application of MC in various industries. 3:45 PM *SB01.02.06* Whey Protein Isolate Composites as Tunable Scaffolds for Cultured Meat Christopher Foley, Irfan Tahir, Patrick Charron and Rachael Floreni; The University of Vermont, United States

**INTRODUCTION**

The rising global population and increasing prevalence of food insecurity highlights the need for alternative food sources. New developments in biotechnology have given rise to many alternative food and protein options, including the research and development of cultivated meat.

Cultivated meat is produced via *in vitro* animal cell culture and their incorporation into manufactured scaffolds. Plant-based, alginate scaffolds are a common material used during manufacturing, due to the tunability of their mechanical properties through modification of molecular weight, chemical composition, and structure; however, alginate does not have the necessary cell adhesion ligands. Whey protein isolate (WPI) is a bioprocess of the dairy processing industry, is a food additive, and has recently been shown in the literature to encourage cell adhesion in bone and cartilage tissue engineering. The objective of our study was to investigate the effect of WPI-based scaffolds on muscle cell adhesion and viability for the production of scaffolding for cultivated meat. **METHODS**

The AlgMA was synthesized by dissolving sodium alginate in deionized (DI) water at a 1% (w/v) and a 20-molar excess of methacyrylate anhydride. WPI was dissolved in 1x phosphate buffered saline (PBS) at 5.25% (w/v). After 24 hours, the solutions were diazoinized (MWCQ = 6-8 kDa) against chilled DI water for three days to remove any residual reactants. Polymer solutions were then frozen and lyophilized. With these dry polymers, 3% (w/v) AlgMA solutions were prepared in DI water at room temperature, to which WPI or WPI-MA, was added to bring the protein concentration to 10% (w/v). One mM esoin Y, 125 mM triethanolamine, and 20 mM 1-vinyl-2-pyrrolidone were mixed with the control (AlgMA) and experimental samples (WPI/AlgMA, WPI-MA/AlgMA). These solutions were then cast into circular molds and exposed to the green light (525 nm) for 10 minutes for crosslinking to occur. The crosslinked polymer solutions were characterized through proton nuclear magnetic resonance (1H-NMR), scanning electron microscopy (SEM), rheological compression testing, swell/weight-loss studies, and immunofluorescent staining of C2C12 myoblast cells. **RESULTS AND DISCUSSION**

A 3D interconnected porous network was created, showing differences compared to an AlgMA control. WPI-based scaffolds exhibited more ordered structures compared to that of the AlgMA control. Pore sizes ranged between 50-200 µm. While moderate weight loss was experienced by the non-modified WPI, the WPI-MA and AlgMA hydrogels displayed minimal weight loss after a period of seven days. Under a compressive load, the WPI-MA/AlgMA scaffolds were more compliant compared to the AlgMA control, and the WPI-based scaffolds exhibited moduli that closely resembled the mechanical properties of native muscle tissue. WPI-based scaffolds were non-toxic to C2C12 cells, and increased cell density over the course of seven days compared to controls. WPI/AlgMA and WPI-MA/AlgMA materials were found to be non-toxic to murine C2C12 myoblasts and promoted increased adhesion and proliferation compared to the AlgMA control. The incorporation of non-modified and chemically modified WPI in alginate scaffolds shows encouraging data that supports the use of WPI-based scaffolds for engineering muscle tissues *in vitro*. Also, the tunability of composition and mechanical properties will allow these materials to be fine-tuned for other properties such as texture and flavor. **CONCLUSION**

Scaffolds were formulated using methacrylated alginate (AlgMA), WPI, and methacrylated WPI (WPI-MA). The resultant scaffold product was a photo-crosslinked, porous network that displayed marked differences compared to the AlgMA control scaffold. In summary, our study provides compelling evidence supporting the use of WPI-based scaffolds in 3D cultivated meat production, highlighting its substantial prospects and benefits. 4:00 PM *SB01.02.07* Biomaterials and Bioprinting of Skeletal Muscle Spheroids for use as Building Blocks for Engineered Muscle Tissue Kent Leach, Nicholas Johnson, Andrea Filler and Alex Kermani; University of California-Davis, United States

Skeletal muscle tissue engineering has the potential to address key clinical and societal challenges such as traumatic muscle injury, our fundamental understanding of skeletal muscle development and disease, and the future of meat production via cell cultured meat. Preclinical animal models and monoculture have driven our understanding of skeletal muscle biology and differentiation. However, two-dimensional (2D) cell cultures lack complex cell-cell and cell-extracellular matrix (ECM) interactions that provide essential biochemical and biomechanical signals directing cell function *in vitro*. Engineered tissue must sufficiently model the complexity of native muscle, which has led to the innovation of advanced fabrication methods such as 3D bioprinting.

Bioprinting is a promising biofabrication technique for generating structured tissue due to the potential to precisely pattern multicellular constructs of relevant cell types. The most common bioprinting applications use monodisperse cells, which requires disruption of essential cell-cell and cell-matrix interactions. A growing body of research confirms the benefits of retaining the endogenous ECM to mimic the native extracellular environment and support cell function, hence exposing a key current limitation of bioprinting.

Spheroids are dense cellular aggregates that exhibit promise as building blocks for tissue engineering due to their retention of endogenous ECM, upregulated cytokine production, and increased cell-cell interactions. Spheroids are advantageous for use in tissue engineering due to their enhanced differentiation, angiogenic potential, and cell survival *in vitro* and *in vivo* compared with monodispersed cells. Spheroids have been fabricated from a wide variety of cell types yet literature on skeletal muscle spheroids, sometimes referred to as myospheres, is sparse. The study of myospheres has primarily been focused on understanding cell behavior of primary muscle cells, but their application in tissue engineering lags behind other tissues such as bone and adipose, among others. While work utilizing muscle spheroids from immortalized cell lines has been limited, initial studies have shown promising results in regard to cell survival and differentiation. For example, C2C12 spheroids, once dissociated, exhibited higher proliferation, upregulated MyoD expression, and enhanced myogenic potential in both 2D and 3D culture. Furthermore, C2C12 spheroids have upregulated myogenic factors compared to monodispersed cells and can differentiate into aligned myotubes on electrospun substrates. However, little is known about how muscle cell spheroids function in contiguous matrices such as bioinks, representing a key information gap in the field.

We hypothesized that skeletal muscle cell spheroids will function as potent building blocks of muscle tissue when embedded in 3D microenvironments. We
bioprinted skeletal muscle spheroids to assess cell function and tissue forming potential compared to monodisperse cells. We utilized 3D bioprinting as a proof-of-concept to determine whether bioprinting may adversely affect cell viability. Experiments were first performed using C2C12 spheroids before translating to more clinically and culinarily relevant primary bovine satellite cells. Both C2C12 and primary bovine SCs formed spheroids of similar sizes, remained viable after bioprinting, and exhibited similar spreading characteristics within an alginate matrix. When bioprinted with alginate as a bioink, spheroids of both cell types fused into larger tissue constructs over time and exhibited tissue formation potential similar to monodisperse cells. These data demonstrate that skeletal muscle spheroids are promising building blocks for muscle tissue and validate 3D bioprinting as a compatible fabrication technique. I will also highlight other studies illustrating the synergy of engineered biomaterials and muscle cell response.

Surface Functionalization of Pickering Emulsion Stabilized by Silk Fibroin Microparticles and Enhanced Adhesion for Foliar Spray Yue Hu and Benedetto Marelli; MIT, United States

Pickering emulsion is a category of emulsion that is stabilized by solid particles. Compared to emulsions stabilized by molecular emulsifiers, Pickering emulsion has high stability, low cytotoxicity, and good biocompatibility. Solid particle emulsifiers could also be modified by functional groups or antibodies to achieve different demands. Thus, Pickering emulsion is widely used in the food, pharmaceutical, and cosmetic industries. Silk-fibroin regenerated from silk cocoons is a natural protein. This fibrosis protein has been widely investigated and applied in the fields of biomedicine, cosmetics, and food coating. In our study, we developed biocompatible protein particles synthesized from silk fibroin to stabilize oleic acid oil-in-water Pickering emulsion. Those Pickering emulsions could be applied to agricultural and food industries.

Specifically, water-insoluble silk fibroin microparticles (SFMPs) with a diameter of approximately 2 µm were synthesized through the salting-out method. These microparticles can act as emulsifiers, stabilizing alkane-in-water Pickering emulsion. In addition, polar oil oleic acid with payloads possessing a pKa below 5 can be stabilized by SFMPs to generate a Pickering emulsion. The research also delves into the mechanism and ability of SFMPs to stabilize both nonpolar and polar oil-in-water Pickering emulsion, as evidenced by the measurement of three-phase contact angles. To functionalize Pickering emulsion, we synthesized antibody-labeled SFMPs, which can partially replace the emulsifier on the surface of Pickering emulsion droplets and improve the droplets' affinity to antibody binding sites. In this work, anti-pectic polysaccharide antibody-labeled Pickering emulsion loaded with plant hormone jasmonic acid exhibited strong binding to the waxy layer weaker part of the leaf even after the wash and effectively boosted the trichome number of Arabidopsis new leaf.

Harnessing Satellite Imagery and Geospatial Analysis for Sustainable Nutrient Management in Agricultural Systems Olatunde D. Akanbi, Deepa Bhuvanagiri, Erika I. Barcelos, Brian Gonzalez Hernandez, Arafath Nihar, Laura Bruckman, Yinghui Wu, Jeffrey Yaras and Roger H. French; Case Western Reserve University, United States

The excessive use of fertilizers in agricultural practices poses significant challenges to environmental sustainability and food security. A substantial portion of applied fertilizers from farms, and concentrated animal feeding operations (CAFOs) and urban activities, more specifically in wastewater treatment plants, are lost through runoff, leading to water pollution, ecosystem degradation, and economical loss. To address these critical issues, this research aims to develop an innovative approach utilizing satellite imagery and geospatial analysis to enable efficient and sustainable nutrient management in agricultural systems. The study leverages the Normalized Difference Vegetation Index (NDVI) derived from satellite imagery to monitor crop growth on a daily basis and optimize fertilizer application. By regularly assessing the NDVI metrics, farmers can precisely determine the timing and location for fertilizer application, ensuring optimal nutrient uptake by crops and minimizing wastage. This approach allows for large-scale monitoring, offering a valuable tool to farmers for daily decision-making in fertilizer management. Furthermore, the research incorporates geospatial analysis and spatiotemporal modeling to monitor nutrient flow from farms and CAFOs to nearby water bodies. Utilizing and integrating data (different resolutions and types) from MODIS satellite imagery, Aster GDEM on elevation, USGS Stream Water, USDA Historical Crop, and Soil, a spatial model is developed to track and quantify nutrient runoff. By understanding the movement and accumulation of nutrients, effective mitigation strategies can be formulated to prevent pollution and minimize water contamination. The outcomes of this research contribute to the overarching goal of enhancing food production while minimizing the environmental footprint of agricultural practices. By implementing satellite-based monitoring and geospatial analysis techniques, we can empower farmers and stakeholders to make informed decisions about nutrient management. This approach not only helps reduce fertilizer usage and associated costs but also protects water quality, mitigates algae blooms, and preserves aquatic ecosystems. This provides a practical and scalable solution for addressing the fertilizer application problem, ensuring long-term agricultural sustainability, and meeting the increasing global food demand.

Biopolymeric Microneedles for Underwater Fish Vaccination Meng Li, Yunteng Cao, Colleen Wolfe and Benedetto Marelli; Massachusetts Institute of Technology, United States

Over the next 30 years, with the world population continues to grow, food supplies will have to increase by 70%. Addressing challenges in food security by promoting healthy and sustainable protein sources is crucial. Aquaculture plays a vital role in meeting these requirements, and fish vaccination is integral to preventing disease spread in densely populated farming environments. However, traditional methods involving intramuscular or intraperitoneal injections require fish sedation, administration outside of water, and poses safety concerns for workers due to accidental needlestick injuries. In this work, we aim to develop an automatic system capable of precise vaccine delivery in aquaculture settings. We adapted microneedle design and fabrication for plants and mammals to meet the requirements for underwater applications. To ensure successful fish skin penetration, we have employed proteinaceous silk fibroin microneedles encapsulated with a water-proofing coating layer of food-grade natural resin. This coating layer preserves the mechanical strength of the silk fibroin microneedles in water for hours. The water-proofing coating layer prevents water absorption and swelling of silk fibroin microneedles, which could otherwise weaken their mechanical strength. The coating layer preserves the mechanical strength of silk fibroin microneedles in water for hours. Additionally, the coating layer prevents the loaded substance from prematurely releasing into the aquatic environment, ensuring controlled release after fish skin penetration. Our results demonstrate that once the microneedles pierce the fish skin, the cargo is released within hours primarily through diffusion. Our study presents a novel microneedle strategy designed specifically for precise injection and substance delivery in aquaculture, offering a promising solution for enhancing fish health, productivity, and sustainability.

8:00 PM SB01.03.07
Supporting Hydroponic Crop Growth using UV-C Light Douglas X. Shattuck1,2, Sophia Salinas1,2, Grace Gunning1,2, Emily Parker1,2 and Saman Abbas1,2; 1St Joseph School Wakefield, United States; 2National STEM Honor Society, United States; 3Malden Catholic High School, United States

Preliminary results indicate that intermittent exposure to UV-C radiation can enhance the hydroponic production of food crops by stimulating plant growth and inhibiting the growth of pathogenic organisms. However, in addition to its benefits, prolonged exposure to UV-C has been known to be harmful to plants (1, 2, 3). Watercress, a species of aquatic flowering plant in the mustard family, was selected for this investigation. It is fast growing, can be eaten raw or cooked, and is rich in vitamins K, A, C, riboflavin, B6, Ca, and Ms(4). It is closely related to the Arabidopsis sp. being studied for germination in
lunar regolith(5). We designed and constructed a hydroponic system that exposed Watercress to commercially available grow lights and UV-C radiation lamps. By exposing the plants to UV-C in monitored 5 or 15 minute intervals we hoped to maximize its growing process and kill any pathogens while minimizing the damage done by the radiation.

The watercress seeds were placed in net pots with moist growing medium and placed in a water-filled box and then exposed to grow lights. The plants were then exposed to five-minute of UV-C radiation followed by long periods of darkness. After each exposure to the UV-C, plants were observed and the growth and general characteristics of the plant recorded. After two days, the plants were exposed to fifteen minute radiation intervals, following the same schedule. Each of the six boxes of plants underwent the same testing procedures for four days. The UV-C plants appeared equally as healthy as the control group but grew taller and tilted towards the light more—exaggerated phototropism.

At the end of the test, we observed mold growing in both the control and UV-C groups. Initially, we observed much more mold in the control group. After being untreated for a week, the group exposed to UV-C light had a considerable amount of mold compared to the control group. This difference suggests that during UV-C light treatment, the mould’s growth was curtailed. In conclusion, we believe the UV-C radiation did have a positive effect on the plants as we hypothesized.

8:00 PM SB01.03.08

In-Situ Corona Discharge Non-Thermal-Plasma based Modification of Bio-Ingredients in an Integrated Food Printer: Towards Developing Novel Methodsologies for Characterization of Engineered Food Materials Derek Xuong1, Prakhyat Gaitani1, David Ryan1, Ederberth Leal-Quiros2, Saquil Ahmed1 and Sankha Banerjee1,4; 1California State University, Fresno, United States; 4University of California, Merced, United States; 2Buffalo State College, United States; 4University of California, Davis, United States

The current work involves the development of novel in-situ non-thermal plasma treatment methodologies of 3D printed starch-based bio-ingredients towards tailoring the properties of starch granule-surface proteins (SGSP). This work also includes the evaluation of continuous and discontinuous gluten networks through the surface interaction of SGSPs with quasi-static corona discharge plasma regimes. The work further studies the binding characteristics of starch-based bio-ingredients based on the plasma current-voltage characteristics. The cured starch-based sample surface will be characterized using profilometry. The binding characteristics, gluten networks, and porosity characteristics will be analyzed using microstructure evaluation through electron microscopy. Advanced hybrid machine learning models will also be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring the surface and bulk properties of these materials.

8:00 PM SB01.03.09

The Impact of Titanium Dioxide Nanoparticles on Keratinocyte Proliferation and Differentiation Derek Zhang1, Ashley Huang2, Shi Fu3, Marcia Simon2, Miriam Rafailovich1, Dina McGinley4 and Alice Shih1; 1The Wheatley School, United States; 2Syosset High School, United States; 3Stony Brook University, The State University of New York, United States; 4Stony Brook University, The State University of New York at Farmingdale, United States

TiO2 nanoparticles are still widely used as food additives in the United States for their whitening properties, UV absorption capabilities, and their potential usage as antibacterial reagents. In fact, these particles are considered valid organic additives and can be incorporated at concentrations as high as 1%. When ingested these particles can circulate in the body in contact with viable cells and the long term impacts of TiO2 build up is currently of concern for the European Food Safety Authority [1]. Additionally, even though nanoparticles may not penetrate the stratum corneum and hence do not come into direct contact with viable keratinocytes, if they are used in wound care treatments, they can come into direct contact with viable epidermal and dermal cells and influence cell function and tissue healing. In early experiments producing skin equivalents with keratinocytes exposed to 0.8 mg/mL rutile TiO2 nanoparticles, we observed nanoparticle aggregation with premature stratum corneum formation and aberrant expression of filaggrin, a late stage multifunctional differentiation marker.

Keratinocytes were grown with lethally irradiated 3T3 cells [2] with media modifications previously described [3]. At 70% confluence feeder cells were removed and cultures were treated with rutile TiO2 (0.4 mg/mL); no TiO2 cultures served as control. After 24 hours cultures were rinsed twice with Ca and Mg free phosphate buffered saline, resuspended in buffered saline with BSA and cells sorted at the Stony Brook University Flow Cytometry Core Facility using a FACS Aria IIU cell sorter. Cells associated with TiO2 were separated from TiO2-free cells based on side scatter using flow cytometry; cells showing low and high side scatter were collected. In these cultures, 90% of the cells exhibited low side scatter, consistent with the absence of nanoparticles. This compares with a low and high scatter population of 57.2% and 42.8%, respectively, in the TiO2 treated cultures.

The impact of 0.4 mg/mL TiO2 on keratinocyte proliferative capacity was also explored as a function of colony forming efficiency (CFE), and the colony forming efficiency of keratinocytes with low and high side scatter was determined; TiO2-free keratinocyte cultures served as control [4]. 12 culture dishes containing 1000 cells each were plated: 4 control plates (low side scatter), 4 plates of TiO2 treated high side scatter, and 4 plates of TiO2 treated low side scatter. Following 12 days of incubation, each culture dish was rinsed with Ca and Mg free phosphate buffered saline and stained with Rhodamine B. Colonies ≥ 1 mm were counted. In these cultures, CFEs are about three-fold lower in the high side scatter population suggesting NP inhibition of plating efficiency or proliferation. To assess the full impact of these NPs in this system and in skin equivalents, ongoing work includes SEM analyses to determine NP location within the cell and differentiation assessment by RT-PCR to determine overall skin development.

References
Humanity faces the huge challenge to supply a growing world population with sufficient and healthy food. To make this a reality we need to rethink how we produce food at large scale. This implies rethinking production on the land in the greenhouse, fractionating raw materials, understanding their functionality during processes used in food production, as well as under digestive conditions to make the connection to health effects that can be created by smart food design.

A big challenge that needs to be addressed to make smarter food design a reality is the investigation of processes that take place at micrometre scale, and even smaller scales, and often within very short times. These dynamic processes underly the food structure that we get, but the dynamics thereof are very difficult to capture due to time and size challenges, and the inaccessibility of food production line for analysis of these processes.

Microfluidics allow visualisation of very fast processes occurring during the production of, for example, two phase systems such as emulsions and foams. Various tools have been developed within our lab that allow to focus on interface formation and stabilisation at very short time scales. These tools also allow distinction of interfacial tension effects from coalescence effects in relation to the size of the structures that are formed, which is a classical dilemma that until now has not been addressed at this level of detail.

These new techniques will contribute to more flexible use of ingredients, allowing product design based on the actual functionality of components. For example, replacement of animal-based products with their plant-based counterparts, and also the use of biomass (e.g., leaves and stems) that are currently considered waist can truly contribute to more sustainable food production practice, but only if the functionality of these components is such that they lead to stable products. I could imagine that the techniques developed are ultimately used to do fast screening, comparison of ingredients, and even to establish a connection with more classic processing technologies, such as high pressure homogenization and foaming techniques given the similarity in conditions.

Thermoplastic Molding of Silk-Curcumin Composites to Enhance Biological Properties  
Ariak Bhattacharjee, Sara Rudolph, Ying Chen and David L. Kaplan; Tufts University, United States

Silk fibroin protein is a natural protein biopolymer generated from the cocoons of Bombyx mori silkworms and a useful biomaterial for many different tissue engineering applications. Flexible process engineering, versatile chemistry, and aqueous processing allow morphological and structural modifications that tailor the physical, chemical, biological, and mechanical properties of this biomaterial. However, conventional solution-based processing methods can impose limitations in terms of solubility, stability as well as scalability. Recently, we reported a thermal processing technique to fabricate dense, regenerated silk fibroin-based structures (plastics) using solid-state thermoplastic molding to address these limitations. The present work expands the utilization of thermoplastic molding of silk-fibroin to enhance the biological properties of plant-derived compounds like curcumin, the active compound of turmeric (Curcuma longa). Curcumin is widely used in traditional medicines. The objective of this study was to study the feasibility of fabricating silk-curcumin composite thermoplastics with enhanced biological properties. The hypothesis was that protective silk thermoplastic formation after curcumin incorporation would enhance the biological properties of curcumin, via the protective features of silk combined with the sustained slow release of the compound to reduce toxicity without affecting anti-bacterial properties. The results show that significantly higher levels of curcumin (~25-fold) can be incorporated into thermoplastic molded silk compared with solution formulations, attributed to the hydrophobic nature and low solubility of curcumin in solution-based processing. The fabricated curcumin incorporated thermoplastics show excellent stability in harsh acidic conditions (e.g., gut-like environment) and low curcumin (~5 % over 14 days) release. The protective silk-curcumin formation led to enhanced cytocompatibility of the curcumin with immortalized human colorectal adenocarcinoma (Caco 2) cells even at higher doses when compared to curcumin without silk. The intestinal epithelial barrier integrity based on zonula occluden 1 (ZO-1) assessments indicated that higher doses of curcumin in the thermoplastic molded silk did not result in detrimental effects to the intestinal barrier. Further work is ongoing to assess additional biological outcomes as well as potential areas of utility for these systems.

Coupling Waste Feedstocks to Microbial Protein for a Circular Food System  
Taylor Uekert, Alissa Bleem, Christopher Johnson and Gregg Beckham; National Renewable Energy Laboratory, United States

The global food system is responsible for approximately 34% of annual greenhouse gas (GHG) emissions and up to 85% of water consumption. This critical sector suffers from intensive and inefficient land and water use, the generation of multiple (solid, liquid, and gaseous) waste streams, and high fuel, fertilizer, and pesticide consumption. The production of waste-derived microbial protein (MP) represents a promising alternative for reducing the environmental impacts of protein production relative to conventional agriculture. MP can be mass-produced in volumetrically scalable cultivation processes on short timescales, enabling facile up-scaling with lower greenhouse gas emissions, land use, and water impacts than animal and, in some cases, plant protein production. MP can also be produced from waste feedstocks, diverting waste from landfills or the natural environment. Here, we present the availability and suitability of waste feedstocks for MP production, as well as the fermentation and downstream processes required to convert MP into human food products. We discuss the challenges and opportunities facing waste-derived bacterial MP and highlight key areas for innovation in both the microbiology and process design space for a more sustainable and circular food system.

10:30 AM SB01.04.04
Design of Biodegradable, Climate-Specific Packaging Materials that Sense Food Spoilage and Extend Shelf-Life  
Yangyang Han1, Song Wang1, Michael S. Strano2 and Benedetto Marelli2; 1Singapore-MIT Alliance for Research and Technology (SMART) Centre, Singapore; 2Massachusetts Institute of Technology, United States

The AgriFood systems in tropical climates are under strain due to a rapid increase in human population and extreme environmental conditions that limit the efficacy of packaging technologies to extend food shelf-life and guarantee food safety. To address these challenges, we rationally designed biodegradable packaging materials that sense spoilage and prevent moulding. We nanofabricated the interface of 2D covalent organic frameworks (COF) to reinforce silk fibroin (SF) and obtain biodegradable membranes with augmented mechanical properties and that displayed an immediate colorimetric response (within 1 second) to food spoilage, using packaged poultry as an example. Loading COF with antimicrobial hexanal also mitigated biotic spoilage in high
temperature and humidity conditions, resulting in a four-order of magnitude decrease in the total amount of mould growth in soybeans packaged in silk-COF, when compared to cling film (i.e., polyethylene). Together, the integration of sensing, structural reinforcement, and antimicrobial agent delivery within a biodegradable nanocomposite framework defines climate-specific packaging materials that can decrease food waste and enhance food safety.

10:45 AM SB01.04.05
Microneedles Carrying Nanosensors for Real-Time Detection of Abiotic Stress in Planta Raju Cheerlavancha1, Benny Sng Jian Rong2, Khong Duc Thinh3, Yanfeng Cao1, Yangyang Han1, Mervin Ang Chuey1, Song Wang1, Gajendra Pratap Singh1, Michael S Strano1, In-Cheol Jung1 and Benedetto Marello1,2; Singapore-MIT Alliance of Research and Technology, Singapore; 1Temasek Life Sciences Laboratory, Singapore; 2Massachusetts Institute of Technology, United States

Abiotic stress refers to adverse environmental conditions that negatively impact plant growth, development, and productivity. These stressors include extreme temperatures, drought, salinity, heavy metals, and radiation. Understanding plant responses and adaptation to abiotic stress is crucial, especially with the increasing severity and frequency of such stressors due to climate change. However, conventional methods for studying plant responses have limitations such as indirect measurements, low spatial resolution, and the inability to visualize real-time changes.

To overcome these limitations, we developed a delivery system using microneedles (MNs) to carry nanosensors. These MNs can be inserted into both soft and hard plant tissues without leaving any residues. By incorporating the nanosensor into the MNs, we successfully demonstrated real-time sensing of abiotic stress in Bok Choy and Nicotiana benthamiana. The embedded nanosensor, designed specifically for abiotic stress, enables rapid and sensitive detection of near-infrared (nIR) fluorescence signals. This allows for accurate measurement and visualization of abiotic stress levels. Furthermore, we confirmed the compatibility of the MNs with the abiotic stress nanosensors.

In summary, the integration of nanosensors with non-invasive delivery systems like MNs presents exciting opportunities for studying abiotic stress in plants. These innovative approaches help us gain a deeper understanding of how plants perceive and respond to environmental challenges. Ultimately, this knowledge can inform the development of stress-tolerant crops, sustainable agricultural practices, and strategies to mitigate the impacts of climate change on plant productivity and food security.

11:00 AM SB01.04.06
Time-Resolved Roasting-Induced Microstructural Evolution of Arabica Coffee Beans using X-Ray Computed Micro-Tomography Eshan Ganju1, Kunal Chawla2, Samuel Yang3 and Nikhil Chawla2; Purdue University, United States; 1Carmel High School, United States

The aroma of coffee is deeply connected to the roasting process, which leads to notable changes in the bean's structure and chemistry. While many research studies have explored the chemical alterations occurring in the coffee bean during roasting, the structural changes have typically only been observed broadly, quantified by changes in size, density, fracture strength, or basic sectional views of the coffee bean. Traditional microscopy techniques are insufficient in providing an in-depth understanding of the coffee beans' microstructure, primarily due to their resolution, two-dimensional (2D) limitations, and the destructive nature of the analyses. These limitations are further exacerbated by the fact that the coffee bean undergoes significant three-dimensional (3D) structural changes during the roasting process. These changes are impacted by the coffee bean variety's properties, the bean's initial microstructure (which is affected by the local environment, including altitude, humidity, etc.), and the roasting process. As a result of the limited information about the initial 3D microstructure of the bean, its impact on the evolution of the emergent microstructure during roasting has been largely unexplored. Furthermore, while global measurements in porosity or pore volume at different roast levels have been reported, the heterogeneity in the evolution of porosity in different regions of the bean, which impacts the uniformity of the ground beans, has not been described. In this study, we conducted a time-resolved study of the roasting-induced microstructural evolution of Arabica coffee beans using X-ray computed micro-tomography (XCT). We combined high-resolution XCT data with computational image analysis techniques to examine the evolution of the microstructure of Coffea arabica beans during roasting. Beans sourced from Brazil, Colombia, and Ethiopia were tracked individually throughout the roasting process going from the green bean to the dark roast stage. The individual beans were tracked and scanned at multiple stages of roasting to capture the 3D tomography data of the entire bean. The XCT data, captured at different roasting levels, revealed detailed, time-resolved information about porosity, pore size distribution, and cracking within different regions of the beans. Results showed a significant increase in porosity and pore size from green-bean to dark-roast state, but the rate of increase wasn't linearly dependent on roasting time. Furthermore, beans from different regions showed markedly difference spatial heterogeneity in porosity and cracking. The effects of the initial green bean microstructure, as influenced by the growth environment, on the subsequent structural evolution will be discussed. The data and analyses presented in this study can assist in advancing research in the realm of food engineering by enabling a deeper understanding of the structural characteristics of coffee beans from various regions of the world and by clarifying the link between the processing and microstructure of the bean at different roasting levels. Furthermore, the 3D characterization and analysis presented here can be applied as a framework to study a diverse class of food materials.

11:15 AM SB01.04.07
Living Filters for Sustainable and Selective Treatment of Drinking Water and Beverages Vicki L. Colvin; Brown University, United States

Many communities in the U.S. and globally suffer because of a lack of access to safe drinking water. Cleaning water, however, using conventional technology is a dirty business that is expensive as well as material and energy intensive. There is a need to broaden access as well as provide more sustainable solutions that can improve people’s water and their health. Living filters are cultures of living microbes that are engineered to both sense and treat contaminants at the very low concentrations relevant for drinking water. Here we demonstrate a system that targets the removal of arsenic from drinking water and beverages such as fruit juice and wine. Conventional remediation based on chemical sorption is challenging because of interferences from phosphates, silicates, flavor compounds, and organic matter; membrane-based separations also can be impacted by these species and more critically will remove all compounds including those that should be preserved for flavor in the case of beverages. Here, we exploit the extraordinary selectivity of biological recognition to solve this problem. Microbial engineering is applied to generate E. Coli that contain multiple copies of arsenic-binding proteins that are highly selective for arsenic and effectively no binding to smaller anions. When protein expression is induced, bacteria remain healthy and produce flavor compounds as measured by mass spectrometry in beverages remain unaffected by these treatment processes. Most recently we have incorporated bioluminescent reporter into the living filters which permit the detection of arsenic to optimize the treatment system. These engineered materials can be freeze-dried with modest impact on performance. Dry powders can be shipped easily under ambient conditions and then cultivated at the site prior to their integration into the treatment system. An important benefit of these materials is that the sorbent is in effect living, allowing for sustainable and low-cost manufacturing.
Home Composting Doesn’t Work as an Environmentally Beneficial Method for Managing Biodegradable and Compostable Packaging
Danielle Purkiss, Ayse Allison, Fabiana Lorencatto, Susan Michie and Mark A. Miodownik, University College London, United Kingdom

Compostable and biodegradable plastics are growing in popularity but their environmental credentials need to be more fully assessed to determine how they can be a part of the solution to the plastic waste crisis. We present results and analysis on home compostable packaging. This type of packaging requires the citizen to be able to correctly identify the packaging as ‘home compostable’, to have composting facilities at home, and to successfully compost the plastic. Using a citizen science approach, we engaged with 9701 UK citizens geographically spread across the UK to examine their capability, opportunity, and motivation to do this. Of this cohort 1648 citizens performed home compost experiments to test the environmental performance of compostable plastics. We report on the type of plastics they tested and their disintegration under real home composting conditions. The results show that the public are confused about the meaning of the labels of compostable and biodegradable plastics. 14% of sampled plastic packaging items tested were certified ‘industrial compostable’ only and 46% had no compostable certification. Of the biodegradable and compostable plastics tested under different home composting conditions, the majority did not fully disintegrate, including 60% of those that were certified ‘home compostable’. We conclude that for both of these reasons, home composting is not an effective or environmentally beneficial waste processing method for biodegradable or compostable packaging in the UK. This talk also outlines the requirements to make industrial composting a viable and sustainable method for managing compostable packaging.
Investigated by in situ observation of the dynamic assembly process with liquid phase transmission electron microscopy (LP-TEM). In combination with the cryo-TEM data, the LP-TEM results revealed that liquid-liquid phase separation was the driving force for the formation of asymmetric polymersomes. Upon infrared laser irradiation (808 nm), the PA-nano-assemblies in the polymersome structure provided photothermal heating and propelled the polymersomes in a controllable way regarding both direction and speed. This study demonstrates the formation of a new nanomotor topology which is driven by the photothermal effect and fully composed of organic building blocks. This nanomotor is further investigated for its application in active drug delivery.

9:05 AM SB01/SB02/SB04/SB10.05 Encapsulation and Delivery of Biomolecules with Cell-Mimicking Nanopipol Bertrand Czarny1,4, Wen Jie Melvin Liew1, Abdullah Alkaifi6, Atul Parikh1,2 and Subramanian Venkatraman1,2; Nanyang Technological University, NTU, Singapore; 3University of California, Davis, United States; 4Tang and National University of Singapore, Singapore; 5University of California, San Diego, United States

High initial burst release of biomolecules is just one of the many challenges faced by lipid based nanoparticulate formulations, even though it is widely used for drug encapsulation and delivery studies. One of the emerging potential strategies is the use of nanopipol (NLG) to encapsulate biomolecules, which can suppress the initial burst release. This gives a level of control and sustain to the release of hydrophilic drugs. However, current works are short on characterisation of the release mechanism. Therefore, varying molecular weight of Poly (ethylene glycol) Diacrylate (PEGDA) were used for the fabrication of PEGDA NLG, to study the mechanism for release of Dextran-Fluorescein Isothiocyanate (DFITC). Fluorescence Recovery after Photobleaching (FRAP), were performed on cell derived micropipol (MLG), a novel system developed as a solution to limitations of FRAP with NLG. Results from the studies has shown that the NLGs’ mesh sizes are controllable via the use of different Mw of PEGDA, where a lower Mw used resulted in a smaller mesh size of the nanogel core, by having a higher crosslinking density. This in turn gave higher suppression of the initial burst release of DFITC, up to a 10-fold difference. FRAP results then gave further validation by showing that the smaller mesh size restricted the diffusion of DFITC, consequential of a lower mobile fraction. These gave clear insight into the possibility of controlling the encapsulation and release of biomolecules, by targeting the fabrication of nanogel core. From this, Chitosan Methacrylate (CMA) NLGs was then studied to expand into other ways in manipulating the nanogel core for greater control, such as a differently charged core. Results was shown that CMA NLGs are also able to suppress the initial burst release of DFITC and it can be controlled by using a different concentration of CMA. This increases the possible strategies for consideration during the design of NLG systems and especially CMA NLGs opens up the possibility of encapsulation of negatively charge biomolecules, such as siRNA. As the NLG system involves two critical components, namely the nanogel core and the bilayer coating, the membrane properties are essential for the designing of NLGs. Herein, cell membrane coating for NLG was studied, with the development of a novel Chitosan Methacrylate-Tripolyphosphate (CMATPP) nanoparticle systems, which allows for the co-extrusion with cell membrane vesicles. The coating of CMATPP nanoparticles can possibly confer the membrane properties, such as prolonged in vivo circulation and improved cellular uptake, to CMATPP nanoparticles. Coating was validated through flow cytometry with characteristic membrane proteins of cell derived nanovesicles (CDN), namely CD9, CD81, TSG101, or with RBC membrane vesicles, CD47. RBC CMATPP NLGs were also shown that it can further suppress the initial burst release and sustained release compared to Liposome CMATPP NLGs. All in all, it was shown that cell mimicking NLG system was able to provide a controlled release of hydrophilic biomolecule, and the release mechanism was studied and characterized using FRAP. Relationships with changes to the nanogel core as well as membrane coatings were also explored and proven to be viable and plausible expansions to other membrane origins were discovered. This study has provided a guide on the design of NLGs for a multitude of needs with regards to encapsulation and delivery, as well as for future in vivo performance.

9:20 AM SB01/SB02/SB04/SB10.06 Spiky Silica Nanoparticles Embedded with ZIF-90: A Promising Approach for Intracellular Drug Delivery Manoj Kumar Sharma1,2, Dan Chang2, Jingjing Qiu3, Hao Song2, Chengzhong Yu2, Ashok Kumar Ganguli1 and Jie Tang1; 1IIT Delhi, India; 2The University of Queensland, Australia

Nanotechnology has emerged as a promising field in treating various diseases, offering significant advancements in drug delivery systems (DDS). These systems offer advantages such as improved drug bioavailability, controlled release kinetics, and prolonged circulation time, leading to increased safety and efficacy. Mesoporous Silica (MSN)-based carriers exhibit desirable properties, including high porosity, biocompatibility, and tunable particle size. The introduction of spiky nanotopography on silica nanoparticles has garnered significant scientific interest due to its unique capabilities, including enhanced bacterial adhesion, intracellular drug delivery, and protection of genetic material. Nonetheless, challenges persist in MSN-based DDS, encompassing limitations such as low drug loading capacity and premature release of anticancer agents. To address these challenges, promising strategies have been explored, such as functionalizing silanol groups on mesoporous silica nanoparticles (MSNs) with amine moieties or integrating organic compounds and metal-organic frameworks (MOFs). The literature provides limited information on silica-Zn-MOF composites. Previous studies have predominantly focused on ZIF-8 formation on silica nanoparticles.

This study successfully synthesized a novel nanocomposite consisting of nature-inspired spiky silica nanoparticles (SNP) embedded with zeolitic imidazolate framework-90 (ZIF-90). The resulting SNP-ZIF-90 composites retained their spiky morphology and demonstrated enhanced drug-loading capacity for doxorubicin (Dox) compared to bare SNP. Furthermore, the modified SNP-ZIF-90 composites exhibited improved cellular uptake and pH-responsive drug release, highlighting their potential as an efficient drug delivery system.

9:35 AM SB01/SB02/SB04/SB10.08 Ultrasound Hydrogel Biosensor with Controllable Self-Adhesion Properties for Electrophysiology Measurement Shuvum Zhuo, Alexandre Tessier and Shideh Kabiri Ameri; Queen’s University, Canada

Hydrogel has recently been utilized to develop health monitoring sensors and devices such as bioelectrodes. Owing to their good electrical conductivity, ultra-softness, and self-adhesion, current hydrogel sensors have found their application in electroencephalogram (EEG), electromyogram (EMG), and electrocardiogram (ECG) recording. However, the highly adhesive hydrogels are hard to peel off from the surface of the skin after laminating it and they are susceptible to losing the water content and unfavorable changes in the electrical conductivity and mechanical softness. Here we report an ultrasound hydrogel-based sensor with controllable self-adhesion properties that can fully conform to the skin and perform reliably for an extended period. An ultrasonic, conformable biosensor with a thickness of less than 10 µm is fabricated based on gelatin-acrylamide-polyacrylamide hydrogel, where the sol-gel transition of the gelatin is utilized to control the modulus and adhesion force. The ultralow thickness and good stretchability of the gelatin-acrylamide-polyacrylamide hydrogel contribute to a seamless interface between the biosensor and human skin, which is desired in wearable devices for high-quality bio-signal acquisitions such as electrocardiography (ECG) and electromyography (EMG).

9:50 AM *SB01/SB02/SB04/SB10.10
From Sub-Micron Resolution Towards 3D-Printing at the Speed of Light: Pushing the Boundaries to Serve Health  Quinten Thijssen1, Laurens Parmentier2, Hayden Taylor3, Steven Ballet3 and Sandra Van Vlierberghe1; 1Ghent University, Belgium; 2University of California, Berkeley, United States Minor Outlying Islands; 3Vrije Universiteit Brussel, Belgium

Current thoroughly described biodegradable and cross-linkable polymers mainly rely on acrylate cross-linking. However, despite the swift cross-linking kinetics of acrylates, the concomitant brittleness of the resulting materials limits their applicability. Here, photo-cross-linkable poly(ε-caprolactone) (PCL) networks through orthogonal thiol-ene chemistry are introduced. The step-growth polymerized networks are tunable, predictable by means of the rubber elasticity theory and it is shown that their mechanical properties are significantly improved over their acrylate cross-linked counterparts. Tunability is introduced to the materials, by altering \(M_c\) (or the molar mass between cross-links), and its effect on the thermal properties, mechanical strength and degradability of the materials is evaluated. Moreover, excellent volumetric printability is illustrated and the smallest features obtained via volumetric 3D-printing to date are reported, for thiol-ene systems. Finally, by means of in vitro and in vivo characterization of 3D-printed constructs, it is illustrated that the volumetrically 3D-printed materials are biocompatible.

In an attempt to mimic nature’s ability to adhere cells, PCL is often coated with nature-derived polymers or its surface is functionalized with a cell-binding motif. However, said surface modifications are limited to the material’s surface, include multiple steps, and are mediated by harsh conditions. In a second part, we introduce a single-step strategy toward cell-adhesive polymer networks where thiol-ene chemistry serves a dual purpose. First, alkene-functionalized PCL was crosslinked by means of a multifunctional thiol (vide supra). Second, by means of a cysteine coupling site, the cell-binding motif C(-linker-)RGD was covalently bound throughout the PCL networks during crosslinking. Moreover, the influence of various linkers (type and length), between the cysteine coupling site and the cell-binding motif RGD, was investigated and the functionalization was assessed by means of static contact angle measurements and X-ray photoelectron spectroscopy. Finally, successful introduction of cell adhesiveness was illustrated for the networks by seeding fibroblasts onto the functionalized PCL networks.

This combination of mechanical stability, tunability, biocompatibility, no post-processing functionalization required and rapid fabrication by volumetric 3D-printing charts a new path toward bedside manufacturing of biodegradable cell-interactive, patient-specific implants.

In addition to photo-crosslinkable polyesters, also progress in the field of high resolution two-photon polymerization and volumetric additive manufacturing of gelatin-based hydrogels will be addressed. Hence, our material platform can serve both hard and soft tissue engineering applications.

**Smart and Programmable Crystalline Sponges for Protection**  
Omar K. Farha; Northwestern University, United States

This talk will focus on metal–organic frameworks (MOFs) from basic research to implementation and commercialization. MOFs are a class of porous, crystalline materials composed of metal-based nodes and organic ligands that self-assemble into multi-dimensional lattices. In contrast to conventional porous materials such as zeolites and activated carbon, an abundantly diverse set of molecular building blocks allows for the realization of MOFs with a broad range of properties. We have developed an extensive understanding of how the physical architecture and chemical properties of MOFs affect material performance in applications such as catalytic activity for chemical warfare agent detoxification.

**11:00 AM **SB02.01.02

**Supramolecular Design of Mesoporous 2D Covalent Organic Frameworks for the Encapsulation of Large and Small Guests**  
Ronald A. Smaldone;
The University of Texas at Dallas, United States

Interlayer interactions in 2D covalent organic frameworks (COFs) have been shown to be important factors in both their formation and bulk properties. There are many previous examples of controlling interlayer interactions in COFs by tuning the monomer or geometry. However, the use of hydrogen bonding is much rarer. The highly directional nature of a hydrogen bonding interaction makes it difficult orient properly in a COF structure. To accomplish this, we have designed monomers with a non-planar structure that arises from steric crowding, forcing the amide side groups out of plane with the COF sheets orienting the hydrogen bonds between the layers. The presence of these hydrogen bonds provides significant structural stabilization as demonstrated by comparison to control structures that lack hydrogen bonding capability, resulting in lower surface area and crystallinity. We have characterized both azine and imine-linked versions of these COFs for their surface areas, pore sizes and crystallinity. The rigidified structure that results from these supramolecular interactions can enable the production of COFs with mesopores capable of hosting large protein guests. In addition to more conventional COF characterization methods (such as powder X-ray diffraction and porosity analysis), we also used variable temperature infrared spectroscopy (VT-IR) methods and van der Waals density functional calculations to directly observe the presence and character of the hydrogen bonding interactions. This talk will also discuss the importance of mesopore design in COFs for the adsorption of different guests in aqueous solutions, ranging from proteins, to small molecule pollutants.

Biocompatible Robust MOFs for New Wound Healing Solutions
Christian Serre, CNRS, ENS, ESPCI Paris, PSL University, France

The development of new wound healing solutions is still a critical issue in order to treat infectious diseases. Biocompatible metal organic frameworks (MOFs) have long term been considered mainly against cancer. We will show in this presentation two new strategies to take benefit from their open metal sites and/or ordered porosity to propose new solutions out of traditional antibiotics treatments. A first strategy relies on the controlled delivery of Nitric oxide (NO), a powerful gaseous therapeutic agent of interest to treat a wide variety of disease states. As it can overcome the bacterial resistance to antibiotics, it is an appealing alternative to conventional drugs, and the development of efficient NO-donating drugs is being demanded. However traditional NO carriers are often toxic which precludes their practical use. It is crucial to find biocompatible carriers with prolonged biological half-life. MOFs have been previously proposed as antibacterial or anti-thrombogenic carriers but only in gas phase mainly through a coordination on their unsaturated metal sites. However once in contact with body fluids, the release of NO occurs within minutes compromising their practical use. We have therefore selected a robust biocompatible Ti-MOF such as MIP-1777 that is enable to release NO within 2 hours in phosphate buffer, due to an unprecedented NO adsorption/release mechanism. Very recently, we also designed a new ultra-narrow pores iron bisphosphonate MOF, denoted MIP-21010, that is stable in PBS while adsorbing NO on its metal sites. Due to the combination of a novel adsorption mechanism, an exceptional stability in PBS and its narrow pores, it leads to a record ca. 3 days of NO release in biological media; in both cases we demonstrate how these controlled releases lead to cell migration or even angiogenesis that are of a crucial importance for wound healing applications, paving the way for the design of new wound healing therapies.

A second strategy consists of encapsulating dyes into biocompatible large pores Fe-MOFs. Through the protective effect of the pores’ confinement considerably slowing down the bleaching of the dye under near-infra-red irradiation, as well as the slow release of Fe3+ ions once in contact with body fluids leading to the formation of ROS, we demonstrate how these new MOF-dyes composites, through a multimodal based on PTT/PDT and chemo-dynamic therapy, are of interest to treat successfully different anti-biotic resistant infections (Chlamydia…).[4-5]

Multifunctional Enzyme Nanocapsules Boost T Cell Immunity and Efficacy of Cancer Immunotherapy
Zheng Cao, Wenting Chen, Duo Xu, Jing
Cancer immunotherapy has reshaped the landscape of cancer treatment, but its effectiveness in treating solid tumors is hindered by overproduction of lactate by cancer cells. Extensive trials are being conducted to regulate lactate levels by inhibiting lactate dehydrogenase, however, such inhibitors can disrupt the metabolism of healthy cells and cause severe non-specific toxicity. In contrast to those strategies, we innovatively target lactate itself by an enzyme, lactate oxidase, which effectively reduces the lactate levels and releases hydrogen peroxide, an immunostimulatory molecule, in the tumor microenvironment. However, recombinant lactate oxidase from microorganisms possesses short circulating half-life, low enzyme activity, and immunogenicity. To circumvent this limitation, we innovatively report herein a nano-encapsulating strategy to encapsulate individual lactate oxidase molecules within a thin polymer shell by in-situ polymerization of monomers and crosslinkers, affording the synthesis of nanocapsules. The nanocapsules stabilize lactate oxidase and prevent it from proteolysis and denature, minimize the immunogenicity, prolong the circulating half-life, enabling their use as a potent therapeutic for cancer immunotherapy. Lactate oxidase nanocapsules can promote the proliferation and activation of effector T cells and suppress tumor-resident regulatory T cells in vitro. As further demonstrated in a murine melanoma model and a humanized mouse model of triple-negative breast cancer, nanocapsules of lactate oxidase avert tumor immunosuppression and enhance anti-cancer T cell immunity by upregulating gene expression for T cell recruitment and activation, as confirmed by single-cell RNA sequencing. Such multifunctional lactate oxidase nanocapsules lead to improved efficacy of immunotherapies for solid tumors.

Metal-Organic Frameworks for the Encapsulation of Bio-Entities.

Joanna Christodoulou1, Jonathan Bachir1, Effrosyni Gkaniatsou1, Nathalie Steunou1 and Clemence Sicard1,2; 1Institut Lavoisier de Versailles, France; 2Institut Universitaire de France, France

Bio-entities benefit from unparalleled activities of high interest in many applications such as high catalytic activities under mild conditions (aqueous media, room temperature). However, these are fragile entities, easily degraded under non-native conditions. Encapsulation, i.e. inclusion within a host matrix, is particularly interesting for bio-entities stabilization and protection as it can provide controlled environment and protection. Metal-Organic Frameworks (MOFs) have been as a host matrix of choice to answer the limitations of traditional immobilization matrices, resulting in the design of novel functional biomaterials.[1] The MOF-bio-entity composites exhibit promising properties, since the biological activity can be preserved while the stability of bio-entities in non-native environments could be improved. Encapsulation can be performed by diffusion of the biological entities into the porosity of preformed MOF. Alternatively, the MOF can be formed “in-situ” around the bio-entities. Both strategies are limited to a number of MOF/bio-entities couples either due to size matching constraints or to a narrow window of compatible synthetic conditions. In this communication we will present our efforts to expand synthetic routes and processing methods to explore new compositions and hierarchical structures of bio-entities-MOFs hybrids. We will describe the synthesis and characterization of MOFs-based living materials.[2] The mesoporous iron polycarboxylate MIL-100(Fe) was synthesized in the presence of Pseudomonas putida bacteria. The synthesis conditions (aqueous media, 30 °C) were compatible with the preservation of the bacteria integrity. High resolution microscopic techniques (TEM, STEM-XEDS) were applied on cross-sections to study the interface between the two components, revealing the presence of an exoskeleton encapsulating individual bacteria cells. We will also discuss our latest finding on the design of novel bio-entities-porous materials with unique properties for potential application in biocatalysis.[3]

Supercritical CO2 Precipitation of Porphyrin-Based MOFs as Potential Materials for Photodynamic Therapy

Ana M. Lopez-Perezaga1, Marta Kubovics1, José A. Ayllon2, Concha Domingo1 and Carme Nogués2; 1Consejo Superior de Investigaciones Científicas (CSIC), Spain; 2Universitat Autònoma de Barcelona, Spain

In the past few years, our research group has focused on synthesizing metal-organic frameworks (MOFs) using environmentally friendly methods based on supercritical CO2 (scCO2)[1], where synthesis and pore activation can occur, in many cases, in a single step. Building upon these advancements, the preparation of MOFs containing porphyrin linkers were of great interest to us, as porphyrins are fundamental building block precursors in various domains of synthetic chemistry. For example, porphyrins can form coordination networks with potential applications in various domains of synthetic chemistry. For example, porphyrins can form coordination networks with potential applications in catalysis, sensors, as well as for cancer treatment.[2] In the latter, porphyrin and its derivatives remain the most extensively employed materials for photodynamic therapy (PDT)[3], an anticancer therapy based on the local application of a photosensitizer in the affected area that, by light radiation of a certain wavelength, produce reactive oxygen species (ROS)[4], which are able to destroy the harmful cells through either necrosis or apoptosis.

In our research, we focused our interest into the possibilities of preparing MOFs using a porphyrin linker with pyridyl motifs, specifically 5,10,15,20-Tetra(4-pyridyl)porphyrin (H2TPyP) using exclusively scCO2 as reaction media. The reaction involved the coordination of the binding sites (pyridyl moieties in meso- position, and the inner tetrapirole ring) with different metals. For this purpose, we employed four metal hexafluoroacetateacetate complexes (M(hfac)2, M = Cu, Zn, Co, Ni) as metal precursors in the production of the metal-organic materials. Among the obtained samples, the scCO2-precipitated Zn(II) MOF demonstrated exceptional performance when tested as a potential photosensitizer in PDT therapy against the SKBR-3 tumoral cell line. This MOF resulted to be nontoxic, but after 15 min of irradiation at 630 nm, using either 1 or 5 μM concentration of the product, almost 70% of tumor cells died after 72 h.

Wen and Yunfeng Lu; University of California, Los Angeles, United States
The most interesting results of this work were recently published in the journal Chemistry of Materials[1].

4:15 PM *SB02.02.07
Broadening the Scope of MOFs for In Situ Biomolecule Encapsulation Mónica Giménez-Marqués, Jesús Cases Díaz and Jana Glatz; University of Valencia, Spain

The use of metal–organic frameworks (MOFs) as robust coating of fragile biomacromolecules has been demonstrated a valuable strategy for their preservation, enabling their ample implementation in biotechnological and biotechnological processes. Essentially, this biomolecule encapsulation requires the MOF assembly under biocompatible conditions and the existence of favorable electrostatic surface conditions at the biomolecule-MOF interface.

Despite recent growth in the field of MOF mineralization, only a limited number of MOFs have been accessed, being ZIFs the most widely explored materials for biohybrid synthesis. However, next directions in the field require revealing the hierarchical organization of these assemblies and for that, it is essential to expand the biohybrid family by using MOFs with distinct nature.

Herein we present alternative synthetic approaches to access previously elusive MOFs that permit to study new biohybrid architectures with undisclosed functionalities.

8:30 AM *SB02.03.01
Enhancing Vaccine Stability and Immunogenicity Through Biomimetic Mineralization using Zeolitic-Imidazole Frameworks (ZIFs) Jeremiah J. Gassensmith; University of Texas-Dallas, United States

Vaccines are susceptible to structural conformational changes under environmental and chemical stressors, compromising their therapeutic efficacy. This lecture presents three innovative case studies that address this challenge to enhance the stability, preservation, and immunogenicity of protein, DNA, and lipid nanoparticle based vaccines.

First, we discuss using zeolitic imidazolate framework-8 (ZIF-8) as a protective agent for a model viral vector against denaturing conditions. Immunoassay and spectroscopy analysis reveal that ZIF-8 provides enhanced thermal and chemical stability to the conformational structure of the encapsulated viral nanoparticle. Long-term biological activity studies in animal models demonstrate the integrity, biosafety, and immunogenicity of the virus-ZIF composite. Furthermore, histological analysis confirms the absence of tissue damage, indicating ZIF-based protein composites as promising candidates for preserving proteinaceous drugs, ensuring biocompatibility, and controlling drug release in vivo.

Next, we explore stabilizing proteoliposomes, supramolecular lipid-protein assemblies that mimic cellular membranes. We demonstrate that metastable lipid, protein-detergent, and protein-lipid complexes can be successfully immobilized within zeolitic-imidazole framework (ZIF) bio-composites. This immobilization strategy enhances their stability against chemical and physical stressors such as elevated temperatures, chemical denaturants, aging, and mechanical stresses. Extensive morphological and functional characterization confirms that the encapsulated complexes maintain their native morphology, structure, and activity, which would otherwise rapidly degrade without immobilization.

Lastly, we address the pressing need for effective vaccines against pathogenic bacteria in the face of increasing antibiotic resistance. The genetic diversity of bacteria poses challenges in selecting appropriate antigens, hindering vaccine development. We present a proof-of-principle method to enhance the immunogenicity of a model pathogenic E. coli strain by forming a slow-releasing depot. Biomimetic mineralization within a metal-organic framework (MOF) effectively encapsulates the E. coli strain, enhancing antibody production and improving survival in a mouse bacteremia model. This approach surpasses the limitations of whole-cell formulations and demonstrates the potential for successful clinical translation.

These innovative strategies utilizing ZIFs and MOFs hold great promise for revolutionizing vaccine design, preservation, and immunogenicity. By enhancing stability and ensuring effective immune responses, these advancements contribute to developing next-generation approaches for combating bacterial infections and preventing the spread of pathogens.

Design of Highly Porous MOFs for Drug Delivery

David Fairen-Jimenez; Department of Chemical Engineering & Biotechnology, University of Cambridge, United Kingdom

Metal-organic frameworks (MOFs) are ideal candidates for payload delivery in drug delivery applications due to their highly tuneable surface properties, with drug capacities as high as 60 wt.%. The use of MOFs can lower the required amount of active pharmaceutical ingredient (API), providing a more efficacious therapy while also decreasing the potential for untargeted and undesired effects. Their controlled and autonomous delivery utilizing such a porous-high capacity loading material ultimately could reduce high dependence on patient compliance.

We have developed a series of nano-sized Zr-MOFs with different pore sizes and volumes, from the microporous UiO-66 family of materials to mesoporous NU-1000, all of them showing minimal cytotoxicity. On the one hand, we show how the post-synthetic modification of the MOFs can allow the controlled release of different payloads, extending the release time from 2 days to 30 days. On the other hand, we show how the particle size and surface chemistry allow tuning the final fate of the MOFs and the metabolic pathways of how they are endocytosed by the cells. By modifying the external surface chemistry of the MOFs or by grafting different motifs, we can extend the release time of the drugs, and improve the efficiency of the MOFs to penetrate the cells and target specific organelles.

Our work has allowed us to understand the fundamental biophysical and biochemical mechanisms of cancer cell death upon treatment with MOFs. The fundamental understanding of the biological aspects of cancer has allowed us to advance not only in small-drug molecule delivery but also in novel solutions based on photodynamic therapy and gene therapy.

Using Zeolitic Imidazolate Frameworks for Creating an Intranasal Depot Effect and Development of a Novel Tuberculosis Subunit Vaccine

Sneha Kumari1, Ryanne N. Ehrman1, Jonathan Martinez-Garcia1, Yalini Wijesundara1, Thomas Howlett1, Lenette Lu2, Angelo Izzo3, Gabriele Meloni1 and Jeremiah J. Gassensmith1; 1University of Texas at Dallas, United States; 2University of Texas at Southwestern, United States; 3Centenary Institute, Australia

Tuberculosis (TB) is the second leading cause of death from infectious diseases in the world after Covid-19. Despite the great strides taken in vaccine development over the last few decades, TB prevention still relies on the century-old BCG formulation, whose efficacy widely varies amongst different populations. Whole cell attenuated vaccines for such pathogenic diseases are a risky avenue of research. Decades of subculturing are required to attenuate the strains, and yet there is always a risk of reverting to virulence. We have hence developed a subunit vaccine candidate which combines two novel antigens, a powerful adjuvant, and a slow-release system using MOFs for depot effect. CipV and McfB are two membrane-bound metal transporter proteins present on the surface of Mycobacterium tuberculosis that are potential virulence factors of TB and can be used to induce a T-cell mediated response upon vaccination. Class A Cpg—a synthetic reproduction of bacterial DNA—has been widely investigated as an adjuvant in research models and fits into our formulation well as it also activates T-cells. It is worth noting that many similar subunit vaccines that fall short in clinical trials are unable to produce high enough antibody titers compared to whole cell vaccines. This is primarily attributed to short exposure time of delicate biomaterials like liposomes, that degrade in the body fast. Our goal is to combat this using zeolitic imidazolate frameworks (ZIF), a metal-organic framework that can be synthesized in

Label-Free Pore-Level Virus and Particle Detection with Bioinspired Inverse Opal Photonic Crystals

Natalie Nicolas and Joanna Aizenberg; Harvard University, United States

For most methods of viral imaging, it is necessary to bind bulky fluorescent molecules to the virus in order to visualize its location with optical microscopy. This increases the complexity of sample processing and may change viral behavior. In this research, we instead electrostatically bind viruses or charged particles to the surface of an inverse opal, which is a bioinspired self-assembled ordered porous material, to create a label-free method for imaging the location of a virus with a light microscope. Attached viruses increase the energy barrier to liquid infiltration in the re-entrant pores of the inverse opal, such that they remain dry when a test solution fills the non-occluded pores. Polarized light microscopy can then be used to distinguish the non-wetted pores, revealing location and concentration information about the viruses. This can create a customizable label-free tool to study viral behavior.
in laboratory or medical settings.

Leblanc¹; ¹University of Miami, United States; ²Univrsity of Miami, United States; ³Florida International University, United States; ⁴Istituto Italiano di Tecnologia, Italy; ⁵Politecnico di Torino, Italy; ⁶Miami Dade College, United States

Alzheimer’s disease (AD) is the most common form of senile dementia, with few effective treatments. AD pathology is characterized by extracellular amyloid plaques and intraneuronal neurofibrillary tangles. A promising drug discovery approach is to develop molecules capable of targeting both hallmarks of AD, by inhibiting Aβ and tau aggregation. In recent years, carbon dots (CDs) have emerged as novel drug nanocarriers with high biocompatibility, low cytotoxicity, and the ability to cross the blood-brain barrier (BBB). This talk will describe a new type of CDs, Congo red-derived CDs (CRCDs), synthesized using Congo red and citric acid as precursors. We will discuss how different mass ratios of the two precursors can produce CDs with different physicochemical properties. We will describe the successful synthesis of CRCDs which can cross the BBB in a zebrafish model. In addition, our synthesized CRCDs show the ability to inhibit both tau and Aβ aggregation. Our findings demonstrate that CRCDs can function as dual inhibitors for tau and Aβ aggregation, in addition to its capacity to cross BBB, enter the central nervous system (CNS), and to carry drugs. Thus CRCDs-based compounds may be a novel formulation component for the development of multi-functional AD therapeutics.

11:15 AM SB02.03.07
Smart Materials for Precized Drug Delivery Ali Trabolsi; New York University Abu Dhabi, United Arab Emirates

The development of multifunctional drug delivery systems (MDDS) targeting diseased areas arose from the need to overcome drug limitations such as cytotoxicity, immunogenicity, short circulation times, uncontrolled bio-distribution, and the inability to target specific tissues. Significant advances in nanobiotechnology have led to the development of MDDS to serve diagnostic and therapeutic purposes through a single medical device capable of performing bioimaging tasks while improving the therapeutic efficacy of marketed drugs. Stimuli-responsive nanostructures can take advantage of changes in the biological microenvironment of the disease in question and respond to changes in temperature, pH, redox conditions, reactive oxygen species (ROS), and enzyme concentration, with combinations of stimuli increasing the therapeutic versatility of MDDS. This approach, defined as a new paradigm in nanomedicine, has applications in several fields, including cancer therapy, drug delivery, tissue engineering, and even bionics. In this scenario, the intrinsic properties of nanoparticles are used to develop active devices with diagnostic, therapeutic, or even theranostic functions. Our group has developed several theranostic covalent organic frameworks (COFs) as smart trigger-responsive MDDS that cover a wide range of applications from cancer therapy to bioimaging to diabetes control. Nanoscale COFs have shown tremendous potential as new candidates for nanomedicine due to their unique properties—large surface area, tunable pore geometry, crystallinity, versatility, as well as responsiveness to physiological environments. COFs exhibit a long-range ordered structure that results in regular pores with diameters that facilitate the loading and controlled release of prominent drugs and proteins/enzymes. Moreover, their high flexibility in molecular design makes them versatile and uniquely responsive to their environment. Recently, we published the formation of imine-linked nanoscale COFs linked for cancer therapy. The resulting COFs were stable under physiological conditions but disintegrated in an acidic medium, an essential property of the microenvironment of most solid tumors, and facilitated site-specific drug release. On the other hand, we reported a triazine-based COF with high stability under harsh acidic environmental conditions for oral insulin delivery to diabetic rats. The insulin-loaded COF crossed the intestinal barrier and sustainably lowered blood glucose levels in vivo in diabetic rats (T1D), and blood glucose levels completely returned to normal without causing systemic toxicity compared with the control group of nondiabetic rats. In my talk, I hope to offer some key elements to answer the question, “Can COF nanoparticles serve as effective therapeutics for various disease treatments?”

SESSION SB02.04: Biomimetic Materials for Delivery II
Tuesday Afternoon, November 28, 2023
Hynes, Level 3, Room 307

1:30 PM SB02.04.02
Three-Dimensional Visualization of Proteins within Metal-Organic Frameworks Joe P. Patterson; University of California, Irvine, United States

Electron tomography holds great promise as a tool for investigating the three-dimensional (3D) morphologies and internal structures of metal-organic frameworks (MOFs). Understanding the 3D spatial arrangement and density of proteins within protein@MOF bio-composites is paramount for developing synthetic methods to control the location of proteins within the MOF material. The direct visualization of the protein Ferritin (Fn) in Fn@MOF bio-composites was probed through a combination of scanning electron microscopy (SEM), transmission electron microscopy (TEM), and electron tomography (ET). Using con-trolled-dose dry-cryogenic electron tomography (dry-cryoET), we obtain a direct 3D visualization of protein@MOFs with individual protein resolution. These direct observations reveal that ligand-to-metal ratios for Fn@MOF bio-composites can be tuned to change the spatial arrangement and localization of the proteins within the MOF crystals.

2:00 PM SB02.04.03
Enzyme-Mimicking of Copper-Sites in Metal-Organic Frameworks for Oxidative Degradation of Phenolic Compounds Ainara Valverde¹, Stefan Wurtk³, José María Porro², Mónica Jiménez-Ruiz³, Pedro Luis Arias⁴, Iker Agirrezabal-Tellería⁴ and Roberto Fernández de Luis⁵; ¹Basque Center for Materials, Applications and Nanostructures, Spain; ²Ikerbasque, Spain; ³Institut Laue Langevin, France; ⁴University of the Basque Country (UPV/EHU), Spain

Through the sequential assembly of simple repetitive units, biology has built up complex three-dimensional scaffolds of metalloproteins, which deposit functional amino acid residues able to coordinate the metal catalytic site in specific spatial configurations. The chemical arrangement of the amino acid residues that conforms the first and second coordination environment of the metal-sites plays a key role in defining the activity and selectivity of metalloenzymes. Thus, an alteration of any of the amino acid sequence into the heart of the metalloenzyme sites, affects drastically their efficiency, selectivity and function. An important example is the case of copper metalloenzymes, where the coordination of copper ions is usually completed by histidine, cysteine and carboxyl amino acid residues. Depending on the copper-biocatalyst, Cu⁰ ions are stabilized as isolated and/or clustered sites able to...
carry out oxidative catalytic reactions. The overall selectivity and oxidoreductive efficiency of copper-enzymes over a specific substrate is partially defined by the coordination modes of the copper sites. Furthermore, their oxidative capacity has important technological implications in water remediation, since it can be adapted to degrade phenolic pollutants via Catalytic Wet Peroxide Oxidation (CWPO).

Extensive research is being carried out to replicate and expand the metalloenzymes’ pockets and catalytic activity to robust porous materials. In this regard, the chemical engineering of bio-catalytic like sites into a particular class of porous ordered materials called Metal-Organic Frameworks (MOFs) holds an enormous promise. MOFs are crystalline solids built from metal ions or clusters that are connected by organic linkers to form extended, ordered, and highly porous networks. Thanks to their (i) impressive and ordered porosity metrics and (ii) their versatility to be encoded with functionalities placed surgically at specific positions of their frameworks, MOFs have been successfully employed as matrices to install amino acids and peptides. Once the pore space has been decorated with specific amino acid moieties, metal-sites can be easily installed by adsorbing them from aqueous or non-aqueous solutions.

In this work, we have decorated the mesopore space of the MOF-808 with amino acid and carboxylic acid molecules, to later, stabilize coppers ions with varied coordination modes and clustering degrees. In a second step, we have unraveled the impact of the characteristics of the metal-sites on the catalytic wet oxidation (CWPO) of phenolic compounds. The features of the copper-sites installed within the framework have been studied by a combination of Infrared (IR), Raman, X-ray photoelectron spectroscopy (XPS), electron paramagnetic resonance (EPR) and inelastic neutron scattering (INS) spectroscopies. Local structural models for the copper-sites have been proposed after a crystallographic study of the copper coordination modes with (amino)acid molecules found in the Cambridge Structural Database. The efficiency and selectivity of our system to oxidize phenolic pollutants through CWPO have been duly assessed, confirming that both the coordination modes and the clustering degree of the copper sites modulate its efficiency and selectivity to oxidize phenols through the hydrogen peroxide activation. The results presented in this work represent a milestone for the installation of metal-amino catalytic sites into the robust architectural backbone of MOFs, which successfully mimic those oxidative functions of metalloenzymes.

Bio-Inspired Photonic Microcapsules that Change Colors via Reversible Osmotic Actuation Ji-Young Lee1, Jaehyun Kim2, Jaekyoung Kim2, Daeyeon Lee2 and Leila Dervin1; 1Northeastern University, United States; 2University of Pennsylvania, United States

Animals have evolved complex and sophisticated mechanisms to control coloration, employing a combination of small molecules and nanomaterials. Notably, chromatophores, specialized organs found in animals such as squids and octopuses, play a crucial role in dynamic color change. Chromatophores have the unique ability to modify the physical shape and size by expanding or contracting pigment-containing cells. This study introduces an artificial chromatophore system that uses osmotic annealing to trigger reversible color switching. To achieve this, we fabricate double emulsion droplets using polystyrene nanoparticles functionalized with the xanthommatin, the primary pigment found in the skin of cephalopods. The pigment size and the pigment loading density into the system are influential factors in controlling the oscillation between pigmentary and structural colors which can be manipulated through annealing. We compared the reflectance spectra of photonic capsules from the presence and absence of pigments.

Delivery of AuNCs into Extracellular Vesicles by Fusion Using Ionizable Liposomes Cargos Ester Butera1,2, Anis Ouzaïd1, Solene Ducarre2, Giuseppe Maccarrone1, Annalinda Contino1, Pascale Even-Hernandez2, Célia Ravel4 and Valérie Marchi4; 1University of Catania, Italy; 2Université de Rennes 1, France; 3CHU Rennes, France; 4University of Rennes 1, France

Extracellular vesicles (EVs) are well-known membrane-limited particles secreted by healthy and cancerous cells. EVs have heterogeneous size and subtypes are described depending on the location of secretion: microparticles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a consequence of ovarian follicle rupture at ovulation.4 Herein, we investigate the interaction of fusogenic liposomes encapsulating the AuNCs with EVs extracted from human seminal fluids. The composition of the membrane was optimized to improve the fusion properties of the liposomes. The mixture of the liposomes and EVs results in lipid exchange as demonstrated by FRET experiments and in increased size revealed by flux cytometry. The resulting fused hybridosomes were successfully isolated by size exclusion chromatography. They exhibit typical fluorescence of the AuNCs together with an increased size in agreement with the expected size of the fused exosomes. Besides their interest to analyze the EVs content, such hybridosomes could serve as drug or macromolecule carriers or nanosensors in living organisms.

Vitalizing Immortal Nanodendritic Cells Functionalized with Immune-checkpoint Inhibitors for Tumor-localized Immunotherapy

Taihyun Kim and Jinkee Hong; Yonsei university, Korea (the Republic of)

Since the development of cancer immunotherapy using immune checkpoint inhibitors (ICIs), significant improvements have been made in cancer treatment. However, there are still limitations in their clinical effectiveness, particularly in terms of low delivery to target sites. To address these limitations, we aimed to enhance the existing IC1-based immunotherapy strategies by combining them with chemotherapeutic agents.

To achieve this goal, we employed a one-pot sol-gel reaction to prepare dendrimer-like porous silica nanoparticles (DPSNs). These DPSNs possess a larger surface area compared to spherical particles of the same size, resulting in enhanced stability during long-term storage. Initially, we focused on conjugating cisplatin, a widely used chemotherapeutic anti-cancer agent, onto the surface of DPSNs. By modifying the DPSNs with carboxyl groups and loading cisplatin as a model anticancer drug, we investigated the release behavior of the drug molecules. Our findings revealed that cisplatin remained intact under neutral conditions but was released under acidic conditions, indicating the successful development of pH-responsive DPSNs (referred to as DPSN-cis).

Furthermore, we performed an EDC/NHS-sulfo reaction to modify aPD-1, one of the ICIs, onto the surface of DPSN-cis. This allowed us to create DPSN-ICIS, where both cisplatin and aPD-1 were simultaneously conjugated. Importantly, DPSN-ICIS exhibited no cytotoxicity even after three days of cell culture and demonstrated long-term physicochemical stability. To evaluate the effectiveness of DPSN-ICIS, we conducted in vitro experiments to assess its binding to PD-1 on T cells and its ability to induce cancer cell death. Subsequently, we validated these findings in vivo by demonstrating that DPSN-ICIS effectively performed both functions and led to tumor eradication. These results were further supported by analyzing immune responses to examine the behavior of DPSN-ICIS within a living organism.

Overall, our study highlights the potential of next-generation cancer immunotherapy by simultaneously loading chemotherapeutic agents capable of directly killing tumors and functionalizing various immune enhancers. The development of DPSN-ICIS addresses the limitations of current immunotherapy approaches, offering a promising strategy for more effective cancer treatment.

8:00 PM SB02.05.01
Metal-Organic Framework Coordinated with Single Fe Nanozymes and Gold Cluster for Biomedical Applications

Subin Yu1,2 and Luke Lee2;
1Ewha Woman's University, Korea (the Republic of); 2Harvard Medical School, United States

Metal-organic frameworks (MOFs) have been extensively utilized as substrates for constructing single-atom catalysts (SACs) due to their abundant ligands, enabling nanozyme-mediated biomedical applications. However, the preparation of SACs using MOF substrates typically involves harsh calcination processes to stabilize the single metal atom catalysts, which can lead to uncertain changes in the oxidation state of the metal centers, impacting the overall catalytic reaction. In this study, we have developed ultrasmall MOF-based single iron (Fe) atom Fenton-like nanozymes (referred to as Fe/MOF) by employing a simple mixing method. These nanozymes were combined with a gold nanocluster-embedded MOF mimic of glucose oxidase (referred to as Au/MOF), enabling cascade enzymatic reactions within living systems. To harness the abundant porosity of MOF and enhance cell cytotoxicity, the
anticancer drug doxorubicin (DOX) was loaded inside Fe/MOF (referred to as Fe/DOX/MOF). Additionally, Au/MOF was further modified with a mitochondrial targeting moiety (triphenylphosphonium, TPP) to target the mitochondria and disrupt the cellular redox system. Internalization of Au/MOF into mitochondria resulted in glutathione (GSH) depletion through thiol-gold interactions, leading to mitochondrial excess lipid peroxidation. The constructed Fe/MOF exhibited an oxidation state of 2+ with Fe-N coordination bonds, demonstrating well-established Fenton-like nanozymes characteristics. The overall cascade enzymatic activity effectively generated hydroxyl radicals from glucose as a substrate. The generated gluconic acid induced an acidic environment that further accelerated the overall Fenton reaction. In vitro, studies demonstrated effective cancer eradication through cascade glucose oxidation and hydroxyl radical generation. GSH depletion-mediated down-regulation of GPx4, along with the delivered Fe2+, induced Fenton reaction-mediated lipid peroxidation, indicating ferropiosis. In vivo, studies further confirmed the overall therapeutic effects of the cascade enzymatic activity of Fe/MOF and Au/MOF. Our novel and straightforward synthesis process for MOF-based single-atom nanozymes and metal clusters present a new paradigm for fabricating single-atom nanozymes for multimodal cancer treatment.

8:00 PM SB02.05.02
Antibody Pre-Coated Zr-MOF as a Cloaking and Plug&Playable Platform for Targeted Delivery System
Jun Yong Oh, Batak Krishna Jana, Junmo Seong, Eun Min Go, Seongeon Jin, Jong-hoon Bae, Chaihee Lee, Seonghwan Lee, Tae-Hyuk Kwon, Jeong Kon Seo, Eunsil Choi, Sang Kye Kwak, Myoung Soo Lah and Ja-Hyoung Ryu; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Metal-organic framework (MOF)-based targeted drug delivery systems have made great strides and are widely used in a variety of scientific disciplines. Nevertheless, the biomolecular corona phenomenon makes it difficult to directly translate MOF agents into focused medication delivery systems. Here, we have established that pre-absorption of antibodies to MOF particle surfaces by supramolecular mixing can decrease protein adhesion in biological contexts, with effects akin to those of stealth shields. Furthermore, we further demonstrated that this mechanism may be influenced by the MOF's surface pore size. The MOF particle was neither readily swapped with nor covered by biomolecule protein once the antibodies had been stably attached to it, indicating a stealth effect and an improved capacity to target both in-vitro and in-vivo. In addition, the generated antibodies-MOF platform may target various cancer cell lines by plugging multi-antibodies (dual and triple kinds). This study provides insights into the use of "antibody pre-absorption" as a promising method for developing MOF-based drug delivery systems.

8:00 PM SB02.05.03
Dual Drug Delivery Systems Based on Porous Fibers Crafted with ZIF67
Jooran Kim; Korea Institute of Industrial Technology, Korea (the Republic of)

Metal-organic frameworks (MOFs) have emerged as promising materials for various applications due to their exceptional tunability and high surface area. In recent years, the integration of MOFs with fibers has gained significant attention in the field of drug delivery systems. The combination of MOFs and fibers offers a unique platform for controlled release, targeted therapy, and enhanced drug stability, ultimately revolutionizing the field of therapeutics. Moreover, researchers have explored the application of dual drug delivery using porous fibers with MOFs in various therapeutic areas, including cancer therapy, antimicrobial treatments, and regenerative medicine. These studies have demonstrated the potential of these systems to overcome drug resistance, reduce side effects, and enhance treatment efficacy by delivering multiple drugs simultaneously.

In this study, we developed porous poly(caprolactone) (PCL) fibers through liquid-liquid phase separation, and then ZIF-67 was grown on the porous PLA fiber to synthesize porous fibers. These carriers were investigated the relationship among pore formation, physical properties, and antibacterial activities of the fibers for identifying their potential as drug delivery carriers. Studies have focused on optimizing the synthesis techniques to achieve uniform ZIF67 coatings on the surface of porous PCL fibers. Suggested dual drug delivery system using porous PCL fibers with ZIF67 are the co-delivery of two drugs including lysozyme and gentamicin with complementary antibacterial effects. By encapsulating dual drugs inside pores of PCL and ZIF67, the dual drug delivery system achieves synergistic effects, improved drug stability, and controlled release kinetics. Furthermore, the selection of appropriate drugs and their optimal ratios play a crucial role in achieving desired antibacterial outcomes.

Overall, the research on dual drug delivery using porous fibers with ZIF67 highlights the potential of these drug carrier systems in achieving controlled release, synergistic effects, and improved antibacterial outcomes. Further advancements in the synthesis techniques, optimization of drug ratios, and comprehensive understanding of the in vivo behavior are crucial to translate these innovative systems into clinical applications and address the challenges associated with their practical implementation.

8:00 PM SB02.05.04
Capping UiO-Based and HKUST-Based Metal Organic Frameworks Towards Trapping and Controlled Release of Guest Molecules
Samuel Darer, Cal G. Lebak, David S. MacLeod, Abigail Berube, Shawn C. Burdette and Ronald L. Grimm; Worcester Polytechnic Institute, United States

Metal-organic frameworks (MOFs) are particularly compelling for enabling capping and controlled release of guest payloads. Previously we utilized bulky triphenylacetate-based caps to trap guests within the pores of MOF-5. Presently, we extend these efforts to the UiO and the HKUST families for their tunable porosity, high stability, and varying chemistry to explore the interplay between interfacial chemical properties on the MOFs and the necessary capping chemistry. We utilized capping reactions including acetate exchange, growth with terminating single-acetate-group organicns, and established functionalities for monolayer chemistries. Utilizing fluorine-tagged capping organicns, X-ray photoelectron spectroscopy established which chemistry successfully capped each MOFs, and supported models of interfacial chemical states that exist on the MOF themselves. We aim to further develop capping capabilities, expanding the control and variability of the caps that can be applied to MOFs and applying this research to wider potential applications.

8:00 PM SB02.05.05
Janus Hydrogel-Based Fuel Stimulant Powered Amplification for Multiple Detections of miRNA Biomarkers in Gastric Cancer
Eun-Kyung Lim; Korea Research Institute of Bioscience & Biotechnology, Korea (the Republic of)

MicroRNAs (miRNAs) circulating in body fluid have emerged as potential biomarkers for various diseases; however, owing to their low concentrations and short lengths (~22 nt), their clinical applications are still limited. Therefore, a highly sensitive and selective novel diagnostic platform for miRNA detection is required. Here, we present a hydrogel-based fuel stimulant-powered (FSP) amplification of fluorescent signals to detect circulating miRNAs from clinical samples of human serum. The advantage of this method is that it has high sensitivity as a fuel-assisted DNA cascade reaction that does not require temperature control and enzymes used for nucleic acid amplification. Further, we developed a Janus-type hydrogel for the simultaneous detection of the gastric cancer-associated miRNAs, miR-135b and miR-21. The detection limit of this hydrogel-based FSP amplification using synthetic miRNAs was estimated as < 10 fmol. We also validated the performance of this amplification process in vitro and in vivo models and clinical samples. Therefore, we demonstrate that Janus hydrogel-based FSP amplification can selectively and sensitively identify the overexpression of miR-135b and miR-21 in clinical samples, thereby helping distinguish gastric cancer patients from healthy donors.
Host Cell-Mimetic Hybrid Nanoparticles as Antiviral Therapeutic Nano-Inhibitors for Influenza Virus

J. R. Hiscock* and N. Allen, L. J. White, J. E. Boles, G. T. Williams, D. F. Chu, R. J. Ellaby, H. J. Shepherd, K. K. L. Ng, L. R. Blackholy, B. Wilson, D. P. Mulvihill*

ChemMedChem

Dynamic covalent chemistry (DCvC) has proven to be highly effective toward the construction of well-defined molecular and polymeric architectures. The error-correction mechanism enabled by the reversible formation of dynamic covalent bonds leads to the formation of structurally ordered, thermodynamically favored species. One such example is the solvothermal synthesis of covalent organic frameworks (COFs) with periodic structural order and low defect density. The chemical compositions of such frameworks are usually well-defined and inter-monomer connectivity (covalent bonding) is robust. Bottom-up synthesis of covalently linked polymers through DCvC has many critical advantages, such as easy tunability of functional and structural properties in a controlled fashion through rational design of the precursors, formation of highly stable linkages, minimized structural defect, and possible access to sophisticated architectures that are hard to obtain otherwise. This talk will focus on our recent progress in the development of DCvC, specifically spiroborate bond exchange. This powerful transformation enabled the bottom-up design and synthesis of novel functional materials, such as unprecedented single-crystal DNA-like helical covalent polymers (HCPs) and shape-persistent redox active organic molecular cages.

Engineering Metal–Phenolic Materials via Supramolecular Assembly Zhixing Liu¹,²; ¹The University of Melbourne, Australia; ²The University of Melbourne, Australia

Coordination polymers (CPs) and their higher-dimensional and potentially porous subset, metal-organic frameworks (MOFs), are supramolecular materials comprising metal nodes and organic ligands. Over the past three decades, CPs in the crystalline state have been the primary focus of the field due to their defined structures, high internal surface areas, and potential for crystal engineering. The periodic arrangement of metals and ligands has facilitated fundamental research on controlling pore size and surface area, which are crucial for achieving improved performance in various applications. However, the practical application of these crystalline materials poses challenges in terms of maintaining accessible pore volumes, integrating into existing infrastructure, and addressing safety concerns arising from the use of toxic precursors and solvents during synthesis, as well as the rigid, brittle, and often unstable nature of crystalline CPs. In contrast, amorphous CPs have gained significant attention over the past decade due to the presence of amorphous domains, which increase pore size, mechanical robustness, and chemical stability of the materials, leading to improved functionality.

One type of amorphous CPs, known as metal-phenolic networks (MPNs), consists of metal ions and phenolic ligands and can be adhesive to diverse surfaces. Due to their ability to coat nanoscale and macroscopic templates, MPNs have garnered considerable interest in various applications, including biomedicine, photonics, forensics, and biomolecule and fruit preservation. Different metal ions can be employed to confer specific functionalities to MPNs, such as fluorescence, magnetic resonance imaging, and catalytic activity, or to produce synergistic effects in combination with the phenolic ligand, such as buffering effects. Additionally, the amorphous structure of MPNs can endowed them with unique material properties, such as higher mechanical robustness, increased stability, and improved processability. This presentation aims to provide an introduction to MPNs, covering their fundamental aspects and will highlight our recent significant progress in developing MPNs for various biomedical applications, including catalysis, intracellular tracking, and drug delivery.

10:45 AM SB02.06.05
Structure and Dynamics of Self-Assembled Lipid Nanoparticles for Nucleic Acid Delivery Shayna Hilburg and Lilo D. Pozzo; University of Washington, United States

Nucleic acids can revolutionize human health outcomes, as evidenced by the mRNA vaccines used to combat COVID-19. Despite the success of these therapeutics, the fundamental physicochemical properties of the non-viral delivery vectors must be better understood to be more easily tuned and optimized. In this work, we use small-angle X-ray (SAXS) and neutron scattering (SANS) to assess how the storage and delivery conditions of the nanoparticles impact their structure and dynamics. The components which come together to encapsulate the nucleic acids have complex non-covalent interactions at the nanoscale which dictate their ability to withstand storage conditions and transport to cells while also disassociating upon intracellular delivery to release cargo. Here we show that the molecular interactions within the drug delivery vehicles, including exchange kinetics of the self-assembled molecules, are impacted by relevant environmental factors, including pH. Such information demonstrates what drives degradation and what parameters can be changed to improve delivery by increasing the efficiency of endosomal escape. Ultimately, these results can be used to optimize efficacy, enabling more flexible storage requirements, lower dosages, and improved therapeutic tolerances.

11:00 AM DISCUSSION TIME

11:15 AM *SB02.06.07
Visible Light as a Benign Stimulus for Additive Manufacturing of Hydrogels Zachariah A. Page; The University of Texas at Austin, United States

Light as an energy source has enabled transformative technologies in imaging, lithography, adhesives, and 3D printing. Its broad utility arises from the unparalleled spatiotemporal control over chemical transformations that it offers. However, contemporary methods rely on high energy UV light (< 400 nm), which limits biocompatibility due to degradation and attenuation that occurs upon absorption and/or scattering. Excitingly, the recent commercialization of inexpensive light emitting diodes has opened up an avenue to examine mild visible-light induced reactions in the fabrication of biologically relevant scaffolds. This presentation will focus on how the ZAP Group has developed low energy light driven reactions to create macroscopic water-swollen scaffolds (i.e., hydrogels) with unprecedented speed and precision. Specifically, catalyst design principles to enable rapid solidification of photopolymer resins using visible-light will be discussed, along with their utility and optimization in high resolution additive manufacturing.
Mimicking Melanin: Nature’s Biopolymer of Intrinsic Microporosity as a Therapeutic Material for Tissue Repair

Nathan C. Gianneschi and Kurt Lu; Northwestern University, United States

Melanin is a class of essential biopolymer found across plant, animal, bacterial and fungal kingdoms with an astonishing array of functions, including pigmentation, radical scavenging ability, radiation protection, and thermal regulation. Nature synthesizes melanin of five known kinds: eumelanin, pheomelanin, neuromelanin and pyomelanin. Among them, eumelanin (black and brown pigment in dark hair) and pheomelanin (the pigment in red hair) are the two most commonly considered forms. The past two decades have witnessed a flourish of eumelanin-based materials, especially polydopamine. In our own work, we have endeavored to explore synthetic analogues that enhance, extend and build on these biomimetic systems to enrich melanin and melanin-like materials with desirable properties for a range of applications. A key property of interest here is the ability of properly engineered synthetic melanins to perform as high surface area “sponges” for absorbing toxins and to act as an efficient and stable scavenger of radicals. These synthetic porous melanin materials and a variety of modified analogues will be described in terms of their function in tissue repair. Specifically in topical applications for healing damaged skin from chemical and radiation induced injury.

2:00 PM *SB02.07.02
Construction of Smart Supramolecular Drug Delivery Systems for Biomedical Applications

Ying-Wei Yang and Chinedum Osuji; Jilin University, China

The design, synthesis, recognition, and assembly of functional macrocyclic receptors have been playing a critical role in supramolecular chemistry. Due to their superior properties and functions, supramolecular macrocycles, including cyclodextrins, cucurbiturils, calixarenes, and pillararenes, have attracted broad attention in the fields of organic supramolecular chemistry and materials science. Meanwhile, nanoparticles with unique characteristics and particular properties, such as mesoporous silica nanoparticles, metal-organic frameworks, gold nanoparticles, magnetic nanoparticles, and semiconductor nanocrystals, have shown ever-increasing importance in chemistry, materials science, nanoscience, and biomedicine. Upon combining the porous/nonporous inorganic solid platforms or even organized organic/polymeric nanosystems with supramolecular macrocycles, there is great potential to enhance the photophysical, chemical, electronic, and other related properties of solid supports and the host-guest property of supramolecular macrocycles expanding and advancing the applications of the resulting organic-inorganic hybrid materials. In this talk, I will present our methodology and research progress of the chemical construction of smart supramolecular drug delivery systems hybridized with synthetic macrocycles and nanoparticles and showcase their applications in the areas of antimicrobial, anticancer, cell imaging, crop protection, biosensing, etc.

Engineering of Advanced Biomaterials by Harnessing Biological Organization Principles

Alvaro Mata; Nottingham University, United Kingdom

Living systems have evolved to grow and heal through biological organization principles (BOPs) capable of organizing molecular and cellular building-
blocks at multiple size scales. These BOPs emerge from cooperative interactions and chemical networks between multiple components, which allow biological systems to diversify, respond, and optimize. This talk will present our laboratory’s efforts to combine supramolecular events found in nature such as self-assembly, disorder-to-order transitions, or diffusion-reaction processes with engineering processes to design bioinspired materials and devices (Figure 1). I will also describe recent efforts aiming to go beyond “bioinspiration” and into “biocooperation”. I will describe methodologies to develop a) dynamic hydrogels and in vitro models for cancer [1,2], b) self-assembling fluidic devices [3,4], and c) regenerative implants [5,6].

11:00 AM SB03.01.02
Biofilm-Inspired Underwater Peptide Adhesives Jing Yan, Xin Huang and Sarvagya Saluja; Yale University, United States

Bio-adhesives are extensively used in biomedical applications including suture-less seal and wearable electronics, where there is a need to adhere two wet surfaces together. However, existing products, largely inspired by mussel adhesives, are expensive to produce and sensitive to environmental conditions that limit their wide application. We recently made a serendipitous discovery regarding how bacterial biofilms formed by Vibrio cholerae, the pathogen responsible for pandemic cholera, adheres to various surfaces using a unique short peptide. In this study, we will show a range of both biotic and biotic surfaces suitable for this biofilm-inspired glue, and the molecular mechanism underlying the adhesive property of this peptide. Finally, we will discuss about our effort in establishing a fermentation-based process to scale up the production of the peptides.

11:15 AM SB03.01.03
Cephalopod-Inspired Optical Engineering of Mammalian Cells Georgia Bogdanov, Nikhil Kainal, Alezea Farrukh, Aleksandra A. Strzelecka, Atsroui Chatterjee and Alon Gorodetsky; University of California, Irvine, United States

During the last several decades, cephalopods (e.g., squids, octopuses, and cuttlefish) have emerged as a powerful source of inspiration for the engineering of dynamic optical systems, due to their complex optical systems, diverse behavioral patterns, and tunable structural coloration. We drew inspiration from the tunable optical functionality of cephalopod skin cells to engineer human cells for production of reflectin-based high refractive index reflective architectures and, as a result, to possess tunable transparency-changing and light scattering capabilities (1). Additionally, we improved our control over the production of reflectin in human cells by genetically engineering cell lines to stably express reflectin, which enabled more extensive studies of reflectin-based subcellular architectures under physiological conditions (2). Moreover, we evaluated the optical properties of single cells with three-dimensional label-free holotomographic microscopy and quantitatively characterized their subcellular reflectin-based architectures with and without external chemical stimuli (1,2). Finally, we demonstrated the potential applications of high refractive index reflectin-based subcellular architectures as high contrast genetically encoded biomolecular reporters for various types of microscopy techniques (2,3). Our combined findings validate prior postulates about the mechanisms of cephalopod tunable skin coloration and may lead to the development of unique protein-based tools for various applications in biophotonics and bioengineering.

11:30 AM SB03.01.04
Molecular Biomimetics - Molecular Technologies of the Future Through Biology Mehmet Sarikaya; University of Washington, United States

Proteins are the workhorses in biology as they are the fundamental building blocks making up the hierarchical structures of the cells, establishing biomolecular communications via signal transduction, transporting ions, and carrying out enzymatic processes, all vital for life’s functions. The proteins, therefore, could be useful tools in developing functional molecular devices, if they can be designed and engineered to function similar to that in organisms. Despite the enormous opportunities provided by proteins as fundamental molecular tools, their utility in engineering and practical technology has not been fully realized, and their use has so far been highly limited for single purposes, e.g., enzymatic functions. In addition to their complexity and cumbersome handling issues, at least for the practical engineer, the main reasons for the limited use of proteins in engineered systems are because of their long amino acid sequences, i.e., 100s of AAs and even 1000s, that lead to unpredictable folding patterns and the resulting functionalities that are not easily predicted or controlled. On the other hand, polypeptides, i.e., short amino acid sequences (10-50 AAs), functional components of proteins, offer similar opportunities as proteins, with the advantage of being easily designed and manipulated, although their folding structures and functions are difficult to control. Despite these difficulties, for more than last two decades, peptides have been used in a variety of practical implementations such as tiny enzymes, drugs, biofunctionalization of nanoparticle drug carriers, probe design for specific targets, and for biominalization. Especially useful are the fact that peptide sequences can be designed such that they may self-assemble into predictable tertiary structures in aqueous solutions with controlled geometries and shapes such as nanofibers, strips, and 3-dimensional gel-like molecular scaffolds. Since the first publication (below), molecular biomimetics has been emerging as a convergent science and technology field in which hybrid technologies are developed by the tools of molecular biology, genetics, computational sciences, and machine intelligence combined with materials science and engineering. For the last 2+ decades, our laboratory has adapted directed evolution approaches and identified thousands of short peptide sequences (7-15AA) and utilizing them as molecular tool sets in developing molecular technologies. These genetically engineered proteins for inorganics, GEPls, also dubbed as solid binding peptides, SBPls, can be used as tiny enzymes in, e.g., regeneration, surface functionalization in implants, designing heterofunctional probes and molecular constructs for molecular and ionic targets, and key components of functional nanodevices, such as peptide-enabled field effect transistors. Recent discovery of coherent bio/nano soft interfaces between the self-assembled solid binding peptides forming monomolecular two-dimensional molecular crystals on, and having chiral crystallographic relationships with, single atomic layer solids provides the key element in the development of brain-inspired molecular probes and logic devices by seamlessly integrating biology and solid-state materials at their smallest respective functional units. Based on the three fundamental biological principles of molecular recognition, gene manipulation, and self-assembly, molecular biomimetics is opening a new era in truly genetically engineered functional molecular materials and system of the future. M. Sarikaya et al., Molecular Biomimetics: Nanotechnology through Biology, Nature Mater., 2, 577-585, 2003.
1:30 PM SB03.02.01

A Novel Bio-Adhesive for Wet Surfaces from Vibrio Cholerae Sarvagya Saluja, Jing Yan and Xin Huang; Yale University, United States

Effective adhesion of surfaces in a wet environment is very useful for the biomedical and engineering fields (wearable electronics, suture-less seals, underwater pipeline repair, etc.). However, underwater adhesion has remained a significant challenge. Water prevents effective molecular contact between the adhesive and the substrate, a key step, and prolonged exposure to the aqueous environment deteriorates the adhesive, leading to cohesive failure. Currently, research efforts are taking inspiration from mussels and bacteria, creatures that overcome these challenges and can strongly adhere to underwater surfaces.

We recently discovered that a sequence of 57-amino acids (57-aa) in Vibrio cholerae biofilms is the primary contributor to their adherence to a variety of surfaces, both biotic and abiotic, such as glass, plastic, and lipid membranes. We have developed several biochemical and biophysical in vitro characterization methods to demonstrate the polypeptide’s potential to function as a wet adhesive. Modifying the sequence and applying it to different surfaces has allowed us to identify key parameters of the polypeptide’s adhesion ability, including aromaticity, positive charge, linkers, and repeating motifs. We also tested multiple Vibrio cholerae mutants to understand the surface adhesion as a biofilm. Finally, we collaborated with simulation groups to corroborate experimental data with theory. Understanding and establishing a model for the adhesion mechanism of the polypeptide enables better engineering of wet adhesives.

Overall, we demonstrate that a 57-aa sequence of a Vibrio cholerae biofilm adhesin could be used as a glue for different underwater surfaces. Our findings contribute to the general development of superior wet adhesives.

1:45 PM SB03.02.02

Intermolecular Interactions of Protein-Mimetic Random Heteropolymers Shayna Hilburg, Tianyi Jin, Priya Ganesh and Alfredo Alexander-Katz; Massachusetts Institute of Technology, United States

Amphiphilic synthetic random heteropolymers, specifically easily synthesized methacrylate-based polymers with side-chains selected to mimic peptide characteristics, have been demonstrated to provide a bio-inspired means for augmenting and even mimicking bio-macromolecular function. However, the statistical distribution of chains makes a nano-scale molecular analysis of particular moieties and motifs challenging experimentally. Through computational modeling, specifically atomistic molecular dynamics simulations, we provide nanoscale analysis of sequences to provide insight into how these synthetic polymers respond to their environments and interact with molecules around them. Having previously examined the self-assembly of single chains into globules with heterogeneous surfaces for the chains in solution, we now characterize their statistically derived properties in more complex environments. We show how the polypeptides which have limited dynamics on their own can change significantly as they interact with organic solvents, macromolecules, or surfaces. We explore environmentally-dependent driving forces and the stochastic behavior of the random polymers which impact kinetics and characterize resultant changes in polymer conformation. These changes are shown to be highly dependent upon the properties of both the polymer and the molecular interactions that take place. Our study, leveraging analysis techniques from both polymer physics and protein sciences, illuminates ways in which the polymers are similar to the proteins they are inspired by as well as avenues for applying the synthetic polymer assemblies in solution.

This work was supported by the Defense Threat Reduction Agency contract HDTRA11910011 and HDTRA12210005.

2:00 PM SB03.02.03

Hierarchical and Stimuli-Responsive Hybrid Materials from High Information Content Building Blocks Francois Baneyx; University of Washington, United States

Solid-binding proteins are genetically engineered chimera that incorporate one or more solid-binding sequences at defined locations of their framework while retaining native function. These macromolecules are versatile building blocks for the fabrication of hybrid hierarchical materials that derive unique properties from the organization, interplay, and reconfiguration of organic and inorganic units. Here, I will discuss how solid-binding proteins can be combined with self-assembled peptoid nanostructures and pre-synthesized or mineralized inorganic elements to create layered 3D architectures, achieve precise control over nanocrystal size, and build photocatalytic nanocomposites. I will also describe recent progress on the use of thermos-responsive solid-binding proteins to control nanoparticle assembly and disassembly and manipulate the outcomes of biomimetic mineralization.

Silk-Nanotraps for Selective Molecular Targeting. Understanding Potentials and Limitations of Functional Protein Super-Assemblies Alessandra Maria Bossi1 and Davide Maniglio2; 1University of Verona, Italy; 2University of Trento, Italy

We report about the development of tailor-made biomimetics stemmed from merging biology with polymer chemistry and material science. Aqueous-soluble nanotraps that behave as biomimetic receptors were prepared in the form of proteinaceous disordered super-assemblies, fixed by non-natural crosslinking. The specific formation of the nanotrap started from the biocompatible, non-toxic material, already in use in regenerative medicine, that is silk fibroin [1].

Pioneering a paradigm change, the tailor-made molecular recognition was conveyed to the silk nanotrap by the unconventional exploitation of the molecularly imprinted polymers (MIPs) technique, that is a specifically designed strategy to entail molecular recognition to a nanomaterial by means of a template-assisted synthesis [2,3], but herein methacrylated silk fibroin polypeptides were used as macromolecular building blocks. Such MIP synthetic protocol was optimized with the aid of surface response method. The silk-nanotrap, called bioMIPs, were physically and functionally characterized, demonstrating high affinity binding (nM) for the targets and selectivity [4]. Enzymatic degradation of the bioMIPs was studied. The biocompatibility of the nanotraps was confirmed. The nanotraps were further labelled with fluorescent tags and tested for imaging in cell cultures [6]. The bioMIPs’s synthesis proved a general route for entailing recognition towards proteins or small molecules [4,5], which let foresee applications in sequestering molecular players in the onset and progression of diseases, to tackle the onset of molecular changes in cells, and opening for translational studies with roles in long term pathologies.
integrin protein is a mechanotransducer establishing mechanical reciprocity between the extracellular matrix and cells at integrin-based adhesion sites. This cellular behavior inside the cell. In order to evaluate the molecular phenomena outside the cell, we investigate the characteristics of integrin molecules. The players in the actin dynamics during the cancer progression. Hence, actin remodeling plays a vital role in cancer metastasis progression and pertains to quantitatively and spatially. Label-free discrimination of cancer progression using Raman imaging and cluster analysis also reveals actin dynamics and binding efficiency to over-effect of tumor tissues. In this respect, the conjugation of nanoparticles with integrin α
Active targeting strategies, exploiting the biological interaction between ligands on the surface of nanoparticles and the cell targets, are known to increase the therapeutic efficacy of cancer treatments with respect to passive targeting strategies that are mainly based on the enhanced permeability and retention effect of tumor tissues. In this respect, the conjugation of nanoparticles with integrin αβ-affine cyclic RGD peptides (cRGD) is a promising approach in nanomedicine to efficiently reduce off-targeting effects and enhance the cellular uptake by integrin-overexpressing cancer cells. We used atomistic molecular dynamics simulations to evaluate key structural-functional parameters of cRGD ligands conjugated to PEGylated TiO2 nanoparticles for an effective binding activity towards αβ integrins. An increasing number of ligands has been conjugated to PEG chains, grafted to highly curved TiO2 nanoparticles, to unveil the impact of cRGD ligand density on its presentation, diffusion, and conformation in an explicit aqueous environment.

We find that a low density leads to an optimal spatial presentation of cRGD ligands out of the "stealth" PEGylated layer around the nanosystem, favoring a straight upward orientation and a spaced distribution of the targeting ligands in the bulk-water phase. On the contrary, a high density favors the clustering of cRGD ligands, driven by a concerted mechanism of enhanced ligand-ligand interactions and reduced water accessibility to the ligand's molecular surface. These findings strongly suggest that the ligand density modulation is a key factor in the design of cRGD-conjugated nanodevices to maximize their binding efficiency to over-expressed αβ integrin receptors.

protein plays a critical role in cell-ECM adhesion and cellular signaling. We conducted steered molecular dynamics (SMD) simulations to investigate the mechanical responses of unigend amelogenin nanoribbons (Amel NR) with and without ligand binding for a variety of mechanical loading paths. The ligand-binding integrin controlled the integrin activation during equilibration by opening the hinge between [A] and the hybrid domain. This activation of liganded αvβ3 integrin influenced the molecule's stiffness observed during tensile loading. Furthermore, we observed that the interface interaction between β-tail, hybrid, and epidermal growth factor domains altered integrin dynamics. The deformation of extended integrin models in the bending and unbending directions of integrin reveals the stored folding energy and the directionally dependent stiffnesses of the integrin molecule. Along with experimental data, the SMD simulations were used to evaluate the mechanical properties of integrin and identify the underlying mechanisms of integrin-based adhesion substrates. The investigation of the mechanics of integrin molecules provides new insights into understanding the mechanotransmission between cells, ECM, and the substrate. Overall the mechanotransduction facilitated by integrins to actin remodeling at the cellular insides is a critical molecular phenomenon that exists over a multiscale regime that synergistically creates the metastasis progression of cancer.

SESSION SB03.04: Synthesis, Restoration and Regeneration of Biological Hard Tissues

Development of Self-Assembled Organothiol-Based Nanolithography Templates for Biomimetic Synthesis of Calcium Phosphate on Amyloid-Like Amelogenin Nanoribbons
Jaysheh Dua, Stefan Habelitz and James J. de Yoreo
University of California, San Francisco, United States; School of Dentistry, University of California, San Francisco, United States; Pacific Northwest National Laboratory, United States

Tooth enamel is the hardest tissue in the body mainly due to the intricate interwoven structure of highly organized apatite filaments that form it. It has been theorized that unidirectionally aligned (co-aligned) amyloid-like amelogenin nanoribbons (Amel NR) guide the formation of apatite by providing an energetically and stereochemically favorable scaffold for nucleation and transformation of amorphous calcium phosphate (ACP) precursor to hydroxyapatite (HAP). To understand the efficacy with which protein structures direct the nucleation of ACP and the subsequent transformation to HAP, studies have been carried out to quantitatively analyze the nucleation of ACP by self-assembled NRs of the full-length protein as well as varying sequences of peptides made up of protein subsegments responsible for self-assembly and ACP binding. Supramolecular block-copolymer templates with alternating hydrophilic and hydrophobic regions were also used to direct the self-assembly of amelogenin-derived peptide nanoribbons having discrete, spatially separated domains. These domains in turn translated the mineralization of filamentous and plate-shaped calcium phosphate. To create more versatile templates, we are using AFM-based nanolithography to create highly modifiable nanopatterns of novel organothiol monolayers self-assembled on Muscovite Mica. By using AFM probes, we perform Nanografting on monolayers of hydrophobic organothiols on Mica in predetermined patterns and backfill the patterns with hydrophilic thiols. The proposed system is similar to the block-copolymer system in its basic function, but with the capability of modifying the design on-the-fly to study the effects of geometry. While similar thiol systems on metal substrates (like nearly-atomically flat Au substrates) have been extensively studied and are even now used for a multitude of applications, the proposed system offers significantly better reproducibility, reusability, and affordability. Although the proposed system has been developed for the use of templating the growth of Amel NRs, it has the potential to be employed for a variety of other applications by modifying the surface chemistry of the Organothiol headgroups. Additionally, since Mica is the preferred substrate for the study of many soft matter systems, it provides the possibility of the direct study of many of these systems, eliminating the need for the modification of the parent molecule to enable its binding to the substrate. Monolayers of long chain alkanethiols (like the ones used on gold substrates) with average roughness ≈0.2nm have already been achieved with extremely adaptable grafting pattern thicknesses ranging from 50 nm-200 nm. For manipulating the spaces and dimensions of the 2D-patterns, as well as the composition of the mineralizing solution, we seek to find understand the controls of scaffold geometry on nucleation and growth rates of the ACP precursor domains, as well as their transformation to HAP. Understanding how manipulating the scaffold geometry affects the fidelity of guided mineralization will move us closer towards the biomimetic synthesis of enamel-like materials.

Peptoid-Controlled Synthesis of Hierarchical Composite Nanomaterials
Chun-Long Chen
Pacific Northwest National Laboratory, United States

In nature, biominerals (e.g. bones and teeth) are excellent examples of hierarchical composite materials whose formation and functions are controlled over multiple length scales by high information content biomacromolecules. Inspired by nature, many biomimetic approaches have been developed for the design and synthesis of composite materials. These approaches are attractive because they generate complex, functional materials under mild aqueous synthetic conditions.1,2 As one of the most advanced classes of sequence-defined peptide-mimetics, peptoids offer tremendous opportunities for bio-controlled synthesis of hierarchical composite materials,3,4,5 mimicking protein- and peptide-like molecular recognition. Due to the lack of backbone hydrogen bonding, tuning peptoid-peptoid and peptoid-particle interactions can be done solely by varying side-chain chemistry.1,3 Peptoids have been exploited as programmable building blocks to assemble into highly ordered nanostructured materials with a variety of morphologies.6,7 In this presentation, we will report our recent progress of developing self-assembling peptoids for controlled formation and morphogenesis of hierarchical composite nanomaterials. A combination of in situ imaging and molecular simulations were used to elucidate the principles underlying peptoid-controlled inorganic crystallization with the ultimate goal of enabling predictive materials synthesis across scales.

Freeze Casting Peptide-Enabled Biomaterials for Tissue Regeneration
Ulrike G. K. Wegst
Northeastern University, United States
While considerable progress has been made over the past years and decades, the challenge persists to synthesize, ideally off-the-shelf materials and scaffolds, with structural, mechanical, and chemical cues akin to the natural tissue or custom-designed for a desired regenerative outcome. Freeze casting permits to manufacture such complex, hybrid materials with excellent control of structural and mechanical properties. As a cold process, freeze casting additionally offers several pathways to introduce what could broadly be called chemical cues such as growth factors, viral vectors and peptides at several processing steps to enhance the functional properties of the final biomaterial. Chemical cues can be introduced already before the freeze casting step through peptide loading and peptide-functionalized components, such as collagen, chitosan, and nanocellulose for soft and hydroxyapatite and tricalcium phosphate for hard tissues, for example. Alternatively, the hierarchical architecture of the freeze-cast scaffolds can be modified with peptides or peptide-enhanced entities once the structure has been ice-templet and lyophilized (freeze-dried). Freeze casting and related manufacturing techniques therefore hold great promise for the manufacture of peptide-enabled biomaterials.

**Biomimetic Strontium Sulfate Mineralization Studied by Multiscale Microscopy and Vibrational Spectroscopy**

Andrienne Martin1, Jordan Hachtel2, Oliver Wang2, Dawn M. Raja Somu1, Steven A. Somi1, Dianne LaCamara-Rivera1 and Vivian Merk3; 1Florida Atlantic University, United States; 2Oak Ridge National Laboratory, United States

In the present study, we investigated the in-vitro crystallization of strontium sulfate (celestite, SrSO₄) in the presence of organic matter, including the synthetic polymer poly(sodium 4-styrenesulfonate), the poly amino acid poly(-glutamic acid), the polysaccharide poly(galacturonic acid) and the amino acid L-aspartic acid. In nature, biogenic SrSO₄ occurs in the skeleton of the unicellular plankton organisms Acantharia[3,4]. These biomimetal systems closely mimic fundamental interactions between mineral and organic matrix in living organisms, while eliminating the complexity and heterogeneity associated with biological systems. This investigation enabled a focused fundamental investigation of SrSO₄ crystallization across multiple length scales, as biologically grown minerals often contain a variety of organic molecules in small weight percentages as well as considerable amounts of foreign ions, such as magnesium, which complicate data interpretation[5]. Even though all studied biomolecules were included into the growing crystals in high weight percentages, poly(-glutamic acid) had the most profound impact on crystal morphology. Using Scanning Electron Microscopy and Atomic Force Microscopy, we observed mesocrystalline features on the crystal surface, which are consistent with biomolecule incorporation. Apart from studying the chemistry of the nanocomposites using bulk infrared spectroscopy, we discerned intracrystalline organics at the nanoscale using monochromated Electron Energy-loss Spectroscopy in the Scanning Transmission Electron Microscope[6,7]. By screening the organic-biomineral model systems with synchrotron X-ray powder diffraction[8,9], we quantified the degree of internal residual strain resulting from biomolecules with diverse functional group chemistry.

**Emulating Nature’s Way of Making Materials**

James J. De Yoreo1,2; 1Pacific Northwest National Laboratory, United States; 2University of Washington, United States

From harvesting solar energy to capturing CO₂ for purifying water, living organisms have solved some of the most vexing challenges now faced by humanity. They have done so by creating a vast library of proteins and other macromolecules that can assemble into complex architectures and direct the mineralization of inorganic components to produce materials characterized by a hierarchy of structure. While the high information content contained within the intricate sequences of the proteins is crucial for accomplishing these tasks, self-assembly and mineralization are nonetheless constrained to proceed according to the physical laws that govern all such processes, even in synthetic systems. An understanding of the mechanisms by which biological systems successfully manipulate these laws to create hierarchical materials would usher in an era of materials design to address our most pressing technological challenges. In this talk, I will present the results of recent research using in situ atomic force microscopy and in situ transmission electron microscopy to directly observe interfacial structure, protein self-assembly, and nanocrystal formation in biomolecular and biomimetic systems, including protein-directed nucleation of calcium carbonate and calcium phosphate and surface-directed nucleation of two-dimensional protein assemblies. The results elucidate the mechanisms by which the interface between biomolecules and materials directs nucleation, self-assembly and crystal growth, leading to unique materials and morphologies. The results reveal the importance of surface charge, facet-specific binding, solvent organization, and, more generally, the balance of protein-substrate-solvent interactions in determining how organized materials emerge in these systems.

**Degradation of Natural Molecules on Mineral Surfaces**

Colin Freeman1, Bia Fonseca2, Matthew Collins2,3 and Karina Sand4; 1University of Sheffield, United Kingdom; 2University of Copenhagen, Denmark; 3University of Cambridge, United Kingdom

Molecular binding at material interfaces is vitally important within a range of contexts. When a molecule has bound to a surface its structure and that structure of the local solvent can be very different to that in solution which can change its functionality and reactivity. In biology deamidisation and hydrolysis are two very common processes to break up peptides and both dependent on water molecules; therefore understanding the behaviour of the solvent molecules is equally important as that of the biologically active binding molecule. These decay processes are very important in a range of scientific fields including archaeology, palaeontology and surface fouling. Peptides extracted from archaeological digs can be used to indicate the diet and patterns of...
early humans, while DNA and proteins can be used to provide information on evolution in the fossil record.

We present a combined molecular dynamics and atomic force microscopy study on the binding of biological relevant molecules to calcite mineral surfaces. Out study examines and identifies the key factors involved in the binding of these molecules to the surfaces. We then explore the structural changes in these molecules and how this exposes/shields them from reactive processes that could lead to their decay. Finally we examine the behaviour of the other reactant species (solvent) and determine the role of the surface in enhancing or hindering their contribution to degradation reactions [1]. With this information we are able to comment on recent experimental findings and the potential preservation of different biological molecules.

Multiplexed Breath Biopsy of Lung Disease by Controlled Chemical Signal Activation Shih-Ting Wang, Melodi Anahtar, Daniel Kim, Tahoura Samad, Cathy Wang, Suhil Patel, Chayanon Ngambenjawong, Jesse Kirkpatrick, Heather Fleming and Sangeeta Bhatia; Massachusetts Institute of Technology, United States

Breath testing is a fast, non-invasive diagnostic method that can link specific volatile organic compounds (VOCs) in exhaled breath to medical conditions. Complementary to blood and urine assays in clinical disease diagnosis, breath is an informative analyte that can provide real-time information of changes in the body’s metabolome affected by disease activity. However, few breath tests are currently used in the clinic to monitor disease due to bottlenecks in biomarker identification and differentiation of endogenous VOCs in complex breath signatures. One approach to overcome this challenge is the in vivo administration of orthogonal exogenous agents with controlled properties that can be expelled from breath upon being metabolized by disease-specific molecular processes. Exogenous agents have been used in clinical breath tests for gastrointestinal and liver diseases and are more recently developed for respiratory disease. As the direct source of breath, the lungs are particularly suited for enzymatic activity-based breath tests. The multiplexed capabilities of designing reliable in vivo probes that release detectable and distinguishable exogenous VOCs are still in the early stages. Here, we report engineered breath biomarkers by protease-sensing nanoparticles for multiplexed detection of dysregulated activities of pulmonary proteases in response to disease and produce volatile reporters that can be detected in the exhaled breath. We show that the nature of proteolytic hydrolysis generating peptide fragments can be engineered to activate and release various types of volatile reporters. Using viral infection and Alk-mutant lung cancer mouse models, we show that multiplexed volatile-releasing activity-based nanosensors (vABNs) can detect and dynamically monitor diseases and treatment response.

Peptide-Functionalized Graphene Sensors for Selective Odorant Detection Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Gas sensing based on graphene field-effect transistors (GFETs) has gained broad interest due to their high sensitivity. Further progress in gas sensing with GFETs requires the detection of various odor molecules for applications in environmental monitoring, healthcare, food, and cosmetic industries. To establish an artificial sense of smell with electronic devices by mimicking olfactory receptors, it is desirable to use synthetic molecules with similar functionality. In this work, we designed three new peptides based on a motif sequence in olfactory receptors. These peptides were designed to have two domains: a bio-probe specific to the target molecules and a molecular scaffold [1,2]. The scaffold peptides have the ability to self-assemble into a molecular thin film on GFETs [3].

To demonstrate the biosensing capabilities, we employed limonene, methyl salicylate, and menthol as representative odor molecules of plant flavors. We investigated the conductivity change of GFETs upon binding to odor molecules at various concentrations. The dynamic response of the sensors revealed distinct signatures for each of the three different peptides against individual target molecules. The kinetic response of each peptide exhibited characteristic time constants in the adsorption and desorption processes, which were further supported by principal component analysis. These results demonstrate the selectivity of the designed peptides in detecting odor molecules.

The development of graphene odor sensors using these designed peptides paves the way for future peptide-array sensors with multiple sequences, enabling selectivity of the designed peptides in detecting odor molecules. To demonstrate the biosensing capabilities, we employed limonene, methyl salicylate, and menthol as representative odor molecules of plant flavors. We investigated the conductivity change of GFETs upon binding to odor molecules at various concentrations. Polymorphs of Short-Sequence Peptoid Assembly on MoS2 Shuai Zhang1, Chun-Long Chen2 and James J. De Yoreo2; 1University of Washington, United States; 2Pacific Northwest National Laboratory, United States

Peptoid is a biomimetic polymer inspired by peptide, with compatible bio-functions but better thermal and chemical stabilities. It has unique capabilities for creating hierarchical assemblies at solid-liquid interfaces, serving as templates for convincing applications in molecular recognition, fabrication of bio-hybrid materials, (bio)mineralization, energy conversion, storage, and transportation of matter and information, etc. Recently, we designed short peptoid sequences with assembly capabilities on MoS2. Using substrates with different hydrophobicity and adjusting the sizes...
of peptoid hydrophobic side chains and the dehydration process, we demonstrated that the peptoid assembly on MoS2 could have diverse phases, including the multilayer hybrid film with high crystallinity, vesicles, lamella, and single-/multi-strands. We further revealed that these phases can co-exist in a complicated phase diagram and can go through phase transitions between each other. Specifically, the peptoid-peptoid interaction, peptoid-solvent interaction, and peptoid-MoS2 interaction, mediated by pH, play crucial roles in this polymorph assembly. These results improve the knowledge of designing hierarchical architectures with biomolecules at solid-liquid interfaces. It also provides opportunities to optimize the future performance of 2D van der Waals materials-based devices.

2:15 PM *SB03.05.04 Subnanoscale Imaging of Nano-Bio Interfaces by 2D and 3D AFM Imaging Techniques Takeshi Fukuma; Kanazawa University, Japan

Atomic force microscopy is a powerful technique that can visualize atomic- or molecular-scale structures, dynamics and properties even in liquids regardless of the conductivity of the sample. In the past decade, there has been significant advancement in the in-liquid AFM techniques. Owing to the development of low noise cantilever deflection sensors[1] and small amplitude operation mode, atomic or molecular resolution can be achieved routinely even with dynamic-mode AFM such as frequency modulation[2] and amplitude modulation AFM (FM- and AM-AFM). This allowed us to visualize subnanoscale surface structures of various biological samples[3]. In addition, the tip scanning scheme has been expanded from 2D to 3D[4] and now we can visualize the 3D distribution of water (i.e., hydration structures), organic solvents, ionic liquids and flexible molecular chains[5-7]. These unique capabilities should be particularly useful in the studies of nano-bio interfaces, where biomolecules, water and ions interact with each other to induce various biological phenomena. However, their applications to the studies on biomaterials have yet been limited. In this presentation, I would like to present our recent works to explore applications of high-resolution in-liquid AFM techniques to studies on nano-bio interfaces. Examples include molecular-scale investigations on cellulose[8] and chitin[9] nanocrystals and self-assembled structures of short peptides on graphite[10].

University of Technology, Austria

Complex systems are characterized by an overall behavior which is different from that of the components making up the systems - hence, (nonlinear) interactions between the components play a very important role. Taking an interdisciplinary approach rooted in theoretical and applied mechanics and engineering mechanics, we report on two types of recently studied systems where individual system components (atoms and patients) interact in a way which unfolds very interesting emerging patterns that can be mathematically quantified through concepts arising from (bio-)mechanics: (i) the interaction of atoms within a short thread of DNA, which, as a compound, result in a family of a highly nonlinear beam structures with varying, but always coupled torsion-stretching modes [1]; (ii) the compliance of sets of patients to the lethal effect of SARS-COV-2 [2,3], which follows integro-differential equations reminiscent of those introduced by Boltzmann in the context of creep (or hereditary) mechanics [4]. We conclude that smart classical concepts of applied mechanics and physics continue to show an unparalleled potential for solving pressing global problems in the context of computational modelling of living systems.

can convert cells into vesicles by sequentially passing several micro-sized pores. Basically, the endocytosis mechanism study on the EVs exhibited new molecular uptake compared to β-1,3-glucan only. We verified that the EVs fabricated in this study notably stimulated the hydrogen activator protein kinase (MAPK) pathway, resulting in release of inflammatory mediators such as nitro oxide, cyclooxygenase-2 (COX-2) and pro-inflammatory cytokines.

The expression level of these immune factors was appropriately leveled to strengthen the immune system, not excessively inducing immune response such as cytokine storms. We also showed that the β-1,3-glucan encapsulated in the EVs, like other polysaccharides, was readily recognized by receptors such as Dectin-1 and TLR4 present on immune cell membranes. These results highlight that our EVs immunomodulatory system has potential for health promotion and disease treatment in various biomedical applications.

Deep Learning-Assisted Nanoplasmonic Digital Immunoassay for Cytokine Profiling in Immune-Suppressed Patients using Designed Peptide Aptamers Shuai Wang, Lang Zhou and Pengyu Chen; Auburn University, United States

Cytokine profiling in immune-suppressed patients plays a critical role in understanding their immune status and evaluating the effectiveness of immunomodulatory therapies. However, current immunoassay technologies face challenges in achieving rapid and accurate detection of multiple cytokines over a wide dynamic range. In this study, we propose a novel approach that combines deep learning with a nanoplasmonic digital immunoassay using rationally designed peptide aptamers as probes. The immunoassay system exhibits three notable features: (i) a simplified high-throughput biosensing chip fabrication process, (ii) an ultrasensitive nanoplasmonic digital imaging technique employing 50nm gold nanocubes (AuNCS) conjugated with antibody-mimicking peptide aptamers as detection probes, and (iii) a rapid and precise deep learning-based image processing method for digital signal analysis.

By utilizing our developed immunoassay, we successfully achieved cytokine profiling with a wide working range of 0.1-10,000 picograms per milliliter (pg/ml) and exceptional detection limits in the femtogram range. This level of sensitivity enables the accurate detection of even trace amounts of cytokines, critical for monitoring immune-suppressed patients.

Our findings demonstrate that this deep learning-assisted nanoplasmonic digital immunoassay, utilizing designed peptide aptamers, holds great potential for precise cytokine profiling in immune-suppressed patients. This innovative approach may contribute to improved clinical outcomes and informed treatment decisions for individuals with rapidly inflammatory disorders and immune suppression.

Electrochemical Activity of Molecular Hybrids: Self-Assembly of (XH)₄ Peptides and Hemin on Graphite Electrodes Marie Sugiyama, Wei Luo and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

The development of artificial enzymes has gained interest in electrochemical biosensors because natural enzymes have a relatively short lifetime and high cost for practical applications. Peptides with a small number of amino acids compared with proteins can be synthesized and chemically stable, thus they can be a good candidate as an artificial enzyme. Short-chain peptides that self-assemble into fiber-like structures in liquid are known to be catalytically active by forming complex structures with cofactors [1]. These catalytically-active peptides often contain histidine, which plays a role in stabilizing the structure and coordinating with cofactors at the imidazole group on the side chain, enhancing the catalytic activity. In our previous work, we found that catalytic peptides containing histidine exhibited their self-assembly on graphite surfaces and revealed electrocatalytic activity combined with the coenzyme hemin [2]. More recent work showed that newly-designed peptides (XH peptides) consisting of a repeating structure of two amino acids with histidine and another amino acid, “X”, also exhibited self-assembly on graphite surfaces. These peptides are a useful tool for understanding the role of the counter amino acid X on their surface self-assembly and in tuning the hydrophobicity of the graphite surface [3].

However, the capability of this XH peptide to immobilize cofactor hemins has not yet been investigated. In this study, we studied the interaction between hemin and the (XH)₄ peptide on the surface of a graphite electrode by atomic force microscopy (AFM). Three counter amino acids, tyrosine (Y), valine (V), and leucine (L), were employed as counter amino acids X for this study, e.g. YHYHYHYF. AFM showed that each peptide formed uniform linear structures with a height of a few nanometers. They also showed a hexagonal symmetry on the graphite surface, which is commensurate with the lattice structures of graphite. When the cofactor hemin was added, dot-like structures with a height of 0.5 nm−1 nm appeared on the peptide nanowires. The peptide with the highest number of particles on the peptide and the smallest particle size was LH, followed by YH and YH. Assuming that the particles on the wire were hemins, the XH peptide can be a suitable scaffold for immobilizing hemin. We also performed the electrochemical measurement to evaluate the hydrogen peroxide reduction capacity of the prepared XH peptide-hemin electrodes, and it was found that these peptides with a simple sequence of XH have enzymatic activity. The observations implied that the activity is closely related to the interactions with the hemin and peptides regarding the surface density of the immobilized hemins and their structural stability.

Graphene Biosensors for Probing Molecular Interactions of Peptides and RNA Forming Liquid-Liquid Phase Separation Kantaro Kikuchi, Yui Yamazaki and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Amyotrophic lateral sclerosis (ALS) is a fatal motor neuron disease affecting both upper and lower motor neurons. Frontotemporal dementia (FTD) is a type of brain disorder with degeneration of the frontal and temporal lobes of the cerebrum. These neurodegenerative diseases share the expansion of GGGGCC hexanucleotide repeats in the C9orf72 gene, identified as a major cause of the diseases [1]. The gene produces dipeptide repeats proteins (DPRs) that cause cell death. These peptides contained arginine (Arg) and counter amino acid in the dipeptide sequence and were found to form liquid-liquid phase separation (LLPS), closely related to their cytotoxicity. A previous report indicated that poly-R is highly charged and interacts with anionic molecules such as RNA but exerts no cytotoxic effect. Poly(PR) and poly(GR), on the other hand, entraps proteins via multivalent interaction in LLPS, impairing protein translation. Thus, it is known that the position of Arg in DPRs profoundly affects the interaction [2]. These findings indicate that the interactions between DPRs and RNA should be unique to form LLPS and entrapment the proteins. However, the understanding of the interactions of DPRs is still limited because of the lack of measurement techniques that can distinguish the weak interactions among them.

In this study, we applied graphene field effect transistors (GFETs) to evaluate the biomolecular interactions. Graphene has excellent electrical properties and high specific surface area and has recently shown promise as an ultra-sensitive biosensor. The interaction between peptides in thevicinity of the graphene surface can be detected as an electrical conduction change of graphene. We immobilized RNA on the graphene surface via pyrene anchors, as same in other works, and measured the interactions of RNA with DPRs known to form LLPS. The interactions are measured by incubating the DPRs of interest across the RNA-functionalized surface. Atomic force microscopy (AFM) was used to ensure these surface modifications. In electrical measurements, the peptides interacting with the RNA were quantified by the shift of the charge-neutral points in their gate responses of GFETs, and differences in interactions due to peptide species were discussed. From the results, we succeeded in detecting the difference in interaction with RNA by peptide species with high sensitivity at the nano-molar level. We believe that this result is helpful in quantitatively discussing the effect of small amino acid
Acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) have particularly dismal patient outcomes, with low 5-year survival rates in adult patients. Outcomes in pediatric patients are more optimistic, mainly due to their ability to withstand more aggressive treatment regimens. Glucocorticoids, although used as a standard treatment, can have severe adverse effects that limit dosing regimens. To address these challenges, directing drugs to hematopoietic progenitor cells implicated in these leukemias via targeted drug delivery therapies would allow for more aggressive and effective treatments, with reduced side effects. Layer-by-layer (LBL) nanoparticles (NPs) are a modular drug delivery system that enables the incorporation of a wide range of charged polymers on the surfaces of a drug-loaded NP core, to tune surface properties, targeting capacity, and biodistribution of NPs. The outer polymers can also be used as scaffolds to conjugate molecules, like antibodies, to aid in targeting drugs to cells of interest. In this work, we developed LBL NPs with dexamethasone loaded in the liposome core and functionalized them with polymers and antibodies to evaluate their targeting capacity to hematopoietic stem and progenitor cells (HSPCs) implicated in AML and ALL.

Dexamethasone palmitate (DXP) was incorporated as part of the lipid bilayer of liposomes using lipid hydration. Drug concentrations were measured via high-performance liquid chromatography (HPLC). Negatively-charged liposomes, empty or encapsulated with DXP, were layered with a cationic polypeptide, followed by a layer of anionic synthetic polymer on top. HSPC-targeting antibodies were then conjugated onto the top polymer layer. NP size and surface charge were monitored throughout the process via dynamic light scattering. NP concentration was determined via fluorescence intensity measurements of dye-conjugated lipids in the liposomal core. A bicinchoninic acid (BCA) assay was used to assess antibody concentration after purification. NP-cell association studies were conducted via fluorescence-activated cell sorting (FACS).

Antibodies were successfully conjugated to the NPs, with no notable impact on their physicochemical properties when measured over a 2-month period. Furthermore, antibody-functionalized LbL NPs demonstrated preferential association with a relevant myeloid progenitor-like cell line (ER-HOXB8), following 90-minute incubation. In fact, two candidate antibodies had a 1.5-fold increase in NP-cell association compared to unconjugated LbL NPs. For DXP-loaded NPs, it was found that the presence of the drug in the liposomal core had minimal impact on the stability of the NP throughout the layering process, with negligible changes in drug loading. Preliminary longitudinal studies found that the presence of the drug had no notable impact on the colloidal stability of the LbL NPs.

Overall, we have shown that LbL NPs can be functionalized with HSC-targeting antibodies, with a preferential association to relevant cell lines, and that the LbL construction of NPs is unhindered by the presence of DXP in the core. Future work would involve combining the drug-loaded NPs and functionalizing them with the candidate antibodies to ensure that similar preferential association is observed in relevant in vitro and in vivo models of acute leukemias.

Biomimetic reaction systems, where small proteins and peptides assist in the growth of inorganic materials, has the potential for making complex structures that are otherwise difficult to achieve. Living organisms use a peptide-inorganic matrix to control the morphology of the inorganic structures. Using this method as inspiration we sought a similar approach for novel materials. Zinc oxide as chosen as the target material due to its many exciting optoelectrical properties. Phage display was performed on ZnO sample and used to identify small peptides with high binding affinity for ZnO. By means of an aqueous based synthesis, these high affinity peptides were added at various concentrations to the solution so growth of the ZnO crystals could occur in the presence of the peptides. In the absence of peptides, the ZnO grows with a long needlelike morphology. When peptides are added to the growth solution they are found to dramatically alter the final morphology of the ZnO substrates. By altering the concentrations of these peptides, the morphology of ZnO nanorods can be controlled, ultimately allowing for the formation of thin films. Through the use of these peptides, we form ZnO thin films on a variety of substrates including glass and flexible PET plastic.

Demystifying The Synthesis and Preparation of Protein-Mimicking Random Heteropolymers Hao Yu, Ivan F. Jayapurna and Ting Xu; University of California, Berkeley, United States

Random heteropolymers (RHPs) with statistically distributed comonomers along the polymer chains are commonly used as functional materials for achieving biomimetic functionality. This is due to their capacity to replicate protein-like phase behavior and functions. However, unlike many branches of chemistry and biology where structures can be constructed precisely on the molecular level, the inherent stochastic nature of monomer sequences in RHPs raises concerns regarding their high material dispersity and difficulties in chemical characterization. Moreover, while extensive research has been conducted on synthesizing and understanding two-monomer systems, there have been limited studies and systematic guidance on the synthesis of multi-monomer copolymers such as RHPs, which involves complex, interdependent reaction kinetics among multiple comonomers. These knowledge gaps present barriers for researchers outside the polymer chemistry community who seek to create protein-mimicking RHPs with targetable structures and properties.

Towards these prospects, here we conduct a comprehensive investigation into the sequence heterogeneity and compositional drift in a family of 4-monomer-based RHPs. We commenced with experimentally determining the relative reactivities of a repertoire of four methacrylate monomers in reversible addition-fragmentation chain-transfer (RAFT) copolymerization. These underlying kinetic factors dictate the sequence heterogeneity of as-synthesized RHPs. Combining with stochastic sequence simulation, we designed four new RHPs, with each ensemble designed to exhibit different levels of hydrophilicity. Of particular interest is our findings that the purification procedures used during RHPs preparation, including pentane precipitation and dialysis against water, can preferentially eliminate different RHP subpopulations. This selectivity can be attributed to the conformations and apparent solubilities exhibited by these subpopulations, which are due to their particular chemical compositions within the whole RHP ensembles. Additionally, we quantitatively mapped out the trajectory of monomer compositions during the whole RHP preparation process. The predicted RHP cumulative compositions are in close agreement with the experimental results. These results validate the fidelity of predictive modeling and multicompontent RHP copolymerization. There are potentially over 300 commodity methacrylate monomers that are available for synthesizing RHPs materials. These findings are readily applicable to study the structure and sequence of heteropolymers beyond those described in this work. Overall, this work provides critically needed information to design and understand RHPs as functional materials while addressing the concerns related to their sequence heterogeneities.

Computational Investigation of Unique Structural Proteins in Cephalopod Skin Arsenii P. Panteleev1, Christophe Magnan1, Pierre Baldi1, Alon Gorodetsky1, Andrew Cannon2, Albert Kwansa2 and Yaroslava G. Yingling2; 1University of California, Irvine, United States; 2North Carolina State University, United States

Cephalopods (e.g., octopuses, cuttlefishes, and squids) are renowned for their remarkable dynamic color-changing and camouflaging capabilities.2,4 These animals possess a skin architecture wherein different cells or organs known as chromatophores, iridophores, and leucophores modulate the transmission, absorption, and/or reflection of light.2,4 Interestingly, these cells or organs all contain light-manipulating nanostructures composed of unique high-refractive index proteins called reflectins.2,4 In our previous work, based on a bioinformatics analysis of the 51 reported reflectins, we had designed a truncated reflectin variant and studied the structure and self-assembly of this polypeptide via a combination of computationally driven experimental methods.6 Subsequently, we had selected a prototypical reflectin isoform and investigated the structure and hierarchical self-assembly of this protein via multiple computational and experimental techniques.1 Recently, we have extended these studies to other truncated and full-length reflectins, obtaining extensive new fundamental insight into their structures and functionalities.1,3,5 When taken together, our experimentally validated computational findings provide additional insight into the camouflage capabilities of cephalopods and suggest new directions for the development of bioinspired optical materials and systems.

Activating the C–H bonds of alkanes without further oxidation to more thermodynamically stable products, CO, and CO2, is a long-sought goal of catalytic chemistry. Inspired by the monocopper active site of methane monooxygenase, a Cu-doped ZIF-8 metal–organic framework is synthesized with 25% Cu and 75% Zn in the nodes and activated by heating to 200 °C and dosing in stepwise fashion with O2, methane, and steam. We found that it does oxidize methane to methanol and formaldehyde. The catalysis persists through at least five cycles, and beyond the third cycle the selectivity improves to the extent that no CO2 can be detected. Experimental characterization and analysis were carried out by PXRD, DRUV-Vis, XANES, EXAFS, SEM, and XAS. The reaction is postulated to proceed at an open-coordinate Cu site generated by defects, and the mechanism of methanol production was explicated by density functional calculations with the revMO6-L exchange–correlation functional. The calculations reveal a catalytic cycle of oxygen-activated Cu2+ involving the conversion of two molecules of CH4 to two molecules of CH3OH by a sequence of hydrogen atom transfer reactions and rebound steps. For most of the steps in the cycle, the reaction is more favored by single-metal species than by triplets. The singlet pathway consists of both closed-shell singlet and open-shell singlet species. The closed-shell singlet calculations were checked for wavefunction stabilities, ensuring the correctness of the calculations. The reaction mechanism along the singlet pathway goes through open-shell singlets until the final step where it passes through a closed-shell singlet transition state to give rise to closed-shell singlet final product, which is a van der Waals complex of Cu and CH3OH. This work provides a biinspired synthesis of a metal-organic framework, whose defective sites carry out selective methane oxidation to methanol. A biomimetic reaction mechanism is postulated and further validated by density functional theory calculations.

Deep Learning Analysis of Scattered Light Intensity for Shape Classification of Nanoparticles Measured by Nano Tracking Analysis Keisuke Yamamoto1, Hiroaki Fukuda1, Hiromi Kuramochi1, Yasushi Shibata1 and Takanori Ichiki1;2; 1The University of Tokyo, Japan; 2Innovation Center of NanoMedicine, Japan

Characterizing particles with sizes below 100 nm, such as peptide or protein-based biopharmaceuticals, necessitates single-particle measurement and multi-parametric analysis to distinguish individual particles. Nano Tracking Analysis (NTA) is a widely used technique for single-particle measurement in liquid samples due to its simplicity. By capturing the scattered light from nanoparticles illuminated by laser light, NTA can measure individual particles [a]. To expand the range of useful properties, we are exploring the application of deep learning to the analysis of NTA data. Recently, by utilizing deep learning analysis, we have successfully detected the effect of shape anisotropy, demonstrating the potential for multiparametric analysis of nanoparticles in liquids[b]. In this study, to further enhance our understanding of physical properties, we investigate the potential of shape classification using the luminance information derived from light scattering images of particles measured by NTA. Experiments were conducted using two types of gold nanoparticles: spherical particles with a diameter of 80 nm and rod-shaped particles with a diameter of 40 nm and a length of 180 nm. The NTA method was employed to capture 100 consecutive frames of images at 100 frames per second. From these images, three types of features were extracted as luminance information: scattered light intensity, cross-sectional area of the scattering pattern, and aspect ratio. Subsequently, a dataset was constructed based on these features. Our deep learning analysis, utilizing a one-dimensional Convolutional Neural Network (1D-CNN) model, successfully learned all the extracted features. The shape classification accuracy using scattered light intensity was found to be 92%, surpassing the 80% accuracy achieved through shape classification based on Brownian motion trajectories. Moreover, even with a limited number of data frames (20 frames), the accuracy for the analysis based on luminance information reached 85%, compared to 60% for the analysis based on Brownian motion trajectories. These results demonstrate the potential of accurately extracting properties in a shorter timeframe using deep learning analysis of scattered light intensity information acquired by the NTA method. In conclusion, our study showcases the effectiveness of employing deep learning analysis of scattered light intensity for shape classification of nanoparticles measured by NTA. This approach not only enhances the accuracy of particle characterization but also reduces the analysis time. The proposed method holds promise for further advancements in the field of nanoparticle characterization and analysis.

Mineral: Peptide Interactions: Using Our Understanding of Molecular Interactions to Develop a Time Efficient Biopanning Approach Carole C. Perry and Valeria Pudda; Nottingham Trent University, United Kingdom

Minerals and biomolecules can interact via a range of binding modalities from electrostatic interactions, though hydrogen bonding to hydrophobic interactions and van der Waals interactions. These binding possibilities lead to a range of biomolecule sequences that can interact with a particular mineral. From our understanding of peptide-mineral interactions gained by extensive, detailed experimental and computational studies we have developed an optimised biopanning approach, utilising multiple chemical eluants that allows the identification and recovery of a wide mineral binder pool in just one or two biopanning rounds.

9:00 AM SB03.07.05
A Dynamics-Informed Approach to Prediction of Protein Melting Temperature via Graph Neural Networks Yen-Lin Chen and Shu-Wei Chang; National Taiwan University, Taiwan

A practical design of biomedical materials requires knowledge of their thermal properties. Melting temperature has a direct influence on molecular stability, functionality, and performance in the case of protein engineering. For example, biosensors and enzymes will only operate as intended within a limited thermal range. As such, the prediction of the thermostability of proteins is a crucial factor with implications in various scientific disciplines and technical applications. This task requires an understanding of the hierarchically organized proteins, which manifests in a dynamically coupled cellular system. The introduction of machine learning methods to biology brought about astounding breakthroughs, such as the prediction of protein structures by AlphaFold. It is a promising approach to undertaking convoluted relationships in protein science. In this study, we propose a machine learning method for the computation of the melting temperature of proteins, taking into account the amino acid sequence, protein structure, and dynamics. Graphs (as in graph theory) are chosen as our data representation due to their rotational invariance and their intuitive mapping to molecular structures. The sequential, structural, and dynamical information are represented as multigraphs, with residues as its nodes, and various node features and edge connections derived from each of these properties. To process the data, a graph neural network architecture that makes use of message passing layers was designed to accommodate the multiple types of connections. Protein structures were computed by AlphaFold and the dynamics were computed based on the torsional network model (TNN) for training. Hence, the learned features and parameters can be readily applied to protein sequences without known experimental structure, satisfying the goal of aiding the prediction of design proteins. We are also able to identify key domains that contribute to the thermal stability/instability of proteins by computing the graph regression activation map, which is based on the partial derivatives of the predicted value with
respect to features on the input nodes. Our method gives insight into the mechanism of natural proteins and provides critical information regarding design proteins.

Scientific Analysis of Synthetic Collagen Compounds using Computational Molecular Modeling Methods
Jordanne A. Davenport and Kristen Rhinehardt; North Carolina A&T State University, United States

Scientists have proven that the health regimen you follow can have a significant impact on the human body. Collagen is found on multiple parts of the body such as skin, bones, lymphatic, cardiovascular, liver, lung, spleen, and intestinal tissue. (Spano, 2019) Although it is prevalent that people lose 1% of collagen each year, there is a way to improve this by maintaining a healthy diet. “Collagen-derived dietary proteins are most commonly extracted from porcine skin (45%), bovine hide (30%), and the bones of both animals (23%) Chicken (bones) and fish (scales and bones) byproducts are also used as production sources of collagen-derived dietary protein” (Holwerda and Loon, 2022). In this research, a biomodel of three synthetic collagen molecules is used to bind biomarker properties including Aptamers, CNA, and Silk. Pymol is a molecular visualization tool that provides an ethically pleasing environment for a three-dimensional structure of a protein molecule to be cleaned by removing water, removing repeated molecules, and retrieving the model sequences. The results from PyMOL are then incorporated into the Basic Local Alignment Search Tool (BLASTp) to generate alignments between a protein sequence (Wheeler, Bhagwat, 2007). The binding energy is calculated along with a visual model of the structural changes of the collagens reaction to its biomarker using HDOCK and PATCHDOCK servers. When docking with PatchDock, the results are collected and refined with a software named FireDock to retrieve the binding energies. The best conformations were compared with differing peptides to see which ligand showed the highest affinity. “While enzyme driven crosslinking plateaus at maturation, connective tissue stiffness has been shown to further increase with age and diabetes. This tissue stiffening has been associated with non-enzymatic, oxidative reactions between glucose and collagen which increases with increased plasma glucose end concentrations associated with advanced aging” (Snedeker, 2014). Further research will utilize molecular dynamics to explore conformational space and explicitly treat structural flexibility and entropic effects of synthetic collagen.

Phytochemical-Enriched Plant Extracts Induce Apoptosis in Bone Metastatic Breast Cancer Cells
Preetham Ravi, Haneesh Jasuja, Dipayan Sarkar, Kalidas Shetty, Dinesh R. Katti and Kalpana Katti; North Dakota State University, United States

The WHO reports that breast cancer is the most common occurring type of cancer with nearly 2.26 million cases being diagnosed each year. Breast cancer is also the second leading cause of cancer-death in women. Majority of the deaths occur due to breast cancer metastasis to bone. Breast cancer cells at bone site experience altered growth and chemoresistance. Furthermore, the infrastructure of the bone is compromised, resulting in skeletal failures in patients. Currently, there is no cure for bone metastasis of breast cancer. There is a shortage of effective therapeutics for bone metastatic breast cancer, due to the reported ineffectivity of commercialized drugs at bone metastatic site. There is a need for accurate drug screening cancer models, which recapitulate the bone-metastatic condition, to effectively test potential anti-cancer therapies. In addition, therapies are needed not only to treat the tumor, but to heal bone, with limited side-effects. In this study, we employ a unique 3D in vitro nanoclays based scaffold model, as a testbed for bone metastatic breast cancer, to screen three phytochemically-enriched plant extracts (Rhodiola Crenulata, Origanum vulgare, and Vaccinium Macrocarpon). These plant extracts have been tested against primary site breast cancer, however, they efficacy against bone metastasized breast cancer cells is unknown. We evaluated the cytotoxicity of the three extracts on bone metastatic breast cancer using the bone-mimetic scaffolds and compared the results with 2D cultured breast cancer cells (MDA-MB-231 and MCF-7). The cell viability studies showed that breast cancer cells growing, both in 2D and 3D Bone-metastatic cultures, were significantly reduced by increasing dosages of all three plant-extracts. Furthermore, it was observed that these extracts induce apoptosis in breast cancer cells grown in 2D and bone-metastatic culture, through upregulation of pro-apoptotic markers, p53, caspase-3, and caspase-9 and downregulation anti-apoptotic markers. Additionally, the bone metastatic breast cancer cultures experienced increased drug resistance. Lastly, we evaluated the effects of these plant extracts on bone cells, and found that they are unaffected after treatment. Overall, our data indicates that these phytochemically-enriched plant extracts can promote cytotoxicity in bone metastatic breast cancer, while unafecting healthy bone cells. Moreover, these specialty derived compounds can be ideal candidates to be investigated as new therapies to treat bone metastasis of breast cancer.

10:30 AM SB03.08.03
Role of Fluid Induced Shear Stresses in Inducing Bone Metastasis in Prostate Cancer
Kalpana Katti, Haneesh Jasuja, Sharad V. Jaswandkar and Dinesh R. Katti; North Dakota State University, United States

The World Cancer Research Fund International reports that prostate cancer is the second most commonly occurring cancer in men. In addition, 1,414,259 new cases of prostate cancer were reported in 2020. The World Health Organization, reports 375,304 deaths in 2020 due to prostate cancer. The majority of deaths due to prostate cancer result from the cancer relocating to a distant location in the body through the process of metastasis. The bone is a common niche of relocation of prostate cancer metastasis. Prostate cancer that has metastasized to bone is incurable. We have developed a novel nanoclays-based tissue-engineered polymeric scaffold in order to mimic the bone metastasis site through sequentially seeding with hMSCs and cancer cells. The role of blood flow in cellular processes is well known through the effect of shear forces exerted by the fluid. It is also known that the fluid flow provides unique biochemical cues for metastasis. We have designed and fabricated a bioreactor that enables physiologically relevant interstitial fluid-flow for prostate cancer bone metastasis. We have also conducted computational fluid dynamics studies to establish that a fluid flow of 0.05 ml/min recapitulates the physiological condition. We did extensive gene expression and protein evaluation studies on the cellular materials grown with and without the effect of fluid flow. We observe that the interstitial fluid-flow does not alter the CXCR4 level, an important regulator of metastasis and invasiveness of cancer. On the other hand, a large impact of bone proximity on the CXCR4 levels. The bone proximity upregulates CXCR4 levels enabling increased MMP-9 levels. We also investigated the levels of integrins which are important cellular adhesion proteins and found that avb3 integrins are overexpressed by fluid-flow causing increased migration under fluid-flow. Hence our studies indicate that avb3 integrins act as potential mechanosensory agents transducing mechanical signals via avb3-MMP 9 signaling to promote fluid induced motility of prostate cancer cells. Overall, these experiments describe the significant role of interstitial fluid-flow in prostate cancer metastasis.
Wastewater-based epidemiology can monitor population-level infections, provide early warnings about disease outbreaks, and help to control disease spread at the community level [1]. However, bacterial identification in wastewater presents outstanding challenges; notably, current methods [2] to identify bacteria are slow and costly, not suitable for high-throughput screening of diverse bacterial species, and may not work well in the complex wastewater matrix. Here, we develop a new electro-optical method that has the promise to detect a wide range of pathogenic bacteria in wastewater.

We combine surface-enhanced Raman spectroscopy (SERS) [3] and electrified interfaces, further assisted with machine learning models [4] to realize rapid and amplification-free detection of bacteria, at cell concentrations as low as 10³ cells/mL in filtered wastewater. First, we collect SERS from bacteria spread into filtered wastewater, including Staphylococcus aureus, Staphylococcus epidermidis, and Escherichia coli. Here, plasmonic gold nanorods electrostatically bind to the bacteria surface, allowing for rapid biomolecular recognition of the cell surfaces. Additionally, two-dimensional gold microelectrodes are patterned on the sensor surface to apply electrical fields to wastewater, which selectively attracts and enriches bacteria present in the complex wastewater matrices within minutes, driven by dielectrophoretic effects [5]. The enrichment of bacteria is directly observed through microscopy, and Raman signal intensities are increased by five to ten fold under electrical fields for bacterial concentrations ranging from 100 cfu/mL up to 10⁸ cfu/mL. Such enhancement enables the detection sensitivity to reach environmentally-relevant concentrations (typically below 10³ cfu/mL) with just ten seconds of integration time. Finally, using machine learning, we identify biologically-relevant “fingerprints” Raman peaks describing proteins, nucleic acids, and lipids from bacteria surfaces, and achieve rapid and accurate identification of bacteria species in wastewater. The method has the promise for future label-free detection and prediction of bacterial outbreaks through wastewater. It also opens up new directions for generalized pathogen detection and molecular recognition in a broader range of complex liquid samples including wastewater, blood, and seawater.

11:00 AM SB03.08.05
Peptidic Luminescent AuNCs for Biosensing
Solene Ducarre1, Raffaello Paolini1, Ester Butera1, Dorian Lemasson1, Regina Cheichio1, Pascale Even-Hernandez1, Celia Ravet2, Ludovic Jullien1 and Valérie Marchi1; 1Institut des Sciences Chimiques de Rennes, France; 2CHU Rennes, France; 3ENS PSL, France

Gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1ns – 1ms) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.

We demonstrated their in vivo targeting ability because of specific peptidic recognition groups (R. Cheichio et al. ACS Nano materials 2023) Here we present the direct synthesis of original ultrasmall luminescent peptidic gold nanoclusters sensitive to pH. The versatility of small peptides permits to adjust the emission wavelength and the sensitivity of the emission intensity as well as the luminescent lifetime.

In addition due to their ultra-small size, we demonstrated that these probes are easily internalized into Arabidopsis plant from the roots and the leafs by adjusting the surface charge of the ligands. Their biodistribution in this model plant was evidenced by confocal microscopy. This chemical platform provides AuNC dual nanoprobes with potential sensitivity to the environment for biosensing applications. Such nanostructures offer promising candidates for fluorescent in vivo biosensing and biolabeling.

We also investigated the interaction of AuNC with Extracellular vesicles (EVs) which are well-known membrane-limited particles that are secreted by healthy and cancerous cells. EVs are heterogeneous in size and three subtypes are described depending on the location of secretion: microvesicles, melanosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle (Neyroud A. S. et al. Int. J. Mollecular Sci. 2022). In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content thanks to AuNCs nanoprobes could provide informations about the origin and the biological function of the EVs. The EVs labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases.

11:15 AM SB03.08.06
Engineering Antigen Binding and Orientation on Alum Adjuvants for Enhanced Humoral Responses and Immunofocusing
Dao Xu and Peter S. Kim; Stanford University, United States

A major challenge in vaccine development, especially against rapidly evolving viruses, is the ability to focus the immune response toward evolutionarily conserved antigenic regions to confer broad protection. For example, while many broadly neutralizing antibodies against influenza have been found to target the highly conserved stem region of hemagglutinin (HA-stem), the immune response to seasonal influenza vaccines is predominantly directed to the immunodominant but variable head region (HA-head), leading to narrow-spectrum efficacy. Here, I will first introduce an approach to controlling antigen orientation based on the site-specific insertion of short stretches of aspartate residues (oligoD) that facilitates antigen-binding to alum adjuvants. I will demonstrate the generalizability of this approach to antigens from the Ebola virus, SARS-CoV-2, and influenza and observe enhanced antibody responses following immunization in all cases. Next, I use this approach to reorient HA in an “upside down” configuration, which I envision increases HA-stem exposure, therefore also improving its immunogenicity compared to HA-head. When applied to HA of H2N2 A/Japan/305/1957, the reoriented H2 HA (reoH2HA) on alum induced a stem-directed antibody response that cross-reacted with both group 1 and 2 influenza A HAs. These results demonstrate the possibility and benefits of antigen reorientation by engineering the interaction between antigens and adjuvants, which represents a generalizable immunofocusing approach readily applicable for designing epitope-focused vaccine candidates.

3D Inverse Modelling to Extract Local Hydrogel Remodelling and Stress Fiber Structure in Human Diseased Aortic Heart Valve Interstitial Cells
Michael S. Sacks and Toni West; The University of Texas at Austin, United States

Direct assessment of three-dimensional (3D) cell single stress fiber (SF) structure and function remains technically challenging, due to the SF feature size falling well below the resolution of light microscopy. Therefore, computational approaches are needed to estimated the effective structures and contractile behavior of SFs in various states. Herein, we developed a 3D computational model of the contracting aortic heart valve interstitial cells (AVICs) embedded
in 3D hydrogels to estimate their SF orientations and contractile forces. We first utilized our hydrogel inverse model to estimate the local hydrogel mechanical properties. Briefly, this approach produces a spatially varying hydrogel modulus field or profile that minimizes the error between the experimentally measured and simulated hydrogel deformations produced by a contracting AVIC. It was determined that AVICs both degrade the gel by enzymatic processes, as well as locally stiffen the gel by collagen deposition. Next, we developed two finite element based inverse models that utilized a single direction and dispersed orientation SF structure. Both models estimated that the greatest levels of SF forces occurred at AVIC protrusions. The second model estimated that the greatest levels of SF alignment occurred at AVIC protrusions while the AVIC midsection revealed less-aligned fibers. To the best of our knowledge, we report the first fully 3D computational contractile cell models which can predict locally varying stress fiber orientation and contractile force levels. Looking forward, these models may help us obtain an increased understanding of SF function at sub-cellular length-scales and can be incorporated into multi-scale models of tissue/organ function.

SESSION SB03.09: Applications and Devices in Materials and Medicine II

8:30 AM SB03.09.01
Application of eIF4E Protein-Ligand Modeling for Cancer Drug Discovery
Melvin Thu1,2, Parth Jain1,2, Evan Xie1,2, Karin Hasegawa2 and Yuefan Deng3
1Great Neck North High School, United States; 2Stony Brook University, The State University of New York, United States; 3Bergen County Academies, United States; 4The Pingry School, United States

The eIF4F complex recruits ribosomal subunits (40S) to initiate translation and is composed of the eIF4E, eIF4G, and eIF4A subunits. eIF4E is the cap-binding protein and binds to the m7gtp mRNA 5’ cap. eIF4G is the scaffolding protein in the complex and binds eIF4E. The protein 4E-BPs can bind to eIF4E where eIF4G binds to prevent the eIF4F complex from forming. eIF4E plays a substantial role in cancers since eIF4F preferentially activates the translation of certain mRNAs, encoding proliferation and survival-promoting proteins such as cyclin D1, e-Myc, and VEGF. The pathway involving PI3K phosphorylation of 4E-BPs results in the unbinding of eIF4E from 4E-BPs and the formation of the eIF4F complex resulting in breast, lung, ovarian, and prostate cancers, and the pathway involving Ras phosphorylation of eIF4E results in the formation of an active eIF4F complex resulting in pancreatic, lung, and colorectal cancers.

Our approach to eIF4E inhibition involves designing a compound to restrain the movement of key eIF4E residues involved in the binding of eIF4E to m7GTP, such as W102, W56, and E103, to prevent binding. An issue with m7GTP analogues of similar structure and stronger binding affinity, however, is that many are negatively charged and thus can’t pass through cell membranes. Molecular docking simulations can predict binding orientation and binding affinity of the ligand to target, producing samples of many ligand conformations in the target binding region to find the optimal conformation. However, high throughput screening through brute force molecular docking is computationally expensive and limited as there are only 1010 known compounds as opposed to the 1060 total compounds.

In order to design an effective ligand, we first have to study the structure of eIF4E, and investigate how key residues involved in eIF4E binding to m7GTP undergo conformational change with and without m7GTP. We optimize eIF4E models without m7GTP using principal component analysis (PCA) and free energy landscape (FEL) calculations. We performed PCA on the trajectory data of 2gpq, 4tpw, and AF protein sources of eIF4E to transform the set of possibly correlated variables (the positions of the protein atoms) into a set of values of linearly uncorrelated variables (the principal components). We then calculated FEL of the 2qpq, 4tpw, and AF protein sources of eIF4E using GROMACS to identify the most stable conformations of eIF4E. FEL is a graphical representation of the thermodynamically stable states of a protein and the transitions between them where the local minima represent the most stable protein conformations and the barriers represent the transition states. The stable conformations of 2gpq, 4tpw, and AF were then used in molecular docking simulations of the eIF4E-m7GTP complex in order to determine the m7GTP pose with the most favorable binding energy. It was confirmed that m7GTP binds to the W56, W102, E103 residues for all three sources of eIF4E. We then performed molecular dynamics simulations on the docked eIF4E-m7GTP complexes using GROMACS with the CHARMM36 force field and TIP3P water model.

We are currently working on identifying the regions of m7GTP that are interacting with W56, W102, and E103, to prevent binding. An issue with m7GTP analogues of similar structure and stronger binding affinity, however, is that many are negatively charged and thus can’t pass through cell membranes. Molecular docking simulations can predict binding orientation and binding affinity of the ligand to target, producing samples of many ligand conformations in the target binding region to find the optimal conformation. However, high throughput screening through brute force molecular docking is computationally expensive and limited as there are only 1010 known compounds as opposed to the 1060 total compounds.

Viability of a Novel Peptide P12 as an Antithrombotic Agent
Sai Pranav Kota1, Richard A. Wong2, Samuel D. Coopersmith3, Avi Talisman4, Pia V. Sudhi1, Sharis Hus3, Adam Hansen3 and Miriam Rafailovich1
1The Pingry School, United States; 2Stony Brook University, The State University of New York, United States; 3Plainview-Old Bethpage John F. Kennedy High School, United States; 4Casandra Grande High School, United States; 5Stony Brook University, United States; 6The Brearley School, United States; 7Valley Christian High School, United States; 8Stony Brook University, The State University of New York, United States

Medical devices and implants are an ongoing point of research due to their impressive capabilities to enhance and support human infrastructure, but pose major challenges as they must incorporate a biocompatible material that can support endothelialization and prevent thrombosis. Specifically, current cardiovascular devices like stents lack reliable endothelialization and because of exposure to constant contact with blood flow within vasculature, result in life-threatening blood clots. Fibrinogen is a plasma-soluble protein that, once cleaved, results in fibrin monomer polymerization into fibrous clots. Previous studies have demonstrated that m7GTP has been shown to prevent fibrinogen deposition and denaturation, which results in conversion into fibrin monomers and polymerization through αC domain connections [1]. A multitude of possible solutions have been studied by utilizing varying hydrophilic or hydrophobic surface properties, which feature different materials or coatings with limited success. Here, we will explore incorporation of a surface coating using P12, a peptide derived from fibronectin, to prevent thrombosis.

Initial studies provided insight on how P12 is effective for inhibiting the fibrin polymerization process on polystyrene (PS) surfaces. We studied various fibrinogen and P12 concentrations, but ultimately we found that incorporation of P12 during the incubation of 4 mg/ml of fibrinogen, the concentration in exposed αC domains of fibrin on the PS surface. This prevented aggregation of neighboring fibrin monomers and ultimately prevented polymerization into fibers. Further studies were conducted to overcome the possible negatives of using P12, which includes the uncertainty of P12 reaching the implant or cytotoxic considerations. In order to utilize P12 properly, we investigated using it as a material coating to enhance its effectiveness in a controlled location. We conducted this by applying 100 µM of P12 solution onto PS surfaces until full coverage was achieved. Fibrinogen solutions of 4 mg/ml incubated the coated surface for one hour. The P12 coating resulted in <1% of the surface containing fibers and adversely, without the coating resulted in >50% of the surface covered in fibers. From this data, we concluded that a coating of P12 is very effective in thrombosis prevention.

Cytotoxicity is another major problem with implementation of a biomaterial coating. We therefore plated fibroblasts on P12 coated tissue culture plastic
Despite the additional P12 to the media to directly test cell survivability. We found that there were no significant differences on P12 coating or adding P12 to cells. These results are indicative of no associated cytotoxicity of the P12 surface. We further investigated this by testing cell adhesion and proliferation on P12 coated polystyrene and found an increase in cell growth and adhesion by the addition of P12 on an otherwise non-bioincompatible polystyrene surface. This data concluded that a P12 coating not only rendered surfaces non-thrombogenic and non-toxic, but also enhanced biocompatibility.

Future research will look to investigate the effects of a P12 coating on its ability to promote endothelialization and look to create a robust interface that incorporates P12 directly into the matrix of the culture chemically so that the coating cannot be degraded or dissolved from the surface.

**9:00 AM** SB03.09.05 **Photo-Induced Structural Changes in Oxidoreductase-Inspired Nanogels** Chae Gyu Lee and Tae-Hyuk Kwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Under the reductive conditions in cancer cells, cysteine-containing oxidoreductases, such as thioredoxin (Trx), glutaredoxin (Grx), and protein disulfide isomerase (PDI), accelerate thiol-disulfide exchange reactions through a reversible reaction (CysS–SCys↔Cys–SH), rendering upstream and downstream signaling pathways to maintain redox homeostasis in metabolism-activated cancer cells. In addition, it is difficult to differentiate between tumorous and healthy tissues as the intracellular GSH concentrations of both cell types are approximately 2–10 mM. Therefore, disulfide-bond-based nanocarriers have potential to exhibit cytotoxicity due to the unmanageable drug release in normal cells. This study investigates the spatiotemporally-controlled irreversible degradation of Ir-based photosensitizer (TIr3)-encapsulating nanogels (IrNG) through the hyperoxidation of resulting intracellular thiols using reactive oxygen species (ROS).1,2 By mimicking the reversible redox reaction of Trx and Grx, we developed IrNG that maintains the self-assembled nanostructure thiol-disulfide interactions and reversible cross-linking between disulfide bonds and thiols in the absence of light. When a highly cytotoxic TiR3 was stably encapsulated within IrNG, it exhibited significantly enhanced biocompatibility under normal cellular conditions. However, upon photoirradiation, TiR3 generated high levels of ROS, irreversibly oxidizing the thiols to induce electrostatic repulsion between the polymer molecules, resulting in the TiR3 release and induction of cancer cell apoptosis. Therefore, we could obtain substantially increased changes in cell viability and *in vivo* tumor growth regarding the presence and absence of photoirradiation, confirming the manual control of cytotoxic drug release.

**9:15 AM** DISCUSSION TIME

**9:30 AM** SB03.09.06 **Functional Materials Integrating Synthetic Biological Modules Guided by Machine Learning Algorithms** Candan Tamerler; University of Kansas, United States

Synthetic biology takes the bio-based and bio-enabled approaches to a step further to enable engineering biology in designing and producing materials and processes with previously unattainable functions. Nature has been a source of inspiration in engineering solutions for many. As our understanding of biological materials and structures expanded, mimicking biological systems for innovative engineering solutions has continued with growing intensity. Our group was among the early adapters of biomimetic principles for harnessing design strategies to develop innovative materials. Mimicking the molecular recognition in biological interactions, we have been exploring the smaller protein domains, i.e., peptides as the key fundamental building blocks. Peptides offer to design hybrid biomaterials that can mimic the functions of proteins, generate biomimetic platforms and modulate microenvironment. Using synthetic biology approaches, we expanded the use of peptide-based building blocks as bioactive modules and design bio-hybrid materials with diverse functions addressing medical and industrial applications. We incorporated machine learning (ML) methods to capture distinct peptide functionalities as elements of critical modular building blocks. We adapted experimental and computational approaches demonstrated transparent ML frameworks for identifying relevant peptide structure features for targeted functions. For antimicrobial hybrid materials, we provided a method for selecting secondary structure features in relation to antimicrobial peptides and expanded our predictions to design peptides for metals in biology as biocatalysts, metalation tools, and metal chelates in manufacturing and nutritional immunity. Using synthetic modular domains, we developed peptide-metal and peptide-polymer hybrids as integral of biomaterials and developed models for allostere-dependent effects of selecting spacers to recover domain function activity. We generated knowledge-potential folded structures to discover robust set theory trends which showed to be relevant for recovering bioactivity. Our examples will include utilization of the biological activity imparted by each biomolecule toward prevention of dental and oral diseases as well as restoration of oral health. Engineered modular peptide and enzyme systems will be also provided as synthetic biointerface material systems applicable to industrial applications. Enabling synthetic biological modular approach guided by ML algorithms offers a fascinating path to reshape our thinking in engineering and represent the functional frontiers to mimic biological systems.

**9:45 AM** BREAK

**10:30 AM** SB03.09.07 **Sequence-Tunable Materials for Silica Biomineralization** Kaylyn Torkelson1, Nada Y. Naser1, Xin Q1,2, Chun-Long Chen1,1, Francois Banex1 and Jim Pfaendtner3,2; 1University of Washington, United States; 2Dartmouth College, United States; 3Pacific Northwest National Laboratory, United States; 4North Carolina State University, United States

Silica biomineralization is a naturally occurring process wherein proteins direct the formation of complex, hierarchical nanostructures. Knowledge of these proteins and their underlying mechanisms has spurred significant efforts to identify routes for biomimetic mineralization that aims to reproduce the exquisite shapes and size selectivity found in nature. A common strategy to achieve this has been the use of short peptide sequences with chemistry mimicking those found in natural systems, like the use of the silaffin-derived R5 peptide. While progress has been made using peptides for this approach, there are many limitations that have prevented substantial breakthroughs in biomimicry. To advance our ability to use charged macromolecules for silica formation, we propose to use sequence-defined synthetic polymers known as peptoids, or N-substituted polyglycines, that present significant capability for precise tuning of sequence and structure beyond what can often be achieved with peptides alone.

This work will highlight recent developments in computational methods for understanding the relationship between polymer aggregate structure, silica surface, silica surface adorption, silicate precursor interactions, and morphology in the biomimetic mineralization process. We use molecular dynamics simulations with the metadynamics family of enhanced sampling methods to analyze binding mechanisms and energetics of the R5 system. Next, we
synthesize two R5-inspired peptoids and validate our prediction through characterization using surface plasmon resonance and electron microscopy. This study holds promise for designing new sequences with unprecedented control of the placement of chemical functional groups, thus allowing for further unraveling of silicification mechanisms and eventual design of sequence-defined synthetic polymers leading to the predictive synthesis of nanostructured functional materials.

**10:45 AM SB03.09.08**

**Modeling Molecular Machines with Dynamic Covalent Bonds using REACTER**  
Jacob Gissinger, Stevens Institute of Technology, United States

Nanoscale devices are the ultimate in mechanical miniaturization. Molecular machines that perform directional transport of small molecules or filaments are a vital aspect of life, performing key biological functions during cell division and muscle contraction. These biomotors have inspired the creation of synthetic versions of molecular ‘walkers’ that can move directionally down a molecular track by the application of stimuli (pH and irradiation) in a specific sequence. The reconfiguration of covalent bonds is achieved by two orthogonal bond exchange reactions: disulfide exchange, which is activated in basic environments, and hydrazone exchange, which occurs under acidic conditions. In this work, we simulate the nanoscale dynamics of molecular machines using REACTER, a method for modeling chemical reactions in classical molecular dynamics (MD) simulations. Although external stimuli such as UV light cannot be modeled directly in classical MD simulations, the dynamics of a molecular walker can be captured explicitly by alternately activating the bond exchange and photoisomerization reactions using REACTER. Certain shape-memory polymers operate via similar bond exchange reactions, and a workflow to model shape-memory effects with atomistic resolution is proposed.

SESSION SB03.10: Virtual Session: Lessons from Biology at the Molecular Dimensions II

**Zwitterion Functionalization of Polyurethanes via Thiol–ene Click for Antifouling Surfaces—Lessons from Nature**  
Shantanu P. Nikam1,2, Peiru Chen1, Karisa Nettleton1, Yen-Hao Hsu1 and Matthew Becker1, The University of Akron, United States; 1Duke University, United States

Inspired by the phospholipids on cell membranes, zwitterionic groups have been widely studied for their antifouling property. Equipped with two oppositely charged groups in the same moiety, zwitterions exhibit properties like super hydrophilicity through ionic solvation and tightly bound hydration layer that enables non-specific protein resistance. Additionally, zwitterionic materials also enhance biocompatibility and reduce immune response. Catheter-associated infections (CAIs) have one of the highest mortality rates among healthcare-associated infections. Besides being a major cause of morbidity and mortality, CAIs also impose a heavy financial burden resulting from prolonged treatment and hospital stays. Increasing cost and health related complications necessitate the research for improving currently employed biomaterials for catheter applications. Creating antifouling surfaces by immobilizing zwitterion molecules on material surfaces has been proved to be a promising strategy. Herein, we investigated zwitterion surface-functionalized thermoplastic polyurethane (TPU) for use in antifouling catheter. The thermoplastic polyurethane was synthesized to have an allyl ether side functionality. Zwitterion surface-functionalization was achieved via thiol–ene ‘click’ chemistry in aqueous conditions. The XPS results confirmed the presence of chemically tethered zwitterion moieties on the zwitterion-TPU surface. The Quartz crystal microbalance (QCM) results show reduced fibrinogen attachment for the zwitterion-TPU when compared to its unfuctionalized controls. The zwitterion-TPU also showed a log scale reduction in bacterial adherence. For P. aeruginosa and S. epidermidis, the zwitterion-TPU resulted in around a 40% and 50% lower bacterial biomass accumulation, respectively. The fibroblast cell viability of TPU remained unaffected by functionalization with zwitterion thiol. Our results suggest a zwitterion modified TPU is a promising candidate for antifouling catheters.

**Carbon Nano-Interfaces for Medical and Biological Applications**  
Roger Narayan, North Carolina State University, United States

Recent studies have evaluated the use of microcrystalline diamond, nanocrystalline diamond, and diamond particles for medical applications. In this talk, materials studies and in vitro studies describing the interactions between diamond and medically-relevant eukaryotic cells and prokaryotic cells will be considered. The attachment of eukaryotic cells and prokaryotic cells to diamond surfaces will be considered. In addition, recent developments involving the use of diamond in active medical applications, including electrochemical sensing, will be described. Our recent finding involving diamond surfaces indicate that diamond surfaces may offer significant improvements for the diagnosis and treatment of medical conditions over the next few decades.

**8:45 AM SB03.10.03**

**Multiscale Small Molecule Interactomics and Behavioural Biomimetics using the CANDO Platform**  
Zackary Falls1, William Mangione1, Brennan Overhoff2, Liana Bruggemann1, Matthew Hudson1, James Schuler1, Manoj Mammen1 and Ram Samudrala1, University at Buffalo, United States;
2Harvard University, United States

Our goal is to understand and engineer small molecule behavior and functionality at multiple scales. We accomplish this by developing technologies to describe small molecule behavior and function in terms of their multiscale signatures, which are utilised to engineer safe and effective chemicals and materials for the betterment of society by discovering optimal probes and therapeutics; generate safer and better chemicals and materials; and promote health, quality of life, and prosperity.

We elucidate the scientific tenets determining small molecule behavior in a variety of contexts, starting from the atomic and macromolecular scales, proceeding to pathways, cells and beyond, eventually reaching the phenotypic and population scales. The tenets are embedded in the form of multiscale signatures, comprising the sub-signatures at each scale, i.e., small molecule-macromolecule, -pathway, -cell and -phenotype signatures. At each scale, we determine the interaction signature using a combination of calculations and measurements, which will be enhanced with relevant information from lower scales.

We developed the Computational Analysis of Novel Drug Repurposing Opportunities (CANDO) platform for shotgun multitarget drug discovery, repurposing, and design, funded in part by a NIH Director's Pioneer Award and multiple NCATS ASPIRE Awards to implement this paradigm and overcome the limitations of traditional single target approaches. The open source platform screens and ranks drugs/compounds for every disease/indication (and adverse event) through large scale modelling and analytics of interactions between comprehensive libraries of drugs/compounds and protein
structures. CANDO is agnostic to the interaction scoring method used; two primary pipelines within the platform allow for rapid screening and assessment of billions of drug/compound to protein interactions with fast bioanalytic docking and machine learning affinity regression protocols. CANDO implements a variety of benchmarking protocols for shotgun repurposing to determine how every known drug is related to every other in the context of the indications/diseases for which they are approved, which enables evaluation of various pipelines and protocols within and external to the platform for their utility in drug discovery. We have performed predictive analytics on the CANDO interaction matrices to classify drug, protein, pathway, disease, and adverse event relationships accurately. The multiple fast and accurate interaction scoring/docking protocols, the proteomic scale, and rigorous all-against-all benchmarking used within the platform make it unique and ideal for the design of novel chemical entities that target a desired proteomic/interactomic space or objective.

CANDO has been extensively validated for drug discovery, repurposing, and design; recent work on COVID-19 shows 25% of our top drug candidates having in vitro efficacy including two nanomolar concentration full virus inhibitors of SARS-CoV-2, one of which was ranked #1. We already produced preliminary designs for various indications (such as non-small cell lung cancer, opioid/substance use disorder and pain, and aging) using the design pipelines implemented in CANDO. CANDO is capable of performing analytics on any arbitrary drug/compound, including those chemicals relevant to industrial use such per-and polyfluoroalkyl (PFAS) substances to design safer and better compounds. The most potent designs will be pursued further for development and regulatory approval. Elucidating multiscale signatures of small molecules lends itself to a paradigm-shifting view of small molecule behavior and function that will enable detailed engineering of small molecules for myriad applications. This talk will describe the current state of the CANDO platform and future plans for use in materials research.

9:15 AM SB03.10.04
Harnessing Gradients for Self-Assembly of Peptide-Based Nanocapsules: A Pathway to Advanced Drug Delivery Systems Haopeng Li1, Xuliang Qian1, Harini Mohanram2, Xiao Han1, Huatian Qi2, Guijin Zou2, Fenghou Yuan2, Ali Miserez1, Qing Yang3, Tian Liu2, Huaqian Gao1,2 and Jing Yu4;1
1Nanyang Technological University, Singapore; 2Dalian University of Technology, China; 3A*-STAR, Singapore; 4Chinese Academy of Agricultural Sciences, China

Biological systems often create materials with intricate structures to achieve specialized functions. In comparison, precise control of structures in man-made materials has been challenging. Here, we report a serendipitous discovery of insect cuticle peptides (ICPs) spontaneously forming nanocapsules through a single-step solvent exchange process, where the concentration gradient resulting from mixing of water and acetone drives the localization and self-assembly of the peptides into hollow nanocapsules. The underlying driving force is the intrinsic affinity of the peptides for a particular solvent concentration, while the diffusion of water and acetone creates a gradient interface that triggers peptide localization and self-assembly. This gradient-mediated self-assembly offers a transformative pathway towards next-generation drug delivery systems based on peptide nanocapsules.

9:30 AM SB03.09.04
Biomimetic Dentin Repair: Amelogenin-Derived Peptide Guides Occlusion and Peritubular Mineralization of Human Teeth Deniz T. Yucesoy1, Hanson D. Fong2, Sami Dogan2 and Mehmet Sarikaya2;1; 1Izmir Institute of Technology, Turkey; 2University of Washington, United States

Dentin hypersensitivity, a widespread oral health concern, is primarily caused by the exposure of dentin tubules due to the loss of protective tissues. Despite being a widespread ailment, no permanent solution exists to address this oral condition. Current treatments aim to alleviate pain by employing desensitizing agents or blocking dentin tubules through mineral deposition or solid precipitates, yet these interventions often provide only short-term relief. To restore the structural and mechanical integrity of teeth with lasting durability, there is a crucial need to reproduce an integrated mineral layer that seals exposed dentin while promoting peritubular mineralization. In this study, we introduce a biomimetic treatment that promotes dentin repair, utilizing a mineralization-directing peptide known as sADP5, derived from amelogenin.

The occlusion of dentin tubules is achieved through a layer-by-layer peptide-guided remineralization process, resulting in the formation of an infiltrating mineral layer on the dentin. The structure, composition, and nanomechanical properties of the remineralized dentin were analyzed by cross-sectional scanning electron microscopy imaging, energy dispersive X-ray spectroscopy, and nanomechanical testing. Elemental analysis revealed calcium and phosphate compositions akin to hydroxyapatite. Furthermore, the measured average hardness and reduced elastic modulus values of the mineral layer were significantly higher than those of the demineralized and sound human dentin. Thermal aging experiments provided evidence of the structural integration between the newly formed mineral layer and the underlying dentin, with no physical separation observed. These findings suggest the creation of a structurally robust and mechanically resilient interface that can endure long-term mechanical and thermal challenges commonly encountered in the oral environment.

The peptide-guided remineralization process outlined herein provide a foundation for the development of highly effective oral care products leading to novel biomimetic treatments for a wide range of demineralization-related ailments and offers a potent long-term solution for dentin hypersensitivity.

SYMPOSIUM SB04

Conducting and Functional Hydrogels—From Materials to Devices
November 27 - November 30, 2023

Symposium Organizers
Anna-Maria Pappa, Khalifa University
Alexandra Rutz, Washington University in St. Louis
Christina Tringides, ETH Zurich
Shiming Zhang, The University of Hong Kong
Additive manufacturing of stimuli responsive materials leads to 3D printed constructs that can adapt their properties in response to an external stimuli. This process is referred as 4D printing. 4D printing is commonly used to fabricate shape-shifting constructs, which change their asprinted shape into a preprogrammed shape post-printing with response to an external stimuli. Although 4D printing of shape-shifting objects have significantly expand the applications of 3D printing, novel ink formulations are needed for 4D printing to create 2D and 3D structures that allow dynamic control of properties beyond shape change. In this study, we present smart inks for material extrusion-based direct ink writing (DIW) printing that display preprogrammed surface wrinkling patterns on 2D and 3D surfaces post-printing, which appear only when exposed to a solvent. Hydrogels displaying surface wrinkling patterns with user-defined order and shape are useful for a range of applications, including microfluidics, flexible electronics, smart adhesives, optical sensors, and cell culture platforms. However, conventional techniques to fabricate wrinkling patterns involve multiple steps and are significantly limited to create hierarchical patterns, wrinkles on 3D and non-planar structure. It is also very difficult to scale-up the manufacturing process and to integrate surface patterning into a continuous manufacturing process. 4D printing is used in this work to overcome these issues. The use of photocurable ink formulations allow us to tailor flow properties and printability by controlling photopolymerization time and partial crosslinking time. The crosslinker concentration is varied to develop distinct ink formulations with preprogrammed wrinkling morphology, including lamellar, peanut and hexagonal patterns. We demonstrate 4D printing of optical devices, solvent sensors, anti-counterfeit devices and high-throughput cell culture platforms.

Achieving Tissue-Like Properties in 3D Printed Conducting Polymer Hydrogels

Conducting hydrogels are sought for integration into bioelectronic devices to impart soft, hydrated, and tissue-like properties. However, the compatibility of these materials with advanced manufacturing and the ability to tailor functional properties for application remain limitedly reported. With regards to structural design, additive manufacturing offers customization and complexity with respect to object shape, dimensions, and internal microstructure. Additionally, materials processing as part of the additive manufacturing procedure can be used to control functional properties important for cell-material interactions and device performance. In this work, we developed methods for 3D extrusion printing conducting polymer hydrogels based on poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). We demonstrate control of hydrogel properties by careful pre-printing ink formulation and solvent, a wide range of conductivity (10 – 10,000 S/m) was achieved. Furthermore, hydrogels printed into microporous scaffolds were stable in fibrotic tissues.

Multifunctional Conducting Polymer Hydrogels for Regenerative Bioelectronics

PEDOT:PSS hydrogels exhibited tissue-like properties including an elastic modulus of ~5 kPa and water content ~99%. When further treated with heat or solvent, a wide range of conductivity (10 – 10,000 S/m) was achieved. Furthermore, hydrogels printed into microporous scaffolds were stable in physiological conditions for at least 28 days, and supported viability and proliferation of seeded human primary cells. Collectively, these results provide methods of fabricating PEDOT:PSS hydrogels that offer customization for various biointerface applications with regards to structural design and functional properties.
Bioelectronic medicine refers to technology which use electrical signals, either recorded from or injected into tissue, for therapeutic effect. To date, the focus of electrical stimulation has almost exclusively been on excitable tissue, such as nerve and muscle cells, which respond to short stimulation impulses. Nevertheless, a much broader range of cells are able to respond to direct current, e.g. many cells change shape, growth or align their migration trajectories in accordance with an applied electrical field. It is hypothesized that such effects can be used to steer regenerative processes, modulate neural function or explain cancer metastasis, however, there is little technology developed that allows for such investigations in complex biological models. In our research we are developing methodologies that would make such exploration possible, in complex cell cultures, in vivo and at later stages also in patients.

Key to success is to identify electrode materials that make it possible to interface intimately with living tissues and deliver direct current without corrosion. The typical noble metal materials have limitations in terms of charge injection and corrosion resilience, and their electrochemistry is in general not well-matched to ionic current stimulation. Meanwhile, conducting polymer hydrogels show great promise as they can transport and deliver ionic current via biocompatible charge injection mechanisms, even in the direct current domain.

In my talk I will showcase how we employ conducting polymer hydrogels for direct current stimulation, and how such technology allows for new discoveries as well as potential future therapies. One such application field is wound healing, where we have used conducting polymer hydrogels to show how direct current stimulation of an in vitro epithelial wound model resulted in 3 times accelerated wound closure. Another possibility is spinal cord repair where we are exploring how to integrate electrodes for direct current stimulation in a flexible implantable bioelectronic system. By paying close attention to aspects such as electrode/electrolyte reactions, substrate electrolyte reactions as well as the interplay between the fundamental properties of the conducting polymer hydrogel and polymer-substrate adhesion layers, we hope to build a concept for fully biocompatible and implantable regenerative DC stimulation.

This work was supported by the European Research Council (ERC) grant agreement No. 759655 (SPEEDER) the CatWalk Spinal Cord Injury Trust and the Health Research Council of New Zealand (Project grant and HRC/Catwalk Partnership 19/895). Further support was provided by the center for Innovative Brain Machine Interfacing Technology at the University of Freiburg.
techniques capable of modulating and recording a diversity of signals deployed by neurons. However, current approaches are limited in terms of effectiveness, side effects, non-specificity, and mechanical invasiveness. Naturally, there is a huge need for new devices or materials allowing for minimally invasive manipulation and monitoring of neural activity. My talk will introduce the complementary strategy to address these challenges with hydrogel-based flexible and stretchable fiber-based probes for interfacing with the brain and spinal cord. This technology enabling the interrogation with neural circuits across their diverse signaling modalities without inducing a foreign-body reaction helps the study of information processing as well as pathologies of the nervous system.

Development of 3D Hydrogel-Based In Vitro Circuits with Cocultures of Human Sensory Neurons and Schwann Cells

Blandine F. Clément1, Christina M. Tringides1, Vilius Dranseika2, Jens Duru1, Tobias Ruf1 and Janos Vörös1; 1ETH Zürich, Switzerland; 2University of Zürich, Switzerland

Engineered in vitro neural networks are promising platforms to rapidly screen drugs and study information flow in the nervous system [1]. While existing polydimethylsiloxane (PDMS)-based microfluidic platforms offer precise architecture and connectivity, the cultured neurons grow inside microchannels on a planar multielectrode array (MEA) substrate in a two-dimensional fashion [2]. To better mimic the native extracellular matrix (ECM) microenvironment, 3D hydrogel scaffolds can be designed so that encapsulated cells can be expected to exhibit more physiological behavior [3]. Here, we propose a hybrid approach by filling the PDMS microstructure with hydrogels to offer both a controlled topology and a physiologically relevant microenvironment to the neuronal cell. First, a gelatin methacryloyl (GelMA) hydrogel was engineered by incorporating ECM components and tuning its mechanical properties to match the native niche environment. The hydrogel material was able to 1) support the growth of human iPSC-derived sensory neurons for more than 9 weeks 2) support co-culture with human Schwann cells where the latter could align along the axons. Next, microchannels were filled with the optimized hydrogel precursor, and after crosslinking, the neurons and glial cells were seeded as pre-aggregated spheroids in desired location(s). This enabled topologically defined growth of neurites in 3D. By further tuning the hydrogel type and its physico-mechanical properties, the microstructures could be filled and tailored for specific cell types, while the underlying MEA allows for the recording of neural activity over time. This platform could offer a promising tool to study cell-cell interactions of single cultures or co-cultures, and to efficiently test the potential of various drugs in a more translational manner.

Biodegradable Materials for Optoelectronic Neural Modulation and Electronic Medicine

Lan Yin; Tsinghua University, China

Devices built on biodegradable materials possess unique characteristics that enable complete biodegradation in physiological environments, thus eliminating the need for retrieval surgery and minimizing the associated risks of infection. These devices can play a critical role in therapeutic and diagnostic processes, including neural modulation, tissue regeneration, etc. Herein, we introduce materials options and fabrication strategies that enable the development of a biodegradable and flexible optoelectronic device, capable of achieving efficient neural stimulation and functional recovery on peripheral nervous systems. Furthermore, we propose a biodegradable and self-powered device as electronic medicine for peripheral nerve regeneration. Successful nerve regrowth and motor functional recovery are realized in rodent models. These works provide new insights for modulating neural activities and repairing nerve injuries.
In situ bioprinting is promising for developing scaffolds directly on defect models in operating rooms, which provides a new strategy for in situ tissue regeneration. However, due to the limitation of the printing depth and bioink, bioprinting scaffolds in deep dermal or extremity injuries remains a grand challenge. Here, we present a ferromagnetic intravital bioprinting approach for in situ tissue regeneration in a minimally invasive manner. The ferromagnetic intravital bioprinting system is able (1) to measure and identify the geometry of organ defects by micro-CT, (2) to plan a matched printing path, and (3) to deliver multiple bioinks to fabricate scaffolds on defects in a minimally invasive manner. The minimally invasive bioprinter is composed of a ferromagnetic soft catheter robot (FSCR) nozzle that can arrive at the deep dermal (0-150 mm) through a small incision (2-4 mm) and a separated remote magnetic actuation system that numerically controls the movement of FSCR. The hydrogel bioink is designed to be electroactive, self-healing, biocompatible, biodegradable, tissue adhesive and extrusion printable. After 3D reconstruction of the defects with computed tomography (CT), conductive hydrogel scaffold is printed within a partial liver resection of live rat, and in situ tissue regeneration is achieved due to the electroactive hydrogel scaffold, promoting the orderly arrangement of fibroblasts and collagen in vivo.

Magnetic Nanogels for Combined Hyperthermia and Chemotherapy of Prostate Cancer Sofia Patri1,2, Thanh T. Nguyen2 and Nazila Kamaly1;
1Imperial College London, United Kingdom; 2University College London, United Kingdom

Iron Oxide Nanoparticles (IONPs) are FDA approved for biomedical applications, such as magnetic hyperthermia: IONPs can generate heat as a consequence of their relaxation mechanism after being placed in an Alternating Magnetic Field (AMF). The heat generation is measured in Specific Absorption Rate (SAR) and agglomerations of IONPs, known as NanoFlowers (NFs), have shown to have some of the highest SAR values out of all the variations of this material. The surface of IONPs and IONF can be modified with an organic coating to increase their biocompatibility. By selecting the appropriate soft material, the organic shell can also encapsulate a cargo and release it over time: this kind of magnetic composite can combine hyperthermia with drug delivery, making it a highly effective treatment against cancer cells. Nanogels, which are hydrogels in the nanoscale, are highly biocompatible and stable in the biological environment thanks to their crosslinked network; more importantly, they can be engineered to respond to an external stimulus. By including a thermo-responsive unit in the nanogel, an increase in temperature will induce a coil-to-globule transition of the chains causing the shrinkage of the nanogel and the expulsion of water along with the encapsulated cargo.

In this multifunctional therapy, we aim to trigger drug release from a nanogel by using the heat generated by the IONFs in an AMF. To improve the stability of the nanocarrier in the physiological environment, we demonstrate the necessity to anchor the nanogel to the IONFs through a surface ligand. The development of functional and stable magnetic nanogels provides a more effective, localized, and precise therapy that combines the benefit of the monotherapies while minimizing the risk of adverse effects due to their highly lower biocompatibility.

8:00 PM SB04.03.04
Conducting Hydrogel Based on Novel Polymer Composite PEDOT:DBSA for Bioelectronic Applications Šárka Tumová1, Romana Malešková1, Petr Smíšek1, Lubomír Kubš1, Jiri Akrmán1, Jiri Smilka1, Michaela Pešková2, Jan Viteček1, Martin Váša1 and Martin Weiter1;
1Brno University of Technology, Czechia; 2Central European Institute of Technology, Czechia

Organic bioelectronics represents a potential revolution in medicine as it holds the promise of personalized treatment with reduced side effects compared to conventional pharmaceutical drugs. Despite the big effort dedicated to this field, there are still challenges to be solved. One of them is the form of organic polymers acting as active material, as the commonly used thin films are not very favourable with regard to the tissues that are supposed to be in proximity contact with them. That is mainly due to the dissimilarities in mechanical and physical properties of these two components, which might be an obstacle preventing the formation of a satisfactory interface, thus reducing the efficiency of signal transport. This properties mismatch arises especially from the differences in water content and elastic modulus values. Hence, there is a big demand for a more tissue-like form of these materials as it can significantly promote contact with tissues at the interface, thus reducing the adverse immune responses of the biological system, decreasing the interfacial impedance and enhancing the efficiency of both signal recording and stimulation. Among other structures, hydrogels seem to be the perfect interface to biological tissues due to their structural similarity with the extracellular matrix, tissue-like mechanical properties, water-rich nature, superior biocompatibility, flexibility and adjustable biochemical properties. In this work, we prepared and characterised a conductive hydrogel based on a completely new polymer composite – PEDOT:DBSA. The rheological characterization revealed that the mechanical strength of this material as well as the gelation time can be easily tailored to the desired application by changing the concentration of cross-linking agent. The electrical properties of the hydrogel were studied using impedance spectroscopy and cyclic voltammetry. It was shown that the total bulk conductivity of prepared hydrogel is 3.8 S/m. The LDH cytotoxicity assay showed a very good biocompatibility of hydrogel compared to that of the culture plastic and glass dish. The structure of the hydrogel was investigated using scanning electron microscopy and was found to be of rough, spongy nature. These results indicate that PEDOT:DBSA hydrogel has great potential for creating an interface between the biological environment and electronic devices used in various fields of regenerative medicine.

Electrosprun Hydrogel Nanoporous Scaffold for Cleaning Ultrafine Contaminants in Semiconductor Manufacturing Somin Shin, Ji-hun Jeong and Sunah Kim; Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

In semiconductor manufacturing, chemical mechanical planarization (CMP) process is an essential step where wafers are polished via chemical and physical actions using externally supplied abrasives. After the CMP step, contaminants which include the remained abrasives and wear debris must be strictly removed from the wafer surface to prevent device failure via unintended particles. Accordingly, CMP cleaning always follows right after the CMP step. Post-CMP cleaning is particularly difficult as the contaminants are strongly adhered on the wafer surface due to as they are mechanically compressed during the polishing step. For such challenges, brush scrubbing techniques are widely employed due to their superb cleaning efficiency. The brush cleaning is in general conducted via porous polyvinyl alcohol (PVA) hydrogel brushes which make a physical contact with the wafer therefore can provide sufficient physical removal force to the surface particles for their removal.

The synthetic PVA hydrogel used as the wafer cleaning brushes comprises micropores, and has high swelling capacity against water-based cleaning solutions. The recent challenge arises as the pore sizes of commercial brush products remain in micro-scale whereas the size of the contaminants to be removed is ever shrinking to even few nanometers. Therefore, the existing brush products cannot effectively deliver the sufficient removal forces on ultrafine particles. In this research, we fabricate a PVA hydrogel scaffold comprising nano-scale porosity which can exhibit high effectiveness in particle removal for cleaning ultrafine contaminants. Insoluble polyvinyl formal (PVF), the raw material of cleaning brush, is synthesized via acid catalyzed acetoacetylation of water-soluble PVA with formaldehyde which occurs with the breaking of PVA chains by modifying hydroxyl groups. We produce nano-scale fibrous sheets using electrosprinning process and investigate the effect of PVA/formaldehyde/sulfuric acid weight ratio as well as the processing conditions on the fiber formation. A heat treatment follows after the electrospinning step which reconstruct the fiber mat into a three-dimensional porous scaffold via creating fiber-to-fiber junctions, resulting in suitable mechanical strength and resilience. To verify the correlation between structural scale and particle removal efficiency, we conduct lab-scale wafer cleaning experiments on substrates contaminated with particles of various sizes, from 1 µm to 80 nm, using conventional microporous brushes and fabricated nanoporous scaffolds. We further experimentally verify that the effect of the structural scale is significantly more dominant. Our new hydrogel nanoporous scaffold exhibit outstanding removal efficiency for ultrafine particles, thus can provide an
Effective engineering solution for the current limit in post-CMP ultrafine contaminant cleaning which is of interest in semiconductor manufacturing industry.

8:00 PM SB04.03.06
Tissue-Adhesive and Anti-Swelling Hydrogel Based Multifunctional Implantable Sensor for Monitoring of Bladder Activity in Overactive Bladder with Surgical-Robot Assisted Laparoscopic Surgery Byungkook Oh and Steve Park; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Electrical properties and mechanical properties of a biological bladder tissue provide useful tissue information for preventing disabling condition of urinary systems as clinical treatments. Recently, there has been a great deal in designing implantable electronics that collect tissue information and provide fundamental treatments. However, intrinsic differences between biological tissues and conventional rigid and dry electronics pose problems with unstable interaction between both surfaces and infection of biological tissues. Here, a highly stretchable and tissue-adhesive multifunctional implantable sensor based on structurally engineered inlets embedded in ultra-soft hydrogel is developed for real-time monitoring of bladder activity in overactive bladder (OAB) induced rat and anesthetized pig. One critical issue with hydrogel in general as implantable substrates, however, is their eventual change in mechanical properties and electrical properties due to the gradual absorption of biofluids in the body. To overcome the critical issue, an anti-swelling coating technique that can prevent absorption of water and biofluids in the body is developed. This coating technique is applicable to various hydrogels that have low sol-gel transition temperatures, while imposing negligible changes in mechanical properties. Using tissue-like, anti-swelling hydrogel, which can sustain its initial mechanical & electrical properties as a role of an implanting substrate, can bridge sensory systems to biological tissue with robust seamless interaction without infection of tissues. The sensory systems integrated to soft bridging materials (hydrogel) consist of strain sensors (directly printed micro-capsules of EGaIn on an anti-swelling hydrogel substrate) and multi-array electromyography (EMG) sensors (Ti/Au) on structurally engineered ferris wheel-shaped inlets that can make it possible to collect tissue information during repetitive micturition of overactive bladder. On the OAB induced rat, stronger signals (change in resistance and EMG root-mean-square) were detected near intra-bladder pressure maxima, thus showing correlation to bladder activity. Moreover, using robot-assisted laparoscopic surgery, the hydrogel-based implantable sensor was placed onto the bladder of an anesthetized pig. During micturition cycle, bladder strain and EMG were monitored. These results confirm that our proposed sensor is a highly feasible, clinically relevant implantable device for continuous monitoring OAB for diagnosis and treatment.

8:00 PM SB04.03.07
Highly Stretchable Hydrogel Fiber Fabricated by a Self-Coiling Mechanism Maintaining High Water-Content Joon Li and Seon Jeong Kim; Hanyang University, Korea (the Republic of)

Hydrogels, which are polymer networks dispersed in water, are widely used in biomedical fields, among others, because of their excellent mass transfer efficiency and biocompatibility. However, hydrogels with a high water content usually have poor mechanical properties and are easily broken. To address this issue, many researchers have incorporated one or more complementary materials into the polymer network of the hydrogel to limit its swelling. Although this method enhances the mechanical properties of hydrogels, it also limits the water content; therefore this method cannot be applied to improve the mechanical properties of high-water-content hydrogels. We have observed that a jellyfish called Physalia physalis preys on fish through its coiled stinging tentacles. Although the body of P. physalis has a water content above 95%, the coiled structure still provides high stretchability. In this study, we developed a coiled hydrophilic polyurethane hydrogel fiber with high stretchability and high water content by mimicking the coiled stinging tentacles of P. physalis. Dry hydrophilic polyurethane yarns produced by electrospinning were twisted under an applied load. When the twisted dry hydrophilic polyurethane yarn swelled with water, the change in Young's modulus and shear modulus elicited self-coiling within 1 s and resulted in a coiled hydrophilic polyurethane hydrogel fiber. The morphology of the formed coiled polyurethane hydrogel fibers can be tuned by adjusting the twist density and the stress resulting from the load applied during swelling. Compared with non-coiled hydrophilic polyurethane hydrogel fibers, the coiled hydrophilic polyurethane hydrogel fibers prepared by this method exhibited ultrahigh stretchability due to the coiled structure and elasticity of the material. When the coiled hydrophilic polyurethane hydrogel fibers are stretched, the uncoiling of the coiled structure provides stretchability, and the fibers can be further stretched due to the elasticity of the hydrophilic polyurethane hydrogel. In summary, we developed a coiled hydrophilic polyurethane hydrogel fiber that can rapidly swell and self-coil under aqueous conditions and possesses high stretchability, while maintaining high water content. It is expected to be used in biomedical fields for applications such as surgical sutures, drug delivery systems, and tissue regeneration.

Controllable Actuator by Reversible Clustering Transition Composed of Temperature-Responsive Hydrogel Jisung Choi and Seongmin Kang; Chungnam National University, Korea (the Republic of)

Hydrogel-based soft actuators, which can change their shape according to the various environment and has safe for the human body, are being utilized in various fields such as smart windows, etc. Among the hydrogels, N-isopropylacrylamide (NIPAm), due to its swelling characteristics dependent on the critical solution temperature (32 degree), can be used as a suitable actuator for different situations. Additionally, micropillars with high aspect ratio easily are transformed to clustering state under external forces, and both their original state and clustering state are being utilized as actuators. However, micropillars of clustering state once do not naturally de-cluster, having limitation of application by its non-reversible property of clustering state. In this paper, we fabricate micropillars actuator of a reversible clustering transition composed of thermo-responsive poly(NIPAm-co-acrylamide) hydrogels, verifying the potential applications of soft actuators. The actuator is clustered due to the decrease in mechanical properties of hydrogels by water, but it is de-clustered due to the increase in mechanical properties by hot temperature. Based on this phenomenon, we demonstrated the potential applications of micro grippers for capturing and transporting micro particles in water, as well as smart windows capable of reversible transitions in surface transmittance outside the water.

8:00 PM SB04.03.09
An Efficient Self-Healable and Recyclable Conductive Polymeric Blend with Excellent Mechanical Properties Based on PEDOT:PSS/PU Jinsil Kim and Fabio Cicoira; Polytechnique Montreal, Canada

Self-healable conductive polymers have been attracting attention because of the promising advances in electronic devices. Self-healable and conductive coating films are fabricated by blending a conductive polymer, poly (3,4-ethylenedioxythiophene): poly (styrene sulfonate) (PEDOT:PSS) with poly(ethylene terephthalate) (PET). The materials exhibit outstanding self-healing capabilities and fast self-healing kinetics and therefore can be used for practical applications like flexible and stretchable electronic devices. The polymeric coating film is cut into two parts completely with a sharp blade then the damaged surfaces are connected under mild temperature for the healing process. The results from experiments exhibit using a mechanical tester to compare the mechanical properties of various compositions of PEDOT:PSS/PET and before and after self-healing processes, respectively. Regarding electrical performance, a cyclic tensile test is
also performed to monitor the elasticity. The electrical conductivity maintains constant electrical conductivity under cyclic tensile stress when tensile stress is loaded up to 30% strain. The PEDOT:PSS/PU-based can be reused, improving the sustainability of electronic devices. All these results revealed that PEDOT:PSS/PU have the potential to enable to development of more sustainable and durable electronic devices by reducing electronic waste and improving the lifespan of electronic components.

8:00 PM SB04.03.10
Designing Azo-Based Color- Changing Hydrogels by Sensing pH Response
Wei-Ting Chang, Violet Pratt, Neel Joshi and Leila Deravi; Northeastern University, United States

The wide applications for environmental sensing and responsible sensing materials using hydrogels can be excellent candidates across systems in biology. For instance, most living cells elicit pH changes during metabolism which we leverage as an actuator in the design of new pH-responsive hydrogels. We synthesized azo-based monomers from anthranilic acid and followed by azo coupling by the treatment of phenylpiperazine and acyl amide. These monomers can then be polymerized with bis-acrylamide, acrylic acid, and polyacrylamide as an adhesive hydrogel that change shape and color different pH environments. Applications of these gels are explored both with and without sensors in different environments.

8:00 PM SB04.03.12
Hydrogel-Enhanced Supported Lipid Bilayers (SLBs) Offer Greater Stability and Functionality in Bioelectronic Devices
Jordan P. Fitzgerald, Zhongmou Chao and Susan Daniel; Cornell University, United States

Supported lipid bilayers (SLBs) have emerged as an indispensable material to functionalize the surface of bioelectronic sensors that facilitates the exploration of cellular membrane interactions with a wide range of molecules. SLBs accurately mimic the structure, composition, and diffusive properties of natural membranes, providing a biomimetic experimental model. Particularly noteworthy is the compatibility of SLB bioelectronics with electrochemical impedance spectroscopy (EIS), allowing for real-time monitoring of changes in impedance across SLBs. Such measurements provide valuable insights into changes in membrane properties, drug interactions, and the behavior of embedded proteins and channels. However, one drawback of these sensors currently is their vulnerability and limited shelf-life that impedes their broader application.

In this study, we combine hydrogels with SLB bioelectronic devices and show that the usable shelf-life of these devices can be extended significantly. Our approach exploits a range of hydrogels, each with unique characteristics that enhance system versatility. PEGDA, a UV crosslinked hydrogel, enhances the stability of model POPC SLBs and native component SLBs. Other hydrogels, such as poloxamer based thermally reversible gel, and chitosan based chemically crosslinked gels, show potential for preserving UV- and temperature-sensitive components within the SLBs. Overall, this strategy extends the shelf-life of the SLBs from a single day over 45 days, all while preserving the electrical signal integrity and functionality of proteins within the SLBs. This hydrogel-enhanced approach not only facilitates longer sensing periods, but also enables the long-distance shipping of functional SLB-based devices, necessary steps for translation to the field.

In addition to enhancing the shelf life and stability of the SLB-functionalized bioelectronic devices, the integration of hydrogels also boosts their functionality. The hydrogel layer not only facilitates improved stability but also enables the use of cell-free expression of proteins directly into the membrane. This expands the utility of our method, creating opportunities for more comprehensive investigations into the behavior of specific proteins and their responses to various agents within a highly stable, extended-lifespan SLB-based bioelectronic system. This research lays the groundwork for the development of sophisticated hydrogel-enhanced SLB systems capable of operating in complex environments, bringing us closer to the construction of advanced devices such as electrode arrays, sensors, and biomimetic devices, and expanding the scope of bioelectronic applications in biomedical research and beyond.

8:00 PM SB04.03.13
Thermo-Responsive Emulsion- Embedded Hydrogel Microparticle and Its Application to RT-qPCR
Seoyoung Lee, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Water-oil-water double emulsions (DEs) have been widely used as compartmentalized systems to encapsulate components for controllable and targeted reagent delivery. The components encapsulated in DE could be efficiently released upon various stimuli, such as changes in temperature, light, and chemical environment. Among them, by utilizing the heating as a controllable release stimulus, we herein developed a novel thermo-responsive DE- embedded hydrogel microparticle reactor suitably applicable for one-step quantitative reverse transcription polymerase chain reaction (RT-qPCR), which mimics the non-specific reaction in the reverse transcription step. For this strategy, we encapsulated target-specific nucleic acid reagents (PCR primers and probes) in DE and subsequently entrapped DE in a micro-sized hydrogel PCR reactor. First of all, we adjusted the surfactant concentrations of DE for enhancing the DNA encapsulation efficiency and optimizing the DNA release efficiency to be maximized in the PCR denaturation step (95 °C) as well as minimized in the reverse transcription step (55 °C). From the perspective of DE itself, DNA encapsulation and release efficiencies at both 95 °C and 55 °C increased and decreased, respectively, with increasing concentrations of hydrophilic surfactant, while they were independent of hydrophobic surfactant concentrations. Moreover, we also investigated the change in DNA release tendency and optimized the surfactant concentrations when DEs were embedded in hydrogel microparticles. As a result, and importantly, the DNA release efficiency of DE entrapped in hydrogel significantly increased about 4 times at 95 °C compared to that of DE itself, indicating that the DEs individually located within the hydrogel are more vulnerable to the release of DNA-encapsulated inner water phases. In addition, 8 CMC of hydrophobic surfactant and 35.7 CMC of hydrophilic surfactant were selected as the optimal conditions where 4.6 µM of DNA reagent was encapsulated, and 40% (1.80 µM) and 9% (0.15 µM) of reagent were released at 95 °C and 55 °C, respectively, demonstrating target-specific reagent delivery on demand. Consequently, under these conditions, we successfully confirmed the operation of one-step RT-qPCR in the thermo-responsive DE-embedded hydrogel microparticle and the developed hydrogel microparticle could be utilized as a powerful point-of-care testing platform for the multiplexed detection of several RNA biomarkers.

8:00 PM SB04.03.14
Nanomulsions- Containing Hydrogel Microparticle Array PCR for Multiplex Discrimination of SARS-CoV-2 Variants
Yoon-Ha Jang, Eui Ju Jeon, Seoyoung Lee, So Young Jeon, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Over time, viruses continually produce new genetic variants of themselves. Surveillance is needed to investigate how mutations in viruses affect the transmissibility and lethality of the virus as well as responses against therapeutic medicines [1]. However, whole genome sequencing, which is currently utilized for variant identification, has a limitation in testing a large number of samples, especially in a pandemic situation. Herein, we present rapid multiplex RT-qPCR for SARS-CoV-2 variant discrimination using the TaqMan probe and primer- incorporated network (TaqPIN). TaqPIN is a hydrogel microparticle where target-specific reagents such as primers and probes are preloaded as encapsulated in nanomulsions [2]. The main challenge is to fabricate TaqPIN because the photoinititators (Ps) required for curing hydrogel destabilize nanomulsions and damage the fluorescently labeled probes encapsulated within the nanomulsion. We found that free radicals generated by Ps damage the probes encapsulated within the nanomulsions via the infiltration of Ps into the nanomulsions. We successfully fabricated TaqPIN by using water-dispersible nanoparticles of 2,4,6-trimethylbenzoyl-
Hydrogels are crosslinked polymer networks that can absorb and retain large quantities of water within their structures. Typically made of hydrophilic polymers, their swelling ability gives these materials properties of both solids and liquids alike. Recent studies highlight that combining hydrogel materials with clay-based nanofillers and charged solvents results in a hydrogel with enhanced properties. However, little is known about the theoretical mechanism of the gel’s network formation. Here, we explore a system of free-floating polymer chains, clay-based nanofillers, and solvent to determine the specific conditions for a stable network formation, and optimal rheology of the gel. The aim of this study is to produce the strongest hydrogel, which can then be used for soil-strengthening applications.

We performed coarse-grained molecular dynamics with the LAMMPS software. Our polymer chains were constructed using the Kremer-Grest model, which defines bond interaction via the finitely extensible nonlinear elastic (FENE) potential. Other pairwise interactions between monomers were modeled by using the simple 12-6 Lennard Jones potential. We implemented this model for different polymer concentrations of N=300, 600, and 900, with varying temperatures upon MAA and DMAEA addition to the precursor mixtures.

Finally, we loaded bakers’ yeast (10^7 cells/g of hydrogel) into the selected hydrogels and analyzed their viability, metabolite production, and morphology by 35% compared to the control. These effects were attributed to the disruption of electrostatic interactions between MAA and DMAEA, which carry opposite charges at neutral pH. The formulated hydrogels demonstrated the necessary mechanical properties for cell-loading applications.

In conclusion, this work demonstrates the potential of the developed hydrogel platform, featuring enhanced mechanical properties and improved ionic conductivity, for the additive manufacturing of ELMs. This platform holds promise for applications in bioengineering and highlights the importance of advanced materials in creating functional ELMs with enhanced capabilities.

References
planar structure. This study utilizes the testing methods of Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) using the VersaStat 4 Potentiostat to measure the capacitor response. Devices with capacitances as high as 53.52 µF were fabricated and tested. The results of this study show the feasibility of using the bioprinting method for fabricating prototype storage devices.

Turgor Pressure Reinforces Mineral-Based Composites Ran Zhao and Esther Amstad; École Polytechnique Fédérale de Lausanne, Switzerland

Nature fabricates hard functional materials from soft organic scaffolds that are mineralized. To overcome the brittleness of inorganic components, biominerals are arranged in hierarchical structures and sometimes develop local compressive or tensile stresses. For example, the precipitation of hydroxyapatite minerals leads to contractile stresses in collagen fibrils, and eventually reinforces mechanical properties of bones [1]. The fibril contraction comes from the dehydration of the polymer matrix, even though it happens in a hydrated environment. Similarly in plant cells, osmotic pressure is used to stiffen leaves by exploiting a strong turgor pressure [2]. Osmotic pressure is well-known to change the mechanical properties of living biological materials. Nevertheless, this strategy has thus far not been leveraged in mineral-based composites. This shortcoming might in part be related to the inferior mechanical behavior of synthetic composites compared to natural counterparts due to the limited structural control over different length scales.

Here, we demonstrate a mineral-based composite whose strength and stiffness can be repeatedly adjusted through osmotic pressure driven swelling and deswelling of confined hydrogels. Specifically, we employ a synthetic porous matrix with a similar degree of structural control from the nanometer up to the centimeter length scale made from an emulsion-based, 3D printable ink [3]. Those pores in the matrix are back-filled with a hydrogel, which can generate internal compressive or tensile stresses triggered by osmotic pressure gradients. The matrix can selectively bind certain cations such as Ca2+ ions, which can serve as mineralization sites upon addition of CO32-. The hydrogel contractions induced through the mineral precipitations and osmotic pressure gradients lead to a synergistic control over the mechanics of the composite. This work provides an exciting concept for enhancing mechanical properties of mineral-based composites through turgor pressure similar to biological systems, which can be used as soft actuators or intelligent devices for underwater applications.

Nanoengineered Ink for Designing 3D Printable Flexible Bioelectronics Akhilesh K. Gaharwar; Texas A&M University, United States

Flexible electronics require elastomeric and conductive biointerfaces with native tissue-like mechanical properties. The conventional approaches to engineer such a biointerface often utilize conductive nanomaterials in combination with polymeric hydrogels that are crosslinked using toxic photo-initiators. Moreover, these systems frequently demonstrate low signal accuracy, poor biocompatibility and face trade-offs between conductivity and mechanical stiffness under physiological conditions. To address these challenges, we introduce a class of shear-thinning hydrogels as biomaterial inks for 3D printing of flexible bioelectronics. These hydrogels are engineered through a facile vacancy-driven gelation of MoS2 nanosheets and naturally derived polymer. Due to shear-thinning properties, these nanoengineered hydrogels can be printed into complex shapes that can respond to mechanical deformation. The chemically crosslinked nanoengineered hydrogels demonstrate twenty-fold rise in compressive moduli and can withstand up to 80% strain without permanent deformation, meeting human anatomical flexibility. The nanoengineered network exhibits high conductivity, compressive modulus, pseudo-capacitance and biocompatibility. The 3D printed crosslinked structure demonstrate excellent strain sensitivity and can be used as wearable electronics to detect various motion dynamics. Overall, the results suggest that these nanoengineered hydrogels offer superior mechanical, electronic, and biological characteristics for various emerging biomedical applications including 3D printed flexible biosensors, actuators, optoelectronics, and therapeutic delivery devices.

9:00 AM SB04.04.03
Conducting Polymer Hydrogels for Hydrogel Bioelectronics Hyunwoo Yuh; SanaHeal, Inc., United States

Electrical interfacing with biological tissues for interrogation and modulation of living systems – or bioelectronics – is one of the most important modes of communication between artificial machines and biological organisms. In conventional applications, bioelectronic interfacing has relied on conventional electrodes and devices made of metals and engineering solids like plastics and elastomers. However, the stark dissimilarity between biological tissues and conventional device materials has posed great challenges for long-term bioelectronic interfacing with living systems, especially for implantable devices. To address these challenges, electrically conductive hydrogels – polymer networks infiltrated with large amounts of water with electrical conductivity – have been substantially studied in the last decades owing to their unique advantages including tissue-like mechanical properties and high water contents, favorable electrical properties, and in vivo biocompatibility. However, conducting polymer hydrogels has faced several key challenges in their practical uses including poor electrical and mechanical properties in physiological environments, unreliable integration within devices and to the target biological tissue, and difficulties in small-scale fabrications into functional devices. In this talk, several advances in conducting polymer hydrogels to address these challenges will be discussed toward the vision of hydrogel bioelectronics.

9:30 AM SB04.04.04
Skin-printable, Self-adhesive and Bio-based Hydrogel for the Bioelectronic Interface Jia Xi Chen1, Yi Xin Zhang1, Terek Li1, Zia Saadatnia1, Milos Popovic1,2 and Hani Naguib1,1; 1University of Toronto, Canada; 2University Health Network, Canada
Inspired by the customizability of injectable hydrogels in the medical field as cell cultures and engineered tissues, a conductive and 3D-printable hydrogel based on bio-polymers is developed to interface between the skin and medical devices during rehabilitation treatments of surface functional electrical stimulation (sFES). The sFES treatment involves delivering electric currents through the skin to induce muscle contraction, with clinical evidence supporting the ability of sFES treatments to restore voluntary motor functions in previously paralyzed patients. However, physiological differences in muscle distribution and body curvatures among individuals require sFES treatments to be personalized. Therefore, to increase the accessibility of sFES, rehabilitation devices enabling remote sessions and shape-configurable electrodes universal to all patients were developed. The authors developed a novel material capable of being adapted to any shape and size, with self-adhesive and electrically conductive properties to ensure conformity to body morphology and to guarantee sFES signal stability. As the electrodes are single-use, the hydrogel is made from naturally occurring, bio-compatible, and eco-friendly polymers that are easy to fabricate and process. Carboxymethyl cellulose is adopted as the matrix for its water solubility and mechanical properties, along with poly(3,4-ethylene-dioxythiophene) polystyrene sulfonate (PEDOT:PSS) as the conductive additive and mussel-inspired polydopamine as the adhesive additive. A mild and biocompatible gelation method exploiting hydrogen bonding is implemented by adding phytic acid, with in situ formation of the extruded hydrogel taking place minutes after being 3D-printed onto the skin. The gelation process is examined with FTIR spectroscopy, which confirms the molecular interactions between bio-polymer components, scanning electron microscopy, which ensures the macroscopic morphology of the formed hydrogel, and rheological measurements over time, which characterizes the printability of the precursor ink. The pre-gel solution exhibits tailorable viscosity, allowing for facile processability and shape-configurability. Adhesive and electrical properties of the hydrogel are studied in contact with porcine skin over time. Although the self-adhesion of the hydrogel is two folds lower than commercial tissue-adhesive, the interfacial electrical impedance is improved by an order of magnitude compared to commercial hydrogel electrodes. The sFES performance of the printable and conductive hydrogel is further assessed with a developed handheld 3D printer, a lightweight instrument to extrude the hydrogel ink in uniformly deposited layers with shape fidelity of mm-thick resolutions. Compared to conventional sFES electrodes of both hydrogel and metal-electrolyte gel systems, the printable hydrogel electrodes can induce muscle movement during sFES with better precision and accuracy, improving the efficiency by 10% when stimulating eye closure to the orbicularis oculi muscle. The printable and conductive hydrogel created for wearable purposes may be adapted for other applications involving bi-directional communications of electric signals across the bioelectronic interface, such as surface electromyography and surface electrocardiography.

9:45 AM SB04.04.05
PEDOT:PSS Hydrogel Based Wearable Biosensor Utilizing Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Lactate Detection
Yuchen Shao1, Luiz Marcelo2, Lixin Zhang1, Manisha Gupta1 and Dipanjan Nandi1; 1University of Alberta, Canada; 2Monterrey Institute of Technology and Higher Education, Mexico

Poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) is a conductive polymer with excellent electrical conductivity, good processibility and biocompatibility. Hydrogels have the advantage of soft, flexible and non-toxicity with cells and tissues. A combination of PEDOT: PSS and a hydrogel offers unique conductivity and mechanical properties, applying an alternative approach for biosensing applications.

In this work, we developed a PEDOT:PSS hydrogel based 3D printed organic electrochemical transistor (OECT) for lactate sensing, since OECTs offer high transconductance, low operation voltage and compatibility with aqueous environments. Optomec Aerosol Jet SX 3D printer is used to fabricate the biosensors on the flexible Kapton substrate. Au was chosen as the metal contact, Pt as the gate with polyimide as the insulator layer. PEDOT:PSS hydrogel is drop casted on Au as the channel material. For PEDOT:PSS hydrogel, it was synthesized by mixing with dimethyl sulfoxide (DSMO) to improve the conductivity under vigorous magnetic stirring for 24 hours, then drop-casted 0.2uL solution on top of the channel for a printed OECT device and was placed into the oven under 60°C for another 24 hours to generate the partially formed gel. After that, 3 times cyclic annealing was applied for the device for 30 minutes at 130°C. Finally, the device was put under -20°C for 12 hours and took out for extra 12 hours, repeating 2 times. The unfunctionalized device exhibits a transconductance up to 110 mS and is compared to the printed PEDOT:PSS based device. Further, tetraethylfulvalene (TTF), chitosan, lactate oxidase (LoX), bovine serum albumin (BSA) and gelatin help realize the functionalization of the device. The functionalized lactate sensor can be preserved in PBS solution under 4°C for over one month. Spike tests on the PEDOT hydrogel-based lactate sensor was performed and achieved a sensitivity range between 100mM and 1mM. In addition, the combination of the printed PEDOT:PSS channel with drop-cast PEDOT:PSS hydrogel exhibited better performance of the device. The results for this device will be presented along with the material characterization.

Stimuli-Responsive Polymers as Precursors to Conductive Hydrogels
Laure V. Kayser; University of Delaware, United States

Electronically-conductive hydrogels, composites of crosslinked and water-swollen polymers with a conducting material (polymer or inorganic nanoparticles) can address the mechanical and electronic mismatch between electronic devices and biological systems. While several methods have been reported to prepare these conductive hydrogels, several issues have to be addressed to enable their translation in bioelectronics. These issues include: (1) the increase in elastic modulus at high loading of conducting material, (2) the irreversibility of the gelation mechanism, which complicates the delivery and potential removal of the conductive hydrogel in vivo, and (3) the difficulty in controlling the micro- and macro-structure of the conductive hydrogels for applications in tissue engineering and wearable electronics. In this talk, I will share our progress towards addressing these issues through the use of synthetic chemistry, particularly using novel stimuli-responsive conducting polymers. In the first part, I will discuss the use of thermo-responsive conducting polymers that displays a reversible sol-gel transition close to body temperature, thereby enabling injectable conductive hydrogels. The second part will be focused on achieving spatiotemporal control by using photo-active polymers to simultaneously photo-catalyze the polymerization of a conducting polymer and photo-crosslink its supporting matrix. This approach has great potential for 3D printing conductive hydrogels with a controlled microstructure and high resolution using light.

11:00 AM *SB04.05.02
Programmable Materials, Structures and Devices for Next Generation Intelligent Machine
Jiyun Kim; Ulsan National Institute of Science and Technology, Korea (the Republic of)
In recent times, virtual intelligence has made significant strides, reaching and even surpassing the functional and cognitive abilities of humans, owing to advancements in computing power and novel operational methodologies. Meanwhile, physical objects or machines in the real world strive to imitate the forms and functions of specific living organisms, such as humans, cheetahs, and octopuses. However, they still lag behind in terms of intelligent and adaptive functions, necessitating the exploration of innovative mechanisms and approaches.

Therefore, our research group aims to develop an integrated robotic platform that possesses the ability to program its morphology, physical properties, interface, and function. This robotic paradigm requires innovation at all levels of the system, including materials, components, architectures for their integration, manufacturing processes, data processing, and operation. In this talk, I will introduce research categories and recent research outcomes from our group. These include (1) the development of programmable robotic components using smart materials such as multifunctional 3D sensors, soft tensile valves, digital metamaterial, and soft end effectors, (2) the exploration of novel algorithmic architecture including tensegrity, lattice metamaterial, and folding-based structures, (3) the exploitation of manufacturing methods realizing the architectures and functions including intuitive pen-drawing and 3D/4D printing, and (4) the excavation of machine design and operation methodology using artificial intelligence for shape-shifting task, in-situ function programming, and robot/HMI device design and operation. Through these works, we aim to blur the boundaries between the virtual and tangible world and, more importantly, between humans and the environment, thereby sharing our vision for the future physical environment for humans.

11:30 AM SB04.05.03
Highly Transparent Conducting Ionic Hydrogels of Double Network Structure for Deformable Electronics Jinhwan Yoon; Pusan National University, Korea (the Republic of)

Highly deformable soft electrodes have garnered significant attention due to their potential to drive innovation in wearable electronics and soft robotics. To render the soft electrodes, stretchable, conductive, and transparent polymer networks have been studied extensively, but fulfilling these requirements remains challenging. In this work, we developed double-network ionic hydrogels of high transparency and stretchability due to the finely tuned network structure and transparent electrolyte. Based on the high performance of the ionic hydrogels, electroluminescent devices were achieved with an inorganic phosphor emission layer, which exhibits high luminance under extreme deformation. The remarkable transparency of the ionic hydrogels further enabled to fabrication of novel electroluminescent devices of tandem structures, allowing color variation by independent control of each emission layer.

Repeatably Autonomously Self-Healing Ultra-Stretchable PAAMPSA/PANI/PA Conductive Polymer Complex as Strain Sensor Colton Duprey1, Yang Lu2 and Evan K. Wujcik1; 1University of Maine, United States; 2Georgia Institute of Technology, United States

Wearable strain sensors should be comfortably adhered to the skin and capable of monitoring human motions with high accuracy/sensitivity while remaining robust with excellent durability/longevity. However, it is challenging to develop electronic materials that possess the properties of skin—compliant, elastic, stretchable, and self-healable while also having a high enough conductivity for adequate sensitivity. This work demonstrates a new regenerative polymer complex composed of poly(2-acrylamido-2-methyl-1-propanesulfonic acid), polyaniline, and phytic acid as a skin-like electronic material. The type-2 (zip) templated polymerization of aniline in the presence of poly(2-acrylamido-2-methyl-1-propanesulfonic acid) with phytic acid as a P-type dopant exhibits ultrahigh stretchability (1935%), repeatable autonomous self-healing ability (repeating healing efficiency >98%), quadratic response to strain ($R^2 > 0.9998$), and linear response to flexion bending ($R^2 > 0.9994$), mechanically outperforming current reported wearable strain sensors. Sensitive strain-responsive geometric and piezoresistive mechanisms of the material owing to the homogeneous and viscoelastic nature provide excellent linear responses to omnidirectional tensile strain and bending deformations. Furthermore, this material is scalable and simple to process in an environmentally friendly manner, paving the way for the next-generation flexible electronics.

SESSION SB04.06: Multifunctional Materials

All-Aqueous Hierarchical Hydrogels for Microfluidics Anderson Shum1,2 and Yafeng Yu1; 1University of Hong Kong, Hong Kong; 2Advanced Biomedical Instrumentation Centre, Hong Kong

Hydrogels have demonstrated promising applications across fields, ranging from delivery of actives, to cell cultures, and to wound protection. Hydrogel designs have focused on the constituent molecules and molecular interactions via modifications of the molecular identities and structures. Hierarchical structures within the hydrogels can also be manipulated by structuring the precursor solution before hydrogel formation. The precursor solution can be directed via the use of microfluidic techniques, achieving underlying hydrogel architectures with different properties. Besides its use for designing and modifying hydrogels, microfluidic devices can also be made formed by hydrogels, rather than traditional elastomeric-based materials. In this talk, I will share our works at the interface between hydrogels and microfluidics, and will discuss the potential functions and properties of the resultant hydrogels and microfluidic devices.

2:00 PM SB04.06.02
Acid-Crystallized PEDOT Nanoparticles: Scalable and Biocompatible Fillers for Highly Conductive Hydrogels Joshua Tropp and Jonathan Rivnay; Northwestern University, United States

Conductive hydrogels are widely used in bioelectronic applications due to their flexibility, biocompatibility, and conductivity. Conductive hydrogels have been leveraged to improve the biocompatibility of electrodes, act as transducing elements within biosensors, and as conductive scaffolds for cells to promote tissue regeneration. While the unique properties of conductive hydrogels make them a promising material for bioelectronics, achieving high conductivity while maintaining mechanical compliance remains a significant challenge. To meet these requirements, functional-pi electron systems (conjugated polymers, carbon nanotubes, graphene, etc.) are typically dispersed within natural or synthetic biomaterials to afford conductive hydrogels. A significant challenge in the field remains the required high nanomaterial loadings to achieve significant conductivity; however, at such loadings the conductive hydrogels become prohibitively rigid for bioelectronic applications. Unlike 2D thin-film applications that leverage the long-range ordering of
Conductive Hydrogels for Multimodal Bioelectronic Interfaces

2:15 PM SB04.06.03
From Conducting Hydrogel to Semiconducting Hydrogel
Dingyao Liu, Yan Wang and Shiming Zhang; The University of Hong Kong, Hong Kong

Thin-film semiconductor-based devices have revolutionized the field of microelectronics. In the realm of biomedical applications, conducting hydrogels have rapidly gained prominence due to their mechanical and biocompatible nature with biological systems. The realization of semiconducting hydrogel materials holds significant value within the field of bioelectronics for developing advanced biologics [1]. Advancing towards flexible and stretchable semiconducting hydrogels can enable direct applications at the interface of soft biological systems [1].

However, the development of semiconducting hydrogels presents challenges, primarily due to the thin-film nature of semiconductors, which are generally less than 1 micrometer in thickness. In contrast, hydrogels tend to have greater thicknesses and struggle to achieve good semiconductor properties.

The advent of organic electrochemical transistors (OECTs) has introduced a new paradigm that can be a powerful testbed to evaluate the performance of a semiconducting hydrogel. In this report, we present the development of the PEDOT-PSS semiconducting hydrogel and its application in the development of OECTs [2]. Furthermore, we provide our insight on how to define a semiconducting hydrogel when using OECT as a testbed. Finally, we delve into the development of stretchable semiconducting hydrogels and explore how they can revolutionize applications in the field of biomedical research.

2:30 PM SB04.06.04
Conducting Polymers Biointerfaces for Bioelectronics
Jadranka Travas-Sejdic; University of Auckland, New Zealand

Conducting polymers (CPs) have been widely used as electroactive biointerfaces in applications such as electrically stimulated tissue engineering and flexible organic bioelectronics. In this talk, several different approaches to advanced electroactive biointerfaces based on conducting polymers will be presented.

The first approach addresses the issue of poor solubility and processability of CP by functionalization of CPs with various moieties, and, in particular, by grafting of CP backbones with polymeric sidechains. That enables modification of optoelectronic, physical and mechanical properties of the CPs and their use as biomimetic biointerfaces, e.g. responsive to stimuli, intrinsically stretchable and self-healing [1].

The second approach addresses the issue that electrodes used in tissue recording and stimulation are commonly 2D and made of rigid conducting materials, and as such cannot adequately probe the actual 3D cell environment within tissues and/or have a significant mechanical mismatch with biological tissue. Our approach to overcome that is based on a precise fabrication of individually addressable, high aspect ratio, soft and flexible 3D CP-pillar microelectrode arrays by means of ‘direct 3D writing’. Such 3D microelectrode arrays could be employed in a variety of applications, from biological sensing to recording and electrically stimulating cells and tissues [2], with the array design easily adjustable.

The third approach to electrochemically addressable biointerfaces is based on flexible, microporous, electrochemically switchable membranes that can selectively and efficiently capture, and then non-destructively release, cancer biomarkers, such as cancer cells/related extracellular vesicles (EVs) [3] and rare cancer cells [4]. The platform allows for the EVs and cells to be captured from large volumes of complex biological samples and released into clean and small volumes of buffers - suitable for further analysis, for example, for medical diagnostics.

3:30 PM SB04.06.05
Conductive Hydrogels for Multimodal Bioelectronic Interfaces
Ivan Minev; 1,2; 1Leibniz Institute for Polymer Science, Germany; 2Technische Universität Dresden, Germany; 3The University of Sheffield, United Kingdom

Hydrogels are attracting attention as materials for bioelectronic implants because they may solve some long-standing challenges encountered at the tissue-electrode interface. This will require appropriate viscoelasticity, hydration, bioactivity and dual electronic-ionic conductivity. Apart from improved integration with brain tissue, hydrogels may enable electrodes with superior charge injection capacity and capability for neuro modulation over the electrical domain (e.g. using biomolecules).

In this talk I will present our efforts to combine Glycosaminoglycans and the conductive polymer PEDOT into interpenetrating network hydrogels that are soft, conductive and bioactive. The material system is highly tunable offering control over electrical and mechanical properties. Furthermore the hybrid material has enabled us to sequester and release small proteins such as growth factors. The release profiles can be electrically tuned. The released proteins are bioactive and can influence cells in culture.
With this work we aim to advance the possibility to engineer synthetic bioelectronic materials that emulate some aspects of the extracellular matrix and may enable applications in next-generation tissue-mimetic bio interfaces.

4:00 PM SB04.06.06
Conducting Polymer Hydrogels for Soft and 3D Bioelectronic Interfaces

Alexandra Rutz; Washington University in St. Louis, United States

Hydrogels are insoluble polymer networks swollen with water (>90% water by mass) and are used widely in biomedical applications for their similarities to native extracellular matrix. For bioelectronics, there are many efforts to build devices based on these materials to achieve tissue-matching stiffness and other tissue-inspired properties in order to improve the biointerface. For making electrodes and other device components based on semiconducting materials, conjugated polymers can be gelled into electronically conducting hydrogels. Such methods include simple mix-and-cast techniques, similar to other methods used widely in traditional (non-conducting) hydrogel processing. We have investigated conducting hydrogels based on the conjugated polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT-PSS) fabricated by mixing in a gelling agent, ionic liquid. We have studied how the hydrogel precursor formulation and other fabrication variables of this method affect gel properties, such as swelling, conductivity, and elastic modulus. Further, we have evaluated the potential of these PEDOT-PSS hydrogels for biointerfaceing applications and have found that these gels when processed appropriately are stable in vitro and support mammalian cell culture. Finally, we are developing these conducting polymer hydrogels for compatibility with additive manufacturing to grant structural control of these soft bioelectronic interfaces. Such techniques provide manipulation of dimensions and microporosity, important for assembling these hydrogels into functional devices and optimizing tissue integration.

4:15 PM SB04.06.07
Ultra-Soft Semiconducting Hydrogels for Tissue-Like Organic Electrochemical Transistors

Yahao Dai and Sihong Wang; University of Chicago, United States

The rapid development of wearable/implantable electronics over the past decade opens the next era of human-integrated biosensors in pursuit of higher sensitivity and more seamless tissue-electronics interfaces. Transistor, especially organic electrochemical transistor (OECT)-based biosensor has attracted considerable attention as an advanced biosensing platform due to their high built-in amplification and water-compatible operation. To achieve the intimate biointerface and acquire the biological signal with the highest possible accuracy, the most ideal approach is to prepare the semiconducting materials with tissue-level softness and stretchability, and directly interface with the tissue surface. However, so far no semiconducting material is able to provide modulus even close to the tissue level due to the general paradox that semiconductors rely on stronger intermolecular interactions to facilitate charge transport. In this research, we proposed a novel material design strategy for developing a gel-like semiconductor that is able to simultaneously provide low modulus, high stretchability/elasticity, and high hole mobility. This is achieved by incorporating a secondary hydrogel matrix into a semiconducting polymer network for enhancing the water uptake to soften the composite, and utilizing solvent treatment to form strong percolation between polymer semiconductors to resist the negative effect of swelling. We further use ultra-soft semiconductors to fabricate gel-like OECTs with desired mechanical and electrical performance for human integration, and demonstrate its capability as the advanced platform for biosensing applications.

4:30 PM SB04.06.08
Developing Multifunctional Hydrogels with Tissue-Like Properties for Improved Cell-Material Interfaces

Christina M. Tringides; Blandine F. Clément; Marjolaine Boulingre; Vilius Dranseika; David J. Mooney; Janos Vörös; ETH Zurich, Switzerland; Harvard University, United States; UZH, Switzerland

Biomaterial scaffolds have emerged as a tool to build 3D cultures of cells which better resemble biological systems, while advancements in bioelectronics have enabled the modulation of cell proliferation, differentiation, and migration. Here, we first describe a porous conductive hydrogel with the same mechanical modulus and viscoelasticity as neural tissue. Electrical conductivity is achieved by incorporating low amounts (~0.3% weight) of carbon nanomaterials in an alginate hydrogel matrix, and then freeze-drying to self-organize into highly porous networks. The mechanical and electrical properties of the material can be carefully tuned and used to modulate the growth and differentiation of neural progenitor cells (NPCs). With increasing hydrogel viscoelasticity and conductivity, we observe the formation of denser neurite networks and a higher degree of myelination. Similarly, fibroblasts can be incorporated into the scaffolds and cell migration can be modulated through the application of exogenous electrical stimulation, for applications to wound healing. To investigate the functionality of neural systems, both in vitro and in vivo platforms can be realized. By placing a polydimethylsiloxane (PDMS) microstructure on an underlying multielectrode array (MEA), we can then explore different materials and techniques to integrate hydrogels into the PDMS microstructures and can facilitate the growth of neuronal networks in 3D. Additionally, implantable surface electrode arrays can be fabricated, with the ability to record from the brain and heart with enhanced tissue conformability and minimal damage to the biological organs. The described biomaterial platforms can be used to investigate neuronal development and disease progression.

4:45 PM SB04.06.09
Superstrong Electronic Hydrogel Actuators (ECO)

Mahiar M. Hamedi; KTH, Sweden

Intelligent systems combine sensing, actuation, and computation to achieve complex tasks and functions. Soft electrically controlled multifunctional materials, especially hydrogels, are the most promising materials for such systems as they are as adaptable as biological systems yet compatible with advanced systems through electronics.

We describe an electroactive hydrogel fabricated from cellulose nanofibrils from trees, and conductive nanomaterials, like CNTs or 2D MXenes. These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other.

The electrochemical charge/discharge of the conductors in the hydrogels controls the internal salt concentration and consequently their osmotic swelling. This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only ±1 V, resulting in up to 300% electroosmotic expansion, with very high pressures reaching 1 MPa.

This mode of electronic actuation has not been shown before. We call these electroosmotic (ECO) actuators. Our ECO hydrogel actuators have emergent properties not present in any previously known soft material. ECOs allow formoneolithic integration of sensors and many other functions into the same composite, rendering a new form of smart soft material not achievable with other materials systems.

Long-Term Durable and Ultrasensitive Multiple-Crosslinked Ionic Hydrogel Sensors with Multi-Functions for Wearable Electronics Byeong Su Kang1, Jin-Young Yu1, Jeong Hun Kim2 and Seongmin Kang1; 1Chungnam National University, Korea (the Republic of); 2Electronics and Telecommunications Research Institute, Korea (the Republic of)

Hydrogels are considered promising for wearable devices because they are soft, flexible, stretchable, and biocompatible. However, existing hydrogels suffer from poor strength, weak and one-time adhesion, non-self-recovery, water evaporation, ice crystallization, and low sensitivity, and these problems have only been partly solved previously. We propose the one-pot synthesis of a multiple-crosslinked poly(2-(methacryloyloxy)ethyl)dimethyl-(3-sulfolpropyl)ammonium hydroxide-co-acrylamide (P(SBMA-co-AAm)) multifunctional hydrogel to overcome these limitations. The synthetic route provided elasticity, self-healing, and transparency, and the incorporation of glycerol and NaCl ions provided moisture stability (e.g., water retention) and antifreeze properties. Zwitterionic SBMA contributed to the increased gauge factor, resulting in high sensitivity and an ability to detect human movements at a strain of 800%–1600%, making the hydrogel sensor practical. The sensor retained its properties after even 300 cycles, indicating its durability and reliability for long-term applications.

8:00 PM SB04.07.02
Multi-Crosslinked Hydrogel-Based Needle Structure Capacitance Sensor with High Sensitivity and Stability Byeong Su Kang1, Jeong Hun Kim2 and Seongmin Kang1; 1Chungnam National University, Korea (the Republic of); 2Electronics and Telecommunications Research Institute, Korea (the Republic of)

The hydrogel-based sensor has better elasticity than the existing elastomer sensor, so the distance between the two electrodes can be reduced. Also, since the amount of change in contact area is also large, the amount of change in capacitance is excellent. Especially, by adopting a micro needle structure that can maximize the change in contact area, the change in capacitance is increased. However, the previous hydrogel-based sensor lacks recipe research to create a structure, and adding a structure reduces stability and repeatability, limiting its application as a sensor. In this paper, poly(acrylamide-co-N,N'-methylenebisacrylamide) multifunctional hydrogel can overcome the aforementioned limitations. Then, by making a hydrogel-based sensor with a micro needle structure, high sensitivity is sought by adjusting the amount of N,N'-methylenebisacrylamide. In addition, by adding sodium dodecylbenzenesulfonate lauryl acrylate, the stability of the structure that does not interfere with sensitivity is increased. This hydrogel-based sensor is a human-friendly material that can be applied not only to the biomedical measurement field, but also to fields where existing elastomer sensors are applied, such as robots, hydraulic pressure measurement, and aviation.

8:00 PM SB04.07.03
Robust Integration of Highly Conductive Hydrogels with Stretchable Electronics for Skin-Interfaced Bioelectronics Hyun Su Lee and Dae-Hyeong Kim; Seoul National University, Korea (the Republic of)

Skin-interfaced bioelectronics mounted on human skin has the potential to revolutionize next-generation medical diagnostics and healthcare. To achieve this goal, designing a compliant and stretchable device is highly desirable for device reliability and long-term user comfort. In the material aspect, the limitations of conventional functional device components that originate from rigid and obtrusive interfaces must be overcome by materials with intrinsic softness and stretchability. Conductive hydrogels that possess tissue-level softness owing to their water-rich nature, can be an alternative option. Generally, for the fabrication of hydrogel-based, skin-interfaced bioelectronics, a hydrogel film is cut and placed onto an electrode. However, during device operation, large amount of water inside the hydrogel film tends to form a slippery surface rather than a robust interface between human skin and electronic device. Such poor integration capability could cause the lack of reproducible device performances, difficulty to scale up, and the loss of intimate physical/electrical contacts, which leads to critical problems in signal sensing and electrical actuation from/to human tissue. Here, we suggest direct polymerization and in-situ chemical-integration of hydrogel onto stretchable electronics as a methodology for enhancing the hydrogel-device interface of skin-interfaced bioelectronics. Highly conductive functionalized hydrogels are polymerized inside stretchable wells placed on a multichannel electrode array. The hydrogels are stably immobilized to the electronic devices during fabrication, and the robust interface contributes to the reliable measurement of bio-signals and effective electrical actuation on tissues. The demonstration shows that the direct polymerization and in-situ chemical-integration of hydrogel are key steps towards the realization of practical skin-interface bioelectronics based on functionalized hydrogels.

8:00 PM SB04.07.04
Self-Healing Stretchable Li-Ion Battery Based on a High-Voltage Hydrogel Electrolyte Peisheng He1, Jong Ha Park1, Chao Fang1, Anju Toor2 and Liwei Lin1; 1University of California, Berkeley, United States; 2Georgia Institute of Technology, United States

Safe and deformable batteries that can be conformally embedded onto irregular surfaces of electrical systems and human body are desirable for wearable electronic applications due to low user friction. Commercial state-of-the-art Li-ion batteries are packaged in rigid hermetic sealing materials that are not deformable. State-of-the-art deformable Li-ion batteries reported in research articles show fast degradation due to severe performance problems such as the penetration of moisture and the leakage of toxic and inflammable electrolytes. Here we report a non-toxic, aqueous hydrogel electrolyte instead of its organic counterpart that is demonstrated to: 1) enable highly safe operations due to its non-toxic and non-flammable nature; 2) alleviate the moisture penetration problem from outside environment; 3) have a high-voltage working window of ~2.8V; and (4) allow the construction of stretchable batteries by using elastic polymer packaging materials instead of rigid hermetic seals. In the prototype tests, fabricated batteries have shown good stretchability (50% strain) and flexibility (radius of curvature < 2mm) to enable conformal attachments to a wide range of geometric surfaces. The prototype battery also shows outstanding cyclic stability, retaining ~90% of the original capacity after 100 cycles for over 2 months in the ambient environment without using any rigid hermetic sealing package. Finally, a prototype battery with a self-healing elastomer package remains functional after being punctured by a needle 5 times at different locations through the package. Furthermore, it can recover >90% of its capacity after being cut through by a razor blade and subsequently healed at 70 for 10 minutes. Such safe and highly stretchable batteries would be useful for several wearable electronic applications such as blood glucose monitoring, hear rate monitoring, temperature monitoring, wireless charging, smart clothing, etc.

8:00 PM SB04.07.05
Highly Sensitive Flexible Sensors using Autonomousy Self-Healable and Temperature-Tolerant Eutectogel Jinyoung Lee and Jeong Sook Ha; Korea University, Korea (the Republic of)
With the increased demand for advanced wearable electronics, hydrogel-based devices have attracted enormous attention. Hydrogels have many advantages such as excellent flexibility, biocompatibility, ion-conductivity, and self-healing property, adequate for wearable devices. On the other hand, hydrogel-based devices exhibit limit in the performance due to the freezing and evaporation of water in the polymer network at low and high temperatures, respectively. To address such a thermal instability issue, there has been extensive effort on replacing the water within the hydrogel network with ionic liquids of low vapor pressure and high ionic conductivity. However, most ionic liquids are expensive and toxic to hamper the practical application to wearable devices. Therefore, research on deep eutectic solvents, mixtures of two or more components characterized by significant depressions in melting points compared to their neat constituent components, has been recently activated. Deep-eutectic solvents show properties similar to those of ionic liquids as well as additional advantages of low-cost, non-toxicity, biocompatibility, and biodegradability. Furthermore, eutectogels having polymer networks composed of deep-eutectic solvents have demonstrated the high potential application to wearable devices.

In this paper, we report on the fabrication of resistive-type strain and pressure sensors based on newly synthesized autonomous self-healing and temperature-tolerant eutectogel. Our synthesized eutectogel is prepared by UV polymerization of acrylamide with trehalose and phytic acid as crosslinkers, and choline chloride, glycerol and a small amount of water as solvents. In addition to the inherent low melting point of deep eutectic solvent, inclusion of biocompatible and highly hydrated polymer networks allowed improved anti-freezing and anti-evaporation properties. Also, the dynamic hydrogen bond interactions between the polymer network and trehalose, phytic acid, and glycerol endowed the eutectogel with self-healing properties. The synthesized eutectogel exhibits high stretchability (>300%), temperature-tolerance, and good self-healing efficiency (>90%) after 24 hours at room temperature. By incorporating conducting polymer onto the eutectogel, highly sensitive resistive-type strain and pressure sensors are fabricated for detecting bio-signals after attachment onto a finger or wrist. The eutectogel-based wearable sensors demonstrate stable signal detection over a wide temperature range even after repetitive self-healing, thereby expanding their potential application to wearable electronics with longevity under extreme conditions.

8:00 PM SB04.07.06 Topology-Based Dual Lock-and-Key Structures for Hydrogel Self-Assembly in Macroscopic Supramolecular Assembly Eunseok Heo, Hye Been Koo and Jae-Byum Chang; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Macroscopic supramolecular assembly (MSA), which refers to the assembly of building blocks at a macroscopic scale, holds great potential for the fabrication of ordered bulk structures. Thanks to the high design flexibility of the building blocks and the precise controllability of the assembly process, MSA has found applications in a wide range of fields, including the fabrication of tissue scaffolds, soft actuators, and more. Additionally, among the candidates for building blocks, hydrogels are highly favored due to their easily tunable properties and diverse type with different characteristics. In MSA, two challenges need to be addressed to achieve a high level of assembly: enhancing the precision of assembly and increasing the number of orthogonally matching pairs. To date, despite numerous attempts, none have effectively tackled both challenges simultaneously. In this study, we introduce topology-based design criteria for achieving precise and selective self-assembly of hydrogel building blocks. We suggest a unique design approach termed “dual lock-and-key structures,” in this design model, only topologically matching pairs can be assembled with exceptional precision. Through the implementation of dual lock-and-key structures, we establish principles for the selection of multiple orthogonally matching pairs. We demonstrate the selective assembly of both simple one-to-one matching and complex one-to-many assemblies. Moreover, by harnessing the easy property tunability of hydrogel, we synthesize DNA-mimicking single-stranded structures, which hybridize into double-stranded structures with sequence-specific arrangements. Finally, we present a hydrogel logic gate system, consisting of a YES gate, an OR gate, and an AND gate. Utilizing the high selectivity of our dual lock-and-key structures, the desired outputs are exclusively obtained when the appropriate building blocks are assembled, following the logic of each gate: YES, OR, and AND.

8:00 PM SB04.07.07 Conducting Polymer Granular Hydrogel Bioinks for 3D Printed In Vitro Bioelectronic Devices Anna P. Goestenkors, Tianran Liu, Somtochukwu S. Okafor, Lianna Friedman, Riley Alvarez and Alexandra Rutz; Washington University in St. Louis, United States

Conjugated polymers have recently been used in their hydrogel form for the creation of soft bioelectronics with improved cell interfacing and the potential for enhanced measurement and stimulation of cellular activities. Cell-encapsulating hydrogels offer a truly 3D culture environment and when designed appropriately can be used as bioinks for 3D printing which grants spatially controlled deposition of cells and materials simultaneously. We developed a bioink based on the conducting polymer poly(3,4-ethylene-dioxythiophene):polystyrene sulfonate (PEDOT:PSS) by creating a granular hydrogel form. Emulsion methodology was developed to fabricate PEDOT:PSS hydrogel microparticles (microgels) with high circularity and monodispersity. Filtration techniques were used to size select microgels with diameters between 10 and 60 µm. When centrifuged to remove significant water, the conducting polymer microgels achieved dense packing characteristic of a granular material state. Increasing centrifugal force decreased the void fraction of the material which increased conductivity. Rheological investigations confirmed shear-thinning and self-healing properties, both ideal for 3D bioprinting for extrusion and ability to keep shape, respectively. Granular PEDOT:PSS hydrogels were in fact 3D printable via pneumatic extrusion and formed various 3D configurations. Evaluation of the material’s printability in the granular state also revealed that increased centrifugal force facilitated better printability as evidenced by increased maximum filament length and filament diameter better matching the chosen nozzle diameter. Structural stability of the material within an aqueous environment for up to three months was achieved using a collagen hydrogel overlay. Human dermal fibroblasts encapsulated and cultured within the granular hydrogel showed high cell viability over fourteen days demonstrating cytoocompatibility. This developed conducting granular hydrogel bioink exhibits balanced properties of printability, conductivity, and cellular responses for the additive manufacturing of future in vitro bioelectronics.

8:00 PM SB04.07.08 Extracellular Matrix-Compatible Additive Manufacturing of Bioactive, Conducting Polymer Hydrogel Electrodes Tianran Liu, Somtochukwu S. Okafor, Anna P. Goestenkors, Sandra Montgomery, Riley Alvarez and Alexandra Rutz; Washington University in St.Louis, United States

Hydrogels of conducting polymers provide a soft and hydrated alternative to metal for interfacing electronic devices with biological systems. To fabricate devices based on conducting polymer hydrogels, the material is often patterned alongside bionert and stiff substrates such as plastics and elastomers which lead to poor cell-material interactions. In order to further promote device integration with cells and tissue, one strategy is to utilize bioactive materials, such as mammalian extracellular matrix (ECM) components, as the substrate material to present a tissue-like microenvironment to cells. However, traditional semiconductor manufacturing is anticipated to impair the bioactivity of these natural materials. Here, we demonstrate methods for mild temperature additive manufacturing of highly conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) hydrogels with collagen substrates. Various types and concentrations of gelation agents were investigated to enable sufficient working time after addition to colloidal dispersions and to result in a water-stable hydrogel network once fully crosslinked. Among gelation agents tested, ionic liquid was found to be suitable for extrusion-based printing while an acidic surfactant enabled deposition by jetting due to low surface tension and appropriate viscosity. After room temperature gelation and treatment, hydrated PEDOT:PSS prints exhibited conductivity as high as 37.2 S/cm and were stable in cell culture conditions for at least 28 days. To complete the device, a top layer was fabricated by casting a collagen slurry onto the PEDOT:PSS prints which had a sacrificial material deposited on top to protect the intended electrodes from coverage. Once the collagen layer formed, the sacrificial material was remov ed with 36 °C water, leaving an unaltered
Air-Permeable Hydrogels with High Water Content

Hydrogels have gained immense popularity as the interface between biological tissues and the environment due to their exceptional properties and unique features. For biomedical applications like long-term signal monitoring, drug release, or pathogen blocking that necessitate continuous epidermal or tissue adhesion, free water and air exchange between the body and its surroundings become crucial. However, despite their excellent water permeability, hydrogels have over an order of magnitude lower oxygen permeability compared to other 'dry' soft materials (e.g. silicone rubber). This poor oxygen permeability in hydrogels is an intrinsic problem caused by the dense polar hydrogen-bonded network, which has long been a challenge to overcome. Herein, we present a strategy that achieves high oxygen permeability without compromising water content. The key to this approach is the fabrication of interconnecting microchannels within the bulk hydrogel material. More importantly, we demonstrate that the designed materials exhibit high oxygen permeability, allowing for long-term wear without causing itchiness or other uncomfortable sensations.

Tough and Recyclable Phase-Separated Supramolecular Gels via a Dehydration-Hydration Cycle

PEDOT:PSS surface for direct biointerfacing. Since the fabrication methods were developed with mild temperatures and processing, the structure and bioactivity of the collagen are believed to be maintained, as evidenced by the support of fibroblast culture that reached confluency and sustained high viability for 28 days. This methodology offers a promising strategy for rapid prototyping soft, hydrated, and bioactive electronic devices that support cell attachment and proliferation.

8:00 PM SB04.07.09

A Zwitterionic Hydrogel-Based Heterogeneous Fenton Catalyst for Efficient Degradation of Persistent Organic Pollutants

Perspective organic pollutants (POPs) are industrial, pharmaceutical, or commercial byproducts that are highly resistant to degradation and decomposition in the environment, while causing significant health and environmental damage even in small concentrations. Significant existing research aims at destroying the POPs in an environmentally safe and cost-effective manner, but challenges remain in destroying POPs at environmental concentrations in scalable and sustainable processes. Many current approaches to degrading POPs require extreme reagents and conditions. One promising candidate, however, for the removal of POPs is the photo-Fenton reaction, where iron(II) ions catalyze the decomposition of hydrogen peroxide, in the presence of UV light, into highly reactive hydroxyl radicals that readily attack organic compounds, including POPs. Fenton oxidation is promising because iron(II) and hydrogen peroxide are low-cost, environmentally-safe materials, and because the process can target a broad range of POPs.

However, the photo-Fenton reaction requires the presence of water-soluble iron(II) ions that are difficult to reuse. As such, methods that immobilize the iron as a catalyst can be constantly reused, while also eliminating the need for further treatment steps to remove iron from water before it can be used. Unfortunately, existing solutions require challenging reaction conditions; due to the higher efficiency of the Fenton reaction at lower pHs, many catalysts require a low pH (usually around 3) to regenerate iron(II) ions, which is unrealistic for large-scale wastewater treatment and can damage the catalyst itself. Furthermore, due to the non-selectivity of the Fenton reaction, catalysts using common polymers such as polyethylene or polyvinyl alcohol to encapsulate iron (II) or iron oxide (in the form of nanoparticles) often degrade easily due to the susceptibility of the polymer to the photo-Fenton reaction, also releasing nanoparticles into the environment. Other attempts at supported catalysts reduce the surface area and limit kinetics.

To address these issues, we developed an iron(II)-incorporated, zwitterion-based hydrogel catalyst. By complexing the iron(II) ions within a zwitterionic hydrogel, we allow for the photo-Fenton reaction to run efficiently at neutral and even slightly alkaline pHs. Furthermore, due to the high oxidation state of the zwitterions and the saturated backbones, the hydrogel is highly resistant to attack by hydroxyl radicals. A zwitterionic backbone helps us make highly porous materials that bind individual, complexed ions, allowing us to maximize both the effective functional area and rate of pollutant transport within the catalyst. POPs quickly and rapidly diffuse into the catalyst, where they rapidly decompose. Experiments at environmentally relevant concentrations showed that our catalyst was able to degrade 85% of a solution of ethinyl estradiol (a xenoestrogen and common POP) within 1 hour, with near 100% degradation within 24 hours. Furthermore, we observed near 100% degradation of dichlorophenol (a common industrial byproduct) and around 70% degradation of perfluorooctanoic acid (a common perfluorinated pollutant). These results show significant promise for our hydrogel as an efficient and environmentally-safe strategy for rapid water purification of POPs.

8:00 PM SB04.07.11

Air-Permeable Hydrogels with High Water Content

Hydrogels are compelling materials for emerging applications, including soft robotics and autonomous sensing. Mechanical stability over an extensive range of environmental conditions and considerations of sustainability, both environmentally benign processing and end-of-life use, are enduring challenges. To make progress on these challenges, we designed a dehydration-hydration approach to transform soft and weak hydrogels into tough and recyclable supramolecular phase-separated gels (PSGs) using water as the only solvent. The dehydration-hydration approach led to phase separation and the formation of domains consisting of strong polymer-polymer interactions critical for forming PSGs. The phase-separated segments acted as robust, physical crosslinks to strengthen PSGs, which exhibited enhanced toughness and stretchability in its fully swollen state. PSGs are not prone to over-swelling or severe shrinkage in wet condition and show environmental tolerance in harsh conditions, i.e., organic solvents with pH between 1 to 14. Finally, we demonstrate the use of PSGs as strain sensors in air and aqueous environments.

8:00 PM SB04.07.14

An Elastomer with Giant Strain-Induced Crystallization

Strain-induced crystallization prevalently strengthens, toughens, and enables an elastocaloric effect in elastomers. However, the crystallinity induced by mechanical stretching in common elastomers (e.g., natural rubber) is typically below 20%, and the stretchability plateaus due to trapped entanglements, impeding performance for advanced applications. We present a new class of elastomers formed by end-linking then deswelling star polymers with a low fraction of defects and no trapped entanglements, which achieve strain-induced crystallinity of up to 50%. The deswollen end-linked star elastomer (DELSE) reaches an ultra-high stretchability of 12.4-33.3, scaling beyond the saturated limit of common elastomers. The DELSE also exhibits a high fracture energy of 4.2-4.5 kJ/m² while maintaining low hysteresis. The heightened strain-induced crystallization and stretchability synergistically promote a high elastocaloric effect with an adiabatic temperature change of 9.3 °C at 54 °C, compared with 3.5 °C at 54 °C in natural rubber.

Advancing Protein Synthesis and Applications with a Recyclable Genomic DNA Hydrogel Platform in Cell-Free Expression Systems Hyangsu Nam1,2 and Jong Bum Lee1; 1University of Seoul, Korea (the Republic of); 2Harvard University, United States

Proteins have the most dynamic entities, performing the diverse role of macromolecules in the body, functional interaction network-based biochemical reactions within a cell or from an organ. Recombinant protein-based therapeutics provide an important breakthrough in biomedical biotechnology. Recent technical advances in cell-free protein synthesis offer several advantages over cell-based expression systems, including easy modification to favor protein folding; increased non-toxicity, and capability for high-throughput strategies for small-volume reaction. Herein, we fabricated the genomic DNA hydrogel (GD-gel) using the dual single-strand circular plasmids employed in cell-free protein expression synthesis. By complementary rolling circle amplification (RCCA) with multi-primers, the genomic hydrogel exhibits a significantly enhanced productivity yield of protein. This synthesis platform has the potential to develop biotechnological in sensing, therapeutics, and diagnosis.

In our study, inspired by the previous DNA hydrogel using a rolling circle amplification technique, we describe a strategy to synthesize genomic DNA hydrogel (GD-gel) via self-assembly of elongated DNA strands encoding multicentric genomic sequences. To achieve the self-assembly of genomic hydrogel, we applied rolling circle chain amplification (RCCA) with the dual single-stranded circular plasmids. Importantly, GD-gel only consists of genomic DNA itself not only to create a hydrogel structure but also to become a medium for protein expression in GD-gel. Hence, our GD-gel is likely to enable a new route for cell-free protein production via s self-assembly of multicentric genomic DNA.

8:00 PM SB04.07.16
A Versatile Conductive Ternary Polymer Complex Nanocomposite Sensor with Repeatable, Rapid, Autonomous Self-Healing and Unprecedented Mechanical Properties Colton Duprey and Evan K. Wujcik; University of Maine, United States

Wearable sensors, stretchable electronics, and many soft robotics materials must have a sufficiently high balance of conductivity, stretchability, and robustness. Intrinsically conductive polymers offer a critical step toward improving wearable sensor materials due to their tunable conductivity, soft/compliant nature, and ability to complex with other synergistic molecules (i.e., polycyads, small molecule dopants). The addition of nanofillers offers the potential to improve the conductivity of polymers for soft robotics and wearable applications, while stand also affects and improves the self-healing and mechanical properties of the material. The development of a robust polymer nanocomposite material that offers ultra-stretchability, an autonomous self-healing ability, and enhanced electronic properties has eluded researchers. Here we show an aqueous polyaniline (PANI)poly(2-acylamido-2-methylpropane sulfonic acid) [PAAAMPSA]/phytic acid [PA] ternary polymer (TP) complex synthesized with silver nanowires (AgNW) to form a polymer nanocomposite with high electronic sensitivity, unprecedented mechanical properties (a maximum strain of 4693% at ambient humidity; ~52 RH%), and repeatable, autonomous self-healing efficiencies of greater than 98%. The AgNW TP complex has an engineering strain higher than all hydrogel and other polymeric sensor materials, in which the interface between the polymer matrix and the AgNW is hypothesized to be integral for the formation of an active conductive network. To illustrate the remarkable sensitivity, the material was employed as a biomedical sensor (pulse, voice recognition, motion), topographical sensor, and high sensitivity sensor.

8:00 PM SB04.07.17
Engineering a Reverse Thermo-Responsive, Cross-Linkable, Biodegradable Liquid Embolic Agent for Brain Aneurysm Treatment Lamia Ayaz1, Hannah Feng2, Ruoxi Jin1, Ann Lee4, Sheldon Liu1, Evan Pang2, Jiariu Peng1, Grace Qiao3, Ruth Pereira2, Robert Wong4, Aaron Sloutski5, Chandramouli Sadasivan2, Daniel Cohn16 and Miriam Raffaiovlitch1; 1Howard School, United States; 2Torrey Pines High School, United States; 3Beijing National Day School, China; 4Seoul International Day School, Korea (the Republic of); 5Stuyvesant High School, United States; 6Mission San Jose High School, United States; 7East Lyne High School, United States; 8The Experimental High School Attached to Beijing Normal University, China; 9Stony Brook University, The State University of New York, United States; 10The Hebrew University of Jerusalem, Israel

Cerebral aneurysms are balloon-like dilations in intracranial arteries that can rupture, leading to fatal hemorrhagic stroke. The majority of current aneurysm treatments involve the implantation of catheter-based endovascular coils and meshes, but they result in unfavorable primary outcomes in at least 20% to 30% of cases [1]. This project aims to develop an injectable, controllably cross-linkable, durable, and multifunctional liquid embolic agent (LEA) using F88-DMA polymer that allows for the body’s natural mechanisms to heal the aneurysm with personalized biodegradation.

As temperature increases and reaches physiological temperatures, F88-DMA micelles group together and entangle, resulting in mechanically strong physical gelation. Chemical crosslinkers ammonium pentamsulfate (APS) and tetramethylethylenediamine (TEMED) enhance the long-term stability of the hydrogel, while ioheal acts as a contrast agent. In order to develop a pluronic-based polymer system that is deliverable in vivo, cold, radiopaque F88-DMA must be injectable through a microcatheter. Gelation must occur at the optimal time and temperature so as not to solidify prematurely or remain liquid within the aneurysm. Various concentrations of F88-DMA and TEMED were tested in vitro to determine the optimal concentration for injectability. Rheology results displayed that a higher concentration of F88-DMA lowers gelation temperature, and this correlation was further confirmed with differential scanning calorimetry for all three concentrations of F88-DMA (2%, 3%, and 33%). Additionally, higher concentrations of TEMED were found to increase the maximum shear modulus and decrease the crosslinking time of F88-DMA gel. To simulate interventional treatment, the LEA was injected into a brain aneurysm model, suggesting 29% F88-DMA to be the most injectable concentration that, when crosslinked, would remain in the aneurysm for prolonged periods of time. Upon gelation and crosslinking, hydrogels swell in situ due to thermodynamic forces, posing a significant risk for compression or rupture. F88-DMA hydrogel swelling was demonstrated to be dependent on polymer concentration (p = 0.019695), and the addition of ioheal significantly decreased swelling over the course of 3 days. Furthermore, hydrogels submerged in flowing saline exhibited less swelling than those submerged in static saline (p = 0.0001), an improved durability that originates from the entangled properties of the micelles.

The durable embolic agent must also allow for vascular remodeling and endothelialization in a controlled manner. Thus, cell adhesion and porosity are vital. Imagery of fibrinogen-soaked gel suggests that natural levels of fibrinogen make the cross-linked F88-DMA cell adhesive enough, providing no need to incorporate cell adhesive materials. Sodium phosphate heptahydrate was effectively employed to control pre-determined porosity that initiates the wound healing process.

After the aneurysm has healed, the pluronic implant must be controllably biodegradable. The biodegradability of the LEA is a function of the patient-specific wound healing process such that the blood vessel returns completely to its original healthy state. Naturally occurring enzymatic F88-DMA degradation is currently being investigated with lactate.

Engineering a Reverse Thermo-Responsive, Cross-Linkable, Biodegradable Liquid Embolic Agent for Brain Aneurysm Treatment Lamia Ayaz1, Hannah Feng2, Ruoxi Jin1, Ann Lee4, Sheldon Liu1, Evan Pang2, Jiariu Peng1, Grace Qiao3, Ruth Pereira2, Robert Wong4, Aaron Sloutski5, Chandramouli Sadasivan2, Daniel Cohn16 and Miriam Raffaiovlitch1; 1Howard School, United States; 2Torrey Pines High School, United States; 3Beijing National Day School, China; 4Seoul International Day School, Korea (the Republic of); 5Stuyvesant High School, United States; 6Mission San Jose High School, United States; 7East Lyne High School, United States; 8The Experimental High School Attached to Beijing Normal University, China; 9Stony Brook University, The State University of New York, United States; 10The Hebrew University of Jerusalem, Israel

Multi-Scale Chemical Insights into The Static and Dynamic Behaviour of Metallo-Polyelectrolyte Gels Seneca J. Velling1, Pierre J. Walker2, Seola Lee1, Connor M. Gallagher2, Michael D. Schulz2, Zhen-Gang Wang3 and Julia R. Greer4,5; 1California Institute of Technology, United States; 2Virginia Tech, United States

Metallo-Polyelectrolyte Complexes (MPEC) in the gel state represent a class of multifunctional, weakly ionizing materials with intriguing properties deeply rooted in their coordination chemistry and metal ion exchange. We provide a comprehensive exploration of the underlying chemical principles governing MPECs, with a primary focus on the profound effects of metal ion valency and system pH on binding thermodynamics, association-dissociation kinetics, and global polymer morphology and their regulation of overall gel behaviour. Employing quantum density functional theory (DFT), we estimate the binding energy between the metal cations and the polymer backbone. Hard mono-, di-, and trivalent metal ions exhibit bidentate bridging coordination environments by carboxylate groups and aqua/hydroxy ligands as verified using FTIR, giving stoichiometric charge balance to the complexes. This results in a range of binding energies of -1 to -8 eV. We corroborated these findings with Isothermal Titration Calorimetry (ITC) to probe the solution-phase binding of metal salts to poly(acrylic acid). We demonstrate that the impact of association kinetics at the molecular level propagates to macroscopic behaviour, with higher valency metal ions distinctly influencing relaxation dynamics, thereby increasing gel stiffness and extending the plateau modulus. The role of proton activity in the solution and gel phases – which systematically modulates polyanion charge sparsity and, accordingly, metal binding sites for the formation of these dynamic bonds – can be readily explained using our theoretical treatment. This treatment is in good agreement with our experimental exploration of the MPEC phase space (dissolution, homogeneous gel, and phase separated metal-rich vs. metal-poor gel phase). Guided by theory, our experimental observations unveil the profound influence of pH on polymer relaxation. As charge sparsity decreases, MPEC gels transition towards behaviour reminiscent of monovalent gels, accompanied by critical alterations in network topology. These findings underscore a competition for polyanion (RCOO-) association between weakly-bound monovalent species in the buffer (eg. Na+), strongly-bound, higher-valency metal species (Mn+), and the drive for carboxylate protonation when pH < pKa. This intricate interplay between metal ion valency and pH-regulated charge sparsity fundamentally governs the global thermomechanical response of solvated MPEC gels: from binding site availability to bond dynamics and overall gel morphology. Local chemistry, therefore, has a profound influence on overall thermal, mechanical, and electrical response of metal cross-linked systems. The assumption – and critical role – of solvent in the gel system cannot be overlooked. Our implicit solvent approaches, taken together with DFT and experimental findings on the collective metal-ligand and metal-aqua/hydroxyl ligand complexation character, explain well the bulk-scale observations in the gel phase, providing mechanistic insights into the polymer-metal interactions, transport, and phase-behaviour. This work unravels the intricate & entangled chemistry underpinning MPEC gels, offering critical insights into their valency-driven, pH sensitive, solvent-dependent global responses.

8:00 PM SB04.07.21
Unusual Temperature Dependence of Water Sorption in Semi-Crystalline Hydrogels Xinrue Liu1, Lenan Zhang1 and Evelyn N. Wang2; 1Michigan State University, United States; 2Massachusetts Institute of Technology, United States

Water vapor sorption is a ubiquitous phenomenon in nature and plays an important role in various applications, including humidity regulation, energy storage, thermal management, and water harvesting. In particular, capturing moisture at elevated temperatures is highly desirable to prevent dehydration and to enlarge the tunability of water uptake. However, owing to the thermodynamic limit of conventional materials, sorbents inevitably tend to capture less water vapor at higher temperatures, impeding their broad applications. Here, an inverse temperature dependence of water sorption in poly(ethylene glycol) (PEG) hydrogels, where their water uptake can be doubled with increasing temperature from 25 to 50 °C, is reported. With mechanistic modeling of water–polymer interactions, this unusual water sorption is attributed to the first-order phase transformation of PEG structures, and the key parameters for a more generalized strategy in materials development are identified. This work elucidates a new regime of water sorption with an unusual temperature dependence, enabling a promising engineering space for harnessing moisture and heat.

SESSION SB04.08: Stimuli-Responsive Materials and Other Special Mechanical Properties II

Rubbery Bioelectronics Cunjiang Yu; The Pennsylvania State University, United States

Electronics that can seamlessly integrate with human body could have significant impact in medical diagnostic, therapeutics. However, seamless integration is a grand challenge because of the distinct nature between electronics and human body. Conventional electronics are rigid and planar, made out of rigid materials. Human body are soft, deformable and curvilinear, comprised of biological materials, organs and tissues. This talk will introduce our solution to address the challenge through the recent development of a new class of electronics, namely rubbery electronics. Rubbery electronics is constructed all based on elastic rubber electronic materials of semiconductors, conductors and dielectrics, which possesses tissue-like softness and mechanical stretchability to allow seamless integration with soft deformable tissues and organs. Rubbery electronic materials (semiconductors, conductors, dielectrics) and device innovations set the foundation. This presentation will describe the development the recent advances of rubbery electronics and rubbery bioelectronics. As a platform technology, rubbery electronics could address many challenges in biomedical research and clinical studies.

9:15 AM SB04.08.03
Fabrication of Multi-Material Stimuli-Responsive Microstructures via Photografting of Functional Microgels to Elastomeric Supports Ruiguo Yang and Stephen A. Morin; University of Nebraska – Lincoln, United States

Hydrogels are functional polymeric materials with stimuli-responsive properties applicable to a wide range of applications including soft electronics and robotics, three-dimensional cell culture, tissue engineering, and adaptive optics. Accordingly, the diversity and reported use cases of these materials has grown tremendously over the past decade, however, the microfabrication of multi-material, hydrogel-based devices remains a challenge. We report a
simple microfabrication strategy that enables the facile production of fixed arrays of stimuli-responsive hydrogel microstructures with dynamic micromotion functionality. Our approach relies on a soft, stretchable electrochromic template which directs the assembly of prepolymer droplets into ordered arrays and presents the surface chemical moieties needed to photograft the hydrogel to the support, simultaneously. Specifically, we achieve three critical operations in one seamless fabrication scheme: (i) Mechanically driven assembly of prepolymer solutions into ordered arrays is executed using stretchable wettability patterns; (ii) Photoinitiated free radical polymerization is used to drive crosslinking of the prepolymer into hydrogel networks; and (iii) Reactive moieties of the wettability patterns result in photografting of the microgel structures directly to the support substrate. To demonstrate the pragmatic utility of our approach and the functionality of fixed microgels in liquid phase applications, we designed, fabricated, and operated microgel arrays with stimuli-responsive (e.g., solvothermal and chemical) microactuation functionality inside microfluidic chips. Our strategy overcomes the limitations of existing fabrication techniques that produce poorly adherent materials and require complicated processing schemes. We envision many technologies, for example, liquid phase soft microactuators, stimuli-responsive 3D cell culture platforms, and micro/optofluidic chips, will directly benefit from the reported strategy.

Hydrogel Bioelectronics, Bioacoustics and Biophotonics Xuanhe Zhao; Massachusetts Institute of Technology, United States

Whereas human tissues and organs are mostly soft, wet and bioactive; machines are commonly hard, dry and abiotic. Merging humans and machines is of eminent importance in addressing grand societal challenges in health, sustainability, security, education and joy of living. However, merging humans and machines is also extremely challenging due to their fundamentally contradictory properties. At MIT Zhao Lab, we exploit hydrogels to form long-term, high-efficiency, multi-modal interfaces and merger between humans and machines. In this talk, I will discuss hydrogel bioelectronics, biometrics, and biophotonics. Specifically, I will discuss examples including nonfibrotic hydrogel bioelectrodes, hydrogel ultrasound couplants that enable wearable imaging, and hydrogel optical fibers that replace rigid optical fibers. I will conclude the talk with a vision for future human-machine convergence aided by materials science and artificial intelligence.

A Conductive Hydrogel with Tissue-Mimicking Mechanical and Rapid Self-Healing Properties Damia Mawad and Nhi Tra; University of New South Wales, Australia

The optimal physical and biological characteristics of a scaffold for tissue engineering include biocompatibility, tissue-like mechanical properties, and a hydrated and porous environment. Hydrogels, 3-dimensional crosslinked polymeric networks, feature many of these characteristics, and thereby, are considered excellent scaffolds for tissue engineering [1]. However, scaffolds tailored for electro-responsive tissues such as neural and cardiac tissue would also benefit from electrical conductivity [2], which has been shown to provide enhanced cell growth and differentiation [3]. Other favourable properties include self-healing [4], providing the scaffold with mechanical and electronic stability under strain, and self-adhesion, enabling the placement of the scaffold at the targeted tissue site in a minimally invasive approach [5]. Here, we report the fabrication and characterisation of a conductive, adhesive, and self-healing hydrogel for tissue engineering applications. We fully characterise its physical and electronic properties. We show that the hydrogel is porous, has high swelling ratio and tissue-mimicking mechanical properties, and exhibits very rapid self-healing. We also demonstrate that it is electroactive in physiological buffer and exhibits both ionic and electronic conductivity. Further, its self-adhesion indicates a facile placement on tissues. Coupled together, these properties indicate that the hydrogel with its individual biocompatible components is a suitable scaffold for cell growth and differentiation.

11:00 AM SB04.08.06
Tunable Conductive Hydrogels via Simultaneous Photo-Mediated Polymerization and Crosslinking Dan-My Nguyen, Chun-Yuan Lo, Taewook Choi, Zachary Swain, Yuhang Wu, Charles Dhong and Laure V. Kayser; University of Delaware, United States

Conductive hydrogels, particularly those containing poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS), have gained popularity in bioelectronic interfaces for their mechanical properties close to that of human body and their electrical properties suitable for electrical recording and stimulation. To minimize the invasiveness of conductive hydrogels for bioelectronics, alternative fabrication methods to the common blending approach have been developed, including the photo-gelation of conducting polymers in aqueous environments. However, the photo-catalyzed formation of conductive hydrogels with complex structures is still a challenging task, as the conductive polymers absorb UV light at a similar wavelength, thereby preventing crosslinking. A photo-mediated method for obtaining conductive hydrogels with good conductivity, tunable mechanical properties, and flexibility akin to human body is still lacking.

We developed an approach that combines the simultaneous photo-crosslinking of a polymeric scaffold and the photo-catalyzed polymerization of a conducting polymer under light irradiation. This approach involved the copolymerization of coumarin-containing monomers with sodium styrene sulfonate to yield water-soluble poly(styrene sulfonate-co-coumarin acrylate) (PSS-co-CoumAc). Under UV irradiation (365 nm), a transparent, non-conducting solution of PSS-co-CoumAc, 3,4-ethylenedioxythiophene (EDOT) and ammonium persulfate transforms to a dark blue, electronically conducting hydrogel. The formation of the conductive hydrogel relies on the simultaneous covalent photo-crosslinking of PSS-co-CoumAc and the photo-catalyzed oxidative polymerization of EDOT. The resulting conductive hydrogels exhibit both ionic and electronic conductivity to reach bulk conductivity up to 9.2 S m⁻¹. They possess tunable elastic moduli (around 10 MPa), and display a reasonable strain at break (up to 16%). These photo-generated conductive hydrogels have the potential to enable the formation of 3D networks with controlled microstructure and offer new possibilities for applications in bioelectronics, including surface electromyography (sEMG).

11:15 AM SB04.08.07
The Effect of Multivalent Interactions on the Electrostatic Stability of Poly(N-isopropylacrylamide) Nanogels Xuchen Zhu1, Jiaxin Hou1, Dominic Gray2, Tom O. McDonald2 and Ahu Gu enam Dumanli1; 1University of Manchester, United Kingdom; 2University of Liverpool, United Kingdom

Poly(N-isopropylacrylamide) (PNIPAM) nanogels are promising responsive colloidal particles that can be used in pharmaceutical applications as drug carriers. With an attempt to understand the stability of the PNIPAM-based drug carriers in complex chemical environments, in this work, we investigated the temperature-dependent morphological changes and agglomeration dynamics of PNIPAM nanogels in the presence of mono- and multi-valent cationic electrolytes. Our work provides new insights on the deswelling, flocculation and aggregated morphology of PNIPAM nanogels over a range of electrolyte
concentrations and temperatures revealing the threshold of stability and spontaneous agglomeration states. To complement our results on flocculation of these colloidal particles, we also implemented a Debye screening model that accounts for the shielding effect of multivalent cationic electrolytes on these nanogel systems. We demonstrated that, while the order of deswelling ability of the electrolytes follows the trend $\text{AlCl}_3 > \text{MgCl}_2 > \text{CaCl}_2 > \text{KCl} > \text{NaCl}$, the nanogels reach a minimum hydrodynamic diameter at 10 mM in all electrolyte solutions. The flocculating ability trend and the response time to form aggregates follow a similar order to the deswelling behavior. Interestingly, our statistical analysis on the SEM and TEM images of the PNIPAM nanogels supported our hypothesis on the presence of a shell-like layer around the nanogels with varying density in the electrolyte solutions as compared to those in aqueous medium, and the shell softness of nanogels became harder in multi-valent electrolyte solution than in monovalent system. Furthermore, the retention of the thermo-induced size reversibility for the Na$^+$ and K$^+$ below 10 mM and for the Mg$^{2+}$ and Ca$^{2+}$ below 1 mM indicates the effective destabilization of the electrolyte system with multivalence following the Schulze–Hardy rule, except for Al$^{3+}$. In terms of surface charge screening effect, cations with a higher valence shortened Debye length to a greater extent and this ability was found to be in the order of Al$^{3+} > $ Mg$^{2+} > $ Ca$^{2+} > $ K$^+$ > Na$^+$. 

11:30 AM SB04.08.08

Precision Mechanical Enhancement and Patterning of Hydrogels using Photo-Click Chemistry

Jun H. Park1,2, Patrick J. Grimes1, Henry E. Symons1, Mark S. Workentin1, Sebastien Rochat1,4 and Pierangelo Gobbo1; 1University of Bristol, United Kingdom; 2The University of Western Ontario, Canada; 3University of Trieste, Italy

Hydrogels have vast biomedical applications due to their highly tuneable properties, such as biocompatibility, adhesion, permeability, viscoelasticity, and stiffness. These extraordinarily adaptable materials can be engineered to be stimuli-responsive by carefully selecting the crosslinking monomers or polymers that make up the hydrogels. A stimulus that allows for excellent spatio-temporal control is light, and the translucent nature of hydrogels is complementary to its use in these materials. There are various photoactive moieties that have been incorporated into photo-responsive soft materials, however, there are very few systems utilising photo-click reactions to modify the mechanical properties of hydrogels.

Click chemistry has become an established category of reactions characterized by rapid, selective, high yielding, and atom economic transformations that require minimal purification and can be carried out under mild conditions. In 2004, Bertozzi and coworkers established a bioorthogonal, click reaction called the strain-promoted alkyne-azide cycloaddition (SPAAC) by modifying the copper-assisted alkyne-azide cycloaddition (CuAAC) using strained alkynes.1 These alkynes are more reactive and do not require cytotoxic copper catalysts due to ring strain and bond angle deformation. To circumvent degradation and unwanted side reactivity of the strained alkyne, a cyclopropene-masked dibenzocyclooctyne (hvDIBO) moiety was developed, capable of facile deprotection to the strained alkyne using ultraviolet light.2 The rapid deprotection can be performed in situ and the resulting alkyne is then free to selectively react with an azide via SPAAC. Along with its great stability and simple deprotection, the application of hvDIBO onto soft materials introduces precise spatial control due to the sensitivity of the cyclopropene group to 350 nm UV-A light. In this communication, the fabrication of photo-responsive hydrogels incorporating hvDIBO and azide moieties will be discussed. Photo-click crosslinking reactions between these groups to mechanically strengthen soft materials will be highlighted. The spatio-temporal control of the photo-click reaction was employed to photo-pattern the surface of hydrogels and to study the kinetics of the materials' strengthening. A recently developed methodology designed to study the mechanical properties of soft materials with a micro-indentor was applied. Microindentation analyses were used to spatially characterize viscoelasticity and height profile changes of these hydrogels, and to determine the reaction order kinetics of the photo-click reaction.3 These analyses aim to relate chemical processes with mechanical measurements. Overall, these photo-responsive hydrogels can be readily strengthened and patterned through clean, facile photo-click chemistry, allowing for exciting potential applications in actuation, soft robotics, biointerfacing, and biomimetic materials.

11:45 AM SB04.08.09

DNA-Polymer Hybrids for Responsive and Repeatable Gating in Nanostructures

Kimberley Callaghan1, Shelley Wickham2 and Amanda Ellis1; 1The University of Melbourne, Australia; 2The University of Sydney, Australia

Deoxyribonucleic acid (DNA) is a remarkable molecule, responsible for cellular information storage, exhibiting unique chemical structure and interactions. These properties have enabled its applications in drug delivery, research tools, and novel materials, with many more potential applications as yet unrecognised. This project aims to develop responsive DNA-polymer hybrid materials capable of sensing and responding to environmental stimuli. These materials will capitalise on the dynamic properties of DNA, whilst utilising the favourable material properties of polymeric materials.

In this work, a DNA-polymer hybrid material was designed to form an aqueous hydrogel upon stimuli addition to generate a gate within a DNA-origami nanostructure to form a biological circuit board. The hydrogel was constructed from an acrylamide backbone, with pendant DNA functionality to relate chemical processes with mechanical measurements. Overall, these photo-responsive hydrogels can be readily strengthened and patterned through clean, facile photo-click chemistry, allowing for exciting potential applications in actuation, soft robotics, biointerfacing, and biomimetic materials.

SESSION SB04.09: Hydrogels and Energy

Multifunctional Zwitterionic Hydrogels as a Platform for the Rapid and Simultaneous Elimination of Organic and Inorganic Micropollutants from Water

Devashish Gokhale, Andre F. Hamelberg and Patrick Doyle; Massachusetts Institute of Technology, United States
The removal of micropollutants from water is made difficult by their chemical diversity, low concentrations, and slow uptake by industrial adsorbents. Traditional adsorbents, like activated carbon and ion-exchange resins, are effective in eliminating only specific classes of micropollutants, necessitating the use of multiple unit operations that sequentially treat water. At the same time, slow kinetics require the unit operations to have long residence times and be much larger to effectively eliminate micropollutants. Here we present a new multifunctional zwitterionic porous hydrogel platform for the single-step bulk absorption of both organic and inorganic micropollutants from water. Shifting from traditional surface adsorbents to hydrogels greatly increases the effective functional area, while allowing us to retain the same process-level equipment that has been well studied in the context of conventional adsorbents.

A facile synthesis allows easy functionalization of the hydrogels for eliminating multiple micropollutant classes, while also allowing a measure of selectivity. The hydrogels can be synthesized in several form factors for specific applications, including microparticles for use in packed beds, or tablets for treating water in a glass or canteen. Transport of micropollutants within the hydrogels is sped by ion-conducting zwitterionic backbones, while encapsulated micelles speed the transport of uncharged organics. The zwitterionic hydrogels are shown to remove six chemically diverse micropollutants (including BPA, xenoestrogens, and other organics, and lead and other metals) at least 10 times more rapidly than a commercial activated carbon/ion exchange resin mixture, and 100 times faster than other multifunctional adsorbents reported in literature. Zwitterionic hydrogels treat complex micropolllutant mixtures, including in the presence of background hardness. Lower compressibility, extremely rapid mass transport, and high stability make our materials highly scalable for real world applications. We demonstrate the use of a prototype packed bed filter with a practical residence time and containing zwitterionic hydrogel microparticles to clean highly contaminated water to below regulatory limits for a period of two weeks.

2:00 PM SB04.09.03

**VOCs-Responsive Hydrogel Electrode based on Changes in Chain Mobilities for Multi-Protection**

Youna Kim and Jinkee Hong; Yonsei University, Korea (the Republic of)

Every year, exposure to volatile organic compounds (VOCs) causes fatal accidents including dyspnea and explosions. Personal protection equipment (PPE), such as VOCs sensors to monitor indoor air quality and masks to prevent inhalation of VOCs, is needed to prevent VOC exposure. However, single-functional PPE leads to inconvenience for workers as they must wear multiple pieces of PPE. Therefore, PPE must have the versatility to check not only air quality but also the health condition of workers. PPE combined with wearable electronics could provide multifunctionality with human health monitoring including strain and motion signals and VOCs detection. The electric materials for wearable electronics should be lightweight, flexible, and stretchable. Hydrogels are attracting attention in wearable electronics because of their flexibility, stretchability, and conductivity. However, it has weak mechanical strength and suffered the deterioration of conductivity and shape shrinkage due to moisture evaporation. Furthermore, few studies have controlled the mechanical and electrical properties of hydrogels due to VOCs exposure except for color changes. In order for VOCs-responsive hydrogels to exhibit various VOC-sensing performances, like actuation and electrical changes, an understanding of polymer behavior caused by VOCs must be investigated.

In this study, we designed a VOC-responsive polymer network (VRN), a wearable electronics that can change its mechanical and electrical properties through VOC reaction. Through a solvation effect by different chemical affinity, the inter/intramolecular interaction and arrangement between polymer chains could be controlled. Based on the solvation effect, we considered (1) the control of polymer chain mobility and hydrogen bonding within VRN and (2) the chemical affinity between the VRN and VOCs. To control the VRN network, VRN is composed of polyvinyl alcohol (PVA) as hydrophilic semicrystalline and deep eutectic solvents (DES) as ionic liquids. DES is used as a processing and conductive additive to increase the entangled polymer chains and inhibit hydrogen bonding between polymer chains. After VOCs exposure, the increased hydrogen bonding and chain relaxation energies affected not only mechanical properties but also the electrical resistance of VRN. A relative resistance change ($\Delta R/R_0$) of VRN is increased by 50% when VRN is exposed to VOCs vapor. The peak voltage based on the triboelectric energy generator (TENG) system decreased by 30% due to VOCs exposure. VRN can be applied to PPE in various forms such as fiber and spray coating.

In addition, we studied the VOCs responsive mechanism of polymer chains using rheological and Raman analysis. We expect VRN to propose VOCs-responsive mechanisms and technologies needed to move towards advanced PPE.

SESSION SB04.10: Skin and Tissue-Interfacing Hydrogels I

**Ingestible Electronic Interfaces for Neuromodulation**

Khalil Ramadi1,2,3; 1New York University Abu Dhabi, United Arab Emirates; 2New York University, United States; 3Massachusetts Institute of Technology, United States

Neuromodulation is emerging as a novel approach to treat both neurological and non-neurologic diseases. However, the brain and nervous system are extremely heterogeneous, where cell types and functions vary on scales from sub-millimeters to centimeters. This heterogeneity presents a major obstacle for targeted modulation and interrogation of specific neural structures. This talk will describe non-invasive, ingestible toolkits for high spatial and temporal resolution targeting of neural circuits.

4:00 PM SB04.10.02

**Kinetic Control Dictates the Operation of PEDOT:Lignosulfonate Thin-Films for Biosensing at Physiological pH**

Alex C. Tseng1, Tomasz Rebis2 and Toshiya Sakata1; 1The University of Tokyo, Japan; 2Poznan University of Technology, Poland

Integrating electrically conductive and redox polymers (RPs) is a promising approach for sustainable development of high-performance electrical and electrochemical materials, not only for energy storage but also for bioelectronics and biosensors. Lignosulfonates (LS) exemplify a particularly green materials selection, being low cost and biorenewable, yet readily providing phenolic groups to access (ortho-)quinone redox (i.e., reversible proton coupled electron transfer, PCET) and sulfonic acids for polyanionic doping of conductive polymers (CPs). When blended with oxidatively stable PEDOT (poly(3,4-ethylenedioxythiophene), remarkable specific capacity (170 F.g$^{-1}$) was reported in acidic conditions (0.1 M HClO$_4$) [1] despite significant loading of electrochemically inactive components.

**Kinetic Control Dictates the Operation of PEDOT:Lignosulfonate Thin-Films for Biosensing at Physiological pH**

Alex C. Tseng1, Tomasz Rebis2 and Toshiya Sakata1; 1The University of Tokyo, Japan; 2Poznan University of Technology, Poland

Integrating electrically conductive and redox polymers (RPs) is a promising approach for sustainable development of high-performance electrical and electrochemical materials, not only for energy storage but also for bioelectronics and biosensors. Lignosulfonates (LS) exemplify a particularly green materials selection, being low cost and biorenewable, yet readily providing phenolic groups to access (ortho-)quinone redox (i.e., reversible proton coupled electron transfer, PCET) and sulfonic acids for polyanionic doping of conductive polymers (CPs). When blended with oxidatively stable PEDOT (poly(3,4-ethylenedioxythiophene), remarkable specific capacity (170 F.g$^{-1}$) was reported in acidic conditions (0.1 M HClO$_4$) [1] despite significant loading of electrochemically inactive components.
Besides enhancing pseudocapacitance, quinone PCET may be further leveraged to serve as an electrochemical interface between technological devices and biological catalyst cycles [2]. However, in the mild pH conditions amenable to biology, it is well known that ortho-quinones exhibit limited stability towards redox cycling. Several possible explanations have been offered up over the years, for instance: microstructural changes inhibiting proton diffusion [1,4], dissolution of the redox polymer [3], hydroxylation to higher order polyphenols [2], phase separation of CP and redox polymer [5], and cross-linking by the formation of ether linkages [6] or phenyl dimerization [7].

These varied conclusions are likely views of the same fundamental property of ortho-quinone RPs—filtered through a range of fabrication and experimental conditions—which is that reversible quinone PCET is a kinetically controlled process. Future biological applications, therefore, require an understanding of how and when alternate electrochemical pathways become activated by the scarcity of protons in physiological conditions. Hence, we investigated the pH-dependent behaviour of PEDOT:LS thin-films via in-situ UV-Vis spectroelectrochemistry, charge transport characterization in an electrochemical transistor, and thermodynamic/kinetic analysis by the Laviron method. Our results paint a surprising picture: PEDOT, typically considered to be a "transparent" conductor serving simply as a wire to enhance electron transfer with quinones, is implicated in the formation of strongly bound complexes that appear to stabilize semiquinone radicals. Accordingly, previously observable PEDOT and quinone states are removed in proportion from experimental timescales. This kinetic process is mediated by the effective overpotential vs. PCET as a function of pH and polarization, and thus informs the optimal operating conditions for biosensing using PEDOT:LS.

4:15 PM SB04.10.03
Waterproof and Gel-Free E-Textile Wearable Systems for Exercise Physiology and Maternal Health Junyi Zhao, Chansoo Kim and Chuan Wang
Washington University in St. Louis, United States

Textile-based electronic systems have emerged as a promising platform for noninvasive and comfortable human-machine interfaces in various applications. These systems integrate multiple technological capabilities such as sensing and wireless communications, making them suitable for daily wearables and physiological monitoring in sports and clinical settings. This work presents a novel E-textile system consisting of printed on-textile electrodes and add-on conductive microfibers, enabling gel-free motion-artifact-tolerant recording of multiple physiological signals, including ECG and EMG from both skeletal and smooth muscles. More specifically, the base layout consists of a screen-printed array of poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), and the fluffy microfibers coated with PEDOT:PSS are stacked on top. The vertically oriented hairy microfibers offer exceptional conformal and robust contact with the skin, while the spreading-out microfiber electrodes substantially increase the effective contact area. As a result, the contact impedance between the electrode and skin is significantly reduced, enabling comfortable all-day wear under dry conditions without the need for ionic gels. To ensure the durability and functionality of the textile, a self-assembled monolayer (SAM) of trichloro(1H,1H,2H,2H-perfluorooctyl) silane (PFOS) is vaporized as a superhydrophobic coating. This treatment preserves the natural physical properties of the textile while maintaining the intrinsic conductivity of the electrodes. Additionally, a portable mini-circuitry was designed and manufactured to enable multi-channel recording and wireless communications. These advancements contribute to the seamless integration of the E-textile system into everyday life and expand its potential applications. This study explores the application of E-textile systems in real-life scenarios, including strenuous exercise and clinical studies. The study begins by demonstrating the robustness and stability of the E-textile system using E-jersey and E-shorts during a 15-minute cycling training session. Remarkably, the recorded signals remained clear and free from motion artifacts, even in the presence of intense sweating, with a signal-to-noise ratio of approximately 30 dB. Real-time monitoring also allowed for additional real-time data analysis, including heart rate and muscle output. Next, the waterproof capability of the system was tested by creating an E-swimsuit with electrodes placed facing the swimmer's back. Throughout the 12-minute swimming training, the fully submerged E-swimsuit consistently delivered reliable ECG recordings, demonstrating its resilience and suitability for aquatic environments, even when encountering water flows, showcasing its strength and suitability for aquatic environments. Finally, the textile-based E-patch with electrode arrays was employed in clinical studies to monitor maternal health. Multiple pregnant subjects were monitored, capturing multichannel maternal-ECG and uterine-EMG signals. The multichannel uterine-EMG signals were further processed to generate noninvasive and high-resolution three-dimensional (3D) electromyometrial images, providing unique insights into uterine behavior and offering a means of predicting the risk of potential preterm birth. These findings emphasize the versatility and potential of wearable E-textile systems in a wide range of real-world applications. The E-textile systems are specifically designed for convenient and comfortable wearing, paving the way for professional sports tracking and personalized healthcare advancements.

4:30 PM SB04.10.04
Materials Design of Functional Gels to Realize 3D Artificial Skin Device based on Extrusion-Based 3D Printing Woohyeon Shin1,2, Hui Ju Choi1 and Kyeongwoong Chung1, Kyungpook National University, Korea (the Republic of); 1Ulsan National Institute of Science and Technology, Korea (the Republic of)

Due to unique properties such as biocompatibility, flexibility, and conductivity, hydrogels are widely investigated in various applications, including tissue engineering, E-skin, wearable, and ionic devices. Especially, in the field of E-skin devices, hydrogels are recognized as one of the promising materials due to their flexibility and capability to realize various sensing functionalities. Still, there are challenges that need to be addressed: the structural freedom of devices. Most E-skin devices have been demonstrated with simple structures such as blocks or films due to the demand for complicated multi-layer structures or limitations in the fabrication process. Especially, because body parts with various shapes and movements (e.g., fingers, elbows, and shoulders) are under massive fatigue by strains in various directions and amounts, it is important to realize artificial skin devices with complex 3D structures that are optimized for the targeted body part.

To realize complex 3D structures of hydrogel via extrusion-based 3D printing, we systemically investigated the correlation between materials design and their characteristics including gelation properties, rheological characteristics, and 3D printing processability. From the investigation, we successfully presented the material design window based on the rheological parameter (G’ < 2500 Pa and tan δ < 0.2) to prepare target-oriented 3D structures of the hydrogel via extrusion-based 3D printing. Based on the defined material design window, we successfully prepared functional hydrogel 3D structures to demonstrate novel artificial skin devices that can detect accurate touch points and spontaneously heal mechanical damage. Ring-shaped and fingertip-shaped artificial skin devices have been successfully prepared to fit the finger model. Furthermore, like human skin, artificial skin devices provide accurate location information for arbitrary touch points without complex device fabrication or data processing.

In hydrogel-based E-skin devices, it is also important to address the inherent drying and freezing problems of hydrogel for practical application. As an approach to these problems, we presented organohydrogel systems via solvent displacement and investigated the correlation between soluble system design and hydration.
and the material properties of organohydrogels. By investigating the rheological properties and ion conductivity of the gels, we provided insights for preparing optimal organohydrogels for various processes and applications. Based on the defined solvent system design, we prepared organohydrogels that show excellent drying resistance even over 1,000 hours and exhibit superior freezing resistance by showing no phase transition down to -60°C. Furthermore, the 3D artificial skin devices are demonstrated based on the organohydrogels, and the artificial skin devices successfully provide the exact position of touchpoints over time and show excellent operation capability even at temperatures below 0°C without losing flexibility.

SESSION SB04.11: Skin and Tissue-Interfacing Hydrogels II
Session Chairs: Anna-Maria Papp, Alexandra Rutz, Christina Tringides and Shining Zhang
Thursday Morning, November 30, 2023
Hynes, Level 1, Room 103

9:00 AM SB04.11.01
Electrically Induced Shape Memory Hydrogels in Biomedical Applications. Georgios Mikaelf, Arjan Sall, Zoe Schofeld, Atif Shahzad, Patricia P. Esteban and Liam Grover; Healthcare and Technologies Institute, United Kingdom

Here we report the development of a novel shape memory hydrogel that changes shape on exposure to an electrical field. This material has been designed to enable the minimally invasive administration of a novel sensor system to monitor real-time changes in blood pressure. The hydrogel will encapsulate a sensor coil and protect against biological interference during measurement. Real-time blood pressure measurement will enable the diagnosis and monitoring of conditions as hypertension and cardiomyopathy, which place a significant financial burden on healthcare systems worldwide.

Polyelectrolyte (PE) hydrogels can exhibit a shape memory effect upon exposure to an electrical current, caused by ions that sit within its structure. PE gels are naturally found throughout the body where they are often associated with oppositely charged molecules. One such example is in the aggrecan, which interacts strongly with collagen in cartilage. PE hydrogels have already been used extensively as biomaterials. Their structure has made them ideal scaffolds for tissue engineering, novel drug delivery systems, soft robots particularly in artificial muscle and actuators, smart fabrics, and implantations for minimally invasive surgeries.

Since hydrogels can exhibit poor mechanical properties, we have made efforts to reinforce the shape-memory polymer structure. We explored 2 different formulations have been synthesised containing the smart material 2-acrylamido-2-methylpropanesulfonic acid (AMPS) and either Polyethylene Glycol Diacrylate (PEGDA) or acrylamide. The mechanical performance and chemical structures of these materials have been evaluated. Finally shape memory testing has been performed to determine the effect of curing on the material’s ability to change shape.

Further testing will include direct contact cytotoxicity testing to determine cell viability as well as surface modification whereby protein adsorption will be implemented to fix the device and so reduce migration upon implantation.

9:15 AM DISCUSSION TIME

9:30 AM ~SB04.11.03
Healable and Stretchable Conducting Hydrogels for Epidermal Electronics Fabio Cicoira; Ecole Polytechnique de Montreal, Canada

Soft and conductive materials with long-term stability have attracted interests in the field of epidermal bioelectronics due to their conformal contacts with skin and the ability to acquire bio-signals for long-term use. Applications include monitoring of vital signs (e.g., electrocardiography (ECG), electromyography (EMG), and electroencephalography (EEG)), measurement of body temperature and blood pressure and detection of analytes in bodily fluids. ECG, EMG, and EEG are typically achieved with metal (ground strap, bar, or cup) or, in most cases, Ag/AgCl gel electrodes. However, rigid metal electrodes are unable to withstand bending or stretching, which can result in skin damage or irritation and lead to high signals noise, whereas Ag/AgCl gel electrodes can lead to skin irritation due to strong adhesion on the skin and are prone to signal degradation in long-term use due to the drying of the gel. Therefore, there is a strong demand for soft conductive electronics that can form conformal interfaces with biological tissues for long-term use without leading to skin damage and irritation.

Various types of conductive soft materials have been used for on-skin electronics, in form of films, bio-inspired adhesives, fabrics, and hydrogels. Conductive hydrogels are promising candidates for epidermal electronics because of their conformal contact with the skin, high water content (70-99%, similar to tissues), ease of processing, tunable electrical and mechanical properties, and biocompatibility. Conductive hydrogels may be obtained from pure conductive polymers, e.g., poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS), polypyrrole (PPy), or polyaniline (PANI)), and graphene) with polymers, such as poly(vinyl alcohol) (PVA), poly(acrylic acid) (PAA), poly(acrylamide) (PAAM), or polyurethane (PU). A hydrogel prepared by mixing a PEDOT:PSS aqueous suspension with 0.1 M H2SO4 exhibited a conductivity of ~9 S/cm after further concentrated sulfuric acid.

Diacrylate (PEGDA) or acrylamide. The mechanical performance and chemical structures of these materials have been evaluated. Finally shape memory testing has been performed to determine the effect of curing on the material’s ability to change shape.

Since hydrogels can exhibit poor mechanical properties, we have made efforts to reinforce the shape-memory polymer structure. We explored 2 different formulations have been synthesised containing the smart material 2-acrylamido-2-methylpropanesulfonic acid (AMPS) and either Polyethylene Glycol Diacrylate (PEGDA) or acrylamide. The mechanical performance and chemical structures of these materials have been evaluated. Finally shape memory testing has been performed to determine the effect of curing on the material’s ability to change shape.

9:45 AM BREAK
Leveraging the bioelectrocatalytic machinery of living organisms for in-vivo fabrication of functional bioelectronic interfaces enables seamless integration of devices in tissue and formation of biohybrid systems. Previously we have demonstrated that plants can polymerize conjugated oligomers in-vivo forming conductors within their structure. We showed that the polymerization is enzymatically catalyzed by endogenous peroxidases, and we developed a series of conjugated oligomers that can be enzymatically polymerized in physiological conditions. The conjugated polyelectrolytes integrate within the plant cell wall structure adding electronic functionality into the plant that is then explored for energy storage. Recently we demonstrated intact plants with electronic roots that continue to grow enabling plant-biohybrid systems that maintain fully their biological processes. The electronic roots are used to build supercapacitors and biolayered hybrid circuits to power low power electrochemical devices. Furthermore, we have extended this concept into an animal model system. We demonstrated that Hydra, an invertebrate animal, can polymerize intracellularly conjugated oligomers in cells that expresses peroxidase activity. The conjugated polymer forms electronically conducting and electrochemically active domains in the μm range integrated within the hydra tissue. Our work paves the way for self-organized electronics in plant and animal tissue for modulating biological functions and in-vivo bio-fabrication of hybrid functional materials and devices.

11:00 AM SB04.11.05
Hydrogel for Multiplexed Multiscale Imaging and Phenotyping of the Human-Organ-Scale Biological Tissues
Jayvak Park1, Ji Wang1, Webster Guan1, Lee Kamentsky1, Nicholas Evans1, Jeffrey Stirman2, Xinyi Gu3, Chuanshi Zhao1, Minyoung Kim1, Seo Woo Cho1, Clover Su-Arcaro4, Xuyuan Tian5, Dae Hee Yun1, C. Dirk Keene3, Patrick Hof4, Matthew Frosch5 and Kwanghun Chung1; 1Massachusetts Institute of Technology, United States; 2LifeCanvas Technologies, United States; 3University of Washington, United States; 4ealn School of Medicine at Mount Sinai, United States; 5Harvard Medical School, United States

Understanding the intricate chemooarchitectural details and regional-specific functions of the human brain poses a formidable challenge in holistic brain imaging and phenotyping. While recent advancements in tissue clearing and labeling techniques have made significant strides, the lack of scalability, thermos-mechanical robustness of tissues, imaging resolution, and cost-effective immunolabeling protocols limit their applicability in multiplexed human brain mapping at various scales. In this study, we present a pioneering hydrogel-based tissue processing technology called mELAST, which transforms biological tissues into soft, tough-elastic, reversibly expandable tissue-hydrogel hybrids, in tandem with mechanical devices and chemicals. Leveraging mELAST, we achieved multi-round immunolabeling and multiscale expansion imaging of volumetric human brain tissues, enabling the comprehensive capture of cytoarchitectures, microenvironment, and synapses within the human brain. We applied the mELAST pipeline to conduct a comparative study of Alzheimer's disease in the human brain, further unraveling neuroscientific enigmas. With mELAST, we anticipate a significant advancement in our ability to navigate deep within the human brain afflicted by pathologies, shedding light on crucial neuroscientific challenges.

11:15 AM SB04.11.07
Intraoral Hydrogel-Graphene Biosensors for In-Situ Detection of TNF-α in Human Saliva
Shaoting Lin; Michigan State University, United States

Technologies that enable in-situ monitoring of biomarkers in human saliva in oral cavities are highly desirable for timely diagnosis, early intervention, and personized treatment of oral diseases. Existing efforts have been mostly focused on flexible electronics made of rigid materials, which inevitably suffer significant challenges in interfacing soft tissues due to their contradictory properties. Hydrogels, polymer networks infiltrated with water, share similar mechanical and physiological properties as biological tissues, regarded as an ideal material candidate to form long-term, high-efficacy, multi-modal interfaces between electronic components and biological systems. In particular, the recent developments of tissue-adhesive hydrogel patches have shown great success in forming rapid and tough adhesion between wet tissues and electronic devices in various organs, but these efforts have not been implemented in oral cavities. In this work, we focus on developing an intraoral hydrogel-graphene biosensor that can achieve highly sensitive, specific, and durable detection of human tumor necrosis factor-α (TNF-α) in human saliva. The design of hydrogel-graphene biosensor is based on an integration of selective-permeable hydrogel and graphene-based sensing probe, which enables sensitive and specific detection of low-concentration TNF-α in human saliva. This work will not only hold the promise of enabling rapid diagnosis of conditions such as recurrent aphthous stomatitis (RAS), periodontal disease, and oral cancer, but also facilitate the planning of medical treatment policies and evaluation of treatment efficacy.

11:30 AM SB04.11.08
A Damage-Mapping, Self-Healing Electronic Skin for Surgical Simulation Training
Samuel E. Root and Zhenan Bao; Stanford University, United States

Modern facilities for surgical education make use of inanimate models to simulate surgical tasks. Such models provide trainees with the opportunity to practice and receive feedback on the procedural and motor skills required to perform complex surgeries with expert-level competency. Existing models for surgical simulation rely heavily upon thermoset polymers such as silicones or hydrogels, which deteriorate after single or repeated use. Such disposable materials are expensive—especially those with physically realistic properties—and incur a prohibitive cost for training programs, limiting opportunities for students to practice with high fidelity models. Moreover, evaluating the performance of trainees on surgical tasks is difficult and requires direct observation by an expert or the use of motion tracking software. There is a need to develop surgical simulation models with realistic physical properties and functional capabilities mimicking that of living tissue including, i) the ability to heal from damage, and ii) the ability to sense and transduce mechanical stimuli including forces, pressures, rates and depths of incisions and punctures. Over the past decade, advances in the science of dynamic polymeric materials (i.e., polymers that are cross-linked with reversible bonds, such as hydrogen bonds) have enabled the molecular design and device integration of stretchable, conductive, self-healing composites. We have recently reported a strategy for improving the functional self-healing efficacy of multi-layer laminate composites through the molecular design of a pair of dynamic polymers with immiscible polymer backbones (poly(dimethylsiloxane) and poly(propylene glycol)) but identical dynamic bonding units (a mixture of bisurea-based hydrogen bonding units). These polymers have a strong, adhesive but thermodynamically restricted interface, which results in an autonomous alignment and healing phenomenon, whereby polymer chains directionally diffuse to minimize the interfacial free energy when multi-layered stacks are damaged and misaligned. In this presentation, I will discuss our current efforts building upon this work towards the design of a damage-mapping electronic skin capable of sensing processes such as punctures with needles, scalpels, or sutures—and self-healing to undergo many operational cycles. We have developed a scalable composting, compression-molding, and layer-based assembly processes for fabricating multi-layer soft electronic films. We have implemented a voltage-based sensing mechanism for mapping the location and depth of needle punctures and surgical incisions. Finally, we demonstrate how these electronic skins can be integrated with surgical simulation technology, including rolling the films into vein-like tubes capable of sensing needle punctures for intravenous access training. Overall, we propose that there are many opportunities for bio-mimetic functional materials and device design within surgical simulation technology, including hybrid self-healing hydrogel-elastomer devices.
Applications are presented. These efforts are expected to address unmet clinical challenges.

Host–Guest Chemistry for The Design of Functional Polymer–Nanoparticle Hydrogels

Antonino Biagio

Tuning the Surface Chemistry of 3D Graphene Hydrogels by Covalent Functionalization: A Flow Chemistry Approach

2:30 PM

Structures were investigated by Cyclic Voltammetry (CV), Differential Pulse Voltammetry (DPV) and Electrochemical Impedance Spectroscopy (EIS), XPS), Scanning Electron Microscopy (SEM) and BET. In addition, the electrochemical performances of the 3D porous graphene hydrogel and aerogel interfacing and they reduce the sensing efficiency and therapeutic efficacy of the soft bioelectronics. Composites of polymers, nanomaterials, and hydrogels are particularly promising material candidates for solving such issues and achieving ideal biotic-abiotic interface. In this talk, the unique strategies in the synthesis of conductive or injectable hydrogels, their seamless integration with soft bioelectronics, and wearable or implantable device applications are presented. These efforts are expected to address unmet clinical challenges.

2:15 PM

Recent advances in soft electronics have attracted great attention due to its potential applications to personalized health-monitoring and point-of-care devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations and drug delivery in feedback therapies. Ultra-flexible and stretchable bioelectronic devices have a low system modulus and intrinsic softness, and have a potential to solve these issues. However, locally incomplete contacts are still found in skin-device interfacing and they reduce the sensing efficiency and therapeutic efficacy of the soft bioelectronics. Composites of polymers, nanomaterials, and hydrogels are particularly promising material candidates for solving such issues and achieving ideal biotic-abiotic interface. In this talk, the unique strategies in the synthesis of conductive or injectable hydrogels, their seamless integration with soft bioelectronics, and wearable or implantable device applications are presented. These efforts are expected to address unmet clinical challenges.

2:00 PM

In this work, two approaches based on cyclodextrin (CD) host–guest interactions were used for the design of PNP hydrogels. In a first approach, α-cyclodextrin (αCD) was added to a cellulose and guest harboring block copolymer (PEG-PLA) NPs were synthesized. The presence of the photoresponsive host–guest complex resulted in reversible gelation of the hydrogel via illumination at various wavelengths of light. This work demonstrates how supramolecular interactions can be used to reversibly gelation of the hydrogel via illumination at various wavelengths of light. This work demonstrates how supramolecular interactions can be used to

SYMPOSIUM SB05
Capable of modulating the behavior of excitable cells and tissues via light. In summary, this presentation will discuss the engineering of optoelectronic peptides that form controllable supramolecular structures on surfaces and in solution. These peptides can be directed to form 1-D nanostructures on the surface nanofeatures. These peptide-modified surfaces present bioadhesive cues towards achieving cellular anisotropy, therefore providing a potential opportunity for directional stimulation of excitable cells. By having the capability to generate photoinduced currents, substrates bearing these assembled optoelectronic peptides can be accessed through a carbodiimide-fueled approach that instructs their self-assembly and hydrolysis-induced disassembly. On polymeric surfaces that have access to aqueous solutions and on nanostructured polymeric surfaces. In solution, the supramolecular assembly and disassembly processes of the designed peptides can be interrogated, and the anisotropic topography and have chemically analogous \( \pi \)-conjugated chains as the central core of our peptide monomers, the resulting self-assembled \( \pi \)-conjugated peptides with controllable assembly-disassembly behavior in aqueous solutions and directed anisotropic assembly on surfaces for biomimetic templating and have chemically analogous \( \pi \)-conjugated units offer the possibility of light-controlled behavior of magnetic nanomaterials. Magnetic fields offer unprecedented access to signaling processes deep within the body due to the low conductivity and negligible magnetic permeability of biological matter. Magnetic fields with a diversity of spatio-temporal characteristics can be transduced into stimuli perceived by biological receptors via tailored magnetic nanomaterials enabling remote modulation of cell function. In this talk, I will highlight physical principles guiding magnetic nanomaterials design with the goal of transducing magnetic fields into mechanical, thermal, chemical, and electric stimuli. I will further describe how these magnetic nanomaterials, coupled with biological mediators, can enable wireless modulation of cell signaling, organ physiology, and animal behavior. Finally, I will discuss strategies to deliver magnetic nanomaterials to specific cells and organs in the body laying a foundation for minimally invasive implant-free and surgery-free bioelectronic interfaces.

11:00 AM SB05.01.02
**Directed Assembly Behavior of Optoelectronic Peptide Biomaterials for Excitable Systems**
*Ze-Fan Yao, Yuyao Kuang, Emil Lundqvist and Herdeline Ann Ardoña*; University of California, Irvine, United States

Organic conjugated materials are known to have molecular design-tunable optoelectronic properties while exhibiting intrinsic flexibility and the ability to form soft networks, which are suitable for biological interfacing. To better utilize these properties towards interfacing with living systems, more efforts are required to render biocompatibility and other physiologically relevant characteristics to these materials. Here, we design, synthesize, and characterize \( \pi \)-conjugated peptides with controllable assembly-disassembly behavior in aqueous solutions and directed anisotropic assembly on surfaces for biomimetic templating. The peptideic segments serve as a biomimetic template for the stimuli-driven self-assembly process of \( \pi \)-conjugated monomers in aqueous solutions and on nanostructured polymeric surfaces. In solution, the supramolecular assembly and disassembly processes of the designed peptides can be accessed through a carbodiimide-fueled approach that instructs their self-assembly and hydrolysis-induced disassembly. On polymeric surfaces that have anisotropic topography and have chemically analogous \( \pi \)-conjugated chains as the central core of our peptide monomers, the resulting self-assembled optoelectronic peptides can be directed to form 1-D nanostructures on the surface nanofeatures. These peptide-modified surfaces present bioadhesive cues towards achieving cellular anisotropy, therefore providing a potential opportunity for directional stimulation of excitable cells. By having the capability to generate photoinduced currents, substrates bearing these assembled optoelectronic \( \pi \)-conjugated units offer the possibility of light-controlled behavior of excitable cells. In summary, this presentation will discuss the engineering of optoelectronic peptides that form controllable supramolecular structures capable of modulating the behavior of excitable cells and tissues via light.

11:10 AM SB05.01.03
**Bioadhesive Polymer Semiconductors and Transistors for Intimate Biointerfaces**
*Nan Li and Sihong Wang*; University of Chicago, United States

Integrating biocompatible electronic devices with living biological tissues is emerging as a highly promising avenue for achieving the real-time measurement of biological signals with high spatiotemporal resolutions for biological studies and health monitoring. Polymer semiconductors-based transistors (e.g., organic electrochemical transistors (OECTs)) as an advanced sensing device, are highly desired for direct electrical biointerfacing due to their low operation voltage, mixed electron-ion conduction, and high sensitivity. To interface with wet and dynamically moving tissues, developing intrinsically bioadhesive polymer semiconductors can significantly improve the devices’ conformability on tissue surfaces and signal acquisition sensitivity.

In this talk, I will present the design of a BioAdhesive polymer SemiConductor (BASC) film by creating a rationally designed polymer network with interpenetrating semiconducting polymers and adhesive brush polymers. The BASC films can form robust and rapid adhesion with bio-tissues (e.g., heart, lung, spleen) under gentle pressure, while providing high charge-carrier mobility. We further fabricate a bioadhesive OECT with the BASC as the active channel and demonstrate its use for reliably monitoring electrophysiological signals on an isolated rat heart and in vivo muscles.

11:30 AM SB05.01.04
**MXene Hydrogels as Soft Bioelectronic Interfaces**
*Raghav Garg1, Stefano Ippolito2, Spencer R. Averbeck1, Yury Gogotsi2 and Flavia Vitale3*;
1University of Pennsylvania, United States; 2Drexel University, United States
Biological tissues and organs, such as the cardiac tissue and the brain, are mechanically soft and exhibit viscoelastic behavior. Real-time diagnosis and treatment of diseases of such electrically active tissues requires continuous electrophysiological monitoring and stimulation. This has been achieved through implantable bioelectronic platforms. However, current implantable bioelectronics are composed of mechanically rigid materials such as metals (Au, Pt), metal oxides (IrOx), and semiconductors (Si). The large mechanical mismatch between the target tissues and the bioelectronics interfaces has been a bottleneck for chronic clinical applications. Although metal nanoparticles and carbon nanomaterials have been leveraged to fabricate electrically conductive hydrogel bioelectronics, they are limited by their electrochemical functionality, biocompatibility, and processability.

Here we leverage safe liquid-phase processing of two-dimensional TiC2Tx MXene to fabricate MXene-based hydrogels for implantable bioelectronic interfaces. We achieve a high-density network of MXene flakes by directly cross-linking individual MXene flakes using transition metal ions. The matrix-free structure of the MXene hydrogels endows them with high electrical conductivity and low electrochemical impedances, thus facilitating their integration into soft bioelectronics for electrophysiological recordings with high signal-to-noise ratio. The capacitive nature of TiC2Tx further allows the hydrogels to exhibit high charge injection capacities for safe delivery of electrical stimulation to target tissues. Finally, we demonstrate modulation of the mechanical properties of the packaged hydrogels by altering the composition and degree of cross-linking of the alginate-based insulation. Our results underscore the application of MXene-based soft bioelectronics in studying neural function and disease pathologies, as well as developing neuromodulation paradigms.

11:45 AM SB05.01.05
Optimizing the Pore Structure of 3D Conducting Polymer Scaffolds for Bioelectronic Devices Rachana Acharva, Douglas van Niekerk, Aimee Withers and Roisin Owens, University of Cambridge, United Kingdom

The integration of 3D tissue-engineered microporous scaffolds based on conductive polymers (CPs) into bioelectronic devices have led to the possibility of dynamic monitoring of biological phenomena through electrical measurements. The 3D structure and morphology of the porous scaffolds mimics the topographical features of human physiology, while the electrically conductive nature of the polymers allows for electrical measurements for label-free monitoring and live-sensing of cells. 3D scaffolds based on the polymer poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) prepared by the freeze drying process have been the focus of many studies and well integrated into bioelectronic devices such as electrochemical transistors[2].

The freeze-drying process involves freezing the aqueous dispersion of the conducting polymer, followed by the sublimation of the ice crystals by lowering the pressure in the system, leaving behind a porous network of the conducting polymer. This porous network is representative of the physiological tissue structure, making the ice nucleation and crystallization a crucial component of the scaffold fabrication process. A deeper understanding of the freeze drying process and a higher degree of control on the freezing parameters will help establish the correlation between the material properties of the scaffolds and the biomimetic tissue engineering requirements for optimum cell culture platforms.

Three different freeze drying protocols were employed, with a pre-cooling treatment used before the freeze-drying process. Two different pre-cooling rates, 0.5 °C/min and 1 °C/min along with a control protocol with no treatment were designed to prepare different scaffold types. Within each protocol, the freezing rate was varied between 0.2 °C/min and 1 °C/min and the thermal profile of the aqueous dispersion was recorded during the entire fabrication process.

The influence of the different protocols and freezing rates on the pore size and structure was examined by scanning electron microscopy and micro-computed tomography. Pores of circular and elongated ellipses were observed by SEM and a pore size distribution (the longest dimension of the ellipsoid) between 80 µm and 220 µm was measured. It was observed that a higher cooling rate generated larger pores with more elongated pore morphology as well as a wider pore size distribution. The pre-cooling treatment with 0.5 °C/min cooling rate was most useful in generating scaffolds with a more homogenous pore structure and a pore size of approximately 100 µm.

The different scaffolds were incorporated into electronic devices such as transmembrane electrodes to characterize the electrical properties and evaluate the reproducibility of the scaffolds prior to cell culture. No significant change in the electrophysiological impedance spectra was observed despite the large difference in porosity of the different scaffolds. In addition, the different scaffolds were used to host and monitor biological cells like fibroblasts and endothelial cells. Cell growth and proliferation in the different scaffolds was also monitored by immunofluorescence microscopy. It was observed that a pre-cooling protocol and a freezing rate of 0.5°C/min helps to fabricate scaffolds with an optimized, uniform and homogenous pore morphology. This design protocol is highly beneficial in reducing the random artifacts of the nucleation process and generating scaffolds highly conducive to cell growth and survival and to create a versatile bioelectronic platform for studying in-vitro cell models.

3D Bioelectronic Models of Gut, Brain and Lung Roisin Owens: University of Cambridge, United Kingdom

Physiologically relevant in vitro human models are urgently required to bridge the gap between over-simplified 2D in vitro models and ill-suited animal models, for drug discovery and disease modelling. Bringing together principles of materials science, tissue engineering, 3D cell biology and bioelectronics, we are building advanced models of the gut, brain (neurovascular unit) and the lung. In the case of the gut and NVU, our aim is to elucidate the role of microbiota in the gut-brain axis communication, a particularly challenging system to model with lab animals. In the case of the lung, our interest is in modelling the air-liquid interface to more accurately study lung disease. Our models are based on the use of electroactive scaffolds which can host tissues, but also monitor their formation, and later their status when challenged with a pathogen or target molecule. Our strategy is to build a stromal layer with the scaffold and layer epithelial or endothelial models on top, preserving tissue stratification. Our most recent work has adapted these scaffolds to the well-known Transwell format, to allowed continued access to both apical and basal aspects. As well as traditional readouts such as immunofluorescence, or biochemical analyses of media, our continuous electrical monitoring readouts from our electroactive scaffolds gives us real-time data on the tissue health.

As humans, our perception of the world relies on the function of our powerful sensory organs. Olfaction in particular is well-documented as a biosensing modality across species, as dogs and insects have been shown to detect the early onset of disease or even harmful substances as part of airport security protocols. As specific ligands bind to their corresponding sensory receptors, they trigger a unique combination of activated neurons that are interpreted downstream. By merging interspecies sensory systems with bioelectronics, we can create a novel biosensor and simulate sensory perception on a chip. Whilst previous platforms have leveraged gas sensors for compound detection, our system instead employs carefully selected mammalian and insect proteins to replicate and enhance sensory perception. By using innovative protein engineering techniques and deliberately designed electronic devices, we have created a fully customizable approach to sensory perception in a way that carefully combines nature's original biosensors with synthetic biology. This unique platform provides a novel approach to the conventional biosensor with immense potential for security and medical applications.

Deformable Composites: From Photostimulation to Living Bioelectronics [Boopi Tian; University of Chicago, United States]

The field of electronic and photonic biointerfaces continues to evolve, with flexible and living composites playing a key role in advancing the development of multifunctional devices such as sensors and modulators. Our research focuses on creating non-genetic approaches for biological modulation and sensing across different length scales. This presentation will provide insights into some of our recent projects. This includes our work related to photostimulation within clinical environments. We have made new progress in the development of a nanoporous/non-porous heterojunction, exemplifying the level of precision and control achievable in bioelectronics. We have also developed a granular system aimed at focal adhesion in bioelectronics and other interfaces for regenerative medicine. Additionally, we have begun exploring the integration of living cells with wearable bioelectronic devices, a new direction within the sphere of living bioelectronics. Our primary goal is to transition these basic studies of modulation tools into applicable clinical practices, with the potential to influence therapeutic strategies and improve patient outcomes. As I conclude the presentation, I will highlight our future research directions. These are designed to further contribute to the extensive field of biological modulation and sensing, with a specific focus on applications that could have a significant impact in the clinical setting.

3:45 PM SB05.02.05
Tissue-Embedded 3D Stretchable Nanoelectronics for Multimodal Charting of the Human Stem Cell-Derived Organoids [Ren Liu, Qiang Li, Zuwan Lin, Xin Tang and Jia Liu; Harvard University, United States]

The development of human induced pluripotent stem cells (hiPSCs) technology has revolutionized the field of disease modeling and holds immense potential for personalized regenerative cell therapies. A comprehensive understanding of stem cell-derived tissues and organoids requires advanced multimodal techniques capable of capturing cell functions with high spatiotemporal resolution in three-dimensional (3D) tissues, profiling numerous genes in recorded cells, and performing multimodal computational analysis. However, none of the existing technologies fulfill these requirements.

In this presentation, I will begin by introducing the development of soft, stretchable mesh nanoelectronics that mimic the physical and mechanical properties of biological tissues. We can distribute these stretchable tissue-like bioelectronics throughout the entire 3D organoids by their organogenetic processes. By establishing seamless and noninvasive connections between electrodes and cells, we can achieve long-term stable electrical contacts with progenitor or stem cells, capturing the emergence of single-cell action potentials. This facilitates continuous, long-term recording from various types of 3D organoids during their development.

Next, I will demonstrate how this technique enables the long-term stable mapping of human 3D cardiac microtissues for the characterization of their functional maturation. Specifically, I will discuss an example in which stretchable mesh electronics were embedded with hiPSC-derived cardiomyocytes (hiPSC-CMs) and hiPSC-derived endothelial cells (hiPSC-ECs). By developing machine learning-based pseudotime trajectory inference of the long-term cardiomyocyte electrical signals from multiple samples, we can quantify the electrical phenotypic transition path during development. Our results showed that hiPSC-ECs drive remarkable hiPSC-CM electrical maturation via multiple intercellular pathways.

Finally, I will discuss our efforts to combine in situ single-cell RNA sequencing with flexible bioelectronics, a methodology we term “in situ electro-seq”. This technique allows us to link cell molecular gene expression with electrical activities. Specifically, I will discuss how in situ electro-seq enables systematic and simultaneous investigation of single-cell electrophysiology and gene expression across hiPSC-CMs during their development. Additionally, I will discuss the potential of using in situ electro-seq to create spatiotemporal multimodal maps in electrogentic tissues, thereby potentializing the discovery of cell types and gene programs responsible for electrophysiological function and dysfunction.

4:00 PM SB05.02.06
Bioelectronic In Vitro Cell Membrane Models for Investigating Intestinal Host-Pathogen Interactions [Rreece McCoy1, Jeremy Treiber2, Alberto Salleo2, George G. Malliaras1 and Roisin Owens1; 1University of Cambridge, United Kingdom; 2Stanford University, United States]

The early stage of pathogen-related diseases often depend on the initial interaction between the pathogen, or its secretions, and the host cell membrane. Interfacing cells with electronics allows for quantitative real time monitoring of barrier integrity. Organic electronics coupled with electrochemical impedance spectroscopy (EIS) are used to probe host-pathogen interactions directly with enterocyte plasma membranes using native supported lipid bilayers which are representative of apical and basolateral surfaces of the intestinal epithelium.

PEDOT:PSS is used in both microfabricated planar electrode arrays which can support the formation of supported lipid bilayers. The Caco-2 adenocarcinoma cell line is used to develop a model that reflects in vivo conditions. Cells are differentiated and polarised for 21 days and chemical vesiculation induced to extracted small membrane vesicle biopsies of the apical and basolateral surfaces before being used to form supported lipid bilayers. Fluorescence microscopy is employed to confirm bilayer fluidity with fluorescence recovery after photobleaching (FRAP). EIS is used to determine the
impedance of the bilayer across frequencies and models are fit to the data to extract resistance and capacitance values. The ADAM10-receptor mediated effects of Staphylococcus aureus alpha hemolysin toxin is demonstrated and found to be highly dependent on the epithelial membrane surface it encounters. The presence on the receptor in the apical bilayer potentiates the effect of alpha hemolysin leading to a pronounced decrease in membrane resistance compared to the basolateral bilayer.

Organic bioelectronics are used to monitor bilayer and barrier impairment caused by pathogens and their secretions. EIS coupled with conventional biological techniques can be used help elucidate pathogen invasion mechanisms and aid discovery of potential therapeutics.

Multiscale Material Engineering of a Conductive Polymer/Liquid Metal Platform for Stretchable and Biostable Human-Machine-Interface Bioelectronic Application
Huanan Zhang; University of Utah, United States

Liquid-metal-based stretchable bioelectronics can conform to the dynamic movements of tissues and enable human-interactive biosensors to monitor various physiologic parameters. However, the fluidic nature, surface oxidation, and low biostability of the liquid metals have limited the long-term use of bioelectronics. Here we have developed a rationally designed material engineering approach to overcome these challenges in liquid metal bioelectronics. To our knowledge, this is the first demonstration of stretchable, leak-free, and highly conductive gallium-based bioelectronic devices with exceptional biostability and electrochemical properties. We first utilized unique gallium oxide properties to create 3D microscale wrinkled structures on the gallium surface. Then, gold nanoparticles and biostable poly(3,4-ethylenedioxythiophene) were successively deposited on the wrinkled liquid metal surface. We demonstrated this multilayer encapsulation material could conform to the stretching deformation and showed excellent environmental stabilities while maintaining high electrical properties. Electromyographic measurements were used to evaluate the bioelectrical performance of the stretchable electronics, and the results demonstrated the encapsulated liquid metal device could outperform bare liquid metal devices. Finally, a sensory feedback study demonstrated our liquid metal bioelectronic device could record precise physiologic signals to control robots for mimicking dexterous hand gestures. This study opens the possibility of chronic liquid-metal-based stretchable bioelectronics.

4:30 PM SB05.02.08
Conformable Multimodal Sensory Facemask for Decoding Biological and Environmental Signals
Jin-Hoon Kim and Canan Dagdeviren; Massachusetts Institute of Technology, United States

Facemasks are considered to be a key instrument in reducing exposure to viruses and other environmental hazards such as air pollution. Current wearable electronics applicable to the facemask have been designed only to monitor biological information such as breathing patterns. However, it remains difficult for the public to assess the status of their facemasks with regard to wearing habits and fit quality. In this work, we developed a widely-deployable, conformable, miniaturized sensory interface, which seamlessly attaches onto the internal side of any user-supplied facemask without compromising fit and protection quality, along with a user-interface capable of interpreting a participant’s mask-wearing behavior under various use-case scenarios. Multimodal signals from a variety of sensors were wirelessly transmitted to a server through a custom-made mobile app. Based on the collected data, it was shown that various biological signals related to the signature of infectious diseases could be monitored while determining the fit status of the facemask without using a conventional mask fit test. A machine learning algorithm was further used to enable the reliable decoding of the facemask position. The novelty of this work lies not only in the system integration, but also in the development of devices which provide real-time mask fit and position analysis, which may benefit medical institutes, industries and the general public in selecting proper facemasks and maintaining a desired mask fit. Additionally, our work could be deployed to multidisciplinary studies such as human behavioral and social sciences to analyze the fit change in real world situations.

4:45 PM SB05.03.08
Paper-Based Wearable Patches for Real-Time, Quantitative Lactate and Temperature Monitoring
Elisabetta Ruggeri1, Giusy Matzeu1, Giulia Guidetti1, Andrea Vergine1, Marco Lo Presti1, Giuseppe De Nicolao2 and Fiorenzo Omenetto1; 1Tufts University, United States; 2Università degli Studi di Pavia, Italy

Wearable sensors are establishing themselves as options for real-time continuous health monitoring in health care and wellness. In particular, the use of flexible interfaces that conform to the skin have attracted considerable interest for the extraction of meaningful physiological and pathological information through continuous and painless sampling and analysis of biofluids. In contrast, conventional techniques for biomarkers analysis are difficult to adapt to real-time portable monitoring due to their invasive sampling protocols, biosample preparation and reagent stabilization. In this work, we present shelf-stable, non-invasive, paper-based colorimetric wearable lactate and temperature sensors. These sensors exploit the ability of silk to control the concentration, print, and functionally preserve labile transducing biomolecules in the format of a shelf-stable digital patch for optical readout. This novel approach overcomes major challenges associated with the commercialization of colorimetric wearable sensors (e.g., enzyme thermal instability, narrow sensing range, low sensitivity, and qualitative response) by showing a combination of unprecedented stability (i.e., up to 2 years in refrigerated conditions), wide sensing range, and high sensitivity. Additionally, real-time quantitative signal readouts are achieved using machine learning-driven image analysis enabling physiological status evaluation with a simple smartphone camera.
Although multifunctional wearable devices have been widely investigated for healthcare systems, augmented virtual realities and telediagnoses, there are few reports on multiple signal monitoring and logical signal processing by using one single nanomaterial without additional algorithms or rigid application-specific integrated circuit (ASIC) chips. Here, we develop multifunctional intelligent wearable devices using monolithically patterned gold nanowires for both signal monitoring and processing. Gold bulk and hollow nanowires show distinctive electrical properties with high chemical stability and high stretchability. In accordance, the monolithically patterned gold nanowires can be used to fabricate the robust interfaces, programmable sensors, on-demand heating systems and strain-gated logical circuits. The stretchable sensors show high sensitivity for strain and temperature changes on the skin. Furthermore, the micro-wrinkle structures of gold nanowires exhibit the negative gauge factor, which can be used for strain-gated logical circuits. Taken together, this multifunctional intelligent wearable device would be harnessed as a promising platform for futuristic electronic and biomedical applications.

8:00 PM SB05.03.03
From Network to Channel—Crack-Based Strain Sensors with High Sensitivity, Stretchability and Linearity via Strain Engineering Wanxi Wang and Youfan Hu; Peking University, China

High-performance stretchable strain sensors are indispensable for mechanical deformation detection in electronic skin applications such as health monitoring and human-robot interfaces. Thus far, achieving a stretchable strain sensor with a high sensitivity that works linearly over a wide working range is still a great challenge. Among various applicable working mechanisms of strain sensors, crack-based strain sensors have the advantages of flexible material selection, easy fabrication, and high sensitivity. Here, we propose a universal strain engineering strategy that introduces an inhomogeneous spatial distribution of stress, which results in a distinguished crack density distribution in space and a critical state of crack propagation behavior between network and channel morphologies. By controlling the occurrence of the critical state, strain sensors are capable to perform high sensitivity, stretchability, and linearity simultaneously. The strain sensors can be tuned to realize a gauge factor of 690.95 in a linear working range of 0-40% \((R^2 = 0.993)\) or a gauge factor of 113.70 in a larger linear working range of 0-120% \((R^2 = 0.999)\). Intracranial pressure monitoring has been demonstrated based on these sensors to show their great application potential.

8:00 PM SB05.03.04
Stimuli Recognition by Polydiacetylene using Hyperspectral Microscopy Jiali Chen and Kaori Sugihara; The University of Tokyo, Japan

Introduction
Polydiacetylene (PDA)-based chem/bio sensors have garnered significant attention due to their exceptional biocompatibility and ability to respond to various signals, such as heat, pH, force, light, and biomolecules. They exhibit visual blue-to-red color changes and fluorescence emission. However, the poor reproducibility of PDA sensors has hindered their practical implementation. The varying structures of PDA, even under identical synthesis conditions, make it challenging to achieve consistent and highly sensitive responses during mass production. Hyperspectral microscopy, initially developed for geology exploration and earth morphology observation, provides precise spectral analysis at the pixel level with high spatial and spectral resolutions. Recent advancements in detector and computing technology have expanded its applications to fields like agriculture, food, and medicine. In this work, we employed hyperspectral microscopy to visualize the inconsistent distribution of PDA structural domains, which contributes to the poor reproducibility and variations in PDA responses. Additionally, these mixtures of PDA structures exhibit distinct blue-to-red transition pathways upon stimulation, indicating their potential for stimulus identification.

Method
We utilized hyperspectral microscopy to capture detailed spectral information at the sub-crystal level of PDA, allowing differentiation among various PDA structures. Using spectral classification techniques, such as spectral angle mapper, we created distribution maps of PDA structural domains within bulk crystals. Moreover, we developed a pixel transition tracking method using MATLAB to quantitatively monitor the colorimetric response of these structural domains. Based on these technologies and discoveries, we observed that PDA exhibits different response patterns to various stimuli, such as heat and pH. Our aim was to comprehensively understand the dynamic transition pathways associated with PDA structural domains and their response patterns to stimuli.

Result and Discussion
We uncovered mixtures of PDA structural domains within blue and red bulk crystals, which explain the main source of poor reproducibility in traditional PDA sensors. It was the first time that hyperspectral microscopy was applied to examine the non-uniform property of PDA sensors, and we developed a new interpretation tool to track their transition pathways. Different structures of PDA displayed varying affinities to stimuli, leading to unique transition patterns specific to the type of stimulus applied. This indicates that the stimuli leave a potential fingerprint on PDA. The observed good reproducibility holds promise for PDA to serve as an identification array for molecules in the future.

Skin-Like Multimodal Sensors Based on Iontronics and Piezoelectricity Liren Wang1,2,3, Peter Zalar4, Yuanyuan Zhou1,3,1 and Naoji Matsuhisa1,3,2;
1The University of Tokyo, Japan; 2Keio University, Japan; 3Institute of Industrial Science, The University of Tokyo, Japan; 4Holst Centre / TNO, Netherlands

The skin possesses softness, stretchability, and the ability to sense a variety of environmental signals, including temperature, slow deformation (static strain), and rapid vibration (dynamic strain). Previous attempts to mimic skin with multimodal sensors have been limited by their multimodal sensing capability (1) and interference between different types of signals (2). In this work, we demonstrate a skin-like multimodal sensor capable of sensing three outputs - temperature, static strain, and dynamic strain - using a soft piezoelectric and ionic composite material. Our sensor is constructed by sandwiching the ionic and piezoelectric composite between a pair of silver-nanowire-based stretchable conductors. Electrochemical impedance provides readings of temperature and static strain, while piezoelectricity measures dynamic strain. We have systematically investigated the influence of ionic conductivity and elasticity of the composite on sensitivity and stretchability. The high conductivity of the silver-nanowire-based stretchable electrodes had a negligible effect on the signal readout. The sensor provided accurate strain-insensitive temperature signals (error ~0.28°C) under 50% strain, and a modest longitudinal artificial finger validate the versatility and reliability of this manufacturing strategy for soft electronics.
Silent speech recognition is a promising technique to restore spoken communication for individuals with voice disorders and to facilitate intuitive communications when the acoustic signal is unreliable, inappropriate, or undesired. However, the current methodology for silent speech faces several challenges, including bulkiness, obtrusiveness, limited portability, and susceptibility to interferences. In this work, we present a wireless, unobtrusive, and robust silent speech interface for capturing and decoding speech-relevant movements of the temporomandibular joint. Our solution employs a single ultrasoft magnetic skin placed behind the ear for wireless and more socially acceptable silent speech recognition, greatly alleviating concerns associated with existing interfaces based on face-worn sensors, including large number of sensors, highly visible interfaces on the face, and obtrusive interconnections between sensors and testing unit. Through optimizations in material composition, sensor structure, and sensing location, we present a lightweight wireless sensor that can conform to the skin surface to capture subtle movements induced by speech. With machine learning-based signal processing techniques, good speech recognition accuracy is achieved (92.7% accuracy for phonemes, 85.6% for word pairs from the same viseme group, and 96.7% for sentences/phrases). Moreover, the reported silent speech interface demonstrates robustness against noises from both ambient environment and user’s daily motions. Finally, we illustrate the great potential in assistive technology and human-machine interactions through two proof-of-concept demonstrations—silent speech enabled smartphone assistant and drone control.

Decoding Silent Speech Commands from Articulatory Movements Through Soft Magnetic Skin and Machine Learning
Penghao Dong and Shanshan Yao; Stony Brook University, The State University of New York, United States

In this study, we explore the development of a highly sensitive, high temporal-resolution dermal tissue-embedding mesh sensor. We functionalize this sensor using molecular pendulums developed by J. Das et al. to measure the concentration of Interleukin-6 (IL-6), a key biomarker in skin inflammation. Miniaturized organ models, including organoids and spheres, serve as powerful platforms for investigating human physiology and pathology *in vitro*, and bioelectronic sensors effective, complementary tools for monitoring them. Current bioelectronic sensor technologies provide insights into thermal, electrophysiological, optical, and oxygenation parameters within these models, yet robust and high-fidelity bioelectronic sensors remain a significant gap. Our device bridges this gap, offering microsecond resolution in the detection and tracking of IL-6 proliferation and movement. This work paves the way for high-resolution interrogation of skin inflammation, significantly enriching our understanding of inflammation, and providing a powerful tool for potential drug efficacy assessment.

Poly Vinyl Alcohol and Carbon Nanotube Based Scaffolds for Engineered Biosensors
Ryan E. Jaworski and Isaac Macwan; Fairfield University, United States

Biosensors are analytical devices that can turn biological responses into electrical signals which can be very useful in the diagnostics of numerous diseases. This work looks into the fabrication of an impedance based biosensor using electrospun Poly Vinyl Alcohol (PVA) and Carbon nanotubes (CNTs) to be used in conjunction with bacteriorhodopsin contained in a purple membrane. Dispersions of PVA are created with and without CNTs in deionized (DI) water, which are then utilized to synthesize porous electrospun nanofibrous scaffolds with fiber diameters ranging from 150nm to 250nm. The detection technique utilized for the fabricated biosensor is through the quantification of electrochemical impedance via the Electrochemical Impedance Spectroscopy (EIS). The parameters for both electrospinning and EIS are carefully optimized to achieve porous nanofibrous scaffolds having expected fiber diameter, porosity and impedance. The parameters which are optimized for the electrospinning process include the flow rate, collection distance, voltage, viscosity of the polymer CNT solution, and the type and configuration of the collector. Similarly, the parameters for the EIS include optimum potential of the applied small ac signal in mV, frequency range, electrolyte concentration and the type of electrodes and their configuration. This careful optimization of the parameters would enable the fabrication and the dynamic response of the designed biosensor to be able to hold its integrity through the entire process of characterization and testing. Two different forms of CNTs are used, which are single-walled carbon nanotubes (SWNTs), and multi-walled carbon nanotubes (MWCNTs). The two different SWNTs used in this study have a 6, 5 chirality and also mixed metallic and semiconducting chirality to assess the differences in the biosensor performance based on the type of SWNT and its comparison to the MWNMs. The synthesized scaffolds are also characterized through atomic force microscopy (AFM) and scanning electron microscopy (SEM), and compared to control samples without CNTs. The synthesized scaffolds are then tested for performance through the detection of a light sensitive protein bacteriorhodopsin (BR), which is a membrane protein found in Archea, most notably Halobacteria. The primary function of the protein is in its use as a proton pump across the cell membrane and its novel characteristic to detect light of different wavelengths make it attractive for application in optical memory. Although this is a specific example, these scaffolds can accommodate different types of analyte for biosensors in many applications.

Fabrication of a Partially Porous Microneedle Array Through Stepwise Integration of Porous and Non-Porous Poly(glycidyl methacrylate)
Hiroaki Kajiyama1,2 and Akichika Kumatani1,2; Toyo University, Japan; Tohoku University, Japan; The University of Tokyo, Japan; Presto, Japan Science and Technology Agency, Japan

The microneedle array, a two-dimensional array of small needles with the height of a few hundreds of micrometers, are being actively studied for the application for minimally invasive transdermal drug delivery and biosensing. Among microneedles of various structures, porous microneedles have the advantages that they have large specific surface area that can be advantageous for high drug loading on the internal pore surface as well as highly sensitive biosensing taking advantage of high electrode area.

Porous polymer microneedle arrays made of crosslinked poly(glycidyl methacrylate) (PGMA), pioneered by Nishizawa’s group, have advantages such as easy fabrication by photopolymerization in a mold and tunability of the properties by molecular design [1] as well as capability for functionalization by organic chemistry to fabricate functional microneedles such as organic/inorganic hybrid microneedle electrodes [2]. The existing porous PGMA microneedle arrays are porous throughout the microneedle body: both the base substrate and needles are homogeneously porous. Therefore, the amount of drug and sensor molecules interfaced with skin and biological fluid cannot be controlled, which prevents the quantitative control of drug release and
reproducible amperometric biosensing. Considering the porous PGMA microneedles for quantitative applications, spatial control of porosity in the microneedle body is important. Monomers (glycidyl methacrylate, and trimethylolpropane trimethacrylate, and triethylene glycol dimethacrylate) were photopolymerized by the irradiation of ultraviolet light to obtain in the presence of a photoinitiator to obtain crosslinked PGMA. In the presence of poly(ethylene glycol) (PEG) as a porogen (a template material to make pores), polymerized PGMA has macropores with the diameter of ~1 µm [3]. Therefore, control of addition of the porogen can be utilized to obtain spatially controlled porosity.

In this study, we present a two-step process for creating a porous PGMA microneedle array with a two-section structure: a porous needle section and a non-porous substrate, both made of PGMA. First, the monomer solution mixed with the porogen was poured into an elastic mold of a microneedle array and excess solution over the needle section was removed by carefully scraping on the mold, followed by the polymerization by ultraviolet light irradiation to fabricate porous needles. Then, the monomer solution without the porogen was poured over the polymerized needle section in the mold and polymerized to fabricate a non-porous base substrate. After the removal of the fabricated microneedle array from the mold, the needle section was in a white opaque color resulting from macroporous structures of PGMA, and the base substrate was colorless and transparent, indicating PGMA in the substrate was non-porous. The two sections were integrated well and no significant breaking of needles was observed. Water absorption properties of the fabricated microneedle arrays were measured by immersing them into water and measuring the change in total mass. The amount of water absorbed by the partially porous microneedle array was significantly smaller than the homogeneously porous microneedle array, yet higher than homogeneously non-porous microneedle array. The developed two-layer, partially porous microneedle array is potentially useful for quantitative control of drug delivery and reproducible biosensing.

Highly Accurate Multiplexed Nanoplasmonic Detection of MicroRNAs using Splinted Ligation Shiwa Joo1, Younju Sung2, Na Rae Jo1, Yong-Beom Shin3 and Min Lee1; 1Korea Research Institute of Standards and Science, Korea (the Republic of); 2Korea Research Institute of Bioscience and Biotechnology (KIRIBB), Korea (the Republic of); 3Korea Institute of Machinery and Materials (KIMM), Korea (the Republic of)

MicroRNAs (miRNAs) are short, non-coding single-stranded RNAs that regulate gene expression by binding to mRNAs. Because miRNAs are abnormally expressed in cancer cells, they have been considered an important cancer biomarker. However, the short length and high homology of miRNAs make them difficult to detect accurately. In this study, we developed a highly accurate miRNA detection method using a multi-channel localized surface plasmon resonance (LSPR) sensing platform. MiRNAs were labelled with a DNA probe using splinted ligation and immobilized on a gold nano-truncated cone (GNTC) array chip fabricated by nanoimprinting. After enzyme-assisted precipitation was performed, the LSPR spectral shift was measured as a function of miRNA concentration. Three miRNAs (miR-34c, miR-99a, and miR-125b) were sensitively detected with the limit of detection ranging from 1.8 to 26.1 nM. Single nucleotide variation (SNV) was clearly discriminated with high contrast. In addition, several miRNAs could be simultaneously detected in the multi-channels of a GNTC chip with high quantitative accuracy. Furthermore, we demonstrated the clinical applicability of our method by accurately detecting miRNAs in total RNA samples extracted from cancer cells.

Biocompatible Silk Films for Transient Tactile Sensors Donggeun Lee1, Jeong Woo Chae2, Sang Min Won2 and Wi Young Lee1; 1Konkuk University, Korea (the Republic of); 2Sungkyunkwan University, Korea (the Republic of)

Research interests in naturally derived polymers with flexibility, stretchability, foldability, transparency, transiency, biocompatibility, and biodegradability has recently received much attention. In addition, the emergence of transient electronics, which are decomposed, absorbed, and disappear after operating for a certain period, can supplement the demerits caused by the survival of implanted devices. These technologies rely heavily on the flexibility, stretchability, biocompatibility, and biodegradability of the used biomaterials. This report presents strategies for utilizing both silk fibroin and silk sericin extracted from silk cocoons of Bombyx mori and fabricating silk-based sensors that detects capacitive touching motion and resistance change form mechanical deformation of the sensors. Decomposition and flexibility in humid condition were controlled by annealing fibroin film. Sericin extracted from cocoons in the process of producing fibroin was used to make an adhesive with good biocompatibility. Furthermore, a conductive silk composite was produced through hybridization with tungsten nanoparticles and was used as a piezoresistive-capacitance sensor. The sensitivity of conductive silk composite was confirmed through EGG and EOG tests. The flexibility of wholly silk based sensors was confirmed by measuring the changes in resistance at various bending condition. Acknowledgement: This work was supported by Korea Institute for Advancement of Technology (KIAT) grant funded by the Korea Government (MOTIE) (P0012770) and grant from the Basic Science Research Program of the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (2023-00208902).

Impedance-Based Polymer Microneedle Patch Sensor for Continuous Interstitial Fluid Glucose Monitoring Hongjin Piao, Jaehyun Kim, YongHo Choi, Heon-Jin Choi and Dahl-Young Kang; Yonsei University, Korea (the Republic of)

Early diagnosis and control of blood glucose is essential for effective prevention and management of diabetes-related complications. This study aims to develop a microneedle-type glucose sensor patch for minimally invasive, painless and continuous glucose monitoring. In situ monitoring of glucose concentration in interstitial fluid using polymeric microneedle arrays is the method used in this study. The experimental section included four subsections, namely substrates fabrication, sensor fabrication, and characterization of the glucose sensor based on microneedle patches. The experimental findings demonstrate the successful penetration of cylindrical microneedles into skin tissue with minimal force, reaching a depth of approximately 520 µm. The microneedle sensor was produced with high precision using the CMOS process, and the immobilization of glucose oxidase was confirmed through phase angle changes. After conducting long-term tests, the sensor was found to be effective for up to 7 days. Glucose concentration measurements were conducted using the developed sensor, resulting in fitted curves with a mean slope of -27.18 and a mean intercept of 197.27. Random glucose concentration tests were conducted, and the range of values obtained shows strong correlation with those obtained from commercially available glucose detectors. MARD ranges from -0.5% to 11.97%. These results suggest the potential for the microneedle sensor to be used as a reliable and accurate tool for glucose monitoring. The study provides a promising approach for developing a wearable and minimally invasive and painless glucose sensor for continuous glucose monitoring.

8:00 PM SB05.03.16
Wireless, Highly Sensitive Biosensors on Contact Lenses for Intraocular Pressure Monitoring Te Xiao; Waseda University, Japan

Glaucoma is one of the common eye diseases to cause a risk of blindness in severe cases. To prevent the blindness by glaucoma, real-time monitoring of intraocular pressure (IOP) becomes particularly important. The contact lenses built-in IOP sensor can contact continuously with the eye, so they are
superior to other IOP measurement system in that it can measure constantly. Many researchers have been working on making wireless smart contact lenses that can detect intraocular pressure. By embedding LCR resonators[1] in the contact lenses, which can generate changes in inductance, capacitance, or resistance of the pressure sensors, and receiving signals through transmission coils, the purpose of real-time wireless detection of intraocular pressure is achieved. However, the development of smart contact lens remains a challenge, including wireless sensor sensitivity, transparency, durability, and safety. Here we demonstrate the use of a wireless and highly sensitive IOP monitoring system on pig eyes that is comfortable while wearing. The IOP monitoring system consists of a stretchable gold antena sensor printed on a moist and soft contact lens for IOP detection. The wireless IOP data reception is made of a reader circuit resonated at 1.39 GHz. We designed a horseshoe-shaped gold antenna, which was then printed on commercially available contact lenses through electrochemical bonding, using poly(3,4-ethylene dioxythiophene) film as an adhesive glue. The printed stretchable IOP sensing lens can be stretched and twisted, which is impossible using a conventional loop antenna[2].

An Electric Contact Lens for Non-Mydriatic Near-Infrared Fundus Imaging Yang Cui; Waseda University, Japan

Ophthalmic fundus imaging has become an important technique for the diagnosis and treatment of eye diseases[1]. A2a ideal imaging system should have high resolution, low cost, and high resolution for the remote monitoring of eye health at home; however, the conventional imaging systems are large and heavy and can only be used in hospitals. To solve this problem, we demonstrate a non- mydriatic near-infrared (NIR) fundus imaging system with light illumination from an electric contact lens (E-lens)[2]. We designed a wireless power transfer system that can be bound to the contact lens and don’t block the eye view[3], and a near-infrared LED is embedded on the contact lens and can be powered wirelessly to light up. The E-lens can illuminate the retinal and choroidal structures in the eyes. The irradiated light is reflected at the layered structures of the fundus, and subsequently, the reflected light passes through the pupil of the eye lens to capture the images with a portable NIR camera.

Because of the strong light scattering effects in the fundus tissue, the captured images are blurred. Therefore, we reconstruct the images with a depth- dependent point-spread function to suppress the scattering effect that eventually visualizes the clear fundus images of the retinal and choroidal vasculature[4]. This method showed superior image reconstruction results compared to other common methods such as high-pass filtering. The proposed imaging system provides a new method for remote monitoring with increased functionality, it makes the portable eye health care possible.

Stretchable Microelectrode Arrays for Brain Spheroid Electrophysiology Eleonora Martinelli°, Camille L. Delgrange°, Ivan Furfar°, Loris Gomez Baisac°, Adrien Roux°, Luc Stoppini° and Stephanie P. Lacour°; °Ecole Polytechnique Federale de Lausanne, Switzerland; °Haute Ecole du Paysage, d’Ingenierie et d’Architecture, Switzerland

Human neural spheroids, i.e. 3D cellular aggregates composed of neurons and glial cells, are a compelling biological model to study neuronal communication both in physiological and pathological conditions. We propose the design of a perforated and stretchable microelectrode array (MEA) to monitor the electrophysiology of brain spheroids under static and dynamic mechanical loading. This is a relevant neuroelectronic system to investigate the consequences of traumatic brain injury (TBI).

The MEAs are prepared with thin-film technology using a platinum thin film sandwiched between two 1 μm thick polyimide films. Stretchabilty is engineered by design introducing patterns of micron scale, Kirigami-like Y-shaped cuts on the whole MEA surface. Each MEA hosts 8 Kirigami-patterned recording electrodes (diameter = 70 μm), and a macroscopic ground electrode to probe one brain spheroid (spheroid diameter = 500-1000 μm). Electrode contacts are coated with electrodeposited PEDOT. The coating conformably follows the profile of the Kirigami-patterned electrodes independently of electrode size and reduces the electrochemical impedance at 1 kHz by 60% (n = 24, diameter = 70 μm).

Next, the permeability of the perforated MEAs is quantified as a function of section designs and perforation methods; this is to ensure sufficient nutrient and oxygen exchange at the air-liquid interface of the brain spheroid. The electromechanical properties of the MEAs are then evaluated when subjected to uniaxial elongation at a constant speed (100 μm/s). The strain parameters are aligned with typical TBI loadings (5-35%). Kirigami-patterned PEDOT-coated electrodes sustain strains up to 10% without showing significantly increased electrochemical impedance amplitude, while patterned platinum electrodes sustain strains only up to 5%. Similar results are shown with cyclic stretching. The electromechanical properties of the MEAs are also evaluated when subject to fast mechanical loading comparable with TBI impacts (elongation speed 1-2 m/s).

Next, the ability of the Kirigami-patterned electrodes to record neural activity from brain spheroids is verified. The MEA is mounted on a fluidic platform to allow for cell culture media change and the brain spheroids are integrated into the system. Spontaneous neural activity from the brain spheroids is reliably recorded for up to 5 days. This work paves the way for studying the effect of mechanical loading on neural activity in 3D in vitro brain models.

Whole-Cell Biosensing and Remediation of Arsenic using Magnetically Separable E. Coli: Towards Sustainable Materials for Water Treatment Eric J. Sorge; Jingge Chen, Megan Kizer and Vicki L. Colvin; Brown University, United States

The World Health Organization (WHO) identifies arsenic as a carcinogenic toxin with exposure limits in drinking water set as low as 10 ppb. Arsenic is abundant in the Earth’s crust and its prevalence in groundwater originates from natural causes as well as anthropogenic activities. Millions of people around the world, especially those in rural areas, are exposed to dangerous levels of arsenic in their water supply each year. Preventing human exposure to arsenic with accessible, inexpensive, and sustainable technology is crucial. We describe a strategy for sensing and removing arsenic from drinking water through electrochemical bonding, using poly(3,4-ethylene dioxythiophene) film as an adhesive glue. The resultable molecular could reduce arsenic concentrations in...
Ultrafast Light-Activated Polymeric Nanomotors

Jianhong Wang, Hanglong Wu, Jingxin Shao and Jan Van Hest; Eindhoven University of Technology, Netherlands

Synthetic micro/nanomotors have been extensively exploited to achieve active transportation over the past decade. This interest is a result of their broad range of potential applications, from environmental remediation to nanomedicine. Nevertheless, it still remains a challenge to build a fast-moving biodegradable polymeric nanomotor. Here we present a light-propelled nanomotor by introducing gold nanoparticles (Au NP) onto biodegradable bowl-shaped polymersomes (stomatocytes) via electrostatic interactions. These biodegradable nanomotors show controllable motion and a very high velocity of up to 125 μm s⁻¹. This unique behavior was explained via a thorough three-dimensional characterization of the nanomotor, particularly the size and the spatial distribution of Au NP, with cryogenic transmission electron microscopy and cryo-electron tomography. Our in-depth quantitative 3D analysis revealed that the motile features of these nanomotors were caused by the nonuniform distribution of Au NPs along the axial direction of the polymersome. This study could offer a new perspective for designing robust biodegradable soft nanomotors, thereby facilitating their applications in a bio-friendly manner.

Fabrication of Water-Resistant Materials using Nanofiber Membranes Inspired by Penguin Feathers

Ryosuke Kawasaki1, Daisuke Ishii1, Yosuke Zaitsu2 and Masanori Kurita2; 1Nagoya Institute of Technology, Japan; 2Port Nagoya Public Aquarium, Japan

When diving, penguins do not get wet due to the feathers that cover their skin, and emperor penguins dive to a maximum depth of 564 meters. This is probably due to the penguin's feather density, which is the largest among birds, the hierarchical microstructure of its feathers with gaps of up to 17 μm, and surface-modifying fat secreted by the tail blubber gland. Even with the feathers without the fat removed by organic solvents, contact angles were as high as about 130°. When a water pressure resistance was measured of surface modified feathers and wire meshes with various pore sizes by self-assembled monolayers, the smaller the pore size and the smaller the surface free energy, the better the water resistance. This result suggests that water repellency and water resistance are synergistic effects of microstructure and surface modification.

This study aimed to fabricate water-resistant materials using nanofiber membranes by electrospinning, inspired by the mechanism of penguin feathers. Polyacrylonitrile (PAN) nanofiber membranes fabricated in previous studies had problems with water absorption. A high surface free energy of PAN causes capillary action within the pores of the nanofiber membrane. Therefore, to improve the water absorption phenomenon, we investigated methods of reducing the pore size by heat pressing and changing to a polymer with low surface free energy. The experimental conditions for the electrospinning were a drum collector rotation speed of 15 rpm, a needle diameter of 0.41 mm, a feed rate of 0.10 ml/min, an applied voltage of 20 kV, and a distance between a collector and needle of 10 cm. Samples of heat pressing were prepared from a 12.5 wt% N,N-dimethylformamide (DMF) solution of PAN, and were pressed under three conditions: room temperature (25°C), glass transition temperature (Tg) of PAN (104°C), and 150°C. A hydrophobic polymer nanofibers were spun from DMF solution of Poly(vinylidene fluoride) (PVDF) (15, 20, 25, and 30 wt%). Static contact angles, water absorption, and wetting behaviors of the nanofiber membranes were discussed.

As a result, water absorption was observed in the nanofiber membrane pressed at room temperature, but no water absorption was observed in the heated press at or above the glass transition temperature. The fibers were not adhered in each other pressed at room temperature, resulting in capillary action. On the other hand, the fibers pressed over Tg were adhered each other. Then pores of the nanofiber membranes became smaller and capillary action did not take place. The contact angles of the pressed nanofiber membrane at over Tg were about 70°. It is considered that the difference in pressing temperature over Tg has no effect on the surface structure. In the case of PVDF, only beads were formed at 15 and 20 wt%, which resembled "electrospray", and 25 and 30 wt% resulted in fibers, although some beads were formed. The beads were probably caused by aggregation on the collector side because the solvent was not fully volatilized. The PVDF nanofiber membrane did not show water absorption, and the contact angle was about 140°. The contact angle of smooth PVDF was about 85°, suggesting that the microstructure of PVDF improves hydrophobicity. These results indicate that the combination of microstructure and low surface free energy has potential for superhydrophobic fabrics and will contribute to the development of new water resistance mechanisms.

Extended-gate structure biosensors offer a promising field-effect transistor (FET) architecture for point-of-care applications by physically separating the sensing region from the transistor. However, few studies have investigated the sensing mechanism of FET biosensors (not limited to extended-gate structure), but rather have shown excellent label-free sensing performance. Herein, we demonstrate the biosensing mechanism of the aptamer modified extended-gate FET biosensor by modulating the dielectric properties and charge properties on the surface of the gold extended-gate. In the extended-gate FET structure, we can consider two capacitors in series: an extended-gate and a FET, which leads to the phenomenon of capacitive coupling. To show how the capacitive coupling between these two components affects the biosensing performance, we vary the capacitance values by modulating the electrode size of extended gates. Furthermore, by modifying an aptamer on the extended-gate surface for selective recognition of biomarkers and connecting it in series with a FET, the sensing performance can be explained by the capacitive coupling effect, and we further compare the results with those obtained by modulating surface charge and dielectric properties to gain insights into the sensing mechanism of the aptamer modified extended-gate FET biosensor. This
Natural leather is produced by processing the hides of cattle, pigs, and other by-products of the meat industry. Therefore, it is a sustainable material that makes effective use of by-products. However, the metallic salts used in the "tanning" process of converting animal skins into natural leather can cause environmental problems such as water pollution and health hazards to the worker. Although vegetable tanning is an alternative tanning method that does not use metallic salts, the proportion of metal salt tanning is still high in industrial materials. Synthetic and artificial leathers are also becoming popular, but it is difficult to replace natural leathers because the characteristics of synthetic and artificial leathers have not been imitated.

Therefore, we aim to solve this problem by reducing the use of natural leather by focusing on the wettability of the surface of the leather and creating synthetic leather that has properties like natural leather. At first, the surface characteristics of each leather material such as wettability and frictional force were compared quantitatively. Based on the results of these comparative evaluations, we will establish guidelines for the development of synthetic leather with surface properties as close as possible to those of natural leather. The differences in surface properties between commercial natural leather and synthetic leather covered by polyurethane were due to differences in wettability and surface and cross-sectional microstructure. Static contact angle measurements were performed using 10 µL of distilled water to compare wettability. In addition, microscopic contact angle measurements were also performed to evaluate the behavior of absorbing a 30 µl water droplet. To clarify the relationship between these wettabilities and surface structures, the surface microstructures were observed by scanning electron microscopy (SEM). The cross-sectional microstructures were also observed, considering the contribution of not only the surface but also the cross-sectional structure to the water absorption behaviors.

As a result, the SEM observation revealed bubbles in resins and regular structures on the surface of the synthetic leather, and a fluffy structure with non-woven fabrics protruding from the surface of the artificial leather. These microstructures, which differ from the surface of the natural leather, have affected surface wettabilities. In the cross-section, the natural leather showed a tendency for the structure to become rough from the outer to the inner surfaces. On the other hand, a structural gradient was not observed for the other materials, suggesting that the structural gradient affects water absorbency. The static contact angle results showed that natural and synthetic leathers had similar contact angles, although their surface structures differed according to the SEM images. The highest value was obtained for the artificial leather, which is thought to be due to its fluffier surface, which allows for a larger air layer and a more effective pinning effect than the other materials.

Finally, observation of water absorption behavior showed that the contact angle decrease rate of natural leather was greater than that of the other materials, suggesting that it has superior water absorption properties. It was thought that the gradient-like structure was responsible for the superior water absorption property. In the presentation, details of surface properties such as frictional force and mechanical properties, as well as quantitative evaluation methods for comparing the properties of each leather material will be established, and guidelines for the development of alternative materials will be explained.

Increasing requirements for neural implantation are helping to expand our understanding of nervous systems and generate new developmental approaches. It is thanks to advanced semiconductor technologies that we can achieve the high-density complementary metal-oxide-semiconductor electrode array for the improvement of the quantity and quality of neural recordings. Although the microfabricated neural implantable device holds much promise in the biosensing field, there are some significant technological challenges. The most advanced neural implantable device relies on complex semiconductor manufacturing processes, which are required for the use of expensive masks and specific clean room facilities. In addition, these processes based on a conventional photolithography technique are suitable for mass production, which is not applicable for custom-made manufacturing in response to individual experimental requirements. The microfabricated complexity of the implantable neural device is increasing, as is the associated energy consumption, and corresponding emissions of carbon dioxide and other greenhouse gases, resulting in environmental deterioration. Herein, we developed a fabless fabricated process for a neural electrode array that was simple, fast, sustainable, and customizable. An effective strategy to produce microelectrodes, leads, and bonding pads onto the Parylene C substrate by laser micromachining techniques combined with the drop coating of the silver paste to stack the laser grooving lines. Sequentially, Parylene C was deposited onto the Parylene C substrate to form the insulation layer for the protection of inner circuits. Following the deposition of Parylene C, the via holes over microelectrodes and the corresponding probe shape of the neural electrode array was also etched by laser micromachining. To increase the neural recording capability, three-dimensional microelectrodes with a high surface area were formed by electroplating PEDOT-GO composite. Our eco-electrode array showed reliable electrical characteristics of impedance under harsh cyclic bending conditions of over 90 degrees. For in vivo application, our flexible neural electrode array demonstrated more stable and higher neural recording quality and better biocompatibility as well during the implantation compared with those of the silicon-based neural electrode array. In this study, our proposed eco-manufacturing process for fabricating the neural electrode array reduces carbon emissions compared to the traditional semiconductor manufacturing process and provided freedom in the customized design of the implantable electronic devices as well.

Soil pH significantly affects agriculture by regulating available nutrients and water-soluble chemicals available to plants, thus driving the need for low-cost, durable soil pH sensors. A few potential solutions include expensive commercial pH sensors and printed sensors that only work in liquid media. Each of these solutions poses its own set of unique challenges perpetuating the affordable soil pH sensing dilemma. Here, we present a novel pH sensor platform based on an array of low-cost, durable, screen-printed electronics for in situ soil sensing. We show the stabilization of the pH-sensitive dye, alizarin, in the printed pH devices allowing for extended sensing periods in soil. We compare different alizarin dye immobilization techniques and electrode configurations and have evaluated the effects of soil pH on sensor durability. This new affordable, stable printed pH system pioneers the development of printed electronics for new alternatives to assess soil pH.

Intelligent bioinspired adhesive devices are attracting attention as a tool for the transdermal drug delivery patch. However, there have been many
challenges in delivering drugs from the wrinkled and rough skin surface through the complex stratum corneum into the body. The rough skin surface interferes with interfacial contact between the drug delivery material and the skin, making close adhesion difficult, which reduces drug delivery efficiency. In addition, the brick-like structure of the stratum corneum, which has a barrier function, is a major obstacle to drug delivery through the skin. Here, we present two strategies to overcome the limitations of transdermal drug delivery based on biomimetics. First, the drug delivery patch, which is designed by combining an adhesive structure that mimics a diving beetle and a drug-loading hydrogel, improves the efficiency of drug delivery through conformal contact. In addition, the symmetric diving beetle adhesive structure provides directional adhesive performance, enabling hypoallergenic detachment. Second, it is an adhesive interface that provides negative pressure to the skin by mimicking the tentacle of a cephalopod. Negative pressure delivered to the skin induces fine structural deformation of the stratum corneum and creates gaps between the stratum corneum, improving drug delivery efficiency. With the aid of bioinspired adhesive architecture, we demonstrated improved drug delivery efficiency in an in vivo model, suggesting a promising development in the medical and skin therapy fields.

Permeability and Anti-Fouling Performance of Microfiltration Membrane Modified by Hybrid Structured Omniphobic Coating Method Seonmin Kim, Moon Sukh Suh, Churl Seung Lee and Hayoung Choi; Korea Electronics Technology Institute, Korea (the Republic of)

Surface characteristics of polymer membrane plays a significant role in bioprocess such as separation, purification, and so on. Generally, hydrophilicity is recommended for better process efficiencies in various commercial biomedical engineering fields. However, omniphobic properties of these fields could be recommendable for better performance because those properties on the surface is more favorable in many reasons. In this study, we try to modify the commercial polyethersulfone (PES) membrane by combining two different coating procedures: electrosprinning and spray coating. Poly(vinylidene fluoride) is used to form the nanofiber mat for the robust roughness by the electrosprinning technique and various fluoro-silane materials is applied to modify the chemical properties of the surface by spray coating method. The modified membrane was analysed by scanning electron microscopy for surface morphology and characterized by the measurement of contact angle for anti-fouling properties. We also measured the permeabilities of membrane for water and bovine solution to test anti-fouling ability in a simulated bioprocess conditions.

Wireless, Fully Implantable and Expandable Bioelectronic Platform for Bidirectional Modulation of the Urinary Bladder Tae-Min Jang, Jeong-Woong Shin and Suk-Won Hwang; Korea University, Korea (the Republic of)

Current standard clinical options for patients with detrusor underactivity (DUA) or underactive bladder -- the inability to release urine naturally -- include the use of medications, voiding techniques, and intermittent catheterization, for which the patient inserts a tube directly into the urethra to eliminate urine. Although those are life-saving techniques, there are still unfavorable side effects, including urinary tract infection (UTI), urethritis, irritation, and discomfort. Here, we report a wireless, fully implantable, and expandable electronic complex that enables elaborate management of abnormal bladder function via seamless integrations with the urinary bladder. Such electronics can not only record multiple physiological parameters simultaneously but also provide direct electrical stimulation based on a feedback control system. Uniform distribution of multiple stimulation electrodes via mesh-type geometry realizes low-impedance characteristics, which improves voiding/urination efficiency at the desired times. In vivo evaluations using live, free-moving animal models demonstrate system-level functionality.

Use of PMMA as a Deep UV Photoresist to Produce Patterned Substrates for Surface-Aligned DNA Deposition with Potential Application to Sequencing Heba Ouerrfell1,2, Boheng Cao1,3, Ellen Hu1,2, Aditi Kiran1,2, Selina Zhang4,5, Alex Zheng6,7 and Jonathan Sokolov; 1Fort Lee High School, United States; 2Stony Brook University, United States; 3North Hollywood High School, United States; 4C. Leon King High School, United States; 5BASIS Independent Fremont, United States; 6North Hunterdon High School, United States; 7Stuyvesant High School, United States

As genetic sequencing grows widespread in diagnosticians and research, increasing its accessibility has become all the more necessary. Current next-generation sequencing (NGS) technologies entail the large-scale assembly of complete sequences from short, free-floating DNA fragments, resulting in high computational costs. Researchers have attempted to address this issue through long-read or third-generation sequencing, extending the length of the contiguous DNA fragments to tens of kilobase pairs. However, repetitive regions of the DNA still limit the ability of software to reassemble unique sequences. Ordered DNA fragmentation is an important tool in reducing the computational bottleneck of rearranging scattered strands in solution. The foundation of our approach lies in the integration of biological materials with a synthetic polymer, creating a novel abiotic-biotic system.

In this work, we explore the use of 996K molecular weight poly(methyl methacrylate) (PMMA)-coated silicon wafers as a suitable substrate for developing suspended DNA segments. The suspended segments provide steric clearance for the application of Tn5 transposases to fragment and label surface-immobilized long DNA molecules. PMMA was used as a deep-UV photosresist to produce latent patterns, followed by DNA deposition and photoresist development. Despite the tendency for UV-exposed PMMA to become more hydrophilic (unfavorable to DNA stretching on surfaces), we were successful in finding a combination of exposure and development times to achieve surface immobilization of long DNA strands such as those of mice genomic DNA and ligated lambda DNA. Initial experiments testing Tn5 activity will also be discussed. The broader implications of this work are a novel and exciting biolibrary way forward in ordered DNA fragmentation for lower-cost sequencing.

8:00 PM SB05.03.34

Impact of Rhizobium Tropici-Produced EPS on Bermuda Grass Root Growth Haaris Alam1, Isana Alicea2, Ashritha Kalakuntla3, Elise Ngo1, Brinley Dai4, Jerry Gao5, Tei Kim6, Tony Guo Feng Tung7, Yiwei Fang8, Aaron Sloutski8, Marcia Simon8, Jay Gao8, Miriam Rafailovich8, Steve Larson9 and Suk-Won Hwang; Korea University, Korea (the Republic of)

Erosion control is imperative to soils vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is provided by extracellular polymeric substances (EPS): hydrated microbial biopolymers whose high water-holding capacity, entrapment of nutrients, and resistance to environmental stressors can elevate soil fertility. EPS also promotes aggregate formation, which helps maintain a soil’s structural integrity. A more indirect benefit of EPS in soil is their ability to enhance subterranean root growth. This corresponding increase in root mass or length can stabilize topsoil and aid in erosion control. However, the specific mechanism by which EPS benefits root growth was studied by different research groups with partial success. This project aimed to further investigate the influence of EPS produced by Rhizobium tropici bacteria (RT-EPS) on Bermuda grass, particularly on its root growth. By gaining a deeper understanding of this impact, a more effective approach for the fabrication and deployment of RT-EPS can be developed, which will be used on large scale applications to minimize the soil damage caused by extreme weather conditions.

EPS produced from the Rhizobium tropici bacteria was used to generate an ethanol precipitate material (EPM). After cell-free biofilms of the bacteria were
Cysteine-containing oxidoreductases, such as thioredoxin (Trx) and glutaredoxin (Grx), play crucial roles in maintaining cellular redox balance through finely tuned reversible redox signaling pathways. However, elevated levels of reactive oxygen species (ROS), often of exogenous origin, can trigger the irreversible hyperoxidation of cysteine thiols into sulfonic acids (-SO₃H), resulting in permanent dysfunction of these proteins. In this study, we present an approach involving a multi-functional nano-sized hydrogel (nanogel, IrNG), encapsulating an iridium-based photosensitizer (TIr₃). In the presence of photoradiation, IrNG maintains its self-assembled nanostructure, even in the presence of high concentrations of reductive glutathione, owing to the rapid hydrophobic interactions and the reversible self-crosslinking between thiols and disulfides. However, upon the photoradiation, the disulfide bonds evenly distributed within IrNG undergo hyperoxidation, transforming into negatively charged sulfonates. This transformation results in the rapid degradation of IrNG. The photo-responsive TiTr₃ generates significant levels of ROS, enabling both spatiotemporally controlled structural modifications in the reversible-redox responsive nanogel and mitochondrial oxidation-mediated cancer cell apoptosis.

The behavior of HIV-1 in culture media was tracked with Dynamic Light Scattering (DLS) and complementary atomic force microscopy (AFM) imaging in the presence of lectins, anti-gp120 Antibodies (Abs), mannansidase, and mucin. After excluding the serum contribution to culture media from extracted DLS data, it is observed that there are clusters/aggregates of about 400-700nm HIV-1 in solutions. The clusters were sheared into single virus particles by filtration but re-clustered back over a short time. It is known that HIV-1 mutates rapidly and is protected by glycan shields of mannose sugars that have challenged the broadly neutralizing of the virus by Abs. In other studies, mannoside residues have been reported to be self-adhesive, but it is not known if these mannoside adhesions drive HIV-1 to be agglomerated in solution, further confounding Ab neutralization. Mannansidase treatment reduced clustering, suggesting the mannos glycan shield is involved in the cluster formation. Mucin molecules (porcine gastric mucin) effectively dispersed HIV-1 clusters, even those stabilized by Abs. It is well known that mucin reduces HIV virulence, but the mechanism has not been clarified. Our findings suggest that mucin reduces HIV-1 virulence by dispersing its clusters, as opposed to the current perspective that mucin aggregates HIV-1.

The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-2-0054) in this research.

Characterizing Oil-In-Water Emulsions as Muscle and Subcutaneous Adipose Tissue Phantoms for T2 Relaxometry Alexa S. Zammitt, Sydney Sherman and Amena Khatun; Massachusetts Institute of Technology, United States

Tissue microstructure can be indicative of pathology and varying microstructural properties can contribute to inaccuracies in several diagnostic tools. Skeletal muscle is hierarchical and highly organized. Additionally, skeletal muscle is an important reservoir of fluid and can be an early indicator of absorption for treatment strategies.
A recent study demonstrates that point-of-care fluid status determination may be possible with the analysis of T2 relaxometry data collected by a bedside NMR sensor. However, given the clinical setting of the study, fluid overload and a typical fluid state were the only two states available for data collection. Here, oil-in-water emulsions are assessed and characterized on a T2 relaxometer. The properties of the emulsions are compared to dissected murine muscle and subcutaneous adipose tissue after data analysis with a multi-exponential fit. Peanut oil is used in the emulsions, as the NMR signal is comparable to the triglycerides in adipose tissue. Varying the fat fraction of the emulsions by changing the oil to water ratio changes the relative amplitudes of the peaks as determined by the multi-exponential analysis. A comparison of different fat fractions enables us to determine that an emulsion with a fat fraction of 40% can be considered a muscle phantom and an emulsion with a fat fraction of 75% can be considered an adipose tissue phantom. As such, the phantoms can be used as standards for calibration and sensitivity testing for T2 relaxometry purposes.

Cortical organoids are valuable tools for studying brain development, modeling neurological disorders, and testing potential treatments. For these studies, we used these devices to experimentally determine neuronal effects on the organoids with the bioelectronic delivery of potassium ions (K+), protons (H+), and γ-aminobutyric acid (GABA). This work is important to reflect bioelectronic device potential in exploring neurological disorders and their potential treatments with a level of precision and detail that was previously challenging to achieve.

The ability to deliver drugs with precise dosages at specific time points can significantly improve disease treatment while reducing side effects. Drug encapsulation for gradual delivery has opened up the doors for a superior treatment regimen. To expand on this ability, programming bioelectronic devices to deliver small molecules enables ad-hoc personalized therapeutic profiles that are more complex than gradual release. Here, we introduce a wearable bioelectronic bandage with an integrated electrophoretic ion pump that affords on-demand drug delivery with precise dose control. In this poster, I will present my contribution to the device fabrication that involves hydrogel synthesis in glass capillaries, testing of the hydrogel conductivity, and device testing. With these devices, delivery of fluoxetine to wounds in mice resulted in a 27.2% decrease in the macrophage ratio (M1/M2) and a 39.9% increase in reepithelialization, indicating a shorter inflammatory phase and faster overall healing. Programmable drug delivery using wearable bioelectronics in wounds introduces a broadly applicable strategy for the long-term delivery of a prescribed treatment regimen with minimal external intervention.

8:00 PM SB05.03.44
Materials and Strategies for Integrating Chloride Membrane Channels with Bioelectronics Le Luo, Emily Lee, Yunjeong Park and Marco Rolandi; University of California, United States

Biological membrane channels actively mediate information exchange between cells and have a main role in molecular recognition. The ‘iono-electronic’ gap between these channels and electronics creates a significant challenge in connecting these channels to electronic devices for efficient signal readout from. To address these challenges, we’ve combined supported lipid bilayers (SLBs) with Ag/AgCl electrodes to specifically target chloride conducting membrane spanning channels. We use the Ag/AgCl contacts to translate the ionic signal from the Cl- ions into an electronic signal at the interface by exploiting the Ag/AgCl electrochemical reaction. With this platform, we show that Cl- conducting channels and Cl- pumping rhodopsins interface better than with other non-selective contacts (Pt) or proton selective contacts (PdH). In the future, this platform can be used to create complementary hybrid devices with membrane spanning channels that are selective to the desired type of ion.

SESSION SB05.04: Engineering Biosynthetic Interfaces
Session Chairs: Guglielmo Lanzani and Flavia Vitale
Tuesday Morning, November 28, 2023
Hynes, Level 1, Room 102

8:00 AM SB05.04.01
Stretchable, High-Modulus Penetrating Microelectrode Arrays for In Vitro Intramuscular Electromyography Qinai Zhao1, Ekaterina Gribkova2, Yiyang Shen1, Jiai Cui1, Noel M. Naughton2, Liangshu Liu1, Jaemin Seo1, Mattia Gazzola2, John A. Rogers1, Rhanor Gillette2 and Hangbo Zhao1; 1University of Southern California, United States; 2University of Illinois at Urbana-Champaign, United States; 3Northwestern University, United States

Three-dimensional (3D) penetrating microelectrode arrays (MEAs) serve as important interfaces with biological tissues in various fields, including neuroscience, tissue engineering, and wearable bioelectronics. These 3D MEAs can penetrate surface layers of tissues, thereby facilitating electrophysiological sensing and electrical stimulation of interior tissues in a minimally invasive manner. Stretchable penetrating MEAs are highly desirable as they can adapt to the deformations of dynamically moving tissues or organs. This adaptability enables stable bioelectronic interfacing,
enhances rendering signal quality, and reduces tissue damage. However, fabricating stretchable 3D MEAs with high electrode modulus required for penetration and customized geometries presents significant challenges in materials integration and patterning. In this study, we present the design, fabrication, and applications of highly stretchable microneedle electrode arrays (SMNEAs) for sensing localized intramuscular electromyography (iEMG) signals in vitro. We have developed a hybrid fabrication scheme utilizing molding, microfabrication, and transfer printing, which enables scalable fabrication of SMNEAs with high electrode modulus (E = 6.6 GPa) and device stretchability (80%). Our SMNEAs also offer controllable electrode dimensions and recording areas, and low electrode impedance. We demonstrate the use of these SMNEAs in recording iEMG signals from the buccal mass of Aplysia. By inserting a multichannel SMNEA with varying electrode lengths into individual muscle groups of the buccal mass, we achieved high-fidelity, localized iEMG recording during muscle contractions and relaxations. The iEMG signals captured by the SMNEAs exhibit distinctive spatiotemporal muscle activation patterns within individual muscle groups of the buccal mass, a level of detail unachievable with surface electromyography (sEMG) using a planar MEA. The high electrode modulus and device stretchability, as well as customized electrode geometries make our SMNEAs potentially useful for local sensing and stimulation of dynamic 3D tissues such as cardiac and neuromuscular tissues.

Biomimetic Designs of Organic Electrochemical Transistors for Human-Interfaced Biosensing and Neuromorphic Computing
Shihong Wang; The University of Chicago, United States

The use of electronic devices for acquiring biological information and delivering therapeutic interventions relies on two aspects: the effective acquisition of physiological information through direct contact with soft bio-tissues, and the high-throughput processing of the acquired data using machine learning. To ensure high-quality signal transactions, the interfaces between bioelectronic devices and bio-tissues must combine signal amplification with stable and conformable contact. Organic electrochemical transistors (OECTs) have been developed as one of the most advanced technologies for high-performance bio-sensing and neuromorphic computing. Moreover, the fastest and most energy-efficient data processing through machine learning is directly on the human body. However, the rigid mechanical properties and the lack of tissue/skin adhesion from transistors largely prevent the formation of such intimate and long-term stable bio-interfaces. In the first part of my talk, I will introduce our material and device designs for introducing three highly important biomimetic properties onto OECT-based biosensors—stretchability, tissue-like softness, and bioadhesive properties. Our rationale designs from the material to the device level allow the realization of these properties with state-of-the-art electrical performance. I will also introduce the strategies and advantages of using these new biomimetic properties in biochemical and bioelectrical sensing. In the second part of my talk, I will introduce our research in imparting intrinsic stretchability onto neuromorphic devices that can provide state-of-the-art computing performance. I will also show the practical applicability of this device for implementing machine-learning computing and algorithms for health data analysis, when the computing hardware is under human-body-induced deformation.

Human Stem Cell-Based Biohybrid Fish
Keel Yong Lee1,2, Sung-Jin Park1, Herdeline Ann Ardoña4, Sean L. Kim2, John Zimmerman2, Andre Kleber2, George Lauder2 and Kevin K. Parker1; 1Sejong University, Korea (the Republic of); 2Harvard University, United States; 3Emory University, United States; 4University of California Irvine, United States

Biohybrid muscular systems have emerged as a valuable test platform for engineering and studying various physiological features, encompassing ion channels to system-level performance. The integration of human cells into simplified synthetic platforms has provided insight into the intricate mechanisms involved. However, the field of biohybrid technology is still in its nascent stages, encountering challenges in attaining system-level structure and performance comparable to their natural counterparts. This study presents a notable breakthrough in biohybrid technology through the development of a human stem cell-based biohybrid fish capable of self-pacing and self-sustaining coordinated locomotion. Taking inspiration from the structural attributes of the sinoatrial node and the multi-layered myocardium, our design incorporates a geometrically insulated cardiac tissue node and muscular bilayer muscle tissues into the biohybrid platform. This integration facilitates spontaneous activation and enables mecanho-electrical signaling coupling between the muscular bilayer muscle tissues. The unique biohybrid design empowers the fish to exhibit spontaneous yet coordinated antagonistic muscle contractions, resulting in self-coordinated body-caudal-fin propulsion. Our autonomous biohybrid fish surpasses existing biohybrid muscular systems in terms of speed and longevity. It attains an optimal performance level comparable to natural body-caudal-fin swimmers, signifying a substantial advancement in the biohybrid technology domain. The achievements of this biohybrid fish lay a remarkable foundation for future autonomous biohybrid species capable of exhibiting complex adaptive behaviors. By harnessing the potential of human stem cells and employing advanced biohybrid designs, we are paving the way for a new era of biohybrid systems that closely mimic and potentially surpass the capabilities of their natural counterparts. These advancements hold immense promise across diverse applications, including regenerative medicine, biomimetic robotics, and enhancing our understanding of the fundamental principles governing biological locomotion.

Modular Biomachines Built from Amphibian Stem Cells
Douglas Blackiston1,2, Sam Kriegman3, Josh Bongard4 and Michael Levin1,2; 1Tufts University, United States; 2Harvard University, United States; 3Northwestern University, United States; 4The University of Vermont, United States

Living organisms remain more adaptive, robust, and regenerative than any synthetic system yet developed. It is thus promising that engineering has seen a surge in novel fabrication materials over the past decade, including a growing catalogue of biological cells and tissues. These living materials have the potential to overcome several problems faced by traditional engineering programs: they are biodegradable, self-powered, self-motile, self-healing, nanometer sized, and contain an inherent biochemistry. Efforts have largely coalesced around biohybrid designs, combining synthetic scaffolds or components alongside living cells and tissues. In complement to this approach, we demonstrate a method for constructing fully biological machines from embryonic amphibian cells, engineered to exhibit a specific behavior. AI methods automatically design diverse candidate lifeforms in silico to perform a desired function. The best performing simulation is then selected, and a living biological representation is constructed using a novel cell-based toolkit sourced from amphibian stem cell lineages. These self-powered representations are then released into aquatic arenas and tested for transference of in silico desired function. The best performing simulation is then selected, and a living biological representation is constructed using a novel cell-based toolkit.

9:00 AM SB05.04.05
Hybrid-Nanomaterials for Cellular Activity Modulation
Tzahi Cohen-Karni; Carnegie Mellon University, United States

My team’s efforts are focused on three major thrusts: (i) synthesis and in depth mechanistic investigation of the unique emergent optical, thermal, electrical and electrochemical properties of novel hybrid-nanomaterials and nanomaterials topologies composed on one-dimensional and two-dimensional building blocks, (ii) application and characterization of hybrid-nanomaterials interfaces with cells and tissue, and (iii) development and engineering of nanomaterials-based platforms to interrogate and affect the electrical properties of tissue and cells such as cardiomyocytes, and neurons, with a specific focus to understand electrical signal transduction in complex 3D cellular assemblies. In this talk I will review our current efforts to control cellular activity.
using photoactive hybrid-nanomaterials. Light has proven itself as a powerful tool to remotely modulate cellular activity with minimal invasiveness. We present a safe neural modulation approach with sub-µJ incident energy using engineered nanostructured Si, Ge, C (out-of-plane grown graphene), and two-dimensional (2D) transition metal carbides nanoflakes without generating cellular stress. Our approach serves as a powerful toolset for studies of cell signaling within and between tissues and can enable therapeutic interventions. Expanding the material library for safe optical modulation and the systematic evaluation of their biosafety will inspire future clinical translation to achieve remote control of cells/tissue in vivo.

Life-Nanomachine Synergism: From Subcellular-Sized Bioelectronic Interfaces to Brain-Like Ultra Energy-Efficient Nanoelectronics
Deblina Sarkar; Massachusetts Institute of Technology, United States

Typical biomedical implants are large (mm-cm in scale) and are highly invasive. To overcome these challenges, we are developing sub-cellular sized bioelectronic devices which are much smaller than the size of even a single cell. These devices can either reside inside a cell or in between cells and provide biological interfacing with high spatio-temporal precision. These can have applications in sensing biological signals as well as modulating them for therapeutics. Going beyond bio-interfacing, I will also discuss how we can learn from biology and build devices that act like the brain for achieving highly energy efficient and environmentally sustainable Artificial Intelligence.

Light-Responsive Cationic Membrane-Targeted Dyes for Cell Membrane Stimulation
Chiara Bertarelli1,2, Guglielmo Lanzani1,2, Valentina Sesti1,2 and Paola Moretti1,3; 1Politecnico di Milano, Italy; 2Fondazione Istituto Italiano di Tecnologia, Italy

In the last few decades, photoswitches are being widely studied as a promising tool for photopharmacology. Light-responsive switches offer the possibility of using light as a clean, non-invasive, and spatio-temporally precise tool to trigger cell signalling and control a variety of biochemical functions. In this framework, reversible light-sensitive ligands successfully allow for a selective and reversible stimulation by means of the photoisomerization of dyes freely diffusing or covalently linked to channels, receptors, or other specific binding sites. Cationic membrane-targeted photochromic materials offer a rather different approach, where the amphiphilic character of the dyes drives their spontaneous partitioning within the cell membrane, with a specific affinity to lipid rafts. The cell signalling is the result of modification of the characteristics of the cell membranes induced by the light-driven conversion of the photoswitch to a metastable isomer. Here, we show the molecular design of these amphiphilic dyes, which combine different families of photochromic compounds and cationic heads targeting the membrane, spaced by alkyl chains. Moreover, the presence of electroactive substituents allows for a high quantum efficiency in the visible range, modifies the isomerization kinetics and the stability in aqueous environment. Among the classes of switching units, azobenzenes demonstrated to be highly promising, and the most effective has proven to be the azepane-aminooazobenzene pyridinum-terminated Ziapin2.2,3 Nevertheless, the use of indigos and Donor-Acceptor Stenhouse Adducts (DASAs) have also been explored. The cationic membrane-targeted azobenzenes have been proven effective in the stimulation of neurons, muscular contraction and in driving optical modulation of bacterial membrane potential. Finally, we demonstrate that the number and the structure of the capping head influence the solubility of the dye, the partitioning, and the stability within the cell membrane, rather than the targeting of membrane-bound cell organelles.

10:45 AM SB05.05.03
Unlocking the Potential and Lessons of 3D Porous Electrodes in Living Biophotoelectrochemical Systems
Linyinng Shang1, Joshua Lawrence1, Laura Wey2, Bartek Witk1, Evan Wroe1, Rachel Egan1, Alyssa Smith1, Silvia Vignolini1 and Jenny Zhang1; 1University of Cambridge, United Kingdom; 2University of Turku, Finland

Living biophotoelectrochemical systems are devices that 'wire' photosynthetic microorganisms (i.e., scalable and sustainable biocatalysts) to 3D-architected electrodes to catalyse reactions for solar-power generation and fuel production using sunlight and water. Despite excellent progress over the last decade, large enhancements in solar-to-charge conversion efficiency are needed to enable real-world applications. One major challenge lies in optimising the bio-electrode interface, where the material and structure of the electrodes play a crucial role. State-of-the-art electrodes in this field are micro-pillar and inverse opal (IO) electrodes fabricated from indium-tin-oxide (ITO) nanoparticles. Here, we provide important lessons for electrode design by tuning the pore sizes and homogeneity of IO-ITO electrodes, characterising their light management ability, surface morphology, electroactive surface area, cells wiring efficiency, and relating these to their biophotoelectrochemical performance. Our results indicate that the bare IO-ITO electrodes of different pore sizes (10-42 µm in diameter) managed light similarly and the larger pore-sized IO-ITO gave rise to the highest photocurrent output. Further attempts to boost light utilisation on these electrodes by adding a bio-mimicking reflective layer at the back of the electrode resulted in increased light reflection but did not influence the photocurrent output significantly, implying the light utilisation of the structure has been optimised. In conclusion, presented is the most comprehensive systematic study in the structure-activity relationship of electrode architecture to biophotoelectrochemical output to our knowledge.
Multifunctional Hybrid Interfaces for Energy Applications
Maurizio Prato1,2; 1Università Degli Studi di Trieste, Italy; 2CIC biomaGUNE, Spain

Among the most innovative strategies in the energy transition, photo-electrocatalytic splitting of water for the production of "green hydrogen" plays a key role, as it provides an ideal energy carrier, obtained from renewable and circular resources and whose production and combustion fuels the H2O2O2 cycle, activated by sunlight. Currently, hydrogen production is mainly obtained from fossil sources, and in particular from natural gas, through thermochemical processes (reforming/pyrolysis) that generate quantities of carbon dioxide with high environmental impact. The perfect mechanisms of the leaf, realized in an artificial environment, allows for the production of hydrogen as a solar fuel, an ideal solution for sustainable development. In particular, a new catalytic system, based on the combination of perylene bisimides and polyoxometalates, arranged in a hierarchical assembly, offers new opportunities for the biomimetic splitting of water.

A Membrane-Targeted Push-Pull Azobenzene for the Optical Modulation of the Membrane Potential
Giuseppe Maria Paternò; Politecnico di Milano, Department of Physics, Italy

The possibility to control living matter with exogenous stimuli can have tremendous impact on synthetic biology, medicine and materials science, among others. For instance achieving control over cells behaviour remains a challenge at the interface between living and non-living matter,[1] and would enable the development of new bio-mimetic and bio-enabled materials able to perform tasks.[2] Within this context, bacteria have arisen as “active and actively-controllable materials”, exhibiting neuro-like behaviour, extended bioelectric signalling[3,4] and tunable assembly properties.[5] In the last decade, it has been observed that the regulatory element of such an active behaviour is the electrical potential across the membrane, which governs bacteria electrophysiology, metabolisms and bioenergetics.[6] Light can be a powerful tool in these regards, as one can control the membrane potential and, thus, cell function and behaviour remotely and with relatively high spatiotemporal precision.

Here, I will show that a membrane-targeted azobenzene can be used to photo-modulate precisely the membrane potential in cells of the Gram-positive bacterium Bacillus subtilis. We found that upon exposure to blue- green light, the isomerization reaction in the bacteria membrane induces hyperpolarisation of the potential (ΔV = 20 mV), within a bio-mimetic mechanism reproducing the initial fate of retinal. Apart from being promising results in the view to photocontrol bacterial motion and assembly behavior in consortia, this approach also highlights the role of previously uncharacterized ion channels in bacteria electrophysiology.[7]

A Membrane-Targeted Push-Pull Azobenzene for the Optical Modulation of the Membrane Potential
Arianna Magni1,2, Valentina Sesti1,2, Matteo Moschetta2, Giuseppe Maria Paternò1,2; 1Politecnico di Milano, Italy; 2Istituto Italiano di Tecnologia, Italy

In the last years, the use of light as a tool for modulating membrane potential and bioelectricity has emerged as a fascinating opportunity, with the broad aim of establishing life-machine symbiosis that can help in healing disorders and restoring biological functions. An approach to induce light sensitivity in animal cells, which are usually transparent to visible light, is the use of photocatalysts. These are photoactive materials that can decorate or localize into the cell membrane and are able to transduce light into a signal that can be processed by the cells. A variety of materials are suitable for the non-genetic opstostimulation of cells, ranging from inorganic nanoparticles to organic polymer films and nanostructures.

The cell membrane and its electrical potential represent the core of bioelectricity, hence constituting an ideal target for exogenous modulation of signalling. For this reason, we chose a push-pull azobenzene molecule (PP-2Pyr) as a membrane-targeting photoactuator that induces a charge displacement upon isomerization. The work comprises the physical characterization of the photoactuator, focusing on the isomerization dynamics, and the evaluation of the photoinduced effects on HEK-293 cells. The focus is on unveiling the photostimulation mechanism, intending to link the photophysical changes occurring in the molecular photoactuator after light absorption, to the biological effects on in vitro cell models. The proposed light-driven mechanism...
organizes from inferences on the molecular partitioning of PP-2Pyr in the two membrane leaflets and on the rearrangement of the charges adsorbed to the membrane due to variations in the molecular dipole moment upon light excitation.

2:15 PM SB05.06.03

Surprising Enhancement of Extracellular Electron Transfer (EET) from Electroactive Bacteria to Charge Collectors by Fumarate and Further Enhancement of EET by Functionalized Carbon Nanotubes (CNTs) Gábor Méhes1 and Arghamalya Roy2; 1Waseda University, Japan; 2Linköping University, Sweden

We are witnessing the convergence of organic electronics with applied microbial electrochemistry for applications of energy harvesting, biosensing, electronics, and other words. Biocompatible films made of conducting organic molecules interface electroactive (and other) bacteria in electronic and electrochemical devices, such as microbial electrochemical cells, biobatteries and transistors. Recently we have contributed to these efforts by creating a 3D hybrid bioelectrode based on PEDOT:PSS and Shewanella oneidensis MR-1 for enhancing the output of MESs[1], and by the first demonstration of amplification of EET by organic electrochemical transistors [2]. After shortly introducing these two papers, we will discuss two ways EET can be enhanced to yield MESs with high performance closer to realistic applications. More concretely, we have been investigating the effect of chemically-functionalized CNTs, as well as the biomolecule fumarate, on the magnitude and temporal dynamics of EET. We observed distinctively different effects on EET based on the chemical agent for functionalization of CNTs, and an unexpected role of fumarate in EET dynamics.

Seeing the Sound—An Ultrasound-Mediated Intravascular Light Source for Noninvasive Brain Modulation Guoseong Hong; Stanford University, United States

Understanding the inner workings of the brain requires a bidirectional interface that enables causal manipulation and simultaneous interrogation of neural activity. Existing electrical and optical brain interfaces are usually based on implanted devices and invasive procedures that necessarily damage the endogenous brain tissue and constrain the subject’s free behavior. To address these challenges, our lab leverages the latest advancements in materials science to develop minimally-invasive functional interfaces for monitoring and modulating the brain. Specifically, in this talk, I will present three materials-inspired strategies: 1) light sculpting in the tissue with ultrasound by turning the endogenous circulation system into an “optical flow battery”, 2) an intravascular light source inspired by the biomineralization process in nature, and 3) deep-brain neuromodulation inspired by the infrared sensitivity of rattlesnakes. I will conclude my talk by presenting an outlook on how advances in materials science may facilitate the development of next-generation brain-machine interfaces.

Integration of Polymers with Synthetic Soft Matter and Biological Matter Towards Sensing Alberto Salleo; Stanford University, United States

An attractive feature of polymeric mixed conductors is their ability to swell in water thus forming a soft interface amenable to interacting with biological matter. Further, their ability to transduce ionic fluxes into electronic fluxes opens opportunities in sensing. Indeed, one can imagine combining the specificity and sensitivity of biological matter with the functionality of semiconductors in a single hybrid device. In this talk I will describe our work on integrating lipid bilayers, either synthetic or obtained from cell walls to sense a variety of environmental cues. For instance, we demonstrate specific sensing of toxins and viral fusion as well as the detection of opening and closing of selected ion channel. I will describe the surface treatments needed to enable such hybrid interface to retain its functionality as well as modeling of the device response and its limitations.

4:00 PM SB05.06.06

Vertical Organic Electrochemical Transistors for Enhanced Performance and Circuit Integration Antonio Facchetti; Northwestern University/Flexterra Inc, United States

Organic electrochemical transistors (OECTs) have been intensively investigated for applications in state-of-the-art wearable electronics and next-generation biosensor technologies due to their outstanding amplification, sensitivity to ionic and ultra-small electrical potential signals, compatibility with roll-to-roll fabrication processes, and low driving voltages. The far majority of OECT studies are based on a device structure comprising coplanar source-drain electrodes in contact with the organic semiconductor. Recently we proposed a new architecture where the electrodes are vertically stacked achieving high transconductance and current on-off ratio for both p- and n-type semiconductors. This vertical OECT architecture (vOECT) is also attracting for dramatically increase transistor density for high-resolution OECT sensors and complementary driving circuits. However, scalable patterning methods for organic semiconductors and optimization of the semiconductor topology for efficient monolithic integration of vOECTs remains technologically challenging, but essential for applications in complex and high-density OECT circuit arrays and multi-functional data acquisition. In this presentation we report on the monolithic integration of flexible vOECT arrays for driving high-density (> 7 M OECT/cm2) active-matrix complementary logic circuits.

Stand-Alone Conformable Bioelectronics Based on Integrated Internal Ion-Gated Organic Electrochemical Transistors Claudia Cea1,2, Zifang Zhao1, Jennifer Gelmans and Dion Khodagholy1; 1Columbia University, United States; 2Massachusetts Institute of Technology, United States

Effectiveness of medical treatments can be greatly influenced by individual variations, prompting the need for methods that enable continuous monitoring of physiological signals and personalized responsive delivery of therapeutics. Implanted bioelectronic devices play a crucial role in these methods, but there are challenges that prevent their widespread adoption. The ability to perform these demanding electronic functions in the complex physiological environment with minimum disruption to the biological tissue remains a big challenge. An optimal fully implantable bioelectronic device would require each component from the front-end to the data transmission unit to be conformable and biocompatible. For this reason, organic material-based conformable electronics are ideal candidates for components of bioelectronic circuits due to their inherent flexibility, and soft nature. Here, we present a vertical internal ion-gated organic electrochemical transistors (vIGT) as a high-density, high-amplification sensing component as well as a low leakage, high-speed processing unit. In addition, a novel wireless, battery-free strategy for electrophysiological signal processing, transmission, and processing that employs IGTS and an ionic communication circuit (IC) is introduced. We show that the wireless-powered IGTS are able to acquire and modulate neurophysiological data in vivo and transmit them transdermally, eliminating the need for any hard Si-based electronics in the implant.
4:30 PM SB05.06.08
Organic Electrochemical Transistors as On-Site Signal Amplifiers for Electrochemical Aptamer-Based Sensing Xudong Ji and Jonathan Rivnay; Northwestern University, United States

Electrochemical aptamer-based sensors are typically deployed as individual, passive, surface-functionalized electrodes, but they exhibit limited sensitivity especially when the area of the electrode is reduced for miniaturization purposes. We demonstrate that organic electrochemical transistors (electrolyte gated transistors with volumetric gating) can serve as on-site amplifiers to improve the sensitivity of electrochemical aptamer-based sensors. By monolithically integrating an Au working/sensing electrode, on-chip Ag/AgCl reference electrode, and Poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) counter electrode — also serving as the channel of an organic electrochemical transistor, we can simultaneously perform testing of organic electrochemical transistors and traditional electroanalytical measurement on electrochemical aptamer-based sensors including cyclic voltammetry and square-wave voltammetry. This device can directly amplify the current from the electrochemical aptamer-based sensor via the in-plane current modulation in the counter electrode/transistor channel. The integrated sensor can sense transforming growth factor beta 1 with 3 to 4 orders of magnitude enhancement in sensitivity compared to that in an electrochemical aptamer-based sensor (292 μA/dec vs. 85 nA/dec). This approach is believed to be universal, and can be applied to a wide range of tethered electrochemical reporter-based sensors to enhance sensitivity, aiding in sensor miniaturization and easing the burden on backend signal processing.

4:45 PM SB05.06.09
Soft Polymer for Enhanced Electron Transfer Rossella Labarile1, Danilo Vona2, Maria Varsalona2, Matteo Grattieri2, Melania Reggente3, Ardemis Boghossian4, Fabian Fischer4 and Massimo Trota5; 1Consiglio Nazionale delle Ricerche, Italy; 2Università degli Studi di Bari Aldo Moro, Italy; 3Ecole Polytechnique Federale de Lausanne, Switzerland; 4Haute école Spécialisée de Suisse Occidentale, Switzerland

Photosynthetic bacteria are anoxygenic microorganisms with highly versatile metabolism, as they use sunlight to oxidize a broad variety of organic compounds in addition to heterotrophic and photoautotrophic alternative metabolisms. Conductive polymer layers on the surface of several bacterial species have been used to intercept and funnel the electron flow produced by microbial metabolism outside the cells and transfer it to an electronic circuit of a biohybrid device. Polydopamine (PDA), produced by self-assembly of dopamine, is a very versatile and bioinspired polymer with widespread applications1 mostly due its ability to adhere and cover surfaces of different chemical composition. The oxidative conditions employed for the formation of this dark insoluble polymer are mild and biocompatible and have inspired scientists to develop novel nanomaterials. Post-functionalization of PDA2 also enables fine tuning of properties. Furthermore, the ability of this monomer to self-assemble and polymerize in the bacterial growth medium was considered one of the requirements of the polymer to be used as coating material beside the tunable conductive properties and the flexible structure. Biocompatibility of dopamine was tested by in vivo addition in the growth media of the photosynthetic purple non sulphur Rhodobacter (R.) sphaeroides3 in anoxygenic conditions.

We have used PDA conductive coatings as biotic-abiotic interfaces in biohybrid photoelectrochemical devices through the encapsulation of entire bacterial cells or single components – e.g. photosynthetic reaction center (RC) - of R. sphaeroides4,5 ensuring electronic communication of the biological component with the electrodes5 surfaces in photoelectrochemical cells.

5:00 PM SB05.06.10
Soft and Ultra-Thin Wearable Tactile Interface with Electrical Impedance Tomography for High Spatiotemporal Resolution Kyabeen Kim, Jung-Hoon Hong and Ki Jun Yu; Yonsei University, Korea (the Republic of)

Wearable tactile mapping devices, a burgeoning area in human-computer interaction, have gained significant attention due to their wide range of applications. These include interfaces for virtual reality and gaming devices, haptic feedback systems, and artificial skin for medical and robotic applications. Tactile sensors, as a cornerstone of this technology, must achieve high spatiotemporal resolution while maintaining soft mechanical properties to replicate the human sense of touch accurately. This is paramount in creating seamless and immersive user experiences, whether it’s in navigating virtual environments or enabling prosthetic devices to mimic real tactile feedback. However, the development of these sensors presents distinct challenges. Current high resolution tactile sensing technologies predominantly rely on inorganic material-based sensors, which, despite offering high spatial resolution and reliability, pose significant limitations. They are inherently brittle and ill-suited to accommodate mechanical deformation, a critical attribute for wearable sensors meant to conform to human skin. On the other hand, soft materials, characterized by a low Young's modulus, are mechanically desirable for wearable tactile systems as they can conform to varied and changing surfaces. However, the fabrication processes for these materials tend to deviate from conventional microelectronics manufacturing techniques. This divergence often results in less sophisticated device structures, hindering the development of advanced and intricate tactile sensing systems.

To overcome these limitations, we propose an ultra-thin tactile sensor offering single-cell based multi-channel array functionality via the application of electrical impedance tomography (EIT). The sensor's stretchable sensing area consists of an elastomeric substrate and encapsulation, alongside a conductive functional layer comprising multi-wall carbon nanotube (MWCNT) layers. With a thickness of just 50 microns, this low-modulus, highly stretchable sensor can conformably adhere to human skin, maintaining robust functionality under applied force and mechanical deformation. The EIT
computational analysis method allows our single-cell device to operate as a multi-channel array by reconstructing high-resolution conductivity changes within the broad sensing area. Piezoresistive effect-induced conductivity changes in the MWCNT-based conductive layer occurred when external forces are applied, causing mechanical deformation, bending, and stretching. These changes can be mapped by EIT measurements using surrounding electrodes, achieving high-resolution detection of force applications. This EIT-based soft tactile interface can differentiate external pressures down to a 1mm scale, and vertical deformation of a few hundred micrometres. We validated our tactile sensor's functionality through two real-time applications: a wearable drone controller and a handwriting recognition interface. Our work illustrates the potential of applying EIT to soft, ultra-thin elastomeric devices for the development of high-performance wearable tactile sensing systems. These systems could find potential applications in healthcare, robotics, and human-machine interfaces, paving the way for more advanced tactile sensors in the future.

SESSION SB05.07: Poster Session II: Functional Soft Materials for Biointerfacing

Battery-Free, Fully Implantable Optoelectronic System for Programmable Photodynamic Therapy and Tumor Growth Monitoring In Sik Min, Kiho Kim and KJ Jun Yu; Yonsei University, Korea (the Republic of)

Photodynamic therapy (PDT) is garnering attention as a promising next-generation cancer treatment modality that utilizes specific wavelengths of light and photosensitizers to target and treat malignant tumors with high selectivity, resulting in minimal side effects and exclusively targeting cancer cells. Photosensitizers are selectively accumulated in cancer cells, transition into an excited state upon exposure to incident light energy. Subsequently, the surrounding oxygen is converted into reactive oxygen species, which serve as the mechanism for destroying cancer cells without inflicting significant damage or pain on normal cells, thus enabling the destruction of malignant tissue. Due to the limited penetration of light into deep tissues within living organisms, conventional PDT has predominantly been confined to epithelial cancers such as skin cancer, bladder cancer, and bronchial carcinoma. Furthermore, light delivery systems for PDT have relied on bulky and expensive laser-based equipment, posing significant constraints on user accessibility. To overcome these challenges, various LED-based fully implantable PDT systems have recently been developed. However, existing fully implantable PDT systems have faced limitations in precise light intensity control and adjustment of PDT parameters, as they are based on passive electronics or simple circuits incapable of performing advanced functions. Moreover, the implementation of wireless systems solely for power delivery has hindered the utilization of tumor-related data monitoring based on bidirectional communication systems. Here, we introduce a battery-free and fully implantable optoelectronic system for PDT that enables precise light intensity control and scattered light measurement for tumor growth monitoring. This system involves the insertion of a μ-LED probe into the tumor to deliver light of 624 nm wavelength for PDT. The system allows for precise control of LED light intensity from 0% to 100% through wireless user control using a Bluetooth Low Energy communication. Additionally, the system incorporates the capability to monitor tumor growth by measuring the scattering of light within the tumor tissue through an external phototransistor placed outside the tumor. We performed in vitro experiments to confirm that the therapeutic effects vary at different light intensities of 0%, 30%, 70%, and 100%, and observed tumor growth inhibition through 624 nm-based PDT performed on a nude mouse model during a three-week in vivo experiment. Furthermore, we validated the feasibility of a system for monitoring relative changes in tumor size by measuring the scattered light from the tumor using a phototransistor, through ray-tracing simulation, ex vivo and in vivo experiments. This wireless electronics-based PDT system holds significant potential for expansion into a multimodal system with diverse functionalities such as a closed-loop system based on simultaneous treating and monitoring system, providing an opportunity to realize an effective and low side-effect cancer treatment while simultaneously collecting valuable feedback data related to the treatment.

The Relationship Between Surface Oxidation States and Antiviral Activity of Nano-Columnar Copper Thin Films Keisuke Shigetoh, Rie Hirao and Nobuhiro Ishida; Toyota Central R&D Labs Incorporated, Japan

Antiviral coatings capable of inactivating a broad spectrum of viruses are crucial in the fight against viral mutation and emergence. Drawing inspiration from cicada wings known for their mechano-bactericidal properties, this study proposes the use of nano-columnar Cu thin films [1]. These thin films of Cu and its oxides were fabricated on a polymer surface by a sputtering technique, and their virus-inactivate capabilities were tested against both enveloped bacteriophage Φ6 and non-enveloped bacteriophage Qβ. Among the fabricated films, the Cu thin films showed the highest antiviral properties. The Cu thin films diminished the infectious activity of the bacteriophages by five orders of magnitude within half an hour, the CuO thin films reduced it by three orders of magnitude, while the CuO thin films lessened it by less than one order of magnitude. Moreover, the excellent antiviral activity of Cu thin films was confirmed under the pseud-practical conditions using viral solutions that contain contaminating proteins, assuming such in human saliva. After being exposed to ambient air for a month, the antiviral activity of the CuO thin film dropped by one order of magnitude. Nevertheless, the Cu thin films consistently demonstrated a higher degree of antiviral activity compared to the CuO thin films. A detailed analysis of the surface chemical states via X-ray photoelectron spectroscopy indicated that the fabricated Cu thin films showed slower oxidation to CuO than that of the CuO thin films. Therefore, the formation of CuO possibly works as a passivation layer for antiviral activity. The significant antiviral activity and oxidation durability of the Cu thin films can have immense practical utility, while their oxidation resistance might be a characteristic property of nanostructured Cu fabricated by the sputtering method. Finally, the antiviral activity of the nano-columnar Cu thin films against infectious viruses in humans was demonstrated by the binding inhibition of the SARS-CoV-2 spike protein to the angiotensin-converting enzyme 2 receptor (ACE2). The cleavage of the disulfide bonds in the spike proteins by copper ions is thought to have led to a significant reduction in binding affinity between spike protein and ACE2. The small mass loading (6 μg cm⁻²) of the Cu thin films ensured transparency and flexibility of the substrates, with a low environmental risk; this is particularly useful for coating applications on disposable masks and filters.

Novel Structural Concept for High-Performance Gold Nanowire Stretchable Electrode Toward Ultra-Flexible Biomedical Applications Satoshi Takahashi, Yuki Noda, Naomi Toyoshima, Takafumi Uemura and Tsuyoshi Sekitani; Osaka University, Japan; National Institute of Advanced Industrial Science and Technology, Japan

Gold nanowires (AuNWs) are attractive candidates to develop stretchable/biocompatible electrodes for use in biomedical sensors and neural interfaces. In
this study, we propose a novel structural concept to enhance the strain-conductive performance of stretchable AuNW electrodes, the formation of a "mesoscale mesh"-shaped "nanowire-thin film composite" structure in the AuNW electrodes. The AuNWs-AuTF composite electrodes with a mesh structure using an Ecoflex substrate decrease the absolute resistance by 22% and the normalized resistance changes by 24% compared with the AuNW electrode without a composite or mesh structure under 80% strain. Furthermore, our stretchable electrodes, composed of AuNWs, AuTFs, and Ecoflex have excellent biocompatibility and thus have great potential for use in biomedical applications. Due to the growing demand for biomedical devices that are mechanically/biologically compatible with human organs, stretchable AuNW electrodes have attracted considerable attention because of their stable strain-conductive performance and biocompatibility owing to the nanowire network structure and the chemical inertness of gold, respectively. Although numerous studies have been conducted on stretchable AuNW electrodes, further improvements in the inadequate performance are required for these electrodes to appear in the industrial market. As performance indicators of stretchable electrodes, two parameters are used to evaluate their strain-conductive properties: absolute resistance and normalized resistance change. Previous studies have suggested unique methods to improve the parameters of stretchable metal nanowire electrodes. For instance, the deposition of metal thin film on metal nanowire electrodes to form nanowire-thin film composite electrodes can reduce the absolute resistance of pristine metal nanowire electrodes over a broad strain range. However, this method may increase the normalized resistance change owing to the mechanical degradation of the metal thin film. In contrast, the formation of a mesh structure over metal nanowire electrodes can suppress the normalized resistance change under tensile strain. However, the formation of the mesh structure decreases the conductive area of the electrodes, which can induce a higher absolute resistance. In this study, we integrate these two unique but imperfect methods and introduce this novel structural concept to AuNW electrodes to improve both their absolute resistance and normalized resistance change simultaneously for the realization of a high-performance and biocompatible electrode. The AuNW-AuTF composite electrodes with a mesh structure demonstrate 22% lower absolute resistance and 24% smaller normalized resistance change than those of the pristine AuNW electrode without a composite or mesh structure under 80% strain. From the result, we consider the AuTF in the composite electrode facilitates the current flow although the mesh structure decreases the conductive area of the electrode, whereas the mesh structure suppresses the mechanical failure of the AuTF by reducing the tensile stress. Additionally, the AuNWs, AuTFs, and Ecoflex have been previously used in biomedical devices and confirmed to be biocompatible. Therefore, mesh-shaped AuNW-AuTF composite electrodes can be applied to biomedical devices. This novel structural concept which can improve strain-conductive performance is versatile for any type of stretchable metal nanowire electrodes. Using the AuNWs, we developed high-performance, elastic, and biocompatible electrodes suitable for use in biomedical devices. Our findings will accelerate the development of biomedical applications not only in academia but also in industry.

8:00 PM SB05.07.04
Silk Fibroin: An Adaptive Natural Surfactant for Aqueous Solution-Processed Nanoelectronics over All Substrates Taehoon Kim and Fiorenzo Omenetto; Tufts University, United States

Universal wettability is especially relevant for aqueous solution processing, which has gained prominence due to the growing demand for water-based fabrication of electronic and photonic components. Although water is an ideal solvent in terms of abundance and environmental sustainability, its relatively high surface tension limits its wetting behavior. Surface pre-treatments, surfactants, or organic co-solvents are commonly used to enable aqueous solution processing. However, these methods have drawbacks, including their potential to impact material composition and morphology, increase costs, and raise environmental concerns. Thus, the development of a practical, versatile, and sustainable strategy for achieving universal wettability of aqueous solvents is of significant importance.

In this study, we present the utilization of silk fibroin (SF), a natural biopolymer, to modulate the interfacial energy landscape of hydrophobic surfaces. By incorporating small amounts of SF in thin-film precursor solutions, we demonstrate its role as an adaptive molecular bridge that enables the deposition of aqueous solutions on otherwise unwettable substrates. The amphiphilic composition of SF chains confers exceptional interfacial energy control, resulting in enhanced wetting behavior. Furthermore, we investigate the vertical self-segregation mechanism of SF during the formation of metal-oxide thin films, which can be harnessed to preserve the electronic properties of the active layers. By combining these effects, we successfully fabricate (opto)electronic structures on substrates with significantly different surface energies using all water-based precursor solutions, without compromising device performance due to the presence of the bioinspired surfactant.

Overall, these results present a comprehensive exploration of SF as a means to regulate the interfacial energy for achieving universal wettability in aqueous solution processing. The findings contribute to the development of practical and sustainable approaches for fabricating electronic and photonic thin films, offering potential benefits in terms of cost, energy consumption, and environmental impact.

8:00 PM SB05.07.06
Thermo-Responsive Shape Memory Polymer for use in Implantable Blood Pressure Measurement Device Arjan Sall, Zoe Schofield and Liam Grover; University of Birmingham, United Kingdom

Hypertension or high blood pressure is a worldwide problem as it has become the leading cause in the growth of cardiovascular disease and premature death. This is especially true in countries of low to middle income [1]. As a result of this it is critical that patient’s blood pressure is measured on a regular basis in order to provide the correct treatment. Current methods of blood pressure measurement such as the sphygmomanometer or ambulatory methods in a clinical setting or electronic monitors used at home are either too invasive for the patient, are subject to the general fluctuation of blood pressure throughout the day or are only able to take singular measurements [2][3]. This has produced the need for a method of blood pressure measurement that is non-invasive and is able to provide continuous and reliable blood pressure measurement throughout the day. The focus of this presentation will be the development of a biocompatible shape memory polymer (SMP) that will be used in the fabrication of a blood pressure sensor that will allow a non-invasive implantation of the device into the subcutaneous layer of the wrist.

Mechanical characterisation of the current sensor material, polydimethylsiloxane (PDMS), will be presented to provide a reference point for the development of the SMP. The fabrication process of the SMP based on a blend of PDMS and Polycaprolactone will be described, and the systematic variation of the polymer composition will be explained detailing its impact on the shape memory effect elicited, while also comparing the mechanical properties of the SMP formulations to the pure PDMS. The mechanical characterisation carried out will focus on the compressive strength of the material where cyclic loading tests will determine the fatigue behaviour of the SMP and maximum compression tests will allow the calculation of the elastic modulus of the material. This will help determine the longevity of the implant. Aging of the samples using PBS at 37°C and 70°C will assess the ability of the material to withstand prolonged subcutaneous implantation. Dynamic mechanical analysis and dynamic scanning calorimetry will be used to determine the transition temperatures (Tg) of each of the SMP formulations with 37°C being the target temperature. Once an SMP with the target Tg has been produced the shape fixity, shape recovery and recovery rate will be tested. The goal for this project is to create a material that is able to withstand both the mechanical and biological stresses of blood pressure measurement and subcutaneous implantation which will allow the sensor to provide a reliable and consistent blood pressure measurement.

References
Novel bio-inspired materials are of great interest to both the materials science and synthetic biology communities. The Gobbo group has recently developed “protocellular materials” (PCMs) assembled from protein-polymer protocol units (called proteinosomes) that are annealed into sheets through interfacial self-assembly. These nanomembranes are comprised of a self-assembled, crosslinked nanoparticle membrane with an inherent molecular weight cut off (MWCO) (ca. 40 kDa) that allows the entrainment of cargoes of sufficiently high molecular weight.[8] The resultant PCMs form a population of covalently bound proteinosomes have been demonstrated to be robust and free standing in water. The current trajectory of research in this area is towards improving the mechanical properties of the PCMs’s constituent proteinosomes, such that the resultant PCM can more closely mimic biological cell consortia. Moreover, developing the responsivity of PCMs to physiochemical stimuli is of great interest to allow the use of PCMs in a range of applications, including their potential use as a substrate on which to grow communities of living cells. The characterisation of PCMs has been restricted to confocal and electron microscopy, which, although both powerful techniques, is naturally limiting in the context of mechanical properties.[8]

In this communication I will show how a novel photosensitive crosslinker and a reactive thermoresponsive polymer can be combined to generate three-dimensional hydrogel “protocytoskeletons” within the proteinosomes of PCMs. This protocytoskeleton can be disassembled on irradiation, leading to the loss of mechanical integrity of the PCM. The selective disassembly of PCMs can be achieved with high spatio-temporal control on irradiation with UV light, and that disassembly can be monitored through the use of microindentation using a recently developed methodology.[9] Moreover, the photobleachable proteinosomes of the PCM can be precisely photo-patterned to generate new, complex three-dimensional architectures. Whilst these novel materials are still in the early stages of development, they have the potential to be used in diverse applications from drug delivery to soft robotics.

8:00 PM SB05.07.09
Hofmeister Salts Enhance the Water-Responsive Actuation Energy of Bacillus Subtilis Cell Walls
Seungr1 Kim1,2, Haozhen Wang2,3, Darjan Podbevšek2 and Xi Chen1,2, 1The City College of New York, United States; 2CUNY Advanced Science and Research Center, United States; 3The City University of New York, United States

Water-responsive (WR) materials have attracted significant attention due to their potential applications as high-energy actuators for soft robotics, smart structures, and energy harvesting devices. Recently, the cell walls of Bacillus (B.) subtilis have shown a high WR energy density of 72.6 MJ m⁻³, surpassing that of existing actuator materials. In this study, we found that the exceptional WR energy density of the cell walls is attributed to nanoconfined liquids' properties. Furthermore, we discovered that strengthening the hydrogen (H) bonding network of these nanoconfined liquids could further increase this energy density. To investigate this, we systematically modulated the H-bonding network using Hofmeister salts, specifically potassium sulfate (K₂SO₄) and potassium iodide (KI), which respectively strengthen and weaken the H-bonding network. Cell walls treated with a 10 mM K₂SO₄ solution exhibited a 22.4% enhancement in energy density, reaching 101.8 MJ m⁻³. However, higher concentrations (30-50 mM) of K₂SO₄ or any KI solutions led to reduced WR energy densities. These observations highlight the crucial role of the enhanced H-bonding network in achieving high-performance WR materials and emphasize the existence of a certain range of H-bonding strength for optimizing WR performance. Moreover, our study presents a cost-effective and scalable approach that utilizes Hofmeister salts to manipulate and enhance the WR performance of hygroscopic materials.

Tunable Interface of Polymeric Composite of Electroactive P3HT-MWCNT Thin Film for Bioelectronics Applications
Paola Campanione1,2,3, Grazia Maria Lucia Messina1, Francesca Santoro2,3 and Giovanni Marletta1; 1University of Catania, Italy; 2Forschungszentrum Juelich, Germany; 3RWTH Aachen University, Germany

One of the main challenges in bioelectronics concerns the development of materials able to respond to external stimuli and that are compatible with excitable tissues. In the last decades, conductive polymers (CPs) have been widely studied and developed as electroactive materials for applications in interfacing biological systems. Their conductive properties allow cells or tissue growth upon stimulation, and their “soft” nature allows to form a better biotic-abiotic interface and reduce the mechanical mismatch between material and cells thanks to the elasticity of polymeric films that is similar to biological tissues [1]. CPs’ physical and ionic-conductive properties can be optimized through the formation of composites enriched with carbon nanotubes or graphene in order to improve electron transport capacity, decrease impedance and increase flexibility. Their biocompatibility can be improved using functionalization methods with biologically active molecules [2] even if the influence of blending agents is still under investigation. The precise control of CP films nano-topography may have interesting effects for biointerfacing and improving the cell-chip coupling for cell activity recording and stimulation, acting on protein adsorption and cell adhesion.

In this work, we report on how to obtain stable electroactive nanocomposite dispersion using semiconducting regioregular poly(3-hexylthiophene-2,5-diyl) (P3HT), with different percentages in weight of multi-walled carbon nanotubes (MWCNT) and how to deposit to form homogeneous thin films. Their morphologies have been investigated by means of atomic force microscopy (AFM) and scanning electron microscopy (SEM), and the attention has been focused on the “cushion” effect due to the presence of the fuller in the polymeric matrix that allow an interesting modification in mechanical properties (Young’s Modulus), analyzed by nanindentation with atomic force microscopy (AFM), and the formation of a “softer” interface. Considering the central role of extracellular matrix protein in cell adhesion, their interactions at the interface with our systems were investigated by means of quartz crystal microbalance with dissipation monitoring (QCM-D). Noteworthy, it has been found that thanks to the larger available surface area of the blend thin film that act like a sponge, proteins are adsorbed in a very different way with respect to the bare semiconducting P3HT. Indeed, both the adsorption kinetics and the adsorbed mass are increased for each extracellular matrix proteins. The biocompatibility of the systems with different cell lines has been investigated as well as the effect on cell metabolism. Moreover, the effect of the systems on the variation of the distance between cell and electrode has been analyzed by focused ion beam - scanning electron microscopy (FIB-SEM). The realization of this nanostructured bioelectronic interface represents an example of 2.5D cell culture and promotes the optimization of the cell-chip coupling by tuning the cleft between the membrane of the cell and the electrode, also acting on the formation of the extracellular matrix protein coating that helps cells attach to, and communicate with, nearby cells, and plays an important role in cell

0244-2

growth, cell movement, and other cell functions.

Modulating Light Transmission using Particle-Based Displays
Patrick A. Sullivan, Daniel Wilson and Leila Derasvi; Northeastern University, United States

E-inks utilize reflected ambient light rather than emitted light to display changes in text or images. As such, they can generate and hold patterns using very low power. Electrophoretic, electroluminescent and electrochromic techniques have been used commonly in this space together with homogeneous materials designed specifically adapted to a biased stimulus to create these low power displays. We asked whether inherently asymmetric materials like Janus particles can be similarly used in low energy adaptive displays. In this work we investigate methods to synthesize and manipulate the transmissivity of Janus particles made with a metal and a dielectric material. Using custom designed optical chambers, we assayed the effect of electric field on particle rotation which ultimately correlated to a change in the transmission of visible light. Our preliminary results demonstrate a realistic approach to using asymmetric Janus materials as active elements for future display applications.

8:00 PM SB05.07.13
3D-Printed, Biomimetic, Electroconductive Scaffolds for the Promotion of Axonal Regrowth after Spinal Cord Injury
Liam Leahy1,2, Ian Woods1,2, Jack Maughan1,2, Javier Gutierrez Gonzalez,2,2, Michael Monaghan1,2, Adrian G. Devan1,2 and Fergal O’Brien1,2; RCSI, Ireland; 2RCSI and TCD, Ireland; Trinity College Dublin, The University of Dublin, Ireland

Spinal cord injury (SCI) induces paralysis by damaging axons, neuronal processes that carry signals about the body. Injured axons are unable to regrow through the injury site, preventing functional recovery. Electrical stimulation (ES) has shown signs of being capable of inducing neuronal regrowth and support functional recovery. We propose that a tailored, electroconductive scaffold with composition designed to support and direct ES to regrowing axons may help drive them toward their distal targets and restore function. This is a difficult challenge to tackle, as the spinal cord is a complex tissue comprising discrete axonal tracts. An ideal scaffold for this system must mimic the structure of the cord and provide the supportive cell environment of the native extracellular matrix (ECM). To overcome this challenge, ECM-functionalised electroconductive scaffolds designed to mimic the axonal tract structure of the human spinal cord were fabricated by coating 3D-printed polycaprolactone (PCL) with conductive polypyrrole (PPy) nanoparticles and filling the structure with freeze-dried ECM to direct ES to promote neurite outgrowth.

Biomimetic PCL scaffolds were 3D-printed with an Allevi 2 printer to produce uniaxially aligned, interlocking cylindrical architectures, with several channel sizes to match the diameters of human spinal cord axonal tracts. PPy was polymerised in situ to form an electroconductive nanoparticle coating on PCL scaffolds, verified via FTIR and SEM imaging. Electroconductivity was measured via the 4-point probe method. Scaffold biocompatibility was assessed by growing neurons on 2D PPy/PCL films and measuring metabolic activity, cellular DNA and neurite outgrowth. Neurotrophic ECM was directionally freeze-dried within scaffold channels to mimic the native spinal cord environment and further promote neurite extension. Neurons were electrically stimulated on ECM-functionalised PPy/PCL and PCL scaffolds using an Ionoptix bioreactor and imaged to assess the effect of ES-induced neurite extension over 7 days.

3D-printed PCL scaffolds of all channel sizes were successfully coated with PPy nanoparticles. Conductivity of the PPy coating was measured at 15±5S/m, 30 times higher than native spinal cord tissue. PPy/PCL substrates were as biocompatible as PCL, indicating the suitability of PPy coated scaffolds for neuronal tissue engineering. Freeze-dried ECM formed aligned pore structures within scaffold channels, providing a physical guide for neurite outgrowth. No difference in electrical properties or cell activity were measured in scaffolds of various channel sizes, showing scaffolds can be scaled to match native cord structures without losing functionality. Electrically stimulated neurons on PPy/PCL scaffolds showed increased average neurite length and total cellular DNA compared to PCL scaffolds, suggesting ES via a conductive scaffold promotes healthy neuronal growth.

In conclusion, biomimetic 3D-printed electroconductive scaffolds were manufactured and characterized and demonstrated excellent biocompatibility. Scaffolds were successfully scaled to match the sizes of axonal tracts, and electrically stimulated neurons exhibited increased neurite extension within PPy/PCL scaffolds compared to inert PCL controls, showing the potential of the electroconductive scaffold to direct neurite growth. Taken together, these results show that ES applied via ECM-functionalised electroconductive scaffolds drives neurite outgrowth, a key requirement to achieving functional recovery post-injury, highlighting the potential use of this novel combination therapy for SCI repair.

Nanomaterials and Additive Processes for Transparent and Stretchable Organic Electrochemical Transistor
Takaaki Abe, Teppei Araki, Shoya Matsuda, Naoko Kurihira, Mihoko Akiyama, Takanori Uemura and Tsuyoshi Sekitani; SANKEN (The Institute of Scientific and Industrial Research), Japan

Flexible electronic devices with optical transparency exhibit biocompatibility and increase the versatility of measurement methods, such as multimodal sensors that allow simultaneous monitoring of both optical and electrical signals. In this study, we develop fully transparent and flexible organic electrochemical transistors (OECTs) using transparent conductors of Ag nanowires (AgNWs) and conductive polymers. They demonstrate the feasibility of multimodal acquisition of biological signals. In addition, stretchable materials are newly developed to construct completely transparent and stretchable OECTs, which can contribute to the creation of next-generation medical sensors. Sensors for use as personal healthcare devices that can measure biological signals continuously and for a long time for the early detection of diseases have been expected [1-2]. OECTs can be used to fabricate circuits suitable for such biological signal measurements owing to their advantages of low operating voltage, mechanical flexibility, and high mutual transconductance [3]. In particular, the high mechanical flexibility decreases the wearing discomfort because flexible biological tissues change their shape. Additionally, if the device has high transparency, it enables multimodal sensing that can utilize electronic, optical, and ionic methods simultaneously, as well as miniaturization through the stacking of devices. Therefore, stretchable and transparent conductors and semiconductor materials for electronic devices can facilitate a new electronic design. In this study, we develop highly transparent and flexible OECTs using AgNWs and poly(3,4-ethylenedioxythiophene)-poly(styrene sulfonate) (PEDOT:PSS) [4]. High bending durability and high visible transmittance (>90%) are achieved by controlling the orientations of the AgNWs used for wiring. Furthermore, additive layering techniques, such as printing and lamination processes, are employed to decrease damage to the nanomaterials constituting the OECT. In addition, these transparent and flexible OECTs exhibit properties comparable to those of conventional opaque OECTs. Consequently, low-noise measurements of brain waves and ion concentrations, as well as simultaneous optical measurements of blood flow and pulse.
waves, are feasible and a step toward the quantification of human stress. Furthermore, stretchable channel materials are developed to create more flexible OECTs. A patterning process of AgNW-based conductors and semiconductors on elastomers is concurrently developed to fabricate fully stretchable and transparent OECTs. In particular, the stretchable conductors and channel materials exhibit durability under 50%–100% strain; thus, they can be used for fully transparent and stretchable sensors for the long-term and multimodal assessment using electrophysiological, optical, and ionic methods.

Transforming the Brain to Transparent Hydrogels for Long-Range Microscopic Analysis of the Nanoparticles Interactions with Brain Tumors
Maryam Golshahi, Hamed Arami and Lavla Khalifehazadeh; Arizona State University, United States

Microscopic analysis of the tumor response to therapeutic reagents such as nanoparticles and chemotherapy drugs is limited to conventional tissue sectioning, which is performed by immunostaining and optical microscopy. Tissue sectioning is destructive and microscopic data obtained from a limited number of thin tissue slices (typically with 5-50 μm thickness) are not representative of the efficacy of the treatment over the entire tumor mass. Microscopic results obtained from a single or limited number of tissue slices can be even more misleading for brain tumors with high levels of heterogeneity such as glioblastoma multiforme (GBM). Therefore, developing methods for microscopic analysis of the whole tumor tissue without any sectioning can be beneficial by providing an overall feedback about the treatment rates at different parts of the tumor mass. This capability can potentially enhance the treatment effects and minimize the probability of the tumor recurrence by optimizing the treatments to target the entire tumor. Here, we used a polymerization method that helps to transform the whole mouse brain to optically transparent acrylamide-based hydrogels without losing the microscopic or nanoscale structure of the tumors at both extracellular and intercellular levels. Orthotopic U87 tumors (human-derived GBM cells with GFP signal) were generated in mouse brains (~n=3). Therapeutic nanoparticles (gold nanoparticles tagged with Cy5 fluorescent molecules) were injected into tumors stereotactically using a magnetic resonance imaging (MRI) guided approach. Mice were euthanized 24h post-injection and brains were excised and immersed in a monomer solution, followed by a low-temperature polymerization and tissue-clearing technique known as CLARITY. Then, the entire volume of these transparent brains were analyzed using different microscopy techniques, including confocal and light-sheet microscopy. The interaction of the nanoparticles with tumors was investigated using their Cy5 and GFP signals, respectively. We were able to generate three-dimensional maps verifying the distribution of the nanoparticles in tumors and other parts of the brains (e.g., the ventricles). Immunostaining of these brains is a reversible process and sectioning can be beneficial by providing an overall feedback about the treatment rates at different parts of the tumor mass. Microscopic data obtained from a single or limited number of tissue slices can be even more misleading for brain tumors with high levels of heterogeneity such as glioblastoma multiforme (GBM).

Aptamer-Decorated Prussian Blue Nanozymes for Selective Detection of Dopamine
Han Been Lee, Do Hyeon Kim, Se Hwa Cheon, Chang Hyeon Ha, Su Jeong Lee and Gi hun Seong; Hanyang University, Korea (the Republic of)

Dopamine (DA) is a catecholamine neurotransmitter that plays a significant role in the central nervous and hormone systems of humans. Abnormal levels of DA can lead to various diseases, including Parkinson's disease and depression. While electrochemical measurements have gained considerable attention for their simplicity and responsiveness, the electrochemical detection of DA is easily influenced by the simultaneous presence of ascorbic acid (AA) or uric acid (UA). This makes DA detection challenging. Therefore, it is crucial to develop a sensitive and selective detection method for DA in biological fluids to overcome these challenges. Colorimetric assays have obtained much attention due to their rapid observation by the naked eye and user-friendly operation. However, assays relying on the reduction of the substrate of DA have limitations in terms of selectivity because substrates such as AA and UA, which have a similar structure to DA, also possess the ability to reduce substrates. To address this issue, we employ an aptamer to enhance selectivity in real samples. Aptamers are molecular recognition components based on nucleic acids. These functional single-stranded nucleic acids can adopt a three-dimensional structure and exhibit exceptional specificity and affinity for target molecules. These functional single-stranded nucleic acids can adopt a three-dimensional structure and exhibit exceptional specificity and affinity for target molecules. Among the different types of nzymes, prussian blue nanoparticles (PBNPs) have gained widespread use in the field of biosensing and immunoassays. This is attributed to their outstanding peroxidase-like activity, robust stability, and high sensitivity.

In this study, we employed chitosan (CS), a polycationic biopolymer with amine groups in its backbone, to stabilize PBNPs. This resulted in the formation of CS-coated prussian blue nanoparticles (CS/PBNPs), which modified the surface charges of the PBNPs to a positive state. By virtue of the positive charges conferred on CS, the negatively charged dopamine binding aptamer (DBA) could be immobilized onto the CS/PBNPs through electrostatic interactions. DBA molecules, known for their specific affinity towards DA, were adsorbed onto the surface of CS/PBNPs, leading to the inhibition of the peroxidase-mimicking activity of the CS/PBNPs. However, upon the introduction of a DA sample solution, the DBA molecules on the CS/PBNPs surface strongly bound to the DA, inducing a conformational change in the aptamer and causing its separation from the CS/PBNPs. Consequently, as the concentration of DA increased, more surface area of CS/PBNPs became exposed, resulting in an elevation of their peroxidase-like activity. In conclusion, we successfully developed an aptamer-based colorimetric assay utilizing CS/PBNPs for the detection of DA in concentrations ranging from 0.25 μM to 100 μM, with a limit of detection (LOD) of 0.16 μM. The recovery results of DA concentrations (0.25 μM, 0.5, μM, and 1 μM) in spiked human serum were 92.6%, 102.1%, and 103.9%, demonstrating high reproducibility and reliability of the CS/PBNP-based apta-sensor for determining DA levels in clinical applications. Furthermore, compared to typical immunoassays, this aptamer-based nanozyme inhibition/activation assay eliminates the need for a washing step, making it highly practical in terms of reducing assay time and maintaining high sensitivity. Based on its excellent performance, this biosensor holds promise as a valuable tool for the rapid, selective, and sensitive detection of clinically significant small molecules, such as hormones, in practical applications.

Modification of Conductive Surfaces via Tailored Dyes Derivatives for Bacterial Detection
Svenja Herdan1, Laurie Neumann1, Lea Könemund1,2, Rebekka Biedendieck1, Hans-Hermann Johannes1,2, Dieter Jahn1 and Wolfgang Kowalsky1,2; 1Technische Universität Braunschweig, Germany; 2Cluster of Excellence PhoenixD, Germany

Nanozymes, nanomaterials that exhibit enzyme-mimicking activities, have emerged as promising alternatives to natural enzymes like horseradish peroxidase (HRP) due to their exceptional catalytic activity, ease of modification, and remarkable stability. Given their intriguing and practical characteristics, nanomaterials have been employed in various biomedical point-of-care applications, including biosensing and immunoassays. Among the different types of nzymes, prussian blue nanoparticles (PBNPs) have gained widespread use in the field of biosensing and immunoassays. This is attributed to their outstanding peroxidase-like activity, robust stability, and high sensitivity.

In this study, we employed chitosan (CS), a polycationic biopolymer with amine groups in its backbone, to stabilize PBNPs. This resulted in the formation of CS-coated prussian blue nanoparticles (CS/PBNPs), which modified the surface charges of the PBNPs to a positive state. By virtue of the positive charges conferred on CS, the negatively charged dopamine binding aptamer (DBA) could be immobilized onto the CS/PBNPs through electrostatic interactions. DBA molecules, known for their specific affinity towards DA, were adsorbed onto the surface of CS/PBNPs, leading to the inhibition of the peroxidase-mimicking activity of the CS/PBNPs. However, upon the introduction of a DA sample solution, the DBA molecules on the CS/PBNPs surface strongly bound to the DA, inducing a conformational change in the aptamer and causing its separation from the CS/PBNPs. Consequently, as the concentration of DA increased, more surface area of CS/PBNPs became exposed, resulting in an elevation of their peroxidase-like activity. In conclusion, we successfully developed an aptamer-based colorimetric assay utilizing CS/PBNPs for the detection of DA in concentrations ranging from 0.25 μM to 100 μM, with a limit of detection (LOD) of 0.16 μM. The recovery results of DA concentrations (0.25 μM, 0.5, μM, and 1 μM) in spiked human serum were 92.6%, 102.1%, and 103.9%, demonstrating high reproducibility and reliability of the CS/PBNP-based apta-sensor for determining DA levels in clinical applications. Furthermore, compared to typical immunoassays, this aptamer-based nanozyme inhibition/activation assay eliminates the need for a washing step, making it highly practical in terms of reducing assay time and maintaining high sensitivity. Based on its excellent performance, this biosensor holds promise as a valuable tool for the rapid, selective, and sensitive detection of clinically significant small molecules, such as hormones, in practical applications.
The improvement of a biosensor which combines fast and highly sensitive detection of bacteria with easy handling is of great interest, for example, in the fields of medicine or the food industry. In the future, pathogenic bacteria could be detected at an early stage. Conventional methods such as enzyme-linked immunosorbent assay (ELISA) or polymerase chain reaction (PCR) are time-consuming, expensive and require professional expertise. Therefore, a sensor with low costs and fast, reliable results is of great importance.

In previous works, functionalized porphyrins with two different linkers have been synthesized for a bacteria sensing system. The linkers are divided into two different groups: linker A which can bind to an electrode (gold or indium tin oxide) and linker B which can bind to bacteria. For linker B there are two possible bio receptors: a peptide group and cysteine group enabled to connect the Gram-negative bacterium Escherichia coli (E. coli) K12, a common well investigated apathogenic model strain. An analysis with fluorescence-lifetime imaging microscopy (FLIM) could already show a decrease of the fluorescence lifetime of the porphyrin molecule due to changes in their chemical environment or conformation as they have an interaction with cell components of the bacteria cells. These results show that both bio receptors in combination with the porphyrin molecule can be used as a bio linker on an electrode surface for further bacteria detection methods. (Neumann, 2021).

The goal of this research is to extend the existing system. For this purpose, porphyrin was replaced by another dye, boron-dipyromethene (BODIPY). Reasons for this are that BODIPYs are thermally and photochemically stable, have a higher fluorescence quantum yield (BODIPYs ≈ 90%; porphyrins ≈ 5%; depending on the substitution of the dyes), are well soluble and chemically stable and they are biocompatible. Furthermore, it should be emphasized that the synthetic effort and thus also the yield loss can be reduced, because only two steps are necessary for the BODIPY linker synthesis and six steps have so far been necessary for the porphyrin linker synthesis. In addition, it is possible to use a boronic acid instead of a peptide or cysteine group for linker B. Boronic acids have the property to bind to cis-diols, which are located on bacterial cell wall. By adapting linker B as previously mentioned, a general sensor could be developed regardless of whether the bacteria are Gram-negative or Gram-positive.

Key words: porphyrin, BODIPY, E. coli immobilization, biosensing

Mediated Electron Transfer in Bacteria for Charge Generation
Ndepana G. Andrew and Hemali Rathnayake; University of North Carolina at Greensboro, United States

The increase in energy demand led to remarkable research activities on energy generation, storage, and conversion, and many different kinds of nanoscale materials have been explored to harness energy. However, recently microorganisms including bacteria and algae have been shown to display significant roles in developing high-performance probes owing to their abilities to reproduce fast, self-repair, self-assembly, and wide range of biosynthetic capabilities. Among a wide variety of microbes, bacteria have been well studied offering their adaptation to broaden research directions for developing a variety of sustainable energy generation, conversion, and storage systems with either improved or new capabilities and performance. However, adapting bacteria to develop the aforesaid systems with required performance entails a clear understanding of how bacteria interact with the surface or mediator and how chemical, physical, and intrinsic properties of the “mediator” affect interaction with bacteria to produce expected results and programmable characteristics. The processes of metabolic electron transfer from bacteria to an extracellular mediator and vice versa in diverse exoelectrogenic and non-exoelectrogenic bacteria have been studied but only a few have been investigated in-depth to understand bacteria responses and study their electron transfer processes at their respective biotic interfaces with a variety of organic and inorganic mediators. Electron transfer in bacteria can occur either directly or indirectly, however, only a limited set of bacterial species can transfer electrons directly to the electrodes, most bacteria require an external electron transfer mediator to transfer charges to the electrode for efficient energy generation. Although Various compounds have been tested in the past as exogenous mediators, there are potential classes of compounds that are yet to be explored. Herein, we gather a new concept of using a metal-organic framework as an external mediator for electron transfer at the interface of E. coli, we grow live E. coli cells on a functional MIL-88B MOF to construct a charge capacitive bio interface. The aim is to study the interactions at the bio interface and employ these interactions to generate a charge-capacitive smart interface for energy storage and study the metabolic electron transfer mechanism at the bio interface resulting in the generation of energy at the bio interface. In theory, the MIL-MOF will stimulate the bacteria's metabolic electron transfer processes by modulating charge injections at the E.coli/MOF interface to generate charge capacity through electron transfer processes. So far from our preliminary result, we obtained a charge capacity of 399 Fg⁻¹ at a scan rate of 5 mV/s in generated at the E.coli/MOF interface as compared to 195 Fg⁻¹ generated at the E.coli (control) interface only at the same scan rate. Our results suggest the potential of MIL-88B MOF as an external mediator in facilitating the electron transfer at the E.coli interface to generate a higher charge capacity twice the magnitude of E.coli charge capacity.

This study proposes that by combining the distinctive functionalities of living bacteria with biocompatible abiotic MIL-MOFs, it is possible to create smart interfacial biosystems for charge generation and storage with programmable features.

The “SLIC” Idea: Superhydrophobic Lubricant Infused Composite (SLIC) is a Non-Toxic, Inexpensive Polymer Composite Coating that Prevents Biofouling
Thomas LeFevre, Joseph Daddona, Wilaiwan Chouyyok, Stony Akins, George Bonheyo, Curtis Larimer and Raymond S. Addleman; Pacific Northwest National Laboratory, United States

This poster will describe the development and testing of a Superhydrophobic Lubricant-Infused Composite (SLIC) coating that inhibits the attachment of organic and biological matter. Biofouling is the unwanted accumulation of biological material, such as bacteria, algae, mussels, and barnacles, on a surface. Biofouling is an expensive and disruptive problem in many water-related industries such as shipping, hydropower, and aquaculture. Antifouling coatings are commonly utilized to mitigate fouling, but the existing coatings that are effective are also toxic or extremely expensive.

To address the toxicity and expense of existing coatings, SLIC is a PDMS-based coating with several additional ingredients that provide strength, texture, and porosity in the coating. This work will describe the design, selection, and optimization of biomimetic additives designed to provide strength, abrasion resistance, and a surface microstructure that mimics the superhydrophobic texture of natural surfaces such as the lotus leaf. We will outline a process for incorporating lubricant oil into the coating to provide a low surface energy liquid layer, similar to fish slime, that inhibits biological adhesion. The oil can flow into cracks and crevices in the coating, providing a self-healing mechanism when the coating is scratched. SLIC was designed to be an antifouling coating that is tough, long lasting, economical, and toxin-free. It can also be easily customized for specific use cases such as nets that require a flexible coating.

Results of experiments to quantify antifouling performance by exposing varying formulations of SLIC to mussels at different life stages will be presented. Use of a machine learning algorithm to assist in the detection and counting of mussel larvae on surfaces will be described. Results of antifouling performance tests showed that SLIC prevented mussel larva attachment in static conditions is better than the leading antifouling paint and significantly better than uncoated stone, metal, and plastic surfaces. In summary, SLIC was designed as a high performance low-cost antifouling coating. It can prevent mussel adhesion and other types of fouling while remaining nontoxic.

A Smart Coating with Integrated Physical Antimicrobial and Strain-Mapping Functionalities for Orthopedic Implants Yi Zhang and Qing Cao; University of Illinois at Urbana-Champaign, United States

As the prevalence of orthopedic implants increases within the aging population, these patients become increasingly vulnerable to risks associated with periprosthetic infections and instrument failures. There have been attempts to reduce the risk of infection by modifying the implant surface to impede bacterial adhesion or applying antibiotics to the surface to kill local bacterial populations. But these methods are rarely used due to their own limitations. For instance, coating implant surfaces with hydrophilic molecules or quorum-sensing inhibitors can block bacterial adhesion, but this strategy fails if even a few bacteria manage to attach and form an antibiotic-resistant biofilm. Another significant complication associated with orthopedic implants is aseptic implant failures, which require surgical revisions and affect over 10% of patients. These failures manifest primarily as loosening caused by mechanical shielding or implant breakage due to fatigue failure. Presently, these complications are diagnosed using x-ray or bone scan imaging. However, these techniques only detect gross implant movement, which occurs long after the inception of loosening or implant-related microfractures, even with harmful radiation and high costs.

To address these challenges, we develop the design of a smart-coating foil that can be applied to the surfaces of orthopedic implants. This foil provides both long-term physical bactericidal action and sensitive strain mapping to mitigate both septic and aseptic orthopedic failures. The outer surface of the foil is designed with high-density nanopillars, mimicking the surface nanotopology of cicada wings. These structures exhibit strong mechanical bactericidal effects against bacteria commonly associated with orthopedic implant infections without directly releasing any chemicals. A multiplexed strain-sensing array is integrated into the foil. The high piezoresistive coefficient of single-crystalline silicon ensures accurate detection of strain down to 0.01% experienced by orthopedic implants. The nanometer-scale film thickness allows the foil to bond with the implant surface, while the integration of silicon gauges with multiplexing transistors enables strain mapping across the implant surface. This can assist in the detection of early-stage spinal fusion and pedicle-screw loosening, guiding patient-specific care and early intervention against aseptic instrument failures. The strain-mapping array and mechano-bactericidal nanostructures both showed excellent biocompatibility and long-term stability in vivo.

Specific Protein Metalization in Cell-Derived Extracellular Matrix via Antibody-Guided Biotemplating for Utilization in Hydrogen Production and Sensing Chang Woo Song and Jaewan Ahn; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

In nature, there is a myriad of hierarchical biological structures consisting of various proteins that are challenging to replicate by artificial synthetic methods. To exploit such complex structures in material science, biotemplating has attracted great attention over the past decades, wherein exotic functionalities from inorganic materials were able to impart into the biological scaffolds by electroless plating or physical vapor deposition of metal. However, the biological architectures used in prior reports were stereotypical and ordinary with the lack of ways to manipulate their morphological features such as porosity, alignment, and organization, limiting their usage in more broad fields. To this end, we propose the cell-derived extracellular matrix (ECM) is an excellent option to be used as a template for achieving diverse biomimetic architectures. ECM has evolved into intricate mesh structures intertwined with various fibrillar protein assemblies to conduct mechanical support of cells, assist in the proliferation and migration of cells, and transport the signal to the cells. Because of these important biological roles of ECM, a variety of ECM have been created with customized morphological and chemical characteristics, especially for cell biology, pharmacology, and tissue engineering. Despite already developed diverse protein assemblies in ECM, there was no attempt to use them as a biological scaffold for metallization. To use a specific ECM protein as a template, we introduced 1.4-nm nanogold-conjugated antibodies and labeled them to a specific protein called fibronectin within the ECM, and then the nanogold acted as the nucleation sites for Au growth. The metalized ECM could be electrically conductive after thermal sintering or second metal growth (e.g., Pd and PdPt alloy) with additional functionality. Following the deposition of PtNPs, the fabricated conductive biocomposite showed catalytic activity in the hydrogen evolution reaction (HER), maintaining its stability for up to 500 repeated cycles. In addition to hydrogen production, the electrically conductive biocomposites by the second metal growth demonstrated the prominent hydrogen sensing performance at room temperature.

8:00 PM SB05.07.23
A Photo-Patternable Stretchable Gold Conductor by Electroless Plating Process Hinata Mitomo1,2, Keita Suzuki, Katsuya Temchii, Yuanyuan Zhou1,2, and Naoji Matsuhisa1,2,3; 1Research Center for Advanced Science and Technology, The University of Tokyo, Japan; 2The University of Tokyo, Japan; 3Department of Electrical Engineering and Information Systems, The University of Tokyo, Japan; 4Fanaka Kikinzoku Kogyo K.K., Japan; 5EEJA Ltd., Japan

Stretchable gold thin-film electrodes exhibit superior biocompatibility and conductivity. In previous studies, stretchable gold thin films have typically been prepared by thermal evaporation1,2. However, to maintain high stretchability, the sheet resistance was limited to an order of 10 Ohm/Sq. Moreover, it is crucial to minimize gold waste resulting from deposition in unnecessary areas.

In this study, we present highly stretchable and conductive gold electrodes fabricated by a photo-patternable electroless plating process. Our gold thin film exhibited a remarkably low sheet resistance of 0.25 Ohm/Sq at 0% strain and 2.7 Ohm/Sq at 50% strain. The film remained highly conductive, even under a 200% strain. These electrical and mechanical characteristics were preserved when the gold was patterned to a resolution of 100 μm. Fabrication began by spin-coating a primer polymer layer, which adheres gold nanoparticles from the colloid solution. Deep ultraviolet exposure can deactivate the capacity to capture gold nanoparticles, enabling patterning. Subsequent electroless plating allowed the gold nanoparticles to grow into a uniform film with a thickness of 200 nm. We controlled the aforementioned plating conditions to regulate microcrack formation under strain, and obtained the high stretchability of our gold. The high conductivity and patterning of our stretchable gold pave the way for the development of stretchable, high-density electrodes for electrophysiology measurements, and stretchable antennas for wireless wearable electronic devices.

8:00 PM SB05.07.24
Design and Characterization of Magnetically Controlled Minicell-Driven Biohybrid Microswimmers for Targeted Drug Delivery Applications Saadet F. Baltaci Demir1,2, Irina Kalita3, Birgul Akolpoglu1,4 and Metin Sitti1,4,5; 1Max Planck Institute for Intelligent Systems, Germany; 2University of Stuttgart, Germany; 3Max Planck Institute for Intelligent Systems, Germany; 4ETH Zürich, Switzerland; 5Koc University, Turkey

Bacteria-based biohybrid microswimmers, combining motile bacteria cells with synthetic materials, have emerged as promising vehicles for alternative therapeutic applications such as active drug delivery. However, existing biohybrid cells face many limitations that hinder their translation to clinical applications considering the poor penetration ability through the barrier or tissue, biostability and limited payload capacity. Here, we propose a magnetically controllable drug-loaded biohybrid microswimmer driven by a bacterial outer membrane vesicle, referred to as minicell, which offers unique capabilities such as enhanced penetration capability thanks to its sub-micron size and long-term stability with self-propulsion because of its non-dividing but metabolically active nature. Additionally, minicells exhibit a large drug encapsulation capacity compared to traditional nanocarriers. In this study, we fabricated motile minicells produced by engineered Escherichia coli sub-inducibly expressing a biotin display system on their surface, enabling us to
benefit from the robust biotin-avidin interaction with streptavidin-coated magnetic nanoparticles onto the minicells. We optimized the production of self-propelled microswimmers via several purification methods and investigated their growth and motile behavior in various culture and physiologic media over time. We showed the magnetic control and guidance of minicell-driven biohybrids by an external magnetic field, and compared their 2D swimming motility with and without applying uniform magnetic fields. Furthermore, we optimized the loading efficiency of the chemotherapeutic drug doxorubicin into the minicells and demonstrated the time-dependent release of the drug molecules. Overall, the minicell-driven biohybrid design proposed here offers a magnetically guided active drug-carrying nanosized platform for targeted delivery while preserving its motility and durability during the extended application period.

**Designed Nanoparticle-Polymer Conjugates as Nucleants for Multiple Protein Types**

Xiaoting Guo and Vicki L. Colvin; Brown University, United States

Determining the three-dimensional structure of proteins is crucial for understanding their function, but the limited ability to form protein crystals suitable for X-ray diffraction has become a bottleneck problem in this field. Through the control of nanocrystal and protein interactions, it is possible to both enhance the nucleation of protein crystals as well as create three-dimensional structures of nanoparticles within the protein crystals. The length of polymers (e.g. poly(ethylene) glycol) bound to a nanocrystal surface can mediate protein interactions with the nanocrystal-polymer conjugates: specifically, longer polymers at the nanoparticle surface allow for more protein association with conjugates. We showed that the addition of AuNP-PEG to hen egg white lysozyme (HEWL) led to an increase in the number of crystal hits across a wide range of crystallization conditions. The compared result in crystallography indicates with the incorporation of conjugate system, protein structures can be dissolved with the existence of the nanoparticle-nucleate within the protein crystals. Surprisingly, the incorporation of AuNP-PEG inside the crystals did not affect their quality. The statistical values listed in Table 1 for the AuNP-HEWL co-crystal remained consistent with those obtained for the pure HEWL crystal, indicating that the addition of AuNPs did not alter the crystal properties in any way. AuNP-PEG can also be used as a general nucleant for different protein species. 5 illustrate a comparison of hit counts for eight proteins, namely Ferritin, Proteinase K, Thaumatin, p-HSA, Concanavalin A, Glucose Isomerase, Insulin, and Xylanase, based on 48 screening conditions. The results indicate that the addition of AuNP-PEG increased the number of hits in each protein species compared to the control group without the presence of AuNP solution. The potential of AuNP-PEG to affect liquid-liquid phase separation (LLPS) of FUS-LC proteins was also investigated, which plays a crucial role in understanding the formation and solubilization of protein droplets in cellular processes. The addition of AuNP-PEG to FUS-LC led to an acceleration of LLPS and the formation of more condensates. Within the protein-nanoparticle conjugate co-crystals, we further demonstrated that the incorporation and arrangement of nanoparticles at regular distances within the protein crystal is reflective of the fact that the protein crystal nuclei form on the nanoparticle surface; for lysozyme, these nuclei have been studied via both light scattering and diffraction. Most studies find that they consist of four or more lysozymes with dimensions near 9 to 18 nm. In the presence of nanoparticles, these proto-nuclei form in and around nanoparticle-polymer conjugates that can themselves have polymer shells as thick as 30 nm. This would suggest that incorporated nanoparticles could have as much as 40 to 50 nm of surface polymer and protein surrounding them, giving rise to a lower limit for the interparticle separations that is in good agreement with that found from the radial distribution function (e.g. 47 nm). The composites grow when these protein-nuclei encounter other similar structures and begin to crystallize, leading to the formation of composite crystals. Anisotropic materials align due to the faster spreading of proteins along the a-b face of crystal during growth which causes the preferential orientation of the rods perpendicular to the c-axis.

8:00 PM SB05.07.26

**Strain Dependency of Charge Transport of Stretchable Conjugated Polymers**

Seoung Hyun Kim and Kilwon Cho; Pohang University of Science and Technology, Korea (the Republic of)

Stretchable polymer semiconductors have attracted significant interest for their potential in flexible and stretchable electronics. However, there remains challenging work in controlling the strain-induced properties of conjugated polymers (CPs), such as crystallinity, morphology, and charge transport properties. Herein, we delve into the contribution of microstructures to their mechanical and electrical stretchability. To achieve stable electrical properties during deformation, specific structural requirements are discussed, such as the inclusion of a less-rigid donor moiety between diketopyrrolopyrrole (DPP) acceptors. This addition reduces crystalline packing, thereby significantly enhancing the mechanical deformability of the CP films. Furthermore, the multiscale structural and electrical analyses revealed that a less-rigid backbone allows for the strain-induced flattening of the polymer chains. The flattening of polymer chains reduces the activation energy barrier for hopping transport to 38 meV at 80% strain. Consequently, strain-induced alignment and conformational changes of polymer chains provide favorable pathways for charge transport, resulting in a significant increase in hole mobility of up to 180% under an 80% tensile strain. We believe that our study on the strain-induced structural changes in CP films, ranging from molecular to mesoscale, would contribute to a better understanding of the strain dependency of charger transport of stretchable conjugated polymers.

**Fabrication and Characterization of Electrospun PU and Vapor Phase Polymerized PEDOT:Tos Fibers for Flexible Electronics**

Jiaxin Fan, Jinsil Kim and Fabio Cicora; Polytechnique Montreal, Canada

Soft conductive materials have gained considerable attention owing to their vast potential in wearable sensors, biomedical devices, and flexible displays. The successful implementation of high-performance flexible electronics requires exploring suitable materials with superior electrical and mechanical properties. 1 Poly-(3,4 ethylenedioxythiophene) (PEDOT) doped with various counterions has been extensively studied for flexible and stretchable electronics due to their ambient stability and solution processability. Additionally, their electrical conductivity and mechanical properties can be further tailored by blending with additives based on the application requirements. 2 PEDOT-based materials are also compatible with various fabrication and processing techniques, such as drop-casting, spin-coating, printing, and electrospinning. Among various techniques, electrospinning offers unique advantages, including a straightforward setup, versatile material choice, scalable production, tunable fiber properties, and compatibility with various substrates. Electrospun nanofibers exhibit desired properties for soft electronics. 3 For PEDOT-based materials, the spinability can be improved by adding carrier polymers.

In this study, we focus on the preparation of conductive fiber mats based on a mixture of polyurethane (PU) and PEDOT doped with tosylate (PEDOT:Tos). The fabrication process involved electrospinning the mixture of PU and oxidant, iron (III) p-toluenesulfonate (tosylate), followed by vapor phase polymerization (VPP) to obtain PEDOT:Tos. PU was utilized as both carrier polymer and an additive for enhancing the electrical and mechanical properties. The resulting fibers have an average diameter of ~ 800 nm. An average sheet resistance of 16.4 ± 1.5 kΩ/sq was obtained for the PU/PEDOT:Tos fiber mat after VPP. To investigate the influence of different electrospinning solution mixtures and conditions, we analyzed the morphology, electrical conductivity, electrochemical behaviors, and mechanical properties of the fiber mats fabricated with various spinning solution mixtures and fabrication conditions. Preliminary demonstration of utilizing the conductive fiber mats for flexible electronics will also be presented. This comprehensive investigation provides insights into optimizing and engineering the properties of fiber mats for their application in soft electronics.
SILENT SPEECH INTERFACE USING WEARABLE STRAIN SENSORS BASED ON CRYSTALLINE SILICON NANOMEMBRANE

Kihoo Kim, Taemin Kim, Kyowon Kang and Ki Jun Yu; Yonsei University, Korea (the Republic of)

The Silent Speech Interface (SSI), which uses non-verbal forms of communication like sign language, provides a promising alternative for those unable to vocalize. This technology interprets intended words by monitoring facial muscle and skin movements during verbal communication. Notably, SSI benefits from wearable sensors that use surface electromyography (sEMG), as it doesn't necessitate constant video surveillance in a fixed setting. However, conventional sEMG electrodes face issues related to signal quality, such as low signal-to-noise ratio and interelectrode interference, obstructing the precision of facial mapping.

In this study, we have developed an innovative SSI incorporating epidermal strain sensors made from crystalline silicon nanomembrane (SiNM). These sensors, thanks to their piezoresistive properties, are considerably more sensitive than standard metal foil-based strain gauges. Each sensor includes two strain gauges placed perpendicularly to measure biaxial strain independently. We attached four sensors to four facial regions with the greatest areal changes, as identified by vision recognition.

We selected 100 English words at random from the Lip Reading in Wild benchmark set and trained 100 strain data sets for each word on a deep-learning-based classifier. To evaluate the classification performance of our system, we used a 5-fold cross validation which resulted in an average accuracy of 87.53%. In the same validation, a 4-channel sEMG system of identical dimensions (< 0.1mm²) to our unit strain gauge exhibited only 41.53% accuracy due to its low SNR caused by high impedance. We also conducted an experiment with 200-word classification to check the effect of spatial resolution on accuracy. Under identical conditions, the 16-channel and 8-channel systems showed 81.87% and 71.63% accuracy, respectively. This demonstrates the potential for this technology to support everyday conversation in the future.

REFERENCES
high sensitivity in pressure sensors. However, previous approaches have often relied on complex material synthesis and expensive manufacturing processes, presenting scalability challenges and severely limiting their practical applications.

This report highlights our recent progress in materials design aimed at controlling the microstructure of conductive composites to realize high-performance printed soft mechanical sensors. We have developed a novel brittle-stretchable conductive network that generates controllable microcracks, resulting in high sensitivity to applied strain while maintaining a large working range [4]. This innovative approach successfully overcomes the trade-off between sensitivity and sensing range commonly encountered in stretchable strain sensors. We have also successfully formulated a novel printable ink by mixing PDMS, CB, and a deep eutectic solvent (DES). This ink spontaneously forms a microporous conductive architecture without the need for complex processing [5, 6, 7]. Leveraging this composite, we have achieved highly sensitive pressure sensors and low hysteresis stretchable strain sensors using straightforward manufacturing techniques. Furthermore, we have utilized thermally expandable microspheres to create irregular microdome surfaces, facilitating the easy fabrication of flexible printed pressure sensors with superior reliability and uniform performance. When compared to previous studies, our approaches offer significant advantages: (i) simple ink preparation without the need for complex materials synthesis; (ii) compatibility with printing technologies permitting superior scalability, manufacturability, and cost-effectiveness; and (iii) easy microstructure control in conductive composites, resulting in soft mechanical sensors with exceptional performance in terms of sensitivity, working range, reliability, and uniformity. We are confident that these achievements will provide valuable insights into materials design and microstructure control of conductive composites, thereby advancing their practical applications in the field of soft electronics.

This study was partially supported by JSPS KAKENHI Grant Number 23K13806.

Engineering Flexible Electronics for Monitoring Epithelial Integrity In-Vitro and Ex-Vivo

SOPHIE OLDROYD, SARAH BARRON, DAVID BULMER AND ROISIN OWENS

University of Cambridge, United Kingdom

Inflammatory bowel disease (IBD) is a widespread condition, with a forecasted prevalence of 1.1% by 2025 [1]. It presents with chronic symptoms such as abdominal pain and diarrhoea and is characterised by a leaky gut barrier, which has increased permeability due to changes in localisation of tight junction proteins [2]. However, a detailed understanding of the disease pathway is limited, and current methods of assessing gut tissue health ex vivo are impeding progress in the field. The techniques need re-designing in the modern era given advancements in technology. This work presents flexible bioelectronic devices that permit real-time recordings of changes in gut tissue. The ability to assess gut health in living tissue is important in establishing and monitoring phenotypes associated with gastrointestinal diseases.

All-planar conformable devices with multiple working electrode sizes (from 25 to 1000 µm) and an internal counter/reference electrode (CE/RE) were fabricated using previously developed techniques [3]. On the bottom, and between each of the layers, parylene C was used for insulation. Conductive tracks, outlines, and contact pads for the electrodes were formed using photolithography and gold deposition. Electrodes were coated with PEDOT:PSS, a conducting polymer used to increase volumetric capacitance. The electrodes were characterised by electrochemical impedance spectroscopy (EIS) and brightfield microscopy. In-vitro testing utilized a human colonic epithelial cell line, Caco-2. The cells were grown on Transwell® inserts and differentiated for 21 days. The ability of the device to measure barrier integrity, perturbations, and recovery in real-time was assessed via the transient addition of EGTA. The devices were tested ex-vivo on small intestine and colonic tissue from wild type-C57Bl6 male mice. Cell viability was confirmed with confocal microscopy and staining. Extracted transepithelial resistance values, based on simple equivalent circuit models, were confirmed against the gold standard methods for in-vitro and ex-vivo, using the EVOM3™ and Ussing Chambers respectively.

This work highlights the first instance of an all-planar flexible electronic device that can monitor epithelial barrier function and perturbations at the air liquid interface. The mechanical flexibility of the device allows for direct and conformable contact with biological surfaces, to provide a quantifiable electrical readout under physiological conditions. The multi-electrode design established a minimum electrode radius (400 µm) needed to capture the epithelial properties, and chemical disruption, of colon cell lines and mouse colon tissue. The sensing area achieved is one order of magnitude smaller than previously reported, highlighting the increased sensing efficiency of the design. The device achieves comparable sensitivity with a planar CE/RE compared to an external CE/RE. As this device was the first of its kind, readouts were validated against gold standard TEER measurements, which showed comparable trends with a reduction in measurement error. We confirm the device is biocompatible and does not negatively affect the barrier properties under study. Future work could look to apply this technology for spatially mapping local and real-time changes in epithelial barrier properties for toxicology and drug screening applications.

Multimodal Flexible Fiber Antenna Sensor for Physiological and Environmental Sensing

MERVE GOKCE1, EILAM SMOLINSKY1, LOUIS VAN DER ELST1, CREASY CLAUSER HUNTSMAN2 AND ALEXANDER GUMENNIK2

1 Indiana University Bloomington, United States; 2 Cook Medical Technologies, United States

The real-time monitoring of a patient’s health condition during medical operations is crucial to the patient’s comfort, safety, and treatment success. While there are many advanced biomedical devices on the market that monitor various physiological parameters, they are limited with respect to sensitivity, accuracy, compatibility, and durability. It is vital to improve physiological monitoring limitations to minimize potential trauma, discomfort, and complications after surgery. Fiber device technology enables the designing of fiber-embedded sensors that provide higher sensitivity, accuracy, and spatial resolution through its complex cross-sectional geometry and material properties [1]. Thermally drawn polymer fibers offer high flexibility, durability, and better compatibility, making integrating fiber sensors into fabrics and biomedical devices easier [2]. Here we present the first sub-terahertz fiber antenna sensor capable of high spatial resolution, high sensitivity, and large dynamic range physiological monitoring and cyber-physical interfacing. The sensitivity and spatial resolution of the fiber sensor is high enough for practical operations such as integrating the flexible fiber sensor into medical devices. The fiber sensor monitors physiological and environmental signals in real-time, where the sensing
modality, either physiological or environmental, is defined by the electronics used to control the order of the mode coupled to the fiber sensor. While the high sensitivity of the fiber sensor is derived from its unique geometry, materials, and unique manufacturing approach [3], its spatial resolution results from the frequency decomposition of the reflected signal off the sensing point along the fiber and thus is the function of the operation bandwidth. Our multimodal flexible fiber sensor is a better candidate for improved monitoring of patients’ well-being and better patient care than the current sensors used in minimally invasive operations. The application area of our fiber sensor is not limited to the biomedical field but also smart fabrics, cyber-physical and human-robot interactions, and environmental detections due to its ability to perform selective, multimodal measurements.

Biomimetic Sequence-Templating Approach Towards a Multiscale Modulation of Chromogenic Polymer Material Properties Yiyao Kuang, Ze-Fan Yao, Sujeung Lim, Catherine Ngo, Megan Rocha, Dmitry Fishman and Heredeline Ann Ardoña; University of California Irvine, United States

Polydiacetylene (PDA) is an established conjugated polymer material useful as a colorimetric indicator of environmental conditions, such as small molecule binding, mechanical force, heat, or solvent, for multiple sensing applications due to the structural dependence of their optical and electronic properties. With its emerging utility for biological applications, there is a critical need to develop PDAs that can be processed in the physiological-relevant environment with predictable structures and properties. Using sequence-tunable peptidic supramolecular interactions to template diacetylene monomer assembly offers a facile synthetic approach and enables a way to rationally influence PDA structure and properties via peptide sequence engineering. This presentation focuses on investigating the structural influences of peptide templating groups on PDA structures and functional properties across length scales by molecularly controlling the properties of peptide moieties through steric effects and hydrophobic interactions. In particular, a library of peptide-PDA conjugates with systematically varied dipeptide segments is established to demonstrate the influence of residue steric, polarity, and position of substitution on multiscale PDA material properties. We show that steric effects predominantly influence the electronic structure and resulting trends in chain conformation-dependent photophysical properties. On the other hand, distinct trends were observed for bulk properties, such as film conductivity and cellular response to material interfacing. By tuning peptidic molecular volume and polarity, we exhibited a general increase in conductivity with smaller peptide molecular volume and higher hydrophobicity at larger length scales. In summary, this work provides new molecular-level insights on how sequence-tunable steric effects and polarity can be used as a synthetic handle to rationally modulate multiscale structure-function correlations for peptide-PDAs as functional biomaterials. These findings pave the way for further developing sequence-defined programmable properties and complex behavior for peptide-PDAs, such as the adaptive evolution of their properties in response to living systems interfaced with these functional biomaterials in physiologically relevant environments.

Biomaterials Strategies Towards Multimodal Neural Probes for Chronic Neural Recording, Chemical Sensing and Delivery Xinwan T. Cui; University of Pittsburgh, United States

Microelectrode array (MEA) devices, placed in the nervous system to record and modulate neuroactivity have demonstrated success in neuroscience research and neural prosthes application. Functionalizing the microelectrode sites on MEAs to enable neurochemical sensing and delivery adds additional dimensions of information, and presents tremendous potential for understanding neural circuits and treating neurological diseases. In this talk, I will introduce the methods by which we enable chemical sensing and delivery from MEAs. By incorporating nanocarbons into the conducting polymer electrode coating, we achieved direct detection of electroactive species such as dopamine, melatonin, and serotonin. By immobilizing enzymes or aptamers on nanostructured electrodes, we achieved multisite detection of glutamate, GABA, and cocaine. By incorporating nanocarriers into conducting polymer coating, we enabled on-demand drug delivery. Multithread and multiple analyte detection or neurotransmitter delivery along with neural recording have been demonstrated with these MEAs. Chronic neural interface performance has been sub-optimum. Quantitative histology, explant analysis, and 2-photon imaging revealed biofouling, neuronal damage, inflammation, and oxidative stress at the site of implants, as well as material degradations. We use several bioengineering strategies to minimize these failure modes. First, materials and devices that mimic the mechanical properties of the neural tissue have been developed and shown to significantly improve device-tissue integration. Secondly, biomimetic coatings and drug delivery have been applied to reduce biofouling and inflammatory responses. These approaches may be combined to achieve long-term and high-fidelity multimodal neural interfacing.

Magneetoelectric Metamaterials and Miniature Bioelectronics Jacob T. Robinson; Rice University, United States

Magnetic fields show very little absorption or reflection in bone and tissue, making these fields magnetic materials ideal as a transducer for bioelectronic systems. Here I will discuss how we can engineer the properties of magnetoelectric materials to show electrical and optical properties not found in nature. With these magnetoelectric metamaterials, we can rapidly control nerve impulses in rodent models for nerve injury and control the activity of engineer cells. Furthermore, magnetoelectrics enables us to create highly efficient, miniature battery-free bioelectronic networks for cardiac and neural applications. Overall, engineering the material properties of magnetoelectrics and magnetoelectric metamaterials provides a route to multifunctional miniature bioelectronic networks.

Cell Mechanotransduction Driven by Bio-Organic Optoelectronic Devices Vanessa Spagnolo1, Leonardo maver1, Johannes Gladisch2, Iwona Bernacka Wojcik2, Gabriele Tullii1, Eleni Stavrinidou2 and Maria Rosa Antognazza1; 1Istituto Italiano di Tecnologia, Italy; 2Linkoping University, Sweden
Biophysical cues, especially mechanosensations, play a fundamental role throughout life, starting from early embryonic development over function and interplay of cells and tissues in the adult body up to regeneration processes. Tissue regeneration, which includes phenomena like cell division, differentiation, migration and expulsion is triggered by extracellular mechanical cues. The body’s capability to regenerate decreases with age and therefore impacts our life in sometimes detrimental aspects.

Currently available tools to modulate or control mechanosensations often lack features necessary for in vitro and in vivo applications, in terms of efficiency, reliability, reversibility and spatial sensitivity. Here we show a novel approach to control mechanosensitive ion channels, through exogenous organic semiconductors. Materials in this class are fully biocompatible, thus offering the perspective for in vivo application, they can be easily processed in several forms, such as thin films, microstructured devices or nanoparticles. Most importantly, they are characterized by distinctive opto-electrical properties, providing excellent visible light responsivity, as well as electron and ion conductivity.

In this work we explore the opportunity to use organic semiconductors, and in particular conjugated polymers, to control the activation of mechanosensitive ion channels, in a reliable and effective manner. We critically discuss results obtained with different tools, including polymer thin films and microstructured devices. In more detail, we present first examples, to the best of our knowledge, of devices based on conjugated polymers to activate PIEZO channels in mammal cells.

Our results may contribute to develop innovative smart materials for tissue regeneration and pathologies involving mechanosensation driven by physical cues.

Monitoring Water Permeation in Flexible Bioelectronic Devices Massimo Mariello and Stephanie P. Lacour, Ecole Polytechnique Federale de Lausanne, Switzerland

Most bioelectronic interfaces call for long-term operation. Their form factor requires new packaging strategies to ensure hermeticity, thinness and mechanical conformability. Inspired from display technologies, organic-inorganic multilayers are promising candidates to package thin, flexible and miniaturised bioelectronic devices. Besides the materials challenges associated with the choice of suitable thin films, stacking and deposition methods, quantitative evaluation of their barrier performance is a must. We have developed real-time monitoring methods of permeability or water transmission rate of thin film multilayers leveraging magnesium (Mg) degradation under physiological conditions. Water permeation drives Mg hydrolysis. Using Mg film electrical and electrochemical sensors prepared with thin-film microfabrication, embedded in bioelectronic interfaces, ultra-low detection of water permeation (as low as of $3 \times 10^{-6}$ g/m²/day at room temperature) can be achieved. This method should provide useful information on novel encapsulation strategies for miniaturised, long-term bioelectronic implantable systems.

Noninvasive Optogenetics to Study Brain-Body Circuits Ritchie Chen, University of California, San Francisco, United States

Viscerosensory signals, such as hunger pangs, pain, and a racing heart, shape our cognitive state and behavior. However, the neural basis that drives these adaptive behaviors remains poorly characterized, largely due to a lack of tools to map, record, and modulate specific cell types within a dynamically moving body. This presentation will highlight recent advances in optogenetics that enable noninvasive photosactivation of electroactive cell types in the body using external, distally placed light sources. I will demonstrate how these methods can be applied to manipulate cardiac physiology and establish causal roles of visceral cardiac signals in influencing anxiety-like behavior in mice.

2:00 PM SB05.10.02
Nanoparticles for Wireless Magnetolectric Neural Modulation Ye Ji Kim, Noah Kent, Florian Koehler, Emmanuel Paniagua, Nicolette Driscoll, Marie Manthey and Polina Anikeeva; Massachusetts Institute of Technology, United States

Magnetic nanomaterials offer a minimally invasive alternative to invasive neurostimulation implants. A variety of magnetic nanomaterials have been developed to transduce physiologically benign magnetic signals (field-frequency product $H \times f < 5 \times 10^4$ Am$^{-1}$s$^{-1}$) to signals perceived by biological receptors including heat, mechanical stimulation, chemical release, and electric field. Magnetolectric nanomaterials composed of magnetoelectric (magnetic field to strain) cores and piezoelectric (strain to electric polarization) shells are particularly promising candidates for wireless transgene-free neuromodulation in deep-brain structures. Although strain-mediated magnetoelastic (ME) materials have been shown effective for neuromodulation at the millimeter and micrometer scale, achieving efficient ME coupling at the nanoscale remains a challenge. Here we report a strategy for enhancing the strain-mediated ME coupling at the nanoscale. We synthesize core-double shell magnetolectric nanodiscs (MENDs) with Fe$_3$O$_4$ - CoFe$_2$O$_4$ - BaTiO$_3$ architecture. In these nanodiscs, magnetostriiction is enhanced through anisotropic shape and interfacial strain between Fe$_3$O$_4$ and CoFe$_2$O$_4$, which collectively enable the generation of 30 µV in BaTiO$_3$ piezoelectric shell, which predicted numerically and measured experimentally via a electrochemical three-electrode cell. Although the electric field generated by individual MENDs is far below than the necessary potential change to reach the action potential threshold in neurons, we find that MENDs robustly evoke neural activity in vitro in the presence of a magnetic field. To explain this finding we propose a biophysical model of repeated neuronal depolarization based on cable theory and stochastic membrane potential fluctuations. Using the proposed model, we optimize the stimulation parameters in vitro, and then translate our approach to neuromodulation in vivo. Specifically, we show remote control of behavior in mice following 1.5 µL MEND injections at 1 mg/mL concentration (~100 times lower concentration than previous studies using the same magnetic transduction regardless of mechanism). We offer a mechanistic approach for further refinement of magnetolectric neuromodulation at the nanoscale with the goal of empowering neurobiological discovery.

2:15 PM SB05.10.03
Engineering a Biolytical Neural Interface for Synaptic Deep Brain Stimulation Léo Sifringer1, Alex Fratzi2, Stephan Ille1, Parth Chansoria1, Jens Duru1, Blandine F. Clement1, Sinead Conolly1, Benedikt Maurer1, Christina M. Tringides1, Leah Minkenküller2, Giulia Anos1, Sean Weaver4, Sophie Girardin1, Katarina Vulić1, Simon Steffens1, Anna Beltraminni1, Eyal Ceylan1, Srinivas Madduri1, Marcy Zenobi-Wong1, Botond Roska2, Janos Vorös2 and Tobias Ruff3; 1ETH Zürich, Switzerland; 2IOB Basel, Switzerland; 3University Geneva, Switzerland
Restoring functional vision in blind patients lacking a healthy optic nerve requires bypassing retinal circuits. This can be achieved by high resolution stimulation of the visual thalamus, which is located deep inside the brain and serves as the main input to cortical circuits underlying vision. However, available deep brain stimulation electrodes suffer from low stimulation resolution, limited biocompatibility and limited coverage of the targeted tissue. To overcome these limitations, we propose a novel living biohybrid neural interface with the goal of restoring functional vision in the blind without a healthy optic nerve. Our interface uses living on-chip grown retinal neurons as relays to convert electrical signals from a stretchable microelectrode array into synaptic stimulation of a neural target tissue. Our interface is based on a stretchable micropatterned microelectrode[1,2] array onto which we align axon guiding microfluidic structures that enable unidirectional guidance and merging of axons to form an artificial optic nerve. We increase the biocompatibility of our device by replacing the Polydimethylsiloxane (PDMS) based nerve forming channel with a collagen or gelatin methacyloyl (GelMA)[3] tube that is only 300 μm in diameter and directly integrated onto the PDMS device. We demonstrate the seeding of retinal spheroids into our biohybrid devices using a modified fluid force microscope. The retinal ganglion cells form an artificial optic nerve up to 3mm long that can transit from the device into the PDMS-bound hydrogel tube to reinnervate a matrigel-based target structure in vitro. We show that we can stimulate individual retinal spheroids using our stretchable microelectrode array. We also present in vitro data on how spikes propagate within the biohybrid implant to modulate thalamic target activity using glass and CMOS[4] multielectrode arrays. Finally, we present first progress towards in vivo implantation.

References
Due to their effective ionic-to-electronic signal conversion and mechanical flexibility, organic neural implants hold considerable promise for biocompatible neural interfaces. Current approaches are, however, primarily limited to passive electrodes due to a lack of circuit components to realize complex active circuits at the front-end. Here, we introduce a p-n organic electrochemical diode (OED) using complementary p- and n-type conducting polymer films embedded in a 15-μm diameter vertical stack. Leveraging the efficient motion of encapsulated cations inside this polymer stack and the opposite doping mechanisms of the constituent polymers, we demonstrate high current rectification ratios and fast switching speeds. We integrate p-n OEDs with organic electrochemical transistors (OECT) in the front-end pixel of a recording array. This configuration facilitates the access of OECT output currents within a large network operating in the same electrolyte, while minimizing cross talk and interference from neighboring elements. We further demonstrate it to generate time-division-multiplexed amplifier arrays. When fabricated in a shank format, this technology enables the multiplexing of amplified local field potentials directly in the active recording pixel in a minimally invasive form factor.

Epilepsy is a chronic neurological disorder characterized by recurrent seizures, affecting millions of people worldwide. Current treatment methods have limitations such as side effects and incomplete seizure control. One potential approach to address these challenges is by targeting the adenosine type 1 receptor, which is abundantly present in the body, for epilepsy suppression. However, it is important to note that this approach may introduce multiple undesired side effects such as dizziness, sleep disturbances, mood, cognitive, memory changes etc. Optopharmacology is an emerging approach for the treatment of focal epileptic seizures by activating and deactivating photoswitchable/photocaged molecules with light. It is a particularly interesting treatment solution which could result in powerful suppression of focal seizures with a limited number of side effects.

In this work, we study the neural dynamics of epileptic networks (in rodent model) and the effect of timely photo-release of a caged adenosine type 1 receptor agonist (caged CPA; N6-cyclopentyladenosine) hereon. To achieve that, we had to develop: i) animal protocols with evoked epileptic seizures, ii) illumination protocols proper for photorelease of the novel caged CPA molecule, iii) efficient microelectrode arrays, to trace the corresponding electrophysiology, that can simultaneously offer large spatial epidural coverage and high signal to noise ratio without sacrificing resolution or hindering illumination and drug application. In more detail, we performed craniotomies on several subjects to place semitransparent microelectrode array based on organic electronics on dura and trace electrophysiology. To provoke focal random epileptic seizures 4 - Aminopyridine (4-AP) was microinjected in different areas of the rat brain through specifically designed perforation paths. Upon microinjection of caged CPA epileptic activity continued but when the brain was exposed to pulses of 405nm light for uncaging of cCPA, local epileptic activity was strongly attenuated.

The results of this study provide a better understanding of propagation of 4AP induced seizures and confinement dynamics upon spatially resolved optopharmacological interventions. These findings are significant because they will positively impact the development of optopharmacological molecules and protocols, microelectrode arrays and therapeutic systems.

Neural interfaces for recording or stimulating cells and tissues require long-term stability, mechanical compliance, low impedance, and high charge injection capacity. However, the mechanical mismatch between stiff metal electrodes (e.g., gold, platinum, and iridium oxide) and soft biological tissue poses a significant challenge, hindering optimal performance. To address this, conductive polymers have been used as an additional interface layer, with poly(3,4 ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) being a widely utilized material. While PEDOT:PSS offers good charge injection capacity and lowers impedance, its long-term stability when implanted in the body remains a bottleneck due to delamination, pH changes, charge injection, and immune responses.

In this work, we propose a chemical approach to enhance the adhesion between gold electrodes and PEDOT:PSS by covalently attaching the polymer to the gold surface, i.e., generating polymer brushes. We designed and synthesized polymer brushes made of block copolymer scaffold using a surface-initiated living radical polymerization (grafting-from). Our polymer brushes comprise a poly(styrenesulfonate) (PSS) block and a soft poly(polyethylene glycol methyl ether methacrylate) (PPEGMEMA) segment. This scaffold serves as a platform for polymerizing PEDOT, creating an adhesive and compliant interface with the brain tissue.

We successfully implemented this approach on a flexible microarrayed neural probe and evaluated its electrical charge transport and long-term stability for brain activity recording. The covalently attached polymer brushes significantly enhanced the adhesion between gold and PEDOT:PSS coating, addressing the challenges associated with delamination over time. The resulting interface exhibited improved long-term stability, and reduced impedance compared to traditional PEDOT:PSS-coated gold electrodes.

Our findings offer insights into the development of more reliable and efficient neuroprosthetic devices. By enhancing the stability of PEDOT:PSS coatings, we pave the way for improved neural interfaces with long-term functionality in neuroscientific research and clinical applications.
system with bio-based carbon composite electrodes recently developed, pose the foundation for a new class of circular coffee-based photoelectrochemical systems.

Engineering Extracellular Electron Transfer in Escherichia Coli for Microbial Electrochemical Devices Mohammed Mouhib1, Melania Reggente1, Lin Li1,2, Nils Schuergers1,2 and Ardemis A. Boghossian1; 1École Polytechnique Fédérale de Lausanne, Switzerland; 2Chongqing University, China;
1Universität Freiburg, Germany

Microbes hold great potential for green electrochemical synthesis as well as bio-electricity generation from organic waste. The key to the successful development of microbial electrochemical devices lies in the ability of the microbes to transport electrons across their outer membranes. These devices thus often rely on the use of microbes known as exoelectrogens, which include bacteria that have evolved metabolic pathways that enable extracellular electron transfer (EET) to solid substrates for cellular respiration. While exoelectrogens demonstrate facilitated electron transfer with the electrodes of these devices, natural exoelectrogens are often restricted to utilizing a narrow range of substrates that limits their versatility for processing different organic wastes and electrossynthesizing a rich diversity of high-value chemicals. By contrast, non-exoelectrogenic microbes such as Escherichia coli that lack efficient EET pathways are host to rich metabolic reaction networks that can be more readily tailored for various applications using synthetic biology.

In this work, we biologically engineer E. coli for enhanced EET. To this end, we expressed different combinations of proteins from the natural exoelectrogens S. oneidensis MR-1, as well as E. coli native proteins to optimize EET of the bioengineered strain [1]. We further introduced biosynthesis pathways for redox mediators to facilitate EET [2]. The bioengineered strains show significant improvements in electron transfer rates, as confirmed through colorimetric reduction assays of soluble electron acceptors and electrochemical characterizations following electrode reduction. The improved EET demonstrated in this work paves the way for increasing the efficiency of existing E. coli-based electrochemical devices while opening the doors to new applications that benefit from the broad chemical repertoire of these microbes.

SESSION SB05.11: Muscular Biohybrid Interfaces
Session Chairs: Heredine Ann Ardoña and Eleni Stavriniidou
Thursday Morning, November 30, 2023
Hynes, Level 1, Room 102

8:00 AM SB05.11.01
Soft Device for Simultaneous Measurements of Contractility and Electrophysiology of Neuromuscular Tissue Poppy J. Oldroyd1, Sophie Oldroyd1, Rajesh Makwana2, Gareth Sanger3, David Bulmer4, George G. Malliaras1 and Roisin Owens1; 1University of Cambridge, United Kingdom; 2Queen Mary University of London, United Kingdom

Biological tissues serve as rich sources of electrical and mechanical signals that offer valuable insights into their function, disease conditions, and metabolic activity. However, certain neuromuscular tissues, such as those in the gastrointestinal (GI) tract, can undergo significant conformational changes when physiologically active. These tissues have received limited research attention due to challenges faced by rigid probes in conforming to their dynamic surface, which can experience strain levels of up to 40%. Conventional inextensible devices cannot capture the relationship between electrophysiological and mechanical responses of these tissues. This hinders the acquisition of crucial neuromechanical information in the gastrointestinal system, essential for understanding GI homeostasis and the connections between the enteric and central nervous systems.

To address these challenges, this study introduces bimodal electrodes made from poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) and polydimethylsiloxane (PDMS) that enable simultaneous monitoring of electrical and mechanical responses of gut tissue. PEDOT:PSS demonstrates long-term stability and outperforms metal electrodes that delaminate, crack, and degrade over time. PDMS, used as a substrate and insulation material, shows promise due to its superior intrinsic strain properties surpassing popular polymers like polyimide and parylene C.

In contrast to traditional electrode fabrication methods, this work utilizes shadow masks and solution-processable spin coating techniques, resulting in a faster and simpler fabrication process. To optimize the spin coating of PEDOT:PSS on PDMS, Capstone FS-300 was added for stability and film homogeneity. Polyethylene glycol (PEG) was incorporated to maintain electrical conductivity during stretch, enabling mechanical monitoring. The PEG concentration can be adjusted to tune the device's electrical sensitivity to strain changes. A low PEG concentration improves sensitivity to smaller strains while a higher concentration makes the device strain insensitive for pure electrophysiology data. The PDMS-PEDOT:PSS-PDMS devices exhibit reduced delamination and cracking during accelerated aging compared to metal-based and parylene C devices.

The device was validated on ex vivo mouse and human gastrointestinal tissues. The device successfully monitored muscle electrical activity and motility. During induced propulsive movements through the mouse small intestine, the device recorded electrophysiological voltage amplitude changes ranging from 2.1 to 3.5 times, corresponding to the strength of the contraction. These voltage changes were temporally correlated with resistance variations resulting from mechanical propulsion. The signals observed from the human stomach were similar in nature to those observed when monitoring the mouse small intestine, highlighting the variety of applications of the devices and ability to detect signals in relatively thick (human) and thin (mouse) tissues. Furthermore, the ability to wrap the electrode system around a small diameter tissue as well as affixing it to a flat surface demonstrates the adaptability of device.

In conclusion, the presented bimodal tissue monitoring device integrates soft, flexible, and stretchable electrodes using thin PDMS and PEDOT-PSS layers doped with PEG and Capstone. Its electrical sensitivity to strain can be finely tuned for specific applications by adjusting the dopants in the PEDOT-PSS. The device's flexibility and stretchability make it suitable for monitoring gastrointestinal muscle activity, including motility and electrical activity, as demonstrated on mouse small intestine and human stomach tissue. It has the potential to provide clinical insights into complex disorders like irritable
Modular Skeletal Muscle Biohybrid Robots: Creation & Multi-Unit Assembly of Functional Muscle Building Blocks

The emerging field of biohybrid robotics aims to create the next generation of soft and sustainable robots by using engineered biological tissues, integrated with soft materials, as actuators. Alongside robotics, such biohybrid muscles will also find biomedical applications in prostheses and drug development and screening. Current skeletal muscle tissue-based robots are powered by bulk-built 3D configurations of muscle tissue (e.g., blocks or ring-like tissues). The size of these constructs is restricted to the sub-cm scale due to biofabrication constraints and limited nutrient perfusion. Further, lack of internal topography within bulk constructs results in poor control of myofiber formation and thus low contraction force. Therefore, to generate larger biohybrid constructs capable of complex motion while avoiding the issues of bulk muscle tissue manufacture, we have developed a bottom-up fabrication approach based on the assembly of muscle building blocks into designs that exploit the characteristics of the single actuators to form a multi-unit configuration. We created the muscle building blocks by integrating thin layers of muscle-cell laden hydrogels onto hydrogel-based exoskeletons characterized by material properties and microtopographic patterns that enhance muscle tissue development (i.e., microgrooves). Our thin cell-laden hydrogel layers allowed nutrient diffusion throughout the layer, and we incorporated microtopography with a layer-by-layer approach.

We used a novel linear volumetric printing technique, named xolography, to form the hydrogel exoskeletons (< 1 mm x 5 mm x 8 mm). Adapting xolography for aqueous hydrogel printing allowed us to take advantage of the quick speed, high resolution, and achievable geometric complexity of the technique. We printed exoskeletons with different mechanical properties by combining polyethylene glycol diacylates with gelatin methacryloyl, e.g. 15% PEGDA700 and 5% GelMA (P700/GelMA, Young's Modulus 140 kPa) and 15% PEGDA575 and 5% GelMA (P575/GelMA, Young's Modulus 270 kPa). The exoskeletons featured microgrooves of 100–300 μm in width to guide formation of uniaxially oriented myofibers. To stably integrate the exoskeletal and the cellular hydrogels, we developed a Matrigel, collagen, and gelatin methacrylate-based cellular hydrogel that, when seeded with myoblasts, allowed for both contractile myofiber formation and effective cross-linking with the exoskeletal hydrogel, as shown via confocal and brightfield imaging and histological analysis.

Directionality analysis of confocal microscopy images of samples stained to visualize myofibers (F-Actin) showed uniaxial alignment in the channel direction with a standard deviation of 10°±20°. The structural deformation of these constructs caused by the contraction via electrical stimulation of their muscle tissue component depended on the exoskeleton composition. Constructs based on P700/GelMA contracted 4% in the direction of myofiber contraction, while constructs based on P575/GelMA contracted <1%. Finally, to form modular multi-unit biohybrid robots with predictable motion abilities, we assembled the muscle building blocks by cross-linking the residual unreacted acrylate groups in the PEGDA/GelMA exoskeletons under UV irradiation.

In conclusion, we developed a method that builds biohybrid robots by the assembly of muscle building blocks with tunable mechanical properties and actuation performance. We have reduced the complexity and increased the predictability of biohybrid muscle fabrication, thus unlocking the potential of engineered muscle tissue as an actuating technology.
Engineered living-synthetic systems possess functions to dynamically control their shape and movements in biological environments that are pertinent to various biomedical applications, such as building biorobots and artificial muscles. To create functional bio-hybrid systems, in vivo-like living natural components such as 2D and 3D muscle tissue constructs, and their contractile function are required to be integrated into artificial platforms. Among various biomaterials, electrically conductive nanoparticles-incorporated hydrogels, which can improve the nanofibrous morphology and electrical and mechanical properties of conventional hydrogels while maintaining the hydrogels’ beneficial properties, such as high porosity, biocompatibility, and biodegradability, are required to develop scaffolds mimicking biological and physical properties of native extracellular matrices (ECMs). These nanofibrous and electrically conductive scaffolds showed excellent myofiber maturation and organization along with cell-cell junction formation, providing self-actuating motions. Also, these nano-biomaterials can be engineered by various microfabrication techniques (i.e., bioprinting) to create 3D complex architectures, such as accordion-inspired hydrogel-based scaffolds which replicated the native myofiber architecture together with its function in terms of robustness and enhanced contractility after culturing with cardiomyocytes. Recently, the maneuvering of bio-hybrid soft robots has been controlled by various strategies, such as electrical and optical stimulations. We have developed advanced technologies to control the biohybrid soft robots by integrating flexible microelectrodes into soft and deformable engineered scaffolds to stimulate muscle actuators locally. Harnessing wireless power transfer technology without requiring batteries and wires, we developed untethered biohybrid soft robots that could swim; whereby, the steering of this swimming motion could be remotely controlled by transmitting electrical power into a cell simulator wirelessly. To this end, wirelessly powered, stretchable, and lightweight cell stimulators were successfully integrated into self-actuating soft muscle bodies without impeding the robot’s underwater swimming ability. Wirelessly modulated electrical frequencies enabled us to control the speed and direction of the biohybrid soft robots. This innovative approach should provide a platform for building untethered biohybrid systems for various biomedical applications.

Cyanoacteria are abundant photosynthetic microorganisms that can be interfaced with electrodes in semi-artificial photosynthetic systems for solar-electricity or solar-fuel generation. [1] This approach relies on the ability of the living organisms to exchange electrons efficiently with the electrode. Redox-active and conductive polymers may be introduced at the cell-electrode interface to improve charge transfer efficiency by providing a direct route for electrons to reach the electrode thus overcoming sluggish diffusional kinetics. At present, the polymer properties that are key for efficient wiring of cyanobacteria to electrodes are poorly understood.

In this study, we systematically tested and compared the capacity of a common osmium-based redox polymer (P0) and the conductive polymer poly(3,4-ethylenedioxythiophene) (PEDOT) to act as a wiring tool for Synechocystis sp. PCC 6803 on hierarchically-structured inverse opal indium tin oxide (IO-ITO) electrodes. By using stepped chronoamperometry and normalising photocurrents against cell loading, we were able to identify the conditions under which each polymer served only as an immobilisation matrix, enhancing the photocurrent by means of increasing the cell loading rather than by mediation. The contribution of various parameters including polymer type (redox vs conductive), deposition method (dropcasting vs electropolymerisation), deposition geometry (layered vs mixed), polymer morphology and polymer loading towards optimal photocurrent outputs were deconvoluted. Increasing the polymer loading in both cases led to an enhanced mediation effect up until a certain point when photocurrents were reduced presumably by a thermodynamic cost, as the onset potential for mediation is 200 mV higher for PEDOT than for P0, respectively) relative to unmodified electrodes at a low light intensity of 1 mW cm⁻². However, the larger photocurrents extracted using PEDOT come at a thermodynamic cost, as the onset potential for mediation is 200 mV higher for PEDOT than for P0. Overall, this study identifies polymer properties that are essential for successful cyanobacteria-electrode wiring and informs future interface design strategies for photosynthetic organisms on complex 3D structures.

11:00 AM *SB05.12.04 Nanomaterial and Biological Engineering of Living Electronics Ardemis Boghossian; EPFL SB ISIC LNB, Switzerland

The vast expansion of available synthetic biology tools has led to explosive developments in the field of materials science. The increased accessibility of these tools has pushed the frontier of materials science into the field of engineering biological and even living materials. By coupling the tunability of nanomaterials with the prospect of re-programming living devices, one can re-purpose biology to fulfill needs that are otherwise intractable using traditional engineering approaches.

Optical technologies in particular stand to benefit from the untapped potential in coupling the optical properties of nanomaterials with the specificity and scalability of biological materials. This presentation highlights applications in sensing and energy technologies that exploit the synergistic coupling of nanobio-hybrid materials. This talk will focus on the development of living electronics, such as photovoltaics based on photosynthetic organisms with augmented capabilities.
monomer, gave very interesting results for the stabilization of R. sphaeroides RCs. RC has been immobilized both in PDA thin films on the electrode surfaces or in PDA nanoparticles, without altering the enzymatic photoactivity, and producing photocurrents in photoelectrochemical cells [5]. PDA has been modified with diamines, leading to more transparent nanostructures incorporating RC molecules, which outperform RC/PDA structures in light transmission and photoconversion [6].

Finally, we have been investigated different approaches for interfacing intact photosynthetic microorganisms with electrodes, enabling photoconversion of whole living cells of R. sphaeroides and R. capsulatus, using PDA as the interface material either as a coating on the cells' surface, or as a film entrapping the cells on the electrode surface [7]. Furthermore, eukaryotic diatoms have been also selected for their efficiency in harvesting and converting sunlight into chemical energy and the feasibility of silica shell functionalization. Electrochemical characterizations have been performed to understand the electronic transfer between diatoms and electrodes, using different redox mediators.

Synergy Between Bacteria and Conjugated Polyelectrolytes to Form Functional Biomaterials

4:00 PM

added to neat CPE-K do not achieve the same properties. Taken all together, the demonstrated abiotic/biotic synergy between microbe and polymer respiration of the bacteria through the polymer promotes conductive network formation with a lower charge transfer resistance than neat CPE-K by itself.

Catalytic Materials Enabled by a Programmable Assembly of Synthetic Polymers and Engineered Bacterial Spores

The proposed biohybrid microrobotic designs presented in these studies hold significant promise for future medical applications by addressing current limitations and employing advanced fabrication techniques. These designs offer improved production efficiencies, enhanced control over locomotion, and various medical functionalities.

3:00 PM SB05.13.08

Synergy Between Bacteria and Conjugated Polyelectrolytes to Form Functional Biomaterials

Combining conjugated polyelectrolytes with electroactive bacteria leads to the formation of living functional materials that improve the performance of bioelectrochemical technologies for biosensing, electricity generation, and electrosynthesis. However, the organization of these hydrogel composites and their effect on microbe physiology remain unexplored. In this study, mixing of a p-type conjugated polyelectrolyte (CPE-K) with Shewanella oneidensis MR-1 leads to a three-dimensional organization that generates ~30-fold greater biocurrent density than control biofilms in electrochemical cells. Further, respiration of the bacteria through the polymer promotes conductive network formation with a lower charge transfer resistance than neat CPE-K by itself. Total RNA-seq analysis revealed differential gene expression between cells in the polymer composite versus standard biofilm. Genes related to bacteriophages (biofilm development) and energy metabolism were upregulated in the composite compared to control biofilms. Correlating, extracellular polymeric substance (EPS) quantity and lactate coulombic efficiency increased in the composite. Cyclic voltammetry, fluorescent staining, and rheological measurements before and after enzymatic treatment in the living composite show the importance of the extracellular matrix for cohesion. EPS components added to neat CPE-K do not achieve the same properties. Taken all together, the demonstrated abiotic/biotic synergy between microbe and polymer
provides new strategies for designing multifunctional living composite materials.

SESSION SB05.14: Implantable and Wearable Devices

Wearable In Situ Sweat Sensors for Health—On-Skin Electrochemical Real-Time Sensors Le Yang1,2; 1Institute of Materials Research and Engineering A*STAR, Singapore; 2National University of Singapore, Singapore

In an increasingly health-aware population and a move towards remote diagnostics, remote healthcare monitoring, cloud-based med-tech, etc, we tap on the ubiquitous and unlimited reservoir of on-skin biomarkers, including sweat metabolites, in developing a wearable, non-invasive, continuous and real-time sensor – a printed, multiplexed biosensor. Our integrated devices are designed and developed with scalability and translation in mind – ensuring printability (for scalable manufacturing), ease of fabrication routes, and solid-state and miniaturised prototype[1-5] We also aim for better validation and correlation studies of non-invasive biomarkers to ensure useful relevance of such non-gold standard devices. Carbon-based electrodes are promising candidates for developing cheap, miniaturized, and disposable biosensors for effective wearable applications. From developing our own printable carbon-based ink, to screen-printing the electrodes, to functionalising each electrode into a specific biosensor, and finally to multiplexing and integration and incorporating of cheap paper-based sweat channels - we show how these devices can potentially add value to home-based/DIY biomarker monitoring. We look at a variation of our flexible electrode, a graphite/carbon fiber (G/CF) hybrid resembling a super-efficient 3D highway network where amplex expressways (CF) run through numerous small factories (locally distributed graphite flakes) for rapid goods pick-up and transportation (electron transfer).[6] Lastly, we zoom in on the top-most layer of the device, the kirigami paper sweat channel, critical in enabling real-time fresh-sweat reading[7]

8:30 AM SB05.14.02
Materials for Cut-And-Seam Fabrication of Soft Functional Interfaces Cindy K. Harnett1 and Samantha Musante2; 1University of Louisville, United States; 2Trinity College, United States

Interfaces between inorganic and biological systems need to be mechanically compatible with soft surfaces that grow, stretch, and distort over time. This requirement has driven the development of soft photonic and electronic circuits. However, the evolving shape of these circuits poses a problem when connecting circuits together: how can we match up distorted contacts that may be impossible to align? The problem comes up not only when repairing, modifying, or temporarily connecting to a stretchable circuit that’s already attached to a biological system, but also when connecting circuit pieces into custom 3D structures to cover one-of-a-kind biological shapes. The usual solution to the distortion problem is to create a stiffened connector region that prevents the circuit from deforming, which is good for alignment but doesn’t conform to biological surfaces as closely as a soft region does. The 3D structure problem may be solved by laying out a new electronic circuit for each individual interface, but this makes it difficult to use woven meshes and other regular structures as bases for soft functional interfaces.

This presentation describes our approach to connect signals across thin seams between soft materials without precise alignment at the connections. Our method relies on mm- and smaller scale electrical components inserted into thin adhesive tapes, producing materials with anisotropic electrical conductivity.

The alignment error tolerances we target are 2 mm in the direction perpendicular to the circuit edge, 2 cm parallel to the circuit edge, and a 70 degree angular tolerance. The reason for the large angular tolerance is that 3D cut-and-seam structures are often made from anisotropic woven or knit materials, often have curved seams, and are subject to external constraints such as packing cuts into a sheet to conserve material. These factors mean there is no guarantee that wires, optical fibers, and other anisotropic features will meet at the same angle along every seam, or even within a single seam.

The cut-and-seam fabrication method will also be discussed here as an interface for highly porous mesh-based biosensor circuits. Mesh circuits’ applications in tissue engineering and biosensing are promising because meshes permit vapor transport, can be perfused with nutrients, and provide paths for cells to extend through during growth. However, the task of collecting signals from individual wires in a mesh is laborious, and mesh materials are often made from fibers that can’t be soldered because of a too-low operating temperature range (for example, metallized polymer threads) or because harsh chemicals are required for solder wetting (for example, stainless steel wires and threads). The seaming materials and methods in this work are designed to make contact to those conductors, forming a distribution network for power and data in the soft sensor interface.

In this presentation, we investigate the above alignment tolerances in circuits made from thin films and fibers, focusing on methods such as capacitance, temperature, strain, and light intensity measurements that function when encapsulated by parylene, silicone and other conformal biocompatible coatings.

Atomically Thin Boundary Between Wearable and Implantable Bioelectronic Interfaces  
Dmitry Kireev, University of Massachusetts Amherst, United States

Modern biosensors reveal a notable trend toward mobile and personalized health monitoring. Monitoring health-related electrophysiological signals, such as brain activity, heart activity, body hydration, or temperature, is essential for better comprehension of human physiology. Continuous long-term monitoring of those signals from individuals of different health conditions is essential to understanding systematic health risk factors and building preventive care solutions, which is paramount for intricate conditions like cardiovascular. However, modern wearable and implantable technologies require substantial improvement in terms of their ability to interact with the tissue without causing harmful consequences. In this work, we report on a substantial advancement of graphene electronic tattoos and use them for bioelectronic applications on the wearable and implantable fronts.

In a groundbreaking advancement in healthcare technology, we have harnessed the power of graphene to create wearable and implantable bioelectronic devices that revolutionize health monitoring and treatment. Using atomically thin and electrically conductive graphene electronic tattoos (GETs), we developed imperceptible monitoring technologies for measuring blood pressure with Grade-A accuracy. Unlike other wearables, GETs are lightweight and skin-conformable, eliminating discomfort during long-term measurements.

Recently, we also translated this technology into implantable sensors, demonstrating the sensing and stimulation of the mammalian heart, including treatment of arrhythmia with graphene pacemakers. The arrays show superior electrochemical properties, and the transparency of the graphene structures allows for simultaneous optical mapping of cardiac action potentials and optogenetic stimulation. Additionally, we advanced in creating tissue-integratable bioelectronic systems resembling biological neurons using soft, flexible, and biocompatible artificial synaptic transistors based on graphene and Nafion, boasting superior energy efficiency. These breakthroughs open up new possibilities for wearable and implantable graphene bioelectronics to transform healthcare and improve patient outcomes.

9:15 AM SB05.14.06  
Intrinsically-Stretchable Cardiac Interfacing Devices for Heart Failure and Ventricular Tachycardia  
Dae-Hyeong Kim1,2; 1Institute for Basic Science, Korea (the Republic of); 2Seoul National University, Korea (the Republic of)

Recent advances in flexible and stretchable electronics have attracted great attention due to its potential applications to personalized bio-integrated healthcare devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations in feedback therapies. Such issues can be amplified in the case of interfacing with dynamically moving organs including the heart, and lead to unsatisfactory monitoring efficiency and therapeutic efficacy. Intrinsically-stretchable bioelectronic devices have a low system modulus and intrinsic softness, and thereby have a potential to solve these issues. Nanomaterials and their composites with the elastomeric matrix are a particularly promising material candidate for realizing this soft bioelectronics concept. In this talk, the unique strategies in the synthesis of nanomaterials, processing as stretchable functional nanocomposites, their seamless integration with dynamically-moving cardiac muscles are presented. These efforts have combined recent breakthroughs in nanomaterials and soft electronics, and are expected to address unmet clinical challenges.

10:00 AM BREAK
Plant Electrophysiology with Conformable Organic Electronics

Abdul Manan Dar, Adam Armada-Moreira, Zifang Zhao, Dion Khodagholy and Eleni Stavrinidou; Linköping University, Sweden; Columbia University, United States

Plant electrical signals are mediators of long-distance signaling and correlate with plant movements and responses to stress. Presently, these signals are studied with macro single surface electrodes that cannot resolve signal propagation patterns and integration, thus impeding their decoding and link to function. Unlike conventional extracellular electrodes, multielectrode (MEA) technology records the distribution patterns of electrical activity in cellular networks using a non-invasive, dense array of electrodes embedded in a substrate. The MEA technology is extensively used in brain and cardiac tissue research to decode the brain connectivity and potential propagation patterns in cardiac myocytes respectively. However, for plant electrophysiology the MEA technology remains fairly unexplored. Here we developed a conformable multielectrode array based on organic electronics for large-scale high-resolution plant electrophysiology. The MEA is developed with standard photolithography fabrication techniques, with parylene C as substrate and encapsulation layer resulting in total device thickness as low as 5 micrometers. The MEA is therefore highly conformable to the plant tissue leading to high Signal to Noise Ratio (SNR). With the conformable MEA, we performed spatiotemporal mapping of the electrical activity of the carnivorous plant Drosophila melanogaster and a Venus Flytrap (VFT). VFT consists of a bilobed trap having three trigger hairs in each lobe which serve as mechanosensors. When the mechanosensitive hair is deflected, the mechanical stimulus is translated into an action potential (AP), by sensory cells at the base of the hair. Two action potentials (or two touches) in a short period (less than 30 secs) are required to induce closure of the trap. We found that the AP actively propagates through the tissue with constant speed and without strong directionality. We also found that spontaneously generated APs can originate from unstimulated hairs and that they correlate with trap movement. Finally, we demonstrate that the VFT circuitry can be activated by cells other than the sensory hairs. Our work reveals key properties of the AP and establishes the capacity of organic bioelectronics for resolving plants electrical signaling contributing to the mechanistic understanding of plants long-distance responses.

SB05.15.03

Soft Optical Implanted for Measuring Water Potential in Plants

Veena Bacheva, Eric Wu, Piyush Jain, Sahayasachi Sen, Alice Gevorgyan, Margaret Frank and Abraham Stroock; Cornell University, United States

Spending their lives rooted in one place, plants exhibit remarkable adaptability in their metabolism and development in response to the changing environment [1]. One crucial aspect for their survival is the control of water uptake and the maintenance of water status (water potential) [2], which is influenced by environmental factors such as soil moisture, air temperature, and humidity. Evidence suggests that the changing water potential of plants not only results from these factors but also serves as a long-distance signaling mechanism that enables plants to communicate these changes effectively [3-5]. Therefore, measuring water potential would improve our understanding of whole-plant signaling and responses to environmental stresses, allowing us to develop effective strategies for plant health and productivity in a changing climate. However, currently, there is lack of tools for measuring water potential that are suitable for field studies and for a variety of plant species.

Here, we present the development of a soft optical implant for measuring water potential in plants. The implant contains water-sensitive nanoparticles that exhibit a fluorescence spectrum dependent on the water potential [6]. The nanoparticles can resolve water potentials across the physiologically relevant range (−3 to 0 MPa) while exhibiting minimal sensitivity to other physical factors like temperature and pH. We use fiber optics to illuminate the implant and capture the fluorescence spectrum to determine the water potential. With its small footprint, the implant can be easily embedded into various plant species. To assess the biocompatibility of the implant, we examined histological sections of the local tissue at the insertion site. In recent years, several polymer-based materials have been developed for packaging of implantable sensors in mammals. Since the effect of these materials has not been studied in plants yet, we are also exploring different polymer- and plant-based materials to enhance the long-term stability of the implant. Additionally, we are considering the integration of a second optical fiber for simultaneous monitoring of sugar concentration, thereby enabling assessment of the osmotic potential.

We believe that the ability to accurately measure the total water and osmotic potential in planta will enable unprecedented access to the dynamics of water in plants and shed light on the propagation of long-distance hydraulic signaling. Moreover, the implant can be used beyond the context of plants by measuring water potentials in various environments such as soil, food, cosmetics, medicines, and cement.

Bioelectronic Platform for Enhancing Plant Growth

Alexandra H. Sandél1,2, Vasileios Oikonomou1,2, Torgny Näsholm3 and Eleni Stavrinidou1,2,3; Linköping University, Sweden; Columbia University, United States

To cover the food demands of the growing population in the changing climate we need to increase crop yield in a sustainable manner. Hydroponics cultivation minimizes water and fertilizer use while it can be integrated in the urban environment. However, so far the substrates used in hydroponics mainly offer support to the root system. Here, we developed a bioelectronic platform that stimulates the growth of plants in a hydroponics culture. We demonstrate that barley, one of the most important crops, grows well within the bioelectronic platform. When stimulated, the biomass of the barley increases by 40%, and the effect is evident in both root and leaf development during the growth period after the stimulation treatment. Results also show that stimulated plants reduce and assimilate NO3 more efficiently than controls, a finding that can have implications on minimizing fertilizers use. Our work opens the pathway for enhancing plant growth in a hydroponics setting using bioelectronics which may result in more sustainable food production.

Biomimetic Reactive Oxygen Species (ROS) Scavenging System for Stability Enhancement of Thylakoid Membrane-Based Photosynthetic Biosolar Cells

Jaehyung Yu1, Jonghyun Kim and WonHyung Ryu; Yonsei University, Korea (the Republic of)

Since photosynthesis of plants has a high quantum yield close to 100%, many studies have been conducted to utilize the photosynthesis for bio-energy harvesting using algal cells, chloroplasts, thylakoid membranes (TMs), and isolated photosystems (PS I, II). The extracted photosynthetic organelles are preferred among these for their direct contact with the electrode and easier transfer of photosynthetic electrons (PES). However, under high light intensity, reactive oxygen species (ROS) are generated during photosynthesis, causing damage to lipid membranes or proteins. Therefore, for long-term stability, a closed system capable of scavenging ROS like chloroplasts is required. In this study, we propose a biomimetic ROS scavenging system for stability.
enhancement of bio-solar cells. We used catalase to scavenge ROS, which causes the damage to extracted photosynthetic organelles and apparatuses. As a popular extracted photosynthetic organelle, TMs were used for bioenergy harvesting, and an artificial independent closed environment that did not interfere with PEs transport was constructed using alginate as extracellular matrix and the Nafion membrane. First, dye release test and catalase assay either in the presence or absence of Nafion membrane were performed to measure the leakage of catalase. The tests confirmed that the release of dye and catalase from the film coated with the Nafion membrane was negligible. However, the Nafion solution used for coating contains aliphatic alcohol that can damage lipid membranes or proteins. To analysis the effect of alcohol on TMs, photocurrents from TMs for different ethanol concentrations used in Nafion membrane were measured. TMs treated with 5% ethanol concentration produced about 82% of photocurrents from the non-treated TMs. Therefore, it was concluded that a sufficiently diluted Nafion solution did not significantly affect the production of TM photocurrent. Based on this, a 10-fold diluted Nafion solution was used for the coating of TM/alginate mixture film containing catalase. Furthermore, the film fabrication conditions were optimized through the photocurrent results according to the ratio among TMs, alginate, and catalase. Finally, in order to confirm the stability improvement of a photosynthetic bio-solar cell by catalase encapsulated system, the photocurrent from the system was observed for 5 hours under AM 1.5G (1 sun = 100 mW/cm²) illumination at intervals of 1,000 s. Afterwards, the stability improvement was evaluated by comparing the initial photocurrent and the photocurrent after 5 hours illumination. As a result, it was confirmed that about 4.3 times improved stability was achieved by the biomimetic ROS scavenging system.

Smart Wearable Healthcare Devices for On-Demand Theranostic Applications  Sei Kwang Hahn, SangHoon Hong and TaeYeoon Kim; Pohang University of Science and Technology, Korea (the Republic of)

A variety of diagnostic and therapeutic devices are routinely used in the clinic. While these devices have a familiar look as wall-plugged in hard packages or placed at patients’ bedside, there has recently been a rapid expansion of new ideas on wearable healthcare devices for greatly improved patient compliance. Here, we developed smart contact lenses and smart wearable devices for both continuous diabetic monitoring and diabetic retinopathy therapy. Smart contact lens could measure tear glucose levels as a non-invasive alternative to the conventional blood glucose tests and deliver drugs from gold coated reservoirs for the treatment of diabetic retinopathy. On the basis of these results, we also developed a smart wearable device for highly sensitive glucose monitoring in sweat for clinically feasible diabetic diagnosis. A blue-tooth system could send data wirelessly allowing patients to check their diabetic diagnosis results on the mobile phones. Furthermore, we developed cell-integrated poly(ethylene glycol) hydrogels for in vivo optogenetic sensing and therapy. The real-time optical readout of encapsulated heat-shock-protein-coupled fluorescent reporter cells made it possible to measure the nanotoxicity of cadmium-based quantum dots in vivo. Using optogenetic cells producing glucagon-like peptide-1, we performed light-controlled therapy and obtained improved glucose homeostasis in diabetic model mice. Taken together, this presentation will provide the current state-of-the-art smart wearable devices for further clinical applications.

2:00 PM DISCUSSION TIME

2:15 PM SB05.16.03
Cephalopod-Inspired Bioelectronic Control of Cellular Differentiation  David Berlin, Aleeza Farrukh, Georgii Bogdanov and Alon Gorodetsky; University of California, Irvine, United States

Cephalopods (e.g., squids, octopuses, and cuttlefish) have recently become recognized as a promising source of natural conductive biopolymers (1,2). Within this context, our laboratory has studied the proton conducting properties of unique cephalopod structural proteins called reflectins, and we have leveraged these proteins for applications in protonic transistors, photochemically dopable devices, and protochromic color-changing platforms (1,2). Moreover, we have demonstrated that reflectin films are inherently biocompatible, as exemplified by their ability to support the growth and proliferation of both human and murine neural stem/progenitor cells (3,4). Recently, we have extended these efforts to the development of cephalopod-inspired bioelectronic devices that afford the voltage-controlled regulation of cellular differentiation in real-time (5). Our combined findings suggest that reflectins are promising materials for applications in cell- and tissue-interfaced bioelectronic platforms.

2:30 PM SB05.16.04
Soft, Skin-Safe Electronic Device Interfaces for Continuous Health Monitoring  Seonggwang Yoo and John A. Rogers; Northwestern University, United States

Abstract
Soft electronic device interface directly with the skin surface allows essential physiological health monitoring. These devices, featuring soft and miniaturized architecture, wireless communication capabilities, and an independent power system, significantly reduce patient burden by eliminating wired connections and bulky hardware of traditional hospital-grade systems. Previous efforts by soft, thin structures with high bio-compatibility addressed the many skin damage problems but still present challenges, especially when in direct contact with the delicate skin of ill infants with small anatomical bodies and low-risk perception ability. Here, we report materials and structural design strategies to enhance skin safety during clinical use, especially for infants, without hampering the unique characteristics of the device architectures and the electronic performance. Pre-curved and holey design conforms to the anatomical body and rapidly and effectively releases interface adhesion, significantly reducing skin irritation. Furthermore, an ultrathin, flexible bladder containing small amounts of liquid with a low boiling point provides an active thermal safety system to these soft, skin electronic devices. In a thermal malfunction, the heat evaporates the liquid inside the bladder, forming an effective thermal barrier and automatically delaminating the device from the skin. Our material and structural design approach aims to ensure the safe and reliable use of soft electronic devices for infant health monitoring, promoting overall well-being and comfort during usage.
Non-Invasive Actuation of Chemical Reactions Through Mechanochemistry and Gas Vesicle Proteins

Cationic membrane-targeted azobenzenes have been recently proposed as light-induced nanomechanical units for neuronal photostimulation.1,2 In previous works, we demonstrated that an azobenzene functions as a promising nanoscale tool for cell photostimulation, namely Ziapin2. Our approach resides in non-specific binding, and Ziapin2 has an amphiphilic character allowing it to partition spontaneously within the cell membrane. The cationic terminal groups interact with the phospholipid polar heads of the membrane while the hydrophobic part of the molecule stabilizes inside the lipidic region. We demonstrated that this azobenzene is an effective light-driven intramembrane actuator, able to modulate neuronal firing both in vitro and in vivo.3 These previous results open to the next generation of light-driven photoswitches aimed at enhancing the performances and improving the partition stability.

In this work, new amphiphilic push-pull azobenzenes (ppABs) were designed and synthesized, which feature a strong electron donor group in the para-position on one phenyl ring and a strong electron acceptor group in the para-position on the opposite phenyl ring. They are designed in order to be hyperpolarized in response to light and to be efficiently planted within lipidic environments.3

Consequently, the operation of DEAs requires kilovolt-scale potentials to achieve targeted actuation strains and energy densities. The incorporation of high-εc fillers affords little improvement, since liquid fillers (e.g., liquid metals) decrease breakdown strength, while solid fillers (i.e., strontium titanate particles) increase modulus. In this talk, we will describe recent advances to design and synthesize intrinsically polarizable elastomers and gels based on a library of small molecules with a large dipole moment and a low melting point – each of which exhibits exceptional permittivity (εr ≥ 10). Consequently, the operation of DEAs requires kilovolt-scale potentials to achieve targeted actuation strains and energy densities. The incorporation of high-εc fillers affords little improvement, since liquid fillers (e.g., liquid metals) decrease breakdown strength, while solid fillers (i.e., strontium titanate particles) increase modulus. In this talk, we will describe recent advances to design and synthesize intrinsically polarizable elastomers and gels based on a library of small molecules with a large dipole moment and a low melting point – each of which exhibits exceptional permittivity (εc ≥ 250) in the low frequency limit. Their synthesis is both facile (3-5 synthetic steps) and scalable (up to 250 g) from inexpensive starting materials. Using this library, we have created elastomers and gels with εc ≥ 100 and E ≤ 1 MPa, which may find potential application in high-strain and energy-dense DEA, haptic, and bioelectronic-based devices.

Non-Invasive Actuation of Chemical Reactions Through Mechanochemistry and Gas Vesicle Proteins

Yuxing Yao, Molly McFadden, Mikhail Shapiro and Maxwell Robb, California Institute of Technology, United States

Recent advances in molecular engineering and biomedical ultrasound provide means to apply physical effects, including mechanical stress, deep inside tissues, but limited capability to enact specific chemical processes for applications including drug delivery and non-invasive control of cellular functions. In this work, we show that mechanochemistry, chemical processes initiated by mechanical stress, can be activated with biocompatible focused ultrasound assisted by acoustically-active proteins. Previously, activation of mechanochemistry relies on ultrasound with parameters that are likely to damage tissues. Through acoustic cavitation seeded by genetically encoded, air-filled protein nanostructures called gas vesicles, polymers undergo bond cleavage at the designed, weakest position in backbones and thus release small molecular payloads, including fluorophores and therapeutic drugs by chemical cascade. The efficiency of mechanochemical activation is comparable to what has been achieved with bulk sonication, though with weaker ultrasound parameters. Focused ultrasound further enables the activation of mechanochemistry with spatial resolution in millimeter range as well as the programmable payload release kinetics. Furthermore, we demonstrate the stimulation of mechanochemistry in tissue-mimicking gels, suggesting its potential applications in remotely controlled drug release inside body. Our platform represents a novel modality for chemical reactivity non-invasively in biological systems and unlocks the translational potential of polymer mechanochemistry for therapeutic and bioimaging applications.
Exploring Cell Behavior Through Blanket and Patterned Reprogramming of Nanotopography

Mona H. Abostate1, Nikolaos Liaros1, Matthew J. Hourwitz1, Wolfgang Losert2,3 and John Fourkas1,3,4; 1Department of Chemistry and Biochemistry University of Maryland, United States; 2Department of Physics, University of Maryland, College Park, MD, USA, United States; 3Institute for Physical Science & Technology, University of Maryland, College Park, MD, USA, United States; 4Maryland Quantum Materials Center, University of Maryland, College Park, MD, USA, United States

The systemic delivery of nanoparticles (NPs) has garnered significant attention from researchers due to its clinical promise. Various strategies have been developed thus far, including the utilization of the enhanced permeability and retention (EPR) effect to target tumors or the modification of NPs with antibodies to target specific proteins. However, delivering NPs to the brain through the blood-brain barrier (BBB) remains a challenge. Additionally, the importance of the communication between the central nervous system (CNS) and the peripheral nervous system (PNS) has been increasingly recognized, leading to a high demand for delivery systems that can flexibly change their target between the CNS and PNS. Translation of delivery strategies between species offers another challenge, especially in the context of bridging the divide between fundamental research in rodents and clinical research in larger models such as non-human primates (NHPs). Therefore, there is a pressing need for a novel strategy for systemic delivery of nanomaterials that is both translational and capable of flexibly selecting targets.

For decades the field of gene therapy has applied engineered viruses to deliver therapeutic transgenes to particular organs or cells of interest. Adeno-associated viruses (AAVs) are the most ubiquitous gene-therapy tools, particularly in neuroscience, owing to their advantageous characteristics: AAVs are non-pathogenic, easily reproducible, and have numerous accessible serotypes, each with distinct tropism. State-of-the-art serotypes, such as AAV.CAP-B10 and AAV.MacCPNS2, have demonstrated the ability to deliver genes to the brain or PNS in mice following intravenous (IV) injection, while simultaneously suppressing gene expression in the liver. These serotypes have also shown promise for gene delivery in NHPs.

In this study, we hypothesized that AAVs could be employed to guide magnetic nanoparticles (MNP) to particular organs through IV injection. This approach allows for easy modification of the target by swapping AAV serotypes, for instance, from the brain to the PNS. Furthermore, the target species can also be altered based on the serotypes of AAVs. This concept, termed viral guidance of MNP, has the potential to serve as a versatile targeting strategy.

We covalently conjugated MNPs and AAVs (MNP-AAV chimeras) through click chemistry. The structure of these chimeras was controlled by adjusting the reaction conditions. In vitro tests were conducted to investigate the efficiency of AAVs in guiding MNPs using MNP-AAV chimeras formed from several different serotypes. As a result, MNP-AAV chimeras retained the tropism of original AAV serotype used, indicating that the delivery target is serotype-dependent and can be easily modified by changing the AAV serotype used for conjugation.

We also investigated an opposite application of MNP-AAV chimeras, namely, the magnetic guidance of AAVs. Since AAVs were conjugated to MNPs, we could manipulate the chimeras using an external magnetic field to exert a magnetic force on the MNPs. HEK293 cells were incubated with MNP-AAV chimeras in a presence of a magnetic field. Following a 24-hour incubation period, the HEK cells expressed high levels of fluorescent protein, which was encoded by the AAVs in the chimeras, near the center of the magnetic field. This result suggests that magnetic guidance of AAVs is feasible, and that AAVs in chimeric form (conjugated to MNPs) are capable of transducing cells. The specificity of gene delivery targeting with AAV was previously determined by a combination of two factors: serotype (capsid) and regulatory elements (promoter, enhancer, Cre-lox system, etc.). Now, our chimeras enable spatial restriction of transduction, which adds another layer of control to gene delivery. To the best of our knowledge, this is the first report of magnetically controlled transduction with AAVs.

Exploring Cell Behavior Through Blanket and Patterned Reprogramming of Nanotopography
Mona H. Abostate1, Nikolaos Liaros1, Matthew J. Hourwitz1, Wolfgang Losert1,2 and John Fourkas1,3,4; 1Department of Chemistry and Biochemistry University of Maryland, United States; 2Department of Physics, University of Maryland, College Park, MD, USA, United States; 3Department of Chemistry and Biochemistry University of Maryland, United States; 4Department of Physics, University of Maryland, College Park, MD, USA, United States

Cellular responses to external stimuli arise from a complex integration of various biochemical and biophysical signals that can occur concurrently, and that exhibit distinct spatial and temporal patterns. Of these signals, nanotopography, which is present in the extracellular matrix, holds special significance in influencing and controlling cell behavior. Nanotopography has the ability to initiate and direct waves of actin polymerization in a phenomenon called esotaxis, which is closely linked to the inherent excitability of cells. For instance, nanoridges can induce a transition from the 2D spreading waves observed on flat substrates to 1D waves.

We have molded large-area master patterns created using conventional lithography, and then replicated these masters using soft lithography. Replicas created using poly (Disperse Red 1 methacrylate, pDR1m), an azobenzene-containing polymer, can be reconfigured with light. The azobenzene moieties undergo photoisomerization from the trans isomer to the cis isomer, inducing macroscopic alterations in the polymer structure that depend on the polarization of the light.

With this technology, a single nanoridge master can be used to generate a wide range of patterns with different surface features. Photomodification of pDR1m nanoridges was achieved through two different methods: blanket exposure and patterned exposure. The newly patterned surfaces can be replicated in a material that is not photosensitive through a straightforward molding procedure. We have examined the response of cells to surfaces featuring buckled nanoridges created through. The presence of buckling has a significant influence on esotaxis, ultimately impacting cell migration. Because this effect is cell-type-specific, and depends on the degree of buckling, it is possible to create surfaces that impact different types of cells in different manners.

SESSION SB05.18: Virtual Session: Biohybrid and Soft Functional Interfaces

10:30 AM SB05.18.01
Stretchable Silent Speech Glove using Myopotentials and Machine Learning
Yuta Kurotaki1,2 and Hiroki Ota1; 1Yokohama National University, Japan; 2Pepabo Research and Development Institute, GMO Pepabo, Inc., Japan

The field of Silent Speech Interface (SSI) exists as an interface for sending information without speaking. Personal and confidential information can be heard by others when spoken, but if speech can be recognized without voice, confidential information can be transmitted safely. In addition, silent speech can send information to machines and people without disturbing the environment. There are many methods for predicting what is uttered from silent
speech, one of which is the use of muscle potentials around the mouth. Recently, it has been shown that muscle potentials can be measured by placing sensors around the mouth, but the integration of a mechanism that uses soft materials to recognize speech using electrodes, muscle potential amplification circuits, and machine learning models has not yet been realized. Although it is possible to place circuits and elements as well as sensors around the mouth, the area around the mouth is limited, and attaching sensors would interfere with mouth movements. The myopotential amplification circuit requires many elements to be placed on the circuit, which would result in a loss of aesthetics in terms of appearance.

To solve these problems, we developed a myopotential measurement device that can be attached to the human hand using soft materials, liquid metal, transparent FPCs (Flexible Printed Circuits), and a microcomputer. The device can be placed near the mouth and electrodes placed around the mouth to collect myopotential information, which can then be used in a machine learning model to classify speech only when speech recognition is performed without speech. By enabling sensing by placing electrodes on the mouth only when the device is being used, there is no need to worry about information being read at times other than when the device is being used, and since there is no need to always wear sensors or circuitry around the mouth, speech will not be read at unintended times. It does not interfere with the movement of the face or mouth, eliminating aesthetic concerns.

In this study, electrodes based on soft materials were created to realize a device that is worn on the hand and repeatedly measures myoelectric potentials around the mouth. The electrodes were wired to circuits on transparent polyimide film using a liquid metal mixture of Galinstan and nickel powder and bonded with a hard-print pattern of silicone rubber and epoxy. The electrodes and substrate, which fit the human hand, can capture information around the mouth without breaking, even when the hand is moved, or the fingers are bent. In addition, a speech classification model was created using machine learning based on the acquired data of myoelectric potentials in silent speech. We propose a new form of silent speech interface that allows many people to send information to machines and people in more situations and with the same privacy as in their conventional lives.

10:45 AM SB05.18.02 Permeable Electronic Skins for Health Monitoring: Van Wang1,2; 1Guangdong Technion–Israel Institute of Technology, China; 2Technion–Israel Institute of Technology, Israel.

One limitation of commercialized wearables, such as smartwatches and bands, is that they cannot form conformable contact with human skin due to their rigid form factor, thereby limiting their monitoring capabilities. Soft bioelectronics, on the other hand, are touted as an ideal platform for personalized health care owing to unique characteristics, such as thinness, lightweight, good biocompatibility, excellent mechanical robustness, and great skin conformability. Permeable skin-mountable electronics that are capable of long-term applications have emerged as promising tools for early disease prevention, screening, diagnosis, and treatment1-3. Dr. Wang’s research interests mainly focus on the development of wearable electronics for biomedical health monitoring, including stretchable conductors, sensors, and soft energy devices. In today’s talk, she will introduce high-performance skin bioelectronics developed by ultrasoft nanomesh systems, which can realize the accurate measurement of minus skin deformations and finger touch without disturbing natural skin motions and sensations, as well as long-term applications for health monitoring4-6.

11:00 AM SB05.18.03 Thin-Film Encapsulations for Compliant Implantable Bioelectronics: Advanced Materials and Characterisation Methods Based on Biodegradable Magnesium Permeability-Sensing Structures: Massimo Mariello1,2, Yves Leterrier2 and Stephanie P. Lacour2; 1University of Oxford, United Kingdom; 2Ecole Polytechnique Federale de Lausanne, Switzerland.

The next-generation bioelectronic implants will be microfabricated, soft and compliant; they need to be protected from the body environment through encapsulations that must guarantee simultaneously hermeticity, biocompatibility, mechanical compliance, compatibility with microfabrication processes, and long-term reliability. This still represents an unsolved challenge: standard biocompatible barrier technologies based on rigid Ti/silicone capsules do not answer such needs. Advanced hermetic barriers should instead rely on thin-film encapsulations (TFE), based on organic or inorganic films. However, water permeation and mechanical defects are prime drivers for TFE failure, especially for in vivo and flexible implantable systems, so a universal solution is still missing. Conventional strategies rely on multilayer architectures, consisting of alternating dyads made of organic and inorganic layers. The accurate evaluation of their barrier performances is challenging because standard measuring systems display too high sensitivity limits (~ 10^-5 g/m2/day) which cannot detect the ultra-low permeation capabilities of the coatings, and are not suitable for flexible microsystem formfactors. We present here for the first time a comprehensive accelerated-aging method to quantify ultra-low permeability of TFE engineered for bioelectronic micro-devices. The method relies on biodegradable magnesium (Mg) thin films. Corrosion of Mg induced by water diffusion through the barrier coating is real-time monitored in several testing conditions, including exposure to wet air, soaking in a phosphate buffer saline (PBS) solution that mimics the body biofluids (in vitro), and in biological tissues (in vivo). The electrical properties of Mg are then monitored and analysed. High temperatures for in vitro tests are chosen to perform accelerated aging whereas specific novel analytical/computational models are used to extract from the measurements the water transmission rates (WTR) of the barriers. The advantages of this approach are that Mg does not need a fully inert atmosphere and it can be easily integrated in the microfabrication processes of implantable bioelectronic devices. Therefore, the proposed characterization strategy answers a long-term need to assess reliably and universally thin-film hermeticity in situ, and for any types of conformal TFE for bioelectronic systems.

11:15 AM SB05.18.05 Modulation of Curli Production on Redox Challenged PEDOT:PSS Surfaces: Sanshita Ray1,2, Susanne Löffler1,2 and Agneta Richter Dahllof1,2; 1Karolinska Institutet, Sweden; 2AIMES, Sweden.

Biofouling is a major problem caused by bacteria colonizing abiotic surfaces, such as medical devices. Biofilms are formed as the bacterial metabolism

Biofouling is a major problem caused by bacteria colonizing abiotic surfaces, such as medical devices. Biofilms are formed as the bacterial metabolism
adapt to an attached growth state. We have previously found that electrically charged surfaces with high charge storage capacity like PEDOT-based conducting polymers can be used to modulate the amount of gross biomass attaching by altering the surfaces redox state( ). Here, we are delivering an in-depth analysis on the process of biofilm formation on redox-challenged PEDOT: PSS surfaces. We are using GFP tagged Salmonella bacteria and a marker for the Salmonella extracellular matrix components curli and cellulose (EbbeBiologic 680) to decipher the relationship between the amount of bacterial cells and extracellular matrix produced by bacteria in Salmonella wt bacteria as well as mutants deficient in curli (AescG) or curli as well as cellulose (AescD). We are using a semi-quantitative spectroscopy method to determine relative amounts of bacterial cells and extracellular matrix (ECM) on a large surface area and are performing detailed microscopic analysis to understand biofilm distribution and structure. When the redox challenge was carried out in a fast-charging whole-cell setup, higher amounts of cells and ECM were found on oxidized PEDOT:PSS surfaces compared to their reduced counterpart. When electrodes were separated and charging was carried out with respect to a Pt electrode, the charging process was slower and incomplete. This resulted in almost similar cell numbers for the two cases but showed much higher amounts of ECM on reduced surfaces. A curli mutant, grown under the same conditions produced biofilms that didn’t respond to the redox challenge. The microscopic structure of the biofilm showed uniform cell and ECM distribution on all oxidized surfaces but showed high density local clusters of around 100-200 μm diameter on all unchallenged and reduced surfaces.

This leads us to believe that redox modulation of biofilm formation mainly depends on curli production. We forward a theory where an oxidized PEDOT:PSS surface works as an alternate terminal electron acceptor for interfacial biofilm, which might be able to boost ATP production and curli formation. We reason that the negative charge of PEDOT:PSS on unchallenged and reduced surfaces leads to a spotty attachment of the bacteria and to the formation of microcolonies, instead of evenly distributed films.

Toward Enhancing Critical Care Monitoring: Continuous Assessment of Blood Lactate and Potassium with Fiber Optic Sensors Integrated into Intravascular Catheters Lawrence Kennedy1,2, Narciso Guzman1, Emily Vuu1, George Harea1, Gerardo Ico3, Teryn Roberts3 and Andriy Batchinsky2;

The determination of disease severity and prediction of outcomes in emergency medicine heavily rely on blood lactate (Lac) and potassium (K+) levels. Traditionally, these biomarkers are assessed through repeated invasive blood sampling and subsequent analysis using laboratory blood gas analyzers. However, recent studies have emphasized the dynamic nature of these biomarkers, highlighting the need for continuous monitoring. In trauma cases, elevated blood Lac levels and poor Lac clearance have been associated with higher mortality rates, demonstrating potential for effectively triaging conditions such as lung cancer, lacunar infarction, sepsis, and cardiac failure. Likewise, high K+ levels, known as hyperkalemia, are linked to life-threatening conditions including arrhythmias and mortality following severe trauma, kidney disease, hemolysis, and acid-base imbalances. In hemorrhaging patients, hyperkalemia can be induced by tissue ischemia, blood transfusion, and acidosis, significantly heightening the risk of death. Consequently, there is an urgent demand for continuous monitoring of blood Lac and K+ levels in critical care settings. This study aims to develop and evaluate the performance of specialized fiber optic sensors that enable real-time monitoring of Lac and K+, thereby providing healthcare providers with timely guidance in rapidly changing situations. The sensors in this study employ a measurement method known as dual lifetime/luminophore referencing (DLR), which ensures high accuracy and mitigates sensitivity to the amplitude of the optical signal. In contrast to previous fiber optic sensors that are single point sensors located at the tip of the fiber and are susceptible to intermittent contact with tissue, a phenomenon referred to as the “wall-effect,” the current sensors utilize a tunable distributed sensing approach. This is accomplished by incorporating redundant “mini-sensors” along a specific section of the optical fiber. Furthermore, optimization of sensor fabrication was conducted to enhance sensitivity specifically for physiologic concentrations. The Lac sensor utilized in this research consists of multiple layers, including a luminescence transducer layer for measuring partial pressure of oxygen, a catalytic enzymatic hydrogel layer, and a diffusion barrier layer to overcome substrate-dependent inhibition. The K+ sensor is designed as a hydrogel that incorporates a luminecent ionophore for K+ detection, and a separate reference luminophore. Finally, sensor-integrated catheter prototypes were tested in an ex vivo flow circuit with fresh porcine blood. The sensor-integrated catheter prototypes showed strong pairwise correlation between the optical sensor measurements and blood gas analysis (Spearman correlation R2 = 0.981 and 0.970, p-value: <0.0001 and <0.0001 for Lac and K+, respectively).

In summary, our study has successfully shown that the DLR-based fiber optic sensors for continuous Lac and K+ monitoring, when integrated into intravascular catheters and evaluated under ex vivo circulation conditions using donor blood, offer a viable alternative to repetitive blood gas analysis. These sensors hold great promise in enhancing clinical decision-making and are now poised for further validation in translational studies focusing on trauma and critical care scenarios under in vivo conditions.

SYMPOSIUM SB06
Experimental and Computational Advances in Biomolecular Electronics
November 30 - December 1, 2023

Symposium Organizers
Anant Anantram, University of Washington
Juan Artes Vivancos, University of Massachusetts-Lowell
Josh Hihath, University of California, Davis
Linda Angela Zotti, Universidad Autónoma de Madrid
paradigm. By moving from materials used in traditional electrochemistry to using unconventional recent developments in the fields of material science, we first of its kind reagent-less molecular sensor for in situ detection of a wide range of targets, such as viral particles and proteins. However, continuous monitoring of chronic disease clinical biomarkers (BNP, Troponin I, IL6, TNFα as proof of concept) to manage patients’ health.

We recently developed the monitor disease progression, inflammation, and biomarker levels. This technology will provide a new generation of devices for the continuous monitoring of vital biomarkers in HF rat models.

Implantable Materials for Chronic Disease Monitoring

Chronic diseases such as heart failure (HF) are increasingly prevalent conditions that are difficult to manage. Patients often experience significant deterioration between clinic visits, and by the time they become symptomatic, their condition cannot be managed outside of the hospital. Inflammation has recently been identified to take roles on promoting and inducing HF but there are no insights on the mechanisms of disease progression. The ability to perform continuous monitoring of protein biomarkers on a body-implanted device will transform our capacity to diagnose disease, preserve wellness, and propose potential treatments. Using Flexible and Implantable sub-millimeter polymeric substrates, we propose a new solution for remote, continuous monitoring of chronic disease clinical biomarkers (BNP, Troponin I, IL6, TNFα as proof of concept) to manage patients’ health. We recently developed the first of its kind reagent-less molecular sensor for in situ detection of a wide range of targets, such as viral particles and proteins. However, continuous monitoring of chronic disease requires installing a miniature device inside the human body and continuously monitoring the patient for an extended period. The small device provides efficient reaction rates with a sub-millisecond resolution, which has not been achieved using the current common diagnostics paradigm. By moving from materials used in traditional electrochemistry to using unconventional recent developments in the fields of material science, we introduce a new generation of sensing platforms that are biocompatible, affordable, reliable, and environmentally friendly to deliver the promised goals of chronic disease management. Using an HF rat model and accessing interstitial fluid via contact with the device’s implantable part, we will be able to monitor disease progression, inflammation, and biomarker levels. This technology will provide a new generation of devices for the continuous monitoring of vital biomarkers in HF rat models.
Beyond the Diffraction Limit—Optomechanics in Biomolecular Contacts

Albert C. Aragonès; University of Barcelona, Spain

Molecular trapping approaches\(^1\) that rely on the electrical detection of single-molecule (SM) junctions\(^2,3\) often face a significant challenge of short lifetimes, typically ranging from tens to hundreds of milliseconds,\(^4\) primarily due to thermally activated junction breaking.\(^5\) The limited detection timescales hinder comprehensive fundamental studies, making the extension of detection times a crucial challenge in SM detection. Our plasmon-supported break-junction (PBJ) technique\(^6\) addresses this issue by significantly increasing the lifetime of SM junctions while preserving the native structure of the target molecule. Remarkably, the optical stabilizing force exerted by the nearfield gradient in PBJ enhances the stability of SM junctions, eliminating the need for chemical modifications of the target molecule or the electrode.

In the first part, we will explore how the nearfield manipulation influences capture and release mechanisms.\(^7\) As the field strength increases, the rate constant of capture kinetics rises while the release kinetics decrease, favoring the capture state over the release state. Consequently, the SM capture state becomes more likely and more stable than the release state above a specific nearfield strength threshold.

In the second part, we will delve into how the PBJ trapping technique can be further enhanced for biomolecular contacts\(^8\) through the manipulation of two physical features: (i) the optical resonance of the target molecule and (ii) the energy of the localized surface plasmon resonance in the nanogap. By leveraging these factors, we can extend the effectiveness of PBJ trapping in capturing and biomolecules.

---

SESSION SB06.02: Applied Biomolecular Electronics—Devices and Sensing II

Thursday Afternoon, November 30, 2023

James Canary, Ruojie Sha, Thanuka Udumulla and Chufan Yang; New York University, United States

We have developed a highly versatile system for the organization of 2-dimensional (2D) materials on the nanoscale. This system is predicated on the use of DNA-based information as an organizing principle, and on our ability to design DNA to encapsulate and orient other molecular and nanoscopic species in a diverse and effective fashion. We apply branched DNA molecules, not simple linear DNA, to the formation of connected networks of materials in a predictable fashion.\(^{1}\) We are able to build robust DNA 2D assemblies. Each of these assemblies can be filled as desired, with any molecules, macromolecules or nanoparticles that can be derivatized to interact, bond or bind with the DNA.

In earlier work, chemistry was developed to enable covalent attachment of organic groups to the 2'-O-riboyl position of RNA nucleotides. Such an attachment strategy minimizes distortion in DNA duplexes by directing appended groups to minimize unfavorable steric interactions with A-form helical structures. A variety of synthetic approaches were examined, involving modifications at different points in DNA oligonucleotide synthesis. Much of the...
chemistry was tested in the context of appended oligomers of nylon and poly(ethylene glycol).

Monodisperse oligomers of electroactive organic polymers were synthesized and appended to DNA oligonucleotides. An octamer of polyaniline, which shows rich electrochemical behavior, was incorporated into a rhombohedral DNA lattice. The resulting crystal showed excellent optical response consistent with cycling between its redox forms [2]. It was later studied in a smaller assembly showing reconfigurable excitonic interactions [3]. A heptamer molecule related to poly(phenylenevinylene) was included in a DNA crystal and found to show strong polarization properties [4].

This presentation will describe unpublished work on the synthesis and assembly of DNA-GNR chimeras within DNA nanostructures.

2:00 PM SB06.02.02
DNA Encoded Self-Assembly of Molecular Semiconductors for Light-Harvesting Jeffrey Gorman, Stephanie M. Hart, Torsten John, Maria A. Castellanos, Adam Willard, Gabriela Schalu-Cohen and Mark Bathe; MIT, United States

Plants transport and convert solar energy into radical-pairs at the ‘reaction center’ to generate fuel. Nature achieves this with a homogeneous set of pigments, where the host protein environment facilitates tailored couplings between many pigments each with their own function. In contrast, exquisite control over artificial semiconductors for exciton circuits and solar cells remains lacking. Our ability to synthetically generate molecular networks with prescribed nanoscale structure is lacking. To address this gap towards well-designed molecular optoelectronics, we report the development of DNA scaffolds hosting chromophores,1 to enhance excited state evolution for solar light harvesting.

Here we study the exciton evolution between strongly coupled perylene diimide (PDI) dye pairs scaffolded in DNA. PDIs are exemplar molecular aggregates as they produce a range of photoinduced excited states, depending on their spatial organization.2 To study how we can map a specific excited-state pathway to a PDI-DNA structure, we exploited the molecular precision of DNA base-pairing and nanoscale rigidity of DNA origami to generate a library of optoelectronic constructs. We make hundreds of nucleic acid-chromophore conjugates and self-assemble them into prescribed shapes. Using ultrafast spectroscopy, we identified designs that gave rise to different photoinduced species, including excimers and charge-transfer states. Next, we use computational modelling to pinpoint geometrical features that can be linked to a specific excited-state pathway. Our synthetic DNA platform offers the ability to rapidly survey the structure-property of molecular aggregates and identify optimized structures that can be useful for applications in excitonic devices, including solar conversion and quantum information.

DNA as a vehicle for molecular programming relies on the predictability and information storage capability of the canonical Watson-Crick base pairs, A:T and G:C. With only four Watson-Crick nucleobases and the poor electronic conduction in A:T pairs, it has become clear that there are strong limitations on the diversity and ensuing complexity of DNA-based electronic systems. To address this limitation, we present an expanded DNA alphabet based on metal-mediated DNA (mmDNA) base pairing in which we substitute hydrogen bonds between pyrimidine nucleobases with templated metal ion coordination.

We employ a self-assembling 3D DNA crystal system, the tensegrity triangle, to determine the biomolecular structures of 30+ metal ion (Ag+, Hg2+, Au+, and Cd2+)-mediated DNA (mmDNA) base pairs, and we further use this comprehensive structural library to elucidate fundamental design rules for an expanded DNA metal coding system. Energy gap calculations elucidate an electronic fingerprint for the base pair classes in our library, and show additional levels in the lowest unoccupied molecular orbitals (LUMO) of mmDNA structures, rendering them attractive molecular electronic candidates. Our results are consistent with previous studies in which mmDNA base pairs have been shown to have superlative electronic and magnetic properties, and we suggest a transmission mechanism to describe this behavior.

We further manipulate our self-assembled DNA crystals using pH to capture by x-ray diffraction a series of reversible, pH-driven chemical reactions involving silver, mercury and gold ions, with implications for bandgap tuning. Importantly, we identify titration points at which mmDNA pairs exist in a heterobimetallic state, where a single DNA base pair binds to both Ag+ and Hg2+ in tandem. The precision self-assembly of heterobimetallic DNA chemistry at the sub-nanometer scale will drive atomistic design frameworks for more elaborate mmDNA-based nanodevices and nanotechnologies. We anticipate the integration of this expanded mmDNA alphabet as a means of programming specific interactions into DNA nanostructures to enable the exploitation of their electronic, magnetic, and catalytic properties for future nanotechnology applications.

3:45 PM SB06.02.05
Selectivity and Real-Time Potassium Ion Sensor Based on dsDNA Sequences Aptamer in ZnO Thin-Film Transistors with Floating Structure Yen Shuo Chen1, Chun Chi Chen2, Hsin-Chiang You3 and Fu-Hsiang Ko1; 1National Yang Ming Chiao Tung University, Taiwan; 2Taiwan Semiconductor Research Institute, Taiwan; 3National Chin-Yi University of Technology, Taiwan

The level of potassium ions in clinical diagnosis is most associated with chronic kidney disease (CKD) and the pathophysiology of insulin secretion. The normal concentration in human blood of potassium ions is 2.5 to 5.5 mEq/L. In the past, the assay was mostly done by Blood Potassium Content Assay Kit, which provided that the potassium ions in the serum interact with sodium tetraphenylborate to form water-insoluble, which is time-consuming. Therefore, a rapid and immediate of detecting potassium ions is helpful for this issue. Recently, thin film transistors (TFTs) such as zinc oxide (ZnO) for biosensors have become the focus of increased research interest due to their high transparency and non-toxicity, and several reports have discussed the impact of floating gate structures on the sensing and reproducibility aspects of biosensors in solution.
In this study, unique double-stranded deoxyribonucleic acid (dsDNA) was used in combination with different concentrations of K ions detected through ZnO-based biosensors with a floating-gate structure. The TFTs were successfully operated as a switching device at a low operating voltage of 5 V. Here, ZnO TFTs with floating gate structures were used to sense dsDNA bound to metal ions in solution by non-contact sensing, and more than 50 detection times were achieved by removing solutions and low-temperature annealing, which is useful for biosensing. The dsDNA at 100 µM was dissolved in DI water and TE buffer to form a solution. The ratio of DI water to Tris-EDTA (TE) buffer was 1:10, and the molecular weight of the dsDNA (GGTTGGTGGTTGG) was 359.8. The KCl concentrations were 0.01 M (0.8 mEq/L), 0.03 M (2.5 mEq/L), and 0.1 M (5.5 mEq/L), respectively. To understand the relationship between the number of combinations of different concentrations of potassium ions and the potential of the DNA sequence, the number of zeta potentials for each concentration was measured. The zeta potential of dsDNA was -23.63 mV. The stability of the 0.01 M KCl solution was tested with -15.01 and -14.41 mV, respectively. The zeta potential was measured within an accuracy of 0.6 mV because a few ions flowing into the solution were unaffected. A positive charge is generated when the DNA sequence binds to potassium ions showing a glove-like shape and can completely wrap around K⁺. When the DNA sequence was bound to K⁺ in the 0.01 M KCl solution, the zeta potential was -15.01 mV. The zeta potential was -2 mV when the concentration of the KCl solution was 0.03 M; the zeta potential was 52.53 mV when the concentration was 0.1 M. These results showed that the KCl elevated by 6.75 mV per 0.01 M concentration.

To investigate ZnO-TFT-based potassium ion detectors, the performance of the ZnO TFT was assessed by analyzing the field-effect mobility (μFE), threshold voltage (VTH), and threshold voltage shift (ΔVTH) for carrier transport. In the initial state, the TFTs exhibited typical electrical performance. Specifically, with VTH = 2.3 × 10⁴ A, the threshold voltage (VTH) was -2 V, and the field-effect mobility (μFE) was 0.006 cm²/V·s. A unique ssDNA sequence combined with 0.01, 0.03, and 0.1 M KCl. The TFTs exhibited selective and sensitive electrical performance: VTH = 2.4 × 10⁴ A, 2.5 V, and -0.0052 cm²/V·s; VTH = 3.9 × 10⁴ A, 2.0 V, and -0.0059 cm²/V·s; and VTH = 3.6 × 10⁴ A, -0.5 V, and -0.0068 cm²/V·s. The ZnO-based TFT showed that KCl was elevated by 0.5 V per 0.01 M of concentration of K⁺. As the concentration rises, dsDNA binds to more K⁺, suggesting that the detected positively and negatively charged objects affect the turn-on voltage of ZnO TFTs. The increase in ΔVTH also indicated increased binding of dsDNA to K⁺ with potassium concentrations ranging from 0.01 M to 0.1 M and showed a linear correlation (0.99706). This ZnO-based TFT with DNA sequences aptamer could be used as a biosensor.

**Long Range Conductivity in Non-Redox Active Proteins**

Stuart M. Lindsay¹, Dmitry Matyushov¹, Aleksei Aksimentiev² and Siddharth Krishnan²; ¹Arizona State University, United States; ²University of Illinois at Urbana-Champaign, United States

It is widely assumed that efficient charge transfer in proteins requires the presence of redox cofactors, but we have found long-range (nS over > 10 nm) conductance in many proteins that do not contain redox cofactors. This is important because it means that fluctuations of many proteins can be followed electrically, as their conductance changes with conformation. For example, we have been able to follow the fluctuations in a DNA polymerase as it actively processes a template. The conductivity of a hopping conductor is proportional to the quantity nD, where n is the carrier density and D is the diffusion constant for carriers. Since proteins do not possess a Fermi sea, charge injection (n>0) is required for conductivity. This is in line with our observations that the protein needs to be coupled to the electrodes via ligands or specific chemical bonds for conductivity to be observed, though adventitious reactive groups on the protein can serve the same purpose. A diffusion constant D> 2x 10⁻⁴ cm²/s is required to account for the most highly conductive protein wires (OmcS cytochrome wires) and this, in turn, requires a reorganization energy on the order of kT, a small fraction of the value derived from the Stokes shift in classical Marcus theory. Molecular dynamics simulations of a series of linear proteins (whose electronic properties have been measured) show that the Marcus picture is not valid, the free energy parabolas associated with charge transfer between aromatic residues being broader than predicted from the Stokes shift. As a consequence, the reaction barriers are typically ~ 40 meV, almost equal to 3/2 kT. The calculated diffusion constant is 2x 10⁻⁴ cm²/s, accounting for the observed decay length. A model for charge injection determines n with one adjustable parameter that is bounded by electrochemical data, and the resulting conductivity is in agreement with experimental data.

**Combinations of Analytical and Machine Learning Methods in a Single Simulations Framework for Modelling of BioFETs**

Vihar P. Georgiev¹, Naveen Kumar¹ and Cesar Pascual Garcia²; ¹University of Glasgow, United Kingdom; ²Luxembourg Institute of Science and Technology, Luxembourg

In this paper, we present the simulation results of a BioFET using a novel simulation methodology implemented in a computational framework called the Biomolecule-Oxide Simulator (BOxSim). Our novel simulation methodology is based on Gouy-Chapman-Stern and the modified Site-binding models in combination with a machine learning methodology.

Moreover, our “BOxSim” framework is the computational simulation framework that works on the hierarchical inclusion of interdependent functions to operate multiple models simultaneously. BOxSim is flexible simulation environment which considers the problems of reactive sites from oxide surfaces or non-specific bindings along with the noise present in the experimental signal to calibrate and extract the required device output characteristics. It can help in generating the sensor response which can be experimentally calibrated to confirm the surface density of the specific and non-specific binding as a yield of the process while filtering the noise with the help of the developed methodology. BOxSim is designed in a way that can interact with the commercial tool (e.g., Synopsys TCAD) and our inhouse-simulator called Nano-electronic Simulation Software (NESS) to simulate the main device characteristics for designing either Ion-sensitive FET (ISFET) or Chem/Bio-FET based on the application. Industry-standard compact (BSIM) models can also be used to interact with the BOxSim which takes the generated surface potential from the BOxSim simulator and transfers it into a circuit simulator to evaluate various ISFET circuit designs.

To show the capabilities of our BOxSim framework, as input we have considered several oxides, amino acids (AA) and short peptides which generate distinct signatures for arch AA or peptide. We have investigated the impact of various high-k dielectric materials as the gate oxide on important Figures of Merit (FoM) such as current in the channel of the device, surface potential (Ψc), sensitivity and intrinsic buffer capacitance. More importantly, the variation
of differential capacitance ($C_p$) with the second gradient of drain current ($d^2J/dV^2$) and surface potential ($d^2\Psi/dpH^2$) are used to uniquely identify the signatures of different amino acids or peptides. The surface potential of oxides is dependent on the affinity constants and the zero-crossover point represents the zwitterion state. Similarly, we have simulated the detection process of different AA such as Glutamic Acid (E) and Lysine (K) immobilized with carboxyl (C-Irrm) or amine (N-Irrm) terminal. The affinity constants, isoloelectric point, and density of amino acids can be extracted from the $d^2\Psi/dpH^2$ variation with the bulk pH. Other than amino acids, we have shown the distinct features of short a peptide Phenylalanine-Proline (FP) immobilized with carboxyl-terminal and the addition of Glutamic Acid to the surface. The sensor output can be observed as the variation of drain current with the pH for the immobilized peptide sequence on the sensing surface. We have also confirmed the reliability of the designed model by calibrating the experimental data for different physiological conditions. The proposed method can be helpful in defining an efficient method for label-free protein sequencing.

9:50 AM BREAK

10:20 AM *SB06.03.03 Electron Transport Through Proteins beyond the Conventional Tunneling Limit David Cahen and Sudipta Bera; Weizmann Institute of Science, Israel

A key conundrum of bio-molecular electronics is the quite efficient electron transport (ETp) through solid-state junctions wider than a few nm, often without temperature activation. Such a behavior challenges known transport mechanisms, given that proteins, lacking extended conjugation, are low charge carrier density molecules and the experimental ETp results are surprising. A wide range of electron transport (ETp) studies has been done, mostly on protein films of comparable thickness, one that is within the limit of quantum mechanical tunneling (2, or for conjugated systems ~5 nm). Typically, for polymer junctions, current decays exponentially with junction width, limiting detection beyond a certain thickness and this should hold also with biopolymers, such as proteins. We find now (Bera et al, submitted) that we can detect and measure protein conduction of from 9 - 60 nm thick junctions of self-assembled bacteriorhodopsin multilayers to test the limit of ETp as a function of junction thickness, in a large (~10^-3 cm^2) area configuration. Junction quality was confirmed by impedance spectroscopy and voltage breakdown. Such junctions show near or complete activation-less transport with the most-efficient length-normalized electron transport reported so far (0.06-0.53 nm^-1).

The small to negligible (<200K) temperature dependence, among other things, excludes hopping as a plausible mechanism. While a modified Landauer model could be a possibility, the large transport distance (60 nm) makes coherent quantum mechanical tunneling physically implausible. The results may be understood by assuming that ETp is limited by injection at (via tunneling through) one of the contacts, followed by a much more efficient charge propagation across the proteins. Additionally, electrostatics of the protein film, whose dielectric constant we measured by impedance, will further limit the number of charge carriers in the protein film. Such a view also defines the question to tackle now, namely how electrons can pass through such wide protein layers at a rate that is measurable by our electronics and, apparently, more efficient than the rate of injection through the contacts.

10:50 AM SB06.03.04 Charge Transport Through Self-Assembled Monolayers—The Roles of Conformation and Chelation Samuel E. Root, George M. Whitesides, Yuan Li and Lee Belding; Harvard University, United States

To elucidate charge transport mechanisms through complex biomolecules—involving conformationally flexible, supramolecular systems—and isolated effects arising from different molecular scale features, it is useful to investigate simple, well-defined model systems. The "EGaIn junction," which uses a liquid metal electrode to measure charge transport through self-assembled monolayers (SAM), paired with a physical-organic approach to systematically modify the molecules within the SAM, provides a powerful platform for approaching this problem. I will discuss two recent works using this approach to understand (i) the role of molecular conformation (and specifically conformational disorder) on tunneling and rectification of current, and (2) charge transport through SAMs terminated by a chelating group and the influence of the binding of different metal ions.

1) Conformation. This work demonstrates that molecular conformation of molecules making up self-assembled monolayers (SAMs) influences the rates of charge tunneling (CT) through them, in molecular junctions of the form AuTS/S(CH2)2CONR1R2//Ga2O3/EGaIn, where R1 and R2 were alkyl chains of different length. The lengths of chains R1 and R2 were selected to influence the conformational structure of the molecules in the monolayer. The conformations of the molecules influence the thickness of the monolayer and their rectification ratios at ±1.0 V. When R1 = H, the molecules are well ordered and exist predominantly in trans-extended conformations. When R1 is an alkyl group (e.g., R1 ≠ H) however, their conformations can no longer be all-trans-extended, and the molecules adopt more gauche dihedral angles. This change in type of conformation decreases conformational order and influences rates of tunneling. When R1 = R2, the rates of CT decrease (up to 6.3x), relative to rates of CT observed through SAMs having the same total chain lengths, or thicknesses, when R1 = H. When R1 ≠ H ≠ R2, there is a weaker correlation (relative to when R1 = H or R2) between current density and chain length or monolayer thickness, and in some cases the rates of CT through SAMs made from molecules with different R2 groups are different, even when the thickness of the SAM (as determined by XPS) is the same.

2) Chelation. This paper describes a surface analysis technique that uses the "EGaIn junction" to measure tunneling current densities (J(V), amps/cm^2) with the second gradient of drain current ($d^2J/dV^2$) and surface potential ($d^2\Psi/dpH^2$) are used to uniquely identify the signatures of different amino acids or peptides. The surface potential of oxides is dependent on the affinity constants and the zero-crossover point represents the zwitterion state. Similarly, we have simulated the detection process of different AA such as Glutamic Acid (E) and Lysine (K) immobilized with carboxyl (C-Irrm) or amine (N-Irrm) terminal. The affinity constants, isoloelectric point, and density of amino acids can be extracted from the $d^2\Psi/dpH^2$ variation with the bulk pH. Other than amino acids, we have shown the distinct features of short a peptide Phenylalanine-Proline (FP) immobilized with carboxyl-terminal and the addition of Glutamic Acid to the surface. The sensor output can be observed as the variation of drain current with the pH for the immobilized peptide sequence on the sensing surface. We have also confirmed the reliability of the designed model by calibrating the experimental data for different physiological conditions. The proposed method can be helpful in defining an efficient method for label-free protein sequencing.

11:05 AM *SB06.03.05 Tunneling-to-Hopping Transition in Multiheme Cytochrome Bioelectronic Junctions Jochen Blumberger1, Xiaojing Wu2 and Zdenek Futer2; 1University College London, United Kingdom; 2University of South Bohemia, Czechia

Multiheme cytochromes (MHCs) have attracted much interest for use in nanobioelectronic junctions due to their high electronic conductances.
Recent measurements on dry MHC junctions suggested that a coherent tunneling mechanism is operative over surprisingly long distances (>3 nm), which challenges our understanding of coherent transport phenomena. In my talk I will present large-scale electronic structure calculations of gold-MHC-gold junctions that have allowed us to obtain the current-voltage characteristic of these proteins in well defined adsorption geometries and orientations[1,2]. We show that the high electronic conductances of MHC proteins is due to (i) a low exponential distance decay constant for coherent conduction (beta = 0.2 Ångstrom−1); and (ii) a large density of protein electronic states which prolongs the coherent tunneling regime to distances that exceed those in molecular wires made of small molecules. We also find that incoherent hopping conduction is uncompetitive in the experimental setup due to the large energy level offset at the protein-electrode interface. Removing this offset, e.g., by gating, we predict that the transport mechanism crosses over from coherent tunneling to incoherent hopping at a protein size of ~7 nm, thus enabling electron transport on the micrometer scale with a shallow polynomial (~1/r) distance decay.

Modeling Spin Transport in Multi-Heme Cytochromes

William Livernois and Anant Anantram; University of Washington, United States

Multi-heme cytochromes have attracted attention due to their conductive properties [1] and, more recently, their spin-selective properties [2]. The small tetraheme cytochrome (STC), a c-type cytochrome prominently found in Shewanella oneidensis, has been experimentally validated to act as a spin filter [3], highlighting its potential integration into the burgeoning field of nano-scale spintronic devices. A spin-dependent transport model was used to model this system, building upon prior work that has proven effective in analyzing similar biomaterials and cytochromes [4]. The improved model incorporates non-collinear effects such as spin-orbit coupling using generalized open shell density functional theory (DFT) in order to analyze the electronic structure of the cytochrome and spin-dependent transport properties. Preliminary findings indicate that collinear effects, arising from electron exchange and spin state, predominantly influence the transport pathway while spin-orbit effects only cause minor shifts in orbital energies.

To complement our electronic structure and transport studies, we have undertaken a detailed analysis of the role of the peptide backbone, employing hybrid Quantum Mechanics/Molecular Mechanics (QM/MM) modeling methods. The modeling results indicate that the peptide backbone functions primarily as a structural scaffold facilitating heme-to-heme electron transport, rather than directly contributing to electron conduction. Additionally, recognizing the importance of solvation effects in biological systems, we have investigated the impact of solvation on the cytochrome’s properties. The solvent, modeled using an implicit model and counterions, was found to modulate the coupling between heme sites and the overall conductivity of the cytochrome.

The research was supported by National Science Foundation NSF Grant Number 2317843, NSF Future of Manufacturing Grant No. 2229131 and the NDSEG fellowship.

Current Rectification via Photosystem I Monolayers Induced by Their Orientation on Hydrophilic Self-Assembled Monolayers on Titanium Nitride
Héctor J. Rojas Rojas1, Feng Liu2, Jerry A. Ferreira3, Domenikos Chryssikos1, Dario Leister1 and Marc Tornow1; Technical University of Munich, Germany; 2Ludwig-Maximilians-Universität München, Germany; 3Indian Institute of Science Education and Research, India

The photosensitive protein Photosystem I (PSI) is considered one of the most efficient light-harvesting molecular complexes in nature [1]. The electron transport studies carried out on PSI monolayer(s) formed on (quasi-) metallic contacts (highly doped silicon, indium tin oxide, silver, or, in the majority of cases, gold) using reliable soft top contacts show high reproducibility [2-5], along with its peculiar ability to rectify electrical current [2,4,5]. In the present study, we introduce titanium nitride (TiN) as a promising alternative bottom contact material to investigate the electronic transport properties of PSI. TiN is a hard, conductive ceramic well-established in CMOS technology, chemically inert, and biocompatible. Self-assembled monolayers (SAMs) of various hydrophilic group-terminated phosphonic acids covalently bound to the TiN surface were used to attach PSI layers onto its head surface electrostatically. Specifically, we investigated -OH, -COOH, and -NH2 terminal head groups and tailored mixtures of these. We used atomic force microscopy to confirm the formation of a PSI monolayer of thickness approx. 6 nm, with about 80% surface coverage. DC electrical measurements using eutectic gallium-indium (EGaIn) soft top contacts showed asymmetric I-V curves, with rectification ratio (RR) values varying from 150 to 460. We assign the observed rectification to possible PSI orientation preferences on a particular linker head group. Current rectification in PSI has been previously attributed to an internal electric dipole originating from charged states of the protein residual groups [4,5]. Our data indicate an orientation in which the stromal side of the protein complex is predominantly in contact with the hydrophilic linker surface. We analyze our data within the framework of tunneling through an asymmetric trapezoidal barrier [6].

2:15 PM *SB06.04.03 Modeling Quantum Charge Transport Through Nucleic Acid Structures: Role of Decoherence Hashem Mohammad1 and Anant Anantram2; 1Kuwait University, Kuwait; 2University of Washington, United States

Understanding the conductance of DNA helps in the development of new sequencing techniques, methods to sense biological processes, disease detection techniques, and future DNA-based nanoelectronics. The challenges in understanding the underlying transport phenomena stem from the facts that: 1) DNA is a floppy molecule that exists in a solvent environment, 2) sequence and conformation affect the energy levels distribution along the strand, and 3) the need to account for the details of the DNA-electrode junction.

Modeling of charge transport through nanoscale nucleic acid structures requires careful attention to the quantum effects. The fluctuating nature of the molecule and the surrounding solvent environment can affect the electron transport process depending on the length scale, going from coherent to decoherent transport, or to an intermediate state of coherent-decoherent transport. One prominent method to model charge transport through nanoscale devices is the Green’s function formalism. This formalism uses the Hamiltonian obtained from quantum mechanical simulations such as DFT to calculate the electron transmission properties. From the transmission, we can calculate other physical properties such as conductance and current-voltage characteristics. This formalism allows us to include the effect of attaching metallic contacts to the DNA through self-energy terms, removing the need for explicitly including them in the quantum-based simulations step. Additionally, it can incorporate decoherence due to scattering through self-energy terms as well.

This presentation focuses on the theory and modeling of quantum transport through nucleic acid structures using Green’s function method with decoherence probes. We model a DNA connected to two metallic contacts in a contact-DNA-contact setup. For a weakly-coupled system such as DNA, we use the decoherence probes method to account for scattering events. This technique uses phenomenological probes to mimic the interaction of electrons with the environment as they lose phase information and/or gain and lose energy (inelastic scattering). Decoherence broadens the energy levels and allows electrons to traverse the structure at energies that were not originally accessible to the electrons. The broadening of energy levels increases the transmission probability across the DNA. This constitutes the main difference between coherent and decoherent charge transport. Thus, the inclusion of decoherence allows us to obtain conductance values within the range of the experimental values, something that the coherent transport could not achieve.

The decoherence probes are included in the model as self-energies controlled by a spatially dependent parameter that represents the average scattering time for the electron. In the previous work, the decoherence parameter used was energy independent. The drawback of this is that it overestimates the transmission in the HOMO-LUMO gap and washes out distinct transmission features within the HOMO or LUMO bands. Therefore, we present an energy-dependent decoherence model that allows us to better describe the transmission spectra. We demonstrate that this model can generate the expected exponential decay of conductance with the increase in DNA length, and yields conductance values that agree with experiments.

We apply the decoherence probe method to a variety of DNA strands to demonstrate its use. The applications involve (i) detecting a single base mutation in a 15-base-pair long DNA strand, (ii) studying the properties of heterostructures created with DNA strands analogous to solid-state heterojunctions, and (iii) doping of DNA by an intercalating molecule (anthraquinone) between the base pairs, which allows a change in conductance depending on the redox state of the intercalator.

2:45 PM BREAK

3:15 PM *SB06.04.04 How Do Electric Bacteria Breathe Without Oxygen or Soluble Electron Acceptors? Protein Nanowires: Structures, Functions, and Ultrafast Electron Transfer Mechanisms Nikolai S. Malvankar; Yale University, United States

Deep in the ocean or underground, where there is no oxygen, Geobacter “breathe” by projecting tiny hair-like protein filaments called “nanowires” into the soil, to dispose of excess electrons resulting from the conversion of nutrients to energy, cleaning up radioactive sites. Although it is long known that Geobacter use filaments for electron transfer (Nature 2002, 2005), it was not clear what they are actually made of and why they are conductive.

Our studies have revealed a surprise: the nanowires have a core of hemes lining up to create a continuous path along which electrons travel (Cell’ 19, Nature Chem.Bio. ’20, Nature Micro ’23) and can be engineered with atomic precision using recombinant DNA technology, making for remarkably versatile electronic components.

We have further found that Geobacter pilli remain hidden inside the cell and serve as a piston to secrete nanowire-forming cytochromes (Nature 2021) rather than functioning as a nanowire themselves as previously thought (Current Opinion 2020).

These studies solve a longstanding mystery to explain our previous findings that these bacteria transport electrons via nanowires on DNA strands that conduct as if they are solid-state (Nature Nano. 2014) over 100-times their size to electron acceptors (Nature Nano. 2011) and partner cells (Science 2010) and store electrons when acceptors are absent akin to how humans use their lungs (ChemPhysChem 2012).

Our contact-free measurements of intrinsic electron conductivity in individual protein nanowires reveals how energetics and proximity of proton acceptors modulate conductivity by 100-fold (PNAS 2021, Biochem. Journal 2021). We have also developed synthetic protein nanowires with tunable conductivity and programmable self-assembly using non-natural click chemistry functionality (Nature Comm. 2022).

In this talk I will present our efforts to identify the physical and molecular mechanism of high conductivity of microbial cytochrome nanowires. Our conducting-probe AFM measurements show one of the highest electronic conductivity ever reported in proteins (>100 S/cm) (Nature Chem.Bio.’20). Femtosecond transient absorption spectroscopy and quantum dynamics simulations reveal ultrafast (<200 fs) electron transfer between nanowire hemes upon photoexcitation, enhancing carrier density and mobility. Photoconductive atomic force microscopy shows up to 100-fold increase in photocurrent in photo-oxidized nanowires. Photocurrents respond rapidly (<100 ms) to the excitation and persist reversibly for hours (Nature Comm.’22). Furthermore, nanowires and biofilms show non-classical temperature dependence of conductivity with cooling accelerating electron transport by 300-fold.

Our efforts to computationally model the heme redox potential and conductivity of nanowires yielded up to a billion-fold lower conductivity than experiments (JPCB ’21, JPCB ’22), illustrating that the existing computational models based on electron hopping assumption fail to capture electron transfer in biological nanowires. This raises the possibility that biological nanowires employ a fundamentally different, currently unknown mechanism. Thus, existing models predict the same conductivity for all nanowires with computed timescales for heme-to-heme electron transfers (100 ns), million-fold lower than that measured using transient absorption in excited-state (Nature Comm.) and conductivity in ground-state for fully hydrated (Nature & Cell) or air-
dried nanowires (Science Adv.).

Notably, multiple computational studies have predicted that invoking quantum effects could account for the high conductivity of these nanowires (Nanotechnology’20, IEEE’21, ACS Nano’23). I will present our efforts to experimentally assess these computational predictions using multiple probes such as light, temperature, electric and magnetic fields. I will also discuss how our studies are helping to understand, predict and control extracellular electron transfer by nanowires used by diverse environmental microbes to capture, convert and store energy.

3:45 PM SB06.04.05
Combination of Droplet Oscillation and Dielectrophoresis to Increase the Sensitivity of Biosensors
Marten Musiol1, Marte Thorns1, Benita Hafemann1, Fenja Schröder1, Felix Hirschberg1, Annalena Eckert1, Rebekka Biedendieck1, Hans-Hermann Johannes1,2, Dieter Jahn1 and Wolfgang Kowalsky1,3; 1Technische Universität Braunschweig, Germany; 2Leibniz Universität Hannover, Germany

Biosensors have become a research field of high interest over the last few years. Especially the detection of bacteria is one of the main issues for biosensors. To prevent human health risks and detect even a small quantity of bacteria e.g. in water sources, reliable and accurate detection of bacteria must be guaranteed even for small concentration of bacteria. To increase the sensitivity of such biosensors it is of high importance to increase the number of bacteria on the sensing area. In this work dielectrophoresis (DEP) is utilized to improve bacteria collection at the sensing area.

DEP accelerates dielectric particles suspended in a liquid towards regions of either high or low electric field gradient by applying an alternating inhomogeneous electric field. The force associated with DEP is called dielectrophoretic force (DEP force). This force operates in a radius of micrometers. The transport of particles to the operating area of the DEP force is improved by droplet oscillation. This method provides liquid turbulences inside the particle solution. Thereby, more bacterial cells are collected on the sensing area.

The droplet oscillations are generated by two oscillation electrodes. Those electrodes are implemented beneath the DEP setup with a distance of micrometers. Between the DEP and oscillation electrodes a droplet of a polar liquid is located. By applying a voltage to one of the droplet oscillation electrodes the polar molecules of the liquid align with the electric field. The alignment of the molecules leads to a decrease of surface tension in the area of the electric field. As a response the liquid starts to flow towards the region of low surface tension. To get a consistent flow inside the droplet the applied voltage switches between the two oscillation electrodes.

This research focuses on optimizing the reciprocal influence of the DEP field and the electric field for the droplet oscillation. In order to enhance the experimental setup, the simulation software COMSOL Multiphysics® was used. In this simulation parameters like the frequencies of the electric fields or electrode geometries were taken into account. The results of the simulations should allow us to construct a setup combining droplet oscillation and DEP, that is capable of improving the sensitivity of biosensors.

Key words: droplet oscillation, dielectrophoresis, liquid turbulences, biosensors, bacteria

4:00 PM SB06.04.06
Seeing is Believing: Quantitative Imaging of Bacterial Electron Export Correlated with Protein Structure and Mechanical Properties
Sibel E. Yalcin; Yale University, United States

Protein nanowires enable Geobacter to survive without-oxygen like soluble electron acceptors perform important functions such as cleaning up radioactive sites, generating electricity (Nature Nano, 2011, or sharing electrons with other bacteria (Science 2010). Although it is known for more than two decades that Geobacter make nanowires (Nature 2002, 2005), it was not clear what they are actually made of and why they are conductive. I will present recent discoveries that resolve two decades of confounding observations in thousands of publications that thought these nanowires as pil filaments (Current Opinion in Chemical Biology 2020).

Our studies have revealed a surprise: the protein nanowires have a core of metal-containing molecules called hemes. Combining high-resolution cryo-electron microscopy with multimodal functional imaging, we found that hemes line up to create a continuous path along which electrons travel. Using multimodal functional imaging (Physical Biology 2020) and a suite of electrical, biochemical and physiological studies, we find that rather than pili, nanowires are composed of cytochromes OmcS and OmcZ that transport electrons via seamless stacking of hemes over micrometers (Cell 2019, Nature Chemistry 2020). I will discuss the physiological need for two different nanowires and their potential applications for sensing, synthesis, and energy production.

As this area of research is in its infancy, many of our advancements are made possible by the new nanoscopic imaging techniques we have developed to address major bottlenecks for the field by quantitatively visualizing the electron export via protein nanowires (Nature Nano. 2014) and also by living diverse bacteria at single-cell-level. For example, the studies described above also established a new atomic force microscopy-based multimodal imaging platform to correlate protein structures with electrical and mechanical properties in response to environmental changes, such as pH and redox potential. Using this platform, we found that the rate of electron transfer in protein nanowires depends on the environment. Thus, we were able to make electron transfer 100-times faster by changing environmental conditions, suggesting a possible path to engineering more conductive protein nanowires. Furthermore, methodological innovation has been a cornerstone of my lab, as the availability of new methods has enabled us to make unexpected discoveries and challenge thinking in the field. For example, our method for growing biofilms in electric fields, allowed not only the first electrontransferable control of biofilm growth (Nature Chem. Bio), but enabled us to make the initial discovery that bacterial biofilms conduct electricity (prior to our work, bacterial biofilms had been thought to be electronically non-conducting).

Our nanoscopic imaging methods are widely applicable to diverse biological systems. For example, we have applied these imaging methods for nanoscopic visualization of water binding to minerals (Science Advances). We revealed that, instead of growing layer by layer as previously thought, water growth starts near edges before surface tension takes over to engulf the surface and forms droplets. This methodology is allowing us to directly visualize how bacteria export electrons to minerals.

I will present our recent experimental and computational studies to identify the mechanism of electron transfer that occurs at unprecedented ultrafast (< 200 fs) rates and over centimeter distances, 10,000-times the size of a bacterium, through measurements of DC and THz conductivity as a function of nanowire length, temperature, frequency, pH and heme stacking (Science Advances, 2022). I will also present how we are experimentally assessing computational prediction of quantum effects accounting for the high conductivity of these nanowires (Nanotechnology’20, IEEE’21, ACS Nano’23), using multiple probes such as light, temperature, electric and magnetic fields.

Quantum Transport with Two Interacting Conduction Channels in Gold-Azurin-Bismuth Solid-State Junctions
Ping’an Li1,2, Sudipta Bera1, Shailendra Kumar-Saxena1, David Cahen1 and Yoram Selzer1; 1Tel Aviv University, Israel; 2Weizmann Institute of Science, Israel

The fundamental question of “what is the transport path of electrons through proteins?” initially introduced while studying long-range electron transfer...
between localized redox centers separated by proteins in vivo is also highly relevant to the transport properties of solid-state, dry metal-protein-metal junctions because the characteristic Fermi wavelength, $\lambda_F$, of the involved electrons is smaller than the contact footprint of the proteins. Under such conditions, the transport path appears to depend on the coupling of the proteins to the leads. For example, in one of the ‘work horses’ of biomolecular electronics, Au-Azurin(Az)-Au junctions, the electrons characterized by $\lambda_F \sim 0.5 \text{ nm}$ appear to be transported coherently by off-resonance tunneling if Az is strongly coupled to the leads and by coherent resonance tunneling associated with levels of the redox center, if it is weakly coupled to the leads. Transport in the latter case is especially puzzling because the modest coupling values invoked for its quantification are sufficiently small to allow the tunneling charges to reside in the resonance levels a sufficient time for structural relaxation (reorganization), which should then entail non-coherent transport by a hopping, i.e., activated hops with tunneling between them.

Here, we report of conductance measurements of molecular ensemble nanopore junctions of Au-Az-bismuth(Bi), with well-defined geometry and containing ~2000 proteins in each pore. We argue that since electrons in Bi have $\lambda_F$ longer than the protein footprint, transport takes place in these junctions by two interacting conducting channels, characterized by different time scales. The slow and fast channels are associated with the redox center and the protein matrix, respectively, and consequently transport takes place in the first channel by a sequential (non-coherent) process and by coherent non-resonant tunneling in the second channel. The resulting overall observed conductance behavior suggests that the two channels are capacitively coupled and that the broad level responsible for the off-resonance tunneling changes its energy in response to the charge occupation of the weakly coupled (redox) channel. This in turn also suggests that transport in these junctions is dominated by the off-resonance (fast) channel, while the slow (redox) channel contribute directly to conductance only negligibly and instead affects transport by intramolecular gating.

Single-Molecule Electrical Detection Methods for Public Health Applications: Towards Sustainable Biosensing

Ajoke Williams and Juan M. Artes Vivancos; University of Massachusetts Lowell, United States

In the face of escalating climate change, which significantly impacts both the global economy and public health, changes in environmental conditions can favor the spread of pathogens and the development of new mutants.[1] Early detection and control of pathogen spread are pivotal in enhancing health outcomes on a broader scale. Among the diverse pathways of pathogen screening, nanotechnology has made remarkable advancements in the last decade. It has also extended its applications to biomolecules, giving rise to BioMolecular Electronics.[2] Notably, the Scanning Tunneling Microscopic (STM)-assisted break junction method (STM-BJ)[3] has led to biophysical studies of individual molecules at the single-molecule level. It stands out as a promising approach for single-molecule biomolecular detection. This concept emerges as a compelling solution for the real-time identification of individual biological molecules.

Our research leverages the potential of the STM-BJ method to showcase the electrical detection of RNA cancer biomarkers, distinguishing KRAS mutants G12V and G12C from the wild type.[4] Furthermore, our investigation highlights the remarkable sensitivity and specificity of this technique in identifying RNA coronavirus biomarkers, even at the sub-variant level.[5] This tool can also be applied for the electrical measurement of biomolecular interactions at the single-molecule level.[6] Beyond these pioneering advancements, our focus extends now to the sustainability and life cycle analysis of biosensors. Our future research will focus on minimizing the environmental impact of biosensors by utilizing sustainable materials and processes.[7]

Soft Actuator-Assisted Minimally Invasive Peripheral Nerve Interfaces
Chaoqun Dong, Alejandro Carnicer Lombarte and George G. Malliaras;
University of Cambridge, United Kingdom

Peripheral nerve interfacing has emerged as a highly promising therapeutic technology in various applications, including prosthetic limbs, chronic pain modulation, and the treatment of visceral organ disorders. However, current electrode designs present challenges related to complex handling and implantation-associated irreversible neural damage. This abstract proposes an alternative approach by introducing novel actuatable electrodes that might address these limitations. Our research leverages recent advancements in thin film bioelectronics and soft robotics to develop thin, flexible, and importantly, shape-morphing nerve cuff electrodes. The microfabricated device allows for programming the shape of the electrodes, enabling it to enclose the nerve while maintaining the flexibility to loosen or tighten as needed. This feature ensures a close-fitting conformal interface between the electrode and the nerve, meanwhile enabling straightforward and minimally invasive device explantation steps. Our work presents a promising pathway towards the development of bioelectronic devices that can be manipulated by surgeons to enhance the minimally invasive nature of neurosurgery while achieving optimal electrode-nerve interactions.

10:45 AM SB07.01.02
Thermo-Responsive Conductive Gels for Injectable Bioelectronics
Vidhika S. Damani1, Xinran Xie2, Khushboo Sunan1, Rachel Daso2, Giana Alepa1, Julian Alberto1, Casey Lorch1, Ai Niu Yang1, Yuhang Wu1, Norman Wagner1, Jonathan Rivnay2, and Laure V. Kayser1,1; 1University of Delaware, United States; 2Northwestern University, United States

Conductive hydrogels have gained traction to interface biological systems with electronics for use in sensing and monitoring, tissue engineering, cell adhesion, and implantable electronics. Most bioelectronic implants depend on inorganic nanoparticles such as carbon nanotubes, metals and graphene for conductivity, but these materials lack mechanical compatibility with biological tissue causing scarring and short-term stability. Hydrogels based on water-dispersible conducting polymers such as PEDOT:PSS have been developed to overcome this challenge, due to their lower Young’s modulus. However, these gels must either be pre-formed before inserting into the body or, if injected as a fluid, require the presence of external trigger methods and small molecules, such as chemical crosslinkers or endogenous metabolites for crosslinking in vivo. Therefore, there is a need for minimally invasive injectable conductive liquids which can gel rapidly in the body irrespective of the type of tissue, are biocompatible, and do not rely on externally applied triggers. To that end, we have developed a thermo-responsive conducting polymer which forms a stable dispersion in water and gels in 41 seconds at 37 °C. We employ the reversible hydrophilic-hydrophobic transition of poly(N-isopropylacrylamide) close to body temperature, which, when combined with the mixed ionic-electronic conduction of PEDOT:PSS yields a fully reversible and conductive gel with a modulus of 20 Pa. In addition, the mechanical and electronic properties can be tuned by changing the concentration of the dispersion in water. The material has shown biocompatibility with L929 cells both by indirect and direct contact assays. This is the world’s first fully reversible conductive gel and has potential for use in cardiac patches, scaffolds for tissue engineering and wound healing and for better contact between electrodes and cells for biosensing.

11:00 AM SB07.01.03
Conductive Polymer Enabled Biostable Liquid Metal Electrodes for Neural Interface
Huanan Zhang; University of Utah, United States

Gallium (Ga)-based liquid metal materials have emerged as a promising material platform for soft bioelectronics. Unfortunately, Ga has limited biostability and electrochemical performance under physiological conditions, which can hinder the implementation of its use in bioelectronic devices. Here, an effective conductive polymer deposition strategy on the liquid metal surface to improve the biostability and electrochemical performance of Ga-based liquid metals for use under physiological conditions is demonstrated. The conductive polymer [poly(3,4-ethylenedioxythiophene):tetrafluoroborate]-modified liquid metal surface significantly outperforms the liquid metal-based electrode in mechanical, biological, and electrochemical studies. In vivo
action potential recordings in behaving nonhuman primate and invertebrate models demonstrate the feasibility of using liquid metal electrodes for high-performance neural recording applications. This is the first demonstration of single-unit neural recording using Ga-based liquid metal bioelectronic devices to date. The results determine that the electrochemical deposition of conductive polymer over liquid metal can improve the material properties of liquid metal electrodes for use under physiological conditions and open numerous design opportunities for next-generation liquid metal-based neural electrodes.

11:15 AM SB07.01.04 Identification of Mitral Valve Disease from Cardiac Potentials in Canine Patients with High-Density, E-Textile, Conducting Polymer BSPM Arrays Ruben Ritz-Mateos Serrenq1, Santiago Velasco Bosom1, Antonio Dominguez-Alfaro2, Matias L. Picchio2, Daniele Mantineo2, David Mecerreyes* and George G. Malliaras1; 1University of Cambridge, United Kingdom; 2University of the Basque Country UPV/EHU, Spain

Valvular heart diseases (VHD) are a major contributor to cardiovascular mortality worldwide, affecting ~75 million people every year. The detection of VHD is currently achieved by means of non-invasive mechanical activity imaging modalities such as magnetic resonance imaging (MRI), computed tomography (CT) or echocardiography. These techniques require expensive equipment and technical user expertise which hinder their employment in general practice clinics. As a consequence, VHD can only be diagnosed at larger medical centres where these machines and the personnel required to operate them are available. In addition, these imaging modalities cannot be employed for the long-term monitoring of acute conditions outside healthcare centres, which forces patients with these conditions to remain in hospital for long periods of time.

Electrocardiography (ECG) is a well-established and inexpensive method for the identification of electrical heart conditions, or rhythms, which is readily available in most local clinics. Despite the fact that ECG is designed to detect electrical activity, it has been shown to be able to capture some of the symptoms caused by VHD. Furthermore, the implementation of deep learning (DL) algorithms which analyse conventional 12-lead ECG data has recently demonstrated the ability of ECG to fully characterise and classify between different types of VHD.

Even though DL algorithms are able to identify VHD, the maximum accuracy they can achieve is limited to ~80%. Furthermore, these complex classifiers require vast amounts of fitting data, long training times and offer little clinical insights into what features of ECG are involved in the identification of VHD. One of the primary factors which restricts the performance of these classifiers is the limited amount of spatial data the 12-lead ECG offers. The sampling of multiple cardiac sites across the torso by means of high-density electrodes in the form of body surface potential maps (BSPM) offers the opportunity to train classical machine learning algorithms on temporal and spatial ECG features, thus increasing both the explainability and the maximum achievable accuracy of VHD classifiers.

In this work, a novel high-density electrode array fabrication technique on e-textiles with conducting polymer coatings is presented through the implementation of a tailored vest for canine models. The data obtained from this vest is presented and specific temporal and spatial features are employed to train a classical machine learning algorithm able to identify mitral valve disease in a canine patient cohort. The results from the classifier are presented in a human-readable format and performance and training metrics are compared and shown to surpass those of state-of-the-art models in the literature. The results hereby obtained pave the way towards the use of BSPM as an affordable and scalable screening technique for VHD.

SESSION SB07.02: Multifunctional Bioelectronics
Session Chairs: Achilles Savva and Georgios Spyropoulos
Monday Afternoon, November 27, 2023
Hynes, Level 1, Room 110

1:30 PM *SB07.02.01 Multifunctional Fiber-Based Interfaces with Central and Peripheral Circuits Polina Anikoeva; Massachusetts Institute of Technology, United States

To probe the complexity of neuronal signaling between the central and peripheral nervous systems our group designs multifunctional, multimaterial fibers based on soft polymers, composites, and hydrogels. Previously limited to passive electrical, optical, and microfluidic features, these fibers have been augmented with active solid-state devices to record and deliver signals to organs as diverse as the brain and the gastrointestinal tract in freely-behaving rodents. Integration of solid-state components further enabled wireless operation of these fibers. In addition to probing electrophysiological activity, we have recently explored optical recording of neurochemistry using multifunctional fibers in conjunction with fluorescent activity indicators. Photometric recordings revealed the effects of drugs of abuse on neural circuits, and for the first time, permitted recording of signaling of non-neuronal tumor cells in vivo, empowering studies of tumor growth and informing brain-cancer therapies.

2:00 PM SB07.02.02 High-Density Soft Bioelectronic Fibers Muhammad Khatib and Zhenan Bao; Stanford University, Israel

Bioelectronic fiber devices hold tremendous potential for both research and clinical applications due to their compactness, ease of implantation, and ability to incorporate advanced functionalities such as sensing/recording, stimulation/modulation, and imaging. However, existing devices are hindered by issues such as bulkiness, rigidity, limited functionality, and low density of active components. These limitations stem from the challenges associated with integrating multiple components on one-dimensional (1D) devices, as they are not compatible with conventional microfabrication methods like photolithography, primarily due to their thin, curved, and elongated structures. In this work, we present a fabrication approach called spiral transformation that overcomes these obstacles by converting 2D thin films containing pertinent microfabricated devices into 1D fibers. This approach allows for the creation of bioelectronic fibers that offer a high density (300 channels on a 250-micron fiber) and variety of components while enabling precise control over their longitudinal, angular, and radial positioning. We have successfully demonstrated the utility of these fibers for motility and serotonin sensing and tissue stimulation within the dynamic and soft gastrointestinal (GI) system. Notably, our soft fibers have shown minimal interference to GI tissue structure and natural movements. Taken together, the developed bioelectronic fibers showcase significant promise for next-generation clinical monitoring and modulation applications, particularly in minimally invasive deployments within the GI tract and other curved and confined regions of the body.

2:15 PM SB07.02.03 Multifunctional Microelectronic Fibers Enable Wireless Modulation of Gut-Brain Axis Atharva Sahasrabudhe1, Laura Rupprecht2, Sirma Orgue1, Diego Bohorquez2 and Polina Anikoeva1; 1Massachusetts Institute of Technology, United States; 2Duke University, United States

The peripheral organs of the body are in a constant bidirectional cross-talk with the brain, that generates a cognitive map of body’s physiological state
which is vital for survival. This is exemplified by the gut-brain communication; wherein hormonally and neurally mediated signals emerging from the abdominal viscera transduce metabolic information to the brain for maintaining energy homeostasis. Although these internally arising brain-to-body sensory cues are consciously imperceptible, recently they have been shown to influence higher level neurocognitive processes such as motivation and affect. These findings create opportunities for co-opting organ-to-brain neural circuits to develop new paradigms for autonomic neuromodulation therapies. However, probing and understanding critical brain-body circuits presents a neurotechnology challenge due to contrasting design criteria imposed on the implantable devices by drastic anatomical differences between the skull-encased brain tissue and mobile, delicate peripheral organs in behaving animal models.

In this talk I will describe our efforts in addressing this challenge. Seeking inspiration from nerve fibers, we design a soft, flexible polymer fiber-based organ-brain neuromodulation. In order to match the inherent signaling complexity of the nervous system we envisaged probes that integrate multiple functionalities while still retaining a miniature device foot print to facilitate chronic bio-integration. To create such a multifunctional and multi-organ neurotechnology we combine the scalability and rapid customization of fiber drawing with functional sophistication of solid-state microdevices. With this approach we successfully produce hundreds of meters of flexible polymer filamentary probes integrating microscale light emitting devices, thermal sensors, microelectrodes, and microfluidic channels. The ability to process thermoplastic elastomers with the same route enables deterministic tunability of device mechanics and allows probes for targeting deep-brain structures and/or various regions of the murine intestine. We custom design a lightweight and modular wireless control circuit, NeuroStack, that offers bidirectional wireless control and real-time programmability of in-fiber microdevices along with an intuitive user interface. The brain fibers offer gene delivery for cell-type specific optogenetic neuromodulation, single-neuron recordings, thermometry, and tetherless control of mesolimbic reward pathway. The soft gut fibers grant access to anatomically challenging and delicate intestinal lumen, allowing intraluminal optofluorescent control of sensory epithelial cells that guide feeding behaviors. Using this technology, we uncover that optogenetic stimulation of vagal afferents from the intestinal lumen is sufficient to drive reward behavior in untethered mice.

We anticipate that these illustrative applications will foreshadow widespread use of wireless multifunctional microelectronic fibers to study the roles of specific cells in bidirectional communication between the peripheral organs and the brain. This will not only empower the field of interoception, but also pave the way for mechanistically guided improved autonomic neuromodulation therapies.

2:30 PM SB07.02.04

In Vivo Bioengineering of Conductive Microfibers: From In Vivo Biosynthesis to Advanced Characterization Claudia Tortiglione1, Marika Iencharelli1, Giuseppina Tommasini2, Valentina Di Meco2, Gennaro Santì3, Alessio Crescentili1, Emanuela Esposito1, Maria Antonietta Ferrara1, Giuseppe Coppola1, Francesca Di Maria1, Mattia Zangoli1, Maria Moros2 and Angela Tino1; 1Istituto di Scienze Applicate e Sistemi Intelligenti, CNR, Italy; 2Instituto de Nanociencia y Materiales de Aragón (INMA), Spain; 3Istituto per la Sintesi Organica e Fotoreattività, CNR, Italy

The unmatchable capability of living cells to fabricate complex structure starting from simple building blocks offers new paradigms to seamlessly integrate new electronic structures into the living matter, creating new hybrid devices. We have previously shown the capability of the living tissue-like organism, the freshwater polyp Hydra vulgaris, to produce fluorescent and conductive interface embedded into the animal tissues, starting from thiophene-based compounds, demonstrating the feasibility to use these organisms as biofactories of novel biocompatible and conformable bioelectronic interfaces [1-2]. Here we show that the potential of biofiber production is broadly valid in other biological systems, and showed that it can be promoted by different human and murine cell lines and by other invertebrate in vivo models (such as the sea anemone Nematostella vectensis). The cell type influences the fiber shape, amount and optical properties. In order to understand the mechanism underlaying the fiber biogenesis, on one side we performed a systematic chemical engineering approach to identify the structure/groups involved in the spontaneous fiber assembling. On the other, we performed several physical and chemical treatments to identify the cell machinery components involved in the biosynthetic process. Finally, by mean of advanced characterization methods (ultrastructural, spectroscopic and imaging techniques) we shed light on the mechanism of biofiber production and the fine structure, paving the way to new bioengineering concepts to fabricate novel living conductive materials.

Prototyping Neuroelectronic Device Concepts in Low-Cost Invertebrate Model Organisms Eric D. Glowacki1, Petra Ondrackova1, Mary J. Donahue2 and Malin Silvera Eneby2; 1Brno University of Technology, Czechia; 2Linkoping University, Sweden

Next-generation bioelectronics hardware evolves through interdisciplinary collaborations between materials and device engineers and neuroscientists, with certain barriers existing between design/fabrication, in vitro, and finally in vivo testing. It is rare for research teams handling device development to have in-house capability for electrophysiology in animals. I will describe our recent work on using simple invertebrate models for in vivo testing of novel recording and stimulation hardware: namely leeches (Hirudo medicinalis) and locusts (Locusta migratoria). Several showcase examples will be discussed. The leech nerve cord provides a suitable testing platform for prototyping nerve cuff devices for recording and stimulation. Stimulation can be validated using highly reproducible muscle electrophysiology or force transduction measurements. The locust, with its segmented body and well-defined skeletal muscle, is a convenient model for testing neurostimulation techniques, including noninvasive electrical stimulation which can be validated by precise activation of limb movements. The overall goal of this work is to present a toolbox of low-cost and ethically favorable approaches to test new device concepts before they are deployed on mammals.
We gratefully acknowledge funding from the Saxon State Ministry for Higher Education, Research and the Arts, project MUDIplex, grant number 100351694.

In this work, we study axonal growth dynamics using rat primary neurons cultured in custom-designed PDMS microfluidic devices containing nanochannels [3] of minimal size 100 nm. To generate the nanoscale features, a thin 350 nm layer of silicon dioxide (SiO2) was deposited on a silicon wafer followed by a thin layer of photoresist that was then patterned using E-beam before the structures were etched in the SiO2 using reactive ion etching. After stripping the remaining photoresist, the two subsequent layers were patterned in SU8 using conventional photolithography. The resulting microstructure design allows for separation of cell soma from axons and thus studying axons in detail. By varying the nano-/microchannel size, we show the spatial limitations for axonal growth and observe changes in axonal guidance depending on the channel width. We note that there is almost no penetration in the channels below 400 nm in width. Furthermore, we analyze the formation and structuring of axonal bundles, their dependence on cell density, and on the type of spatial constraint. We observe more frequent formation of bundles in cases where we topologically force the narrowing. The opposite is seen in the channels that are orders of magnitude larger than the average axon size, where they tend to spread along the available space. We also see that bundling is present in the nodes with lower cell density. We also see that axons grow the longest in the channels of 10-12 µm width range. Finally, we assess neuronal activity by culturing neurons in PDMS microstructures on MEAs. The temporal precision of action potentials recorded by MEAs in combination with spatial precision of axonal growth within the PDMS, enabled to analyze action potential fidelity, e.g. its velocity, shape and amplitude depending on the the number of cells, the width of the formed axonal bundle and the age of an in vitro culture.

Looking forward, we aim to improve the system further by modifying substrate stiffness to make it more physiologically relevant, by adding hydrogels into the microstructures. The potential to expand our findings on human induced pluripotent stem cell (hiPSC) derived neurons and the diseased cells, offers yet another application. Additionally, a promising direction is the investigation of axon fasciculation [4] by alternating the angle at which axons approach one another with PDMS. With its wide range of capabilities, this highly tunable system holds promise for unlocking new insights and advancing our understanding of axon function and pathology.

Laminin Adsorption and Adhesion of Neurons and Glial Cells on Carbon Implanted Titania Nanotube Scaffolds for Neural Implant Applications
Jan Frenzel1,2, Astrid Kupfer1,2 and Stefan G. Mayr1,3; 1Leibniz Institute of Surface Engineering, Germany; 2Universität Leipzig, Germany

As the world's population ages, the incidence of neurodegenerative disorders such as Parkinson's disease inevitably increases. Currently, brain-machine interfaces are used to study these diseases ex vivo, while neural electrodes are employed to treat them symptomatically in vivo. However, numerous obstacles arise at the interface between the brain and the brain-machine interface. Long-term adhesion is often weak, and rejection reactions such as glial scarring occur. We demonstrate that ion-implanted titania nanotube scaffolds are a promising candidate to overcome these problems, as they combine high biocompatibility with appropriate electrical conductivity.

In our systematic study, we show how implantation-induced tube shrinkage and altered electrical conductivity of titania nanotube scaffolds influence protein adsorption kinetics. Interestingly, laminin adsorption is affected by changes in surface free energy upon implantation. An increase in the pH-dependent ζ-potential of the surfaces leads to changes of the laminin binding. In addition, viability, toxicity and morphology of U87MG glial cells and differentiated SH-SYSY neurons is analyzed after one and four days, respectively, and correlated with surface characteristics. Environmental electron microscope images reveal that cells on all scaffolds stretch out and expand even after one day. This first evidence of biocompatibility is confirmed by a high cell viability. Significant differences of cell viability are explained by changes of protein adsorption induced by ion implantation. Additionally, the increase in conductivity does not affect neuronal viability after four days but inhibits glial cell proliferation.

Based on these findings, there is great potential for novel neural electrode materials with tailored morphology and unique conductivity that suppress glial scar formation.

We gratefully acknowledge funding from the Saxon State Ministry for Higher Education, Research and the Arts, project MUDIplex, grant number 100351694.
Electrode-based electrical stimulation is foundational for numerous clinical bioelectronic devices, including deep brain stimulators and cardiac pacemakers. However, achieving multisite or random access stimulation, vital for high-fidelity and efficient biological regulation, remains challenging even in high-density electrode arrays due to spatial access constraints. While optogenetics offers high-spatiotemporal multisite stimulation capabilities, its clinical adoption presents hurdles. In this work, we introduce a multisite photostimulation technique for cardiac systems via a non-genetic platform utilizing semiconductor-based biomodulation interfaces. We investigate the precision, accuracy, and resolution of the photostimulation by analyzing spatiotemporal photoelectrochemical currents in four leadless silicon-based monolithic photoelectrochemical devices. Our study validates the multisite stimulation capacity of these systems through optical overdrive pacing applied to cultured cardiomyocytes targeting multiple regions and length scales, isolated rat hearts in a Langendorff setup, and in vivo rat heart ischemia models. To demonstrate cardiac control under clinical conditions, we also perform the first optical pacing of a pig heart in vivo. To further solidify the clinical potentials, we fabricated minimally invasive device delivery and fiberoptics platform and successfully performed pig heart stimulation without opening the chest. Our findings underscore the potential of this leadless, lightweight photostimulation platform, possibly revolutionizing cardiac pacemaking in treatments like cardiac resynchronization therapy where lead-placement complications often arise.

Organic Semiconducting Nanoparticles for Neural Interfacing: Integrating Mechanical, Chemical and Optoelectronic Stimuli for Wireless Neuromodulation Rafael Croyader1, 2, Jessie Posar3, 4, Paul Dixoort5, Alan Brichta1, Rebecca Lim1 and Matthew Griffith3, 5; 1University of Newcastle, Australia; 2The University of Sydney, Australia; 3University of Wollongong, Australia; 4University of South Australia, Australia

Electronic devices capable of stimulating neurons have revolutionized the treatment of several neurological conditions by providing a direct interface with the nervous system. These devices hold great potential for treating disorders such as Parkinson's disease, epilepsy, spinal cord injuries, and even blindness.1) However, the use of traditional electronic materials such as metals and silicon in such devices have significant limitations due to poor biocompatibility,2) mechanical mismatch with tissue, low spatial selectivity, and the requirement for external power supplies. Soft and flexible organic semiconducting materials represent a new frontier in electronic materials that are capable of overcoming these challenges.3) The solution processability of organic semiconductors also enable several additional attractive features, including low-cost manufacturing of devices on flexible substrates using industrial scale printing techniques, and the ability to introduce neurotransmitter molecules to the electroactive solutions to chemically assist neuromodulation, adjustable topography to induce mechanical cues for neuron attachment and growth, and optically triggered charge generation for wireless electrical neuromodulation.

In this study, we present our recent endeavours to tackle these challenges of mechanical, chemical and electronic stimulation of neuronal cells simultaneously in a single bioelectrode. We achieve this by forming soft carbon-based organic conductors into aqueous nanoparticle dispersions using established solution-based mini-emulsion chemistry methods.4) We subsequently integrated the organic nanoparticle dispersions with neurotrophic factors prior to the device fabrication process. These pharmacological components subsequently enhance cell adhesion and neural network outgrowth upon release from solid films cast from the electroactive nanoparticle dispersions.

Bioelectronic nanoparticle-based devices were fabricated from n-type material Poly(9,9-diocetylfluorene-alt-bithiophene) (F8T2), which were shown to exhibit high biocompatibility with primary neuron cultures from mice via anatomical (live-dead assay) and functional (neuronal cell stain) protocols. Kelvin Probe Force Microscopy measurements demonstrated the creation of photo-capacitive charge under direct light stimulus, potentially capable of depolarising the neuronal cell membrane and generating action potentials (wireless electronic neuromodulation). By adjusting the surface roughness of devices by tailoring the nanoparticle size during synthesis, we verified by AFM analysis an optimal nano-topography that promotes neuronal cell growth.

Implantable Iontophoretic Devices for Cancer Therapy

Xudong Tao, Tobias Naegle and George G. Malliaras; University of Cambridge, United Kingdom

Chemotherapy has a fundamental limitation for the treatment of brain tumours – poor penetration through the blood-brain barrier, leading to sub-therapeutic concentrations in brain tumours. This study focuses on an implantable electrophoretic drug delivery device (left behind in the tumour after biopsy), which uses an electric field to improve drug transport. The technology is called iontophoresis – a ‘dry’ delivery that only delivers the charged drug ions into the tumour region by electric fields and avoids pressure-related problems. This study explores a novel iontophoretic device which significantly improves the efficiency of drug delivery.

Translational Neuroelectronics

Dion Khodagholy; Columbia University, United States

Our understanding of the brain’s pathophysiology relies on discoveries in neuroscience and neurology fueled by sophisticated bioelectronics enabling visualization and manipulation of neural circuits at multiple spatial and temporal resolutions. In parallel, to facilitate clinical translation of advanced materials, devices, and technologies, all components of bioelectronic devices have to be considered. Organic electronics offer a unique approach to device design, due to their mixed ionic/electronic conduction, mechanical flexibility, enhanced biocompatibility, and capability for drug delivery. We design, develop, and characterize conformable, stretchable organic electronic devices based on conducting polymer-based electrodes, particulate electronic composites, high-performance transistors, conformable integrated circuits, and ion-based data communication. These devices established new experimental paradigms that allow monitoring of the emergence of neural circuits during development in rodents and elucidated patterns of neural network maturation in the developing brain. Furthermore, the biocompatibility of the devices also allowed intra-operative recording from patients undergoing epilepsy and deep brain stimulation surgeries, highlighting the translational capacity of this class of neural interface devices. In parallel, we are developing the fully-implantable, conformable implantable integrated circuits based on high-speed internal ionic gated organic electrochemical transistors that can perform the entire chain of signal acquisition, processing, and transmission without the need of hard Si-based devices. This multidisciplinary approach will enable the development of new devices based on organic electronics, with broad applicability to the understanding of physiologic and pathologic network activity, control of brain-machine interfaces, and therapeutic closed-loop devices.

Garrido1,2; 1Catalan Institute of Nanoscience and Nanotechnology, (ICN2), CSIC and BIST, Spain; 2Bernstein Center for Computational Neuroscience Munich (Synergy), LMU, Germany; 3Instituto de Microelectrónica de Barcelona IME-CNM (CSIC), Esfera UAB, Spain; 4Institute of Neurology, UCL, Queen Square, United Kingdom; 5ICREA, Spain

Large effort is being dedicated to the integration of novel materials into neural interface devices that offer certain advantages in terms of recording and/or stimulation of neural activity. In the particular case of the recording capabilities, they need to be such to allow the detection of brain activity over large areas and with a high spatial resolution. Because its two-dimensional nature, graphene exhibits a rather unique combination of physicochemical properties which make it attractive for the development of active sensors for neural technologies. This contribution will focus on the recording capabilities of active sensor technology based on single-layer graphene, highlighting its potential for the development of the next-generation neural prostheses and brain-computer interfaces. Recently, solution-gated field-effect transistors (SGFET) based on
graphene are being explored with increasing interest as novel transducers for neural signals. The electrochemical stability of graphene and its facile integration with flexible substrates were among the initial triggers that attracted the interest of the community to develop flexible neural probes for brain interfacing. In addition, other properties such as the high carrier mobility and the field effect associated to single-layer graphene allows for the implementation of an active sensor configuration that will be shown in this contribution to offer significant advantages with respect to the classical passive metallic electrodes. Further, this presentation will discuss how SGFET-type sensors allow us the implementation of multiplexing strategies, time-domain and frequency-domain multiplexing, that reduce the footprint of connectivity, permitting an aggressive scaling up in the number of recording sites. Very interestingly, we will demonstrate that SGFETs also have a distinctive capability to expand the temporal resolution of classical electrocorticography technologies, allowing the recording of the relatively unexplored infra-slow brain activity and, thus, potentially enabling the study of novel biomarkers for monitoring neurological disorders.

This work has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement N. 881603 (GrapheneCore3).

Spatially Controlled Microcortical Stimulation using High-Density PEDOT:PSS Surface Electrodes Ilke Uygun and Kenneth L. Shepard; Columbia University, United States

Most neuromodulation approaches rely on extracellular electrical stimulation with penetrating electrodes at the cost of cortical damage. Surface electrodes, in contrast, are much less invasive but are challenged by the lack of proximity to axonal processes leading to poor resolution. Here, we demonstrate that high density (40 µm pitch), high capacitance (> 1 nF), single neuronal resolution PEDOT:PSS electrodes can be programmed to shape the charge injection front selectively at depths approaching 300 µm with a lateral resolution better than 100 µm. These electrodes, patterned on thin film parylene substrate, can be subdurally implanted and adhere to the pial surface in chronic settings. By leveraging surface arrays that are optically transparent with PEDOT:PSS local interconnects and integrated with depth electrodes, we are able to combine surface stimulation and recording with calcium imaging and depth recording to demonstrate these spatial limits of bidirectional communication with pyramidal neurons in mouse visual cortex both laterally and at depth from the surface.

11:45 AM SB07.05.04
Foldable Three Dimensional Neural Electrode Arrays for Simultaneous Brain Interfacing of Cortical Surface and Intracortical Multilayers In Young Lee, Young Uk Cho and Ki Jun Yu; Yonsei University, Korea (the Republic of)

The brain is a complex three-dimensional network composed of billions of interconnected neurons that respond to important activities such as cognitive function, memory, or even communication by transmitting neural signals. The development of neural interfaces that can precisely measure the complex activities of neurons are helping to understand for identifying unpredicted neuronal diseases and brain functions. Therefore, to understand the functionality of the brain via these diverse activities, it is essential to measure the brain activity with three-dimensional structure. Current diagnostic methods for brain disorders involve functional magnetic resonance imaging (fMRI) that detect the changes of related cerebral blood flow and positron emission tomography (PET) that detect emit positrons distribution in the body through receptor or metabolic imaging. These imaging techniques can capture the changes in brain signals in three-dimensions by combining continuous two-dimensional sectional imaging frames. However, despite their excellent spatial resolution, these methods suffer from poor temporal resolution because of the limitations of captured series of two-dimensional frames. To overcome these time-resolution limitation, for the proper neuropathological analysis, electrophysiological approach serves as a major strength as it provides an excellent temporal readout resolution compared to upper imaging method.

The electrophysiological approach to the measuring the neural propagation is broadly classified into three methods, 1) Electroctorigraphy (ECoG), 2) Michigan probe, 3) Utah array. However, these traditional methods have limitation of two-dimensional measurements. Frist, ECoG arrays for brain surface recording provide high-resolution signals over a large area but cannot map the intracortical area. In contrast, Michigan probe and Utah arrays for intracortical or deep brain recording do not provide clues about the propagation of expressed signals from inside the brain to the surface. Several attempts have been made to measure neural signals in three-dimensional form to overcome this limitation, but these efforts have encountered challenges due to the separate devices for simultaneous measurement of surface and intracortical area that leading to recording mismatch, or due to the use of rigid shanks for device implantation that leading to immune response with mechanical mismatches between the brain recording surface and the device.

Here, we introduce the foldable, flexible three-dimensional neural mapping electrode that achieved by extending the three-dimensional structure of the neural interface in way to accurately analyse complex neural signalling. The device establishes a single integrated platform with four flexible penetrating shanks and surface electrodes by combining advantages of the ECoG arrays and neural probe with Utah array shape for multisite recording. This system can simultaneously measure both surface signals of the brain and neural activity occurring in the intracortical area. To provide sufficient insertion of the device, the penetrating shanks were coated with a biocompatible/bioresorbable stiffener. To demonstrate the performance of the device, the inserting device into the somatosensory cortex of mice and stimulating whisker of the mice. The device can measure both the local field potential (LFP) and single neuron spike in simultaneously from the surface and intracortical area of the brain. Consequently, this platform will pave the way for neuroscience studies and biomedical practices by providing unprecedented electrophysiological signals in three-dimensional form.
high invasiveness and reduced brain coverage, ultrasound waves benefit from low wavelengths, scattering, and absorption in brain tissue and hence, can be focused virtually anywhere in the brain, with high-spatial-resolution and without requiring brain surgery. This reduces the risk of infection, tissue damage, and other complications associated with invasive procedures, making it a safer option for patients, and also allows for accessing a broader range of neural circuits with high precision.

Despite the abovementioned promise, there is still a knowledge and technological gap in LIFU neuromodulation to maximize its potential. LIFU neuromodulation is achieved by means of an ultrasound transducer. These transducers generate low-intensity focused ultrasound waves that can penetrate deep into tissues while maintaining spatial specificity. By adjusting the parameters of the ultrasound waves, specific regions of the brain or peripheral nerves can be targeted with precision. However, similar to their use in medical diagnostic imaging, conventional ultrasound transducers used in LIFU neuromodulation have hand-held form factors and require off-the-shelf equipment. These bulky setups lead to two severe limitations: in pre-clinical research, the mismatch of size between bulky transducers and in-vitro/in vivo models (mice, rats) impose severe limitations in understanding the effects of ultrasound on the nervous system and how to better apply LIFU neuromodulation for different disease models; secondly, in clinical applications, the use of LIFU neuromodulation can only be applied in a bed-side scenario, where the patient either would visit the clinic once or twice per week to receive a treatment or would operate a LIFU neuromodulation system at home.

This talk will describe the recent research in the field of ultrasound microsystems towards developing the next generation of LIFU neuromodulation systems that can be seamlessly integrated into in vitro/in vivo experimental setups in pre-clinical settings and used as wearable and minimally-invasive devices for clinical treatments. This description will answer two questions: how to massively integrate all the necessary LIFU neuromodulation functionality into a single-miniaturized and battery-powered microsystem? How can ultrasound microsystems be designed to be mechanically flexible to better adjust to the body's natural curvature?

To answer these questions, the talk will focus on novel ultrasound microfabrication and microsystem integration methods and next-generation ultrasound electronics. Furthermore, the talk will also show a few examples of ongoing projects featuring in vitro and in vivo validation, showcasing the potential of LIFU microsystems for minimally invasive and precise neuromodulation for treating neurological diseases.

2:00 PM SB07.06.02 Learning in Spiking Neural Networks with a Calcium-Based Hebbian Learning Rule Willian Soares Girao and Elisabetta Chicca; University of Groningen, Netherlands

The effectiveness of neural interfaces depends on the ability of electronic systems to speak the same language of the biological counterpart. Furthermore, the mechanisms underlying learning in biological systems should be better understood to harness the adaptability of the brain when interfacing it to artificial systems. In particular, understanding how biological neural networks are shaped via local plasticity mechanisms can lead to energy-efficient and self-adaptive brain-like information processing systems which can enhance neural interfaces with unprecedented adaptability.

In this work, we present a Hebbian local learning rule, the Bistable Calcium-based Local Learning (BCaLL) rule, that models synaptic modification as a function of pre- and post-synaptic calcium traces tracking neuronal activity, based on a large body of work that has established the role of calcium transients in modulating plasticity. The calcium trace variable, modeled via a first-order differential equation, integrates neuronal activity over time such that both the time since the last spike and mean firing rate information can be encoded in this trace. The learning rule we propose reads out the calcium traces from the neurons it connects and computes whether its weight should be increased or decreased. We show that BCaLL is able to reproduce both spike-time dependent plasticity (STDP) and spike rate plasticity outcomes. With it, we are able to demonstrate that temporal correlations added at the spike-pair level can modulate the learning rate in spiking neural networks, without modifying the rule's parameters or the mean rate activity of neurons in the network.

We showcase this property by simulating and comparing recurrent Spiking Neural Networks (SNNs) with and without excitatory neurons' subthreshold membrane oscillations. We demonstrate that in the networks where the neurons oscillate, the learning rate of attractors is increased due to an increase in their synchronicity. This is particularly interesting for simulating and studying learning in models of brain structures like the Inferior Olivary Nucleus, where previous work has shown that the lack of electronic coupling, which plays an important role in synchronizing the activity of neurons within the nucleus, leads to impaired learning of motor tasks. This modulated learning rate via synchronization we show can provide a starting point in understanding such learning dynamics.

By applying BCaLL to feedforward SNNs, we describe the mechanisms necessary to train such networks for classification problems and how these mechanisms resolve the coding-level problem that arises from learning with binary synapses. Thanks to our simulations, we find that allowing the networks' transient activity during the switching of input patterns to interact increases classification performance, contrary to what previous work has reported, by reducing overlaps in the learned class representations. This could be a benefit of tracking spiking activity via traces: while some models might rely on the neuron's membrane voltage to compute weight updates, utilizing traces allows us to decouple from the membrane dynamics the extent to which correlated activity in time can be measured.

Elucidating how computation in such systems can benefit from encoding information in traces is not only important for better modeling the complex biochemical machinery existing in biological neural networks but also for the design of analog application-specific integrated circuits (ASIC) implementing these algorithms. This integration step is crucial for the embedding of such algorithm into neural interfaces.

2:30 PM SB07.06.03 Origami-Inspired Smart Implants for New-Age Neurology Prasanth Velvaluri, Huan Liu, Lars Thormählen, Hanna Lewitz, Olav Jansen, Richard D. James, Dirk Meyners, Nian Sun, Eckhard Quandt; 1Kiel University, Germany; 2University of Minnesota, United States; 3University Hospital Schleswig-Holstein, Germany; 4Northeastern University, Germany

Intraocular aneurysms are balloon-like disfigurements along the brain blood vessels. If not treated such aneurysms can rupture and cause brain hemorrhage. Many different implants are available in the market for intraocular aneurysm treatment. Though the available implants fabricated from wire braiding and laser cutting are successful, specific gaps must be filled to allow for low treatment complications. One such gap is that all the available implants have simple geometries and do not allow any personalization. Such individualization of implants is essential to provide safer treatments to patients with complex aneurysms. Second, all available implants have passive operation and currently, there are no “smart aneurysm implants” that could potentially monitor the treatment over time. Such a smart implant could detect if the intended blood flow reduction is not achieved after its placement and could potentially alert to early intervention. Smart implants require integrated antennas for data and energy transfer as well as sensors for the measurement of blood flow. Magnetoelastic (ME) antennas consisting of magnetostriective and piezoelectric layers have shown that they can be scaled down by orders of magnitude in size compared to conventional electromagnetic antennas [1]. This is because the ME antennas operate at their acoustic resonance rather than at their electromagnetic resonance. Such compact miniaturized ME antennas on the implant surface provide an optimal way to transmit the data wirelessly for a smart implant operation. However, there are certain difficulties to integrating such antennas into conventional implants as their fabrication technology of wire braiding and laser cutting does not allow monolithic integration of ME composites. Second, the conventional implant design does not allow such sensitive components to survive the harsh crimping process, which is pre-requisite for a minimally invasive treatment.

On the other hand, the origami-based design approach provides an attractive alternative for implant design. It consists of a 2D pattern with regions of rigid panels and flexible hinges. The folding pattern for origami can be generated from a flat 2D sheet and converted into a complex 3D shape on folding. Such structures have great potential as medical implants as they provide two major advantages: they allow the folding of large implants into a compact area to
Atomic Layer Infiltration for the Enhanced Longevity of Thin-Film Polymer Implant Encapsulation

Recent developments in microsystem technology offer a method to fabricate freestanding nitinol (NiTi) shape memory thin films. The fabricated implants are flexible, biocompatible, and have high design freedom, e.g., allowing films with multiple thicknesses [2]. Thus, providing a solution for origami-based implant fabrication. The wafer-based approach allows the monolithic integration of functional layers for biosensing and smart implant functioning. Thus, allowing for the incorporation of ME antennas on the NiTi implant surface.

The current work focuses on fabricating an ME antenna on top of a NiTi substrate using microsystem technologies, as a first step in realizing origami-based smart implants. In this work, we discuss the various challenges and possible solutions for integrating an ME antenna on top of a NiTi substrate.

Furthermore, we consider the choice of magnetostriuctive and piezoelectric materials that are essential for the required antenna operation at a frequency that is permissible for human use. We intend to demonstrate the potential of an origami-based design approach for fabricating brain implants.

Final Program 1/25/24
Two-way communication between electronics and neural tissue is key for advancing diagnosis and therapies for neurological diseases and disorders. Establishing such neural interfaces is a major challenge, as the tissue response to implants can have a detrimental effect on the signal quality and functionality of the implant. Matching of the mechanical properties of the electronic implant to the soft interfaced tissue can reduce the tissue response and improve the long-term performance of the device. This requires soft and stretchable conductors, which typically are composed of elastomer/hydrogels and conductive fillers. However, the tough materials requirements on biomedical implants, including material chemistry, mechanical and electromechanical properties, and long-term stability, disqualifies most of the developed stretchable electronic materials for such applications. Here I will present our efforts in developing inert soft neural electrodes based on stretchable gold nanowire composites, covering aspects ranging from synthesis and processing to devices and applications.

www.liu.se/en/research/soft-electronics

Soft and Stretchable Neural Electrodes Based on Gold Nanowire Composites
Laura Seufert, Mohammed Elmahmoudy, Mary J. Donahue, Yuyang Li, Samuel Lienemann, Simon Farnebo and Klas Tybrandt; Linkoping University, Sweden

The peripheral nervous system is crucial for the communication between the brain and the rest of the body. Implantable devices interfacing with this part of the nervous system hold great potential for the development of treatments for a wide range of clinical conditions, whether by recording electrical activity carried by nerves, or influencing it through electrical stimulation. However, current nerve interfacing technologies lack the necessary resolution to selectively record and stimulate from nerves at the sufficient resolution and stability to enable their therapeutic use.

Here, we present a nerve cuff implant with an ultraconformable design that achieves high-quality and stable interfacing with nerves in chronic implantation scenarios. The cuffs are comprised of a parylene-C body 4 μm in thickness, rendering them highly flexible and able to conform to the surface of nerves. Combined with low impedance PEDOT:PSS microelectrodes, we show that these features allow the ultraflexible cuffs to record neural signals from awake animals for 21 days while exhibiting minimal fibrotic scarring. We furthermore show that high-resolution interfacing capabilities of the cuffs can be used to record action potentials with fascicle-specific resolution and extract from these physiologically-relevant features such as conduction velocity and direction of propagation. We evaluate the potential of this technology in two nerve systems in freely-moving rodent animal models: movement and sensory perception in the arm, and monitoring and control of bladder function.

The developed implantable devices represent a platform enabling new forms of fine nerve signal sensing and modulation, with applications in physiology research and closed-loop therapeutics.

Ultraconformable Cuff Implants for Long-Term Bidirectional Interfacing of Peripheral Nerves at Sub-Nerve Resolutions
Alessandro Canciuer Lomba, Alexander J. Boys, Amparo Guemes, Johannes Gurke, Santiago Velasco Bosom, Sam Hilton, Damiano Barone and George G. Malliaras; University of Cambridge, United Kingdom

Soft and stretchable materials were evaluated in a three-dimensional in vitro model by seeding primary cortical cells around microwires to reveal independent innate neuroinflammation. We demonstrated the use of ceria nanoparticles for reducing oxidative stress, increasing neuronal density, and reducing functional connectivity in wire implanted samples. These results indicate that antioxidant ceria nanoparticles may be efficacious drug treatment for protecting neural function at the device-tissue interface. We optimized ceria nanoparticles for small diameter, biocompatibility, and colloidal stability using reactive polymer coatings. To evaluate their utility in combating inflammation, we developed a 3D in vitro model of the device-tissue interface. This system can disentangle the different contributions of the innate immune system to neuroinflammatory device responses. Ceria nanoparticles reduced the oxidative stress, increased neuronal density, and reduced functional connectivity in wire-implanted samples [2]. The development and characterization of a novel 3D in vitro model of the device-tissue interface revealed a significant innate immune response to neural implants. This study has broad implications for the role of the innate immune system and potential treatment strategies for the chronic foreign body response to neural implants. The mitigation of oxidative stress, neuronal density, and functional connectivity with antioxidant ceria nanoparticles offers significant supporting evidence to indicate that many symptoms of the tissue reaction are related to redox dysregulation. Successful treatment of the device-tissue interface with long-acting antioxidant ceria nanoparticles shows potential for a local long-term antioxidant treatment strategy for clinical applications that need the long-term use of implanted neural devices.

4:30 PM SB07.07.04
Towards Longer Working Times for Implanted Electrodes through Integration of Perpetual Antioxidants at Device Interfaces
Vicki L. Colvin; Brown University, United States

Medical devices implanted in the human body are increasingly common in the management and treatment of disease. An important and growing subset of these devices termed here ‘active’ implants, require electrical contact with tissues. For these devices the foreign body response to an electrode can preclude chronic function and limit many applications. The local delivery of an antioxidant able to protect tissue for months or even years is one possible solution. Nanoparticle ceria is a perpetual antioxidant due to its large cerium(III) content and the possibility of recovering cerium(II) from cerium(IV) after use [1]. For this work its antioxidant capacity was augmented by the use of molecular tethers that stabilized the reactive Ce(III) state. The efficacy of these materials was evaluated in a three-dimensional in vitro model by seeding primary cortical cells around microwires to reveal independent innate neuroinflammation. We demonstrated the use of ceria nanoparticles for reducing oxidative stress, increasing neuronal density, and reducing functional connectivity in wire implanted samples. These results indicate that antioxidant ceria nanoparticles may be efficacious drug treatment for protecting neural function at the device-tissue interface. We optimized ceria nanoparticles for small diameter, biocompatibility, and colloidal stability using reactive polymer coatings. To evaluate their utility in combating inflammation, we developed a 3D in vitro model of the device-tissue interface. This system can disentangle the different contributions of the innate immune system to neuroinflammatory device responses. Ceria nanoparticles reduced the oxidative stress, increased neuronal density, and reduced functional connectivity in wire-implanted samples [2]. The development and characterization of a novel 3D in vitro model of the device-tissue interface revealed a significant innate immune response to neural implants. This study has broad implications for the role of the innate immune system and potential treatment strategies for the chronic foreign body response to neural implants. The mitigation of oxidative stress, neuronal density, and functional connectivity with antioxidant ceria nanoparticles offers significant supporting evidence to indicate that many symptoms of the tissue reaction are related to redox dysregulation. Successful treatment of the device-tissue interface with long-acting antioxidant ceria nanoparticles shows potential for a local long-term antioxidant treatment strategy for clinical applications that need the long-term use of implanted neural devices.

4:45 PM SB07.07.05
Improving Cytocompatibility of Commercial PEDOT:PSS for Bioelectronic Applications
Aaron Lee1, Joshua Killiea1, Estelle Cuttaz2, Christopher Chapman2, Jost Goding1 and Rylie Green1; 1Imperial College London, United Kingdom; 2Queen Mary University of London, United Kingdom

Conducting polymers have emerged as a strong candidate material for bioelectronic applications owing to their mixed ionic-electronic conduction which allows them to efficiently transfer charge in aqueous environments. Commercial formulations of water-dispersible poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) have facilitated development of flexible conductors, sensors, organic electronics and electrode interfaces. While PSS is an efficient counterion and dopant for PEDOT, its presence in excess to enable water-based processing can result in variable processability and electrochemical performance. While chemical crosslinking approaches can be used to address the stability of PEDOT:PSS in aqueous environments, it can hinder further processing. Importantly for bioelectronic applications, the release of excess PSS in aqueous environments from commercially based PEDOT:PSS materials can result in cytotoxicity. To ameliorate these effects, the use of physical separation was explored to remove the excess dopant. PEDOT:PSS dispersions were produced in N,N'-dimethylacetamide and separated by centrifugation. Analysis of the supernatant by NMR indicated the presence of PSS and the remaining polymer was blended with a polyurethane to produce a conductive elastomer. The electrochemical performance of the conductive elastomer and its resultant cytotoxicity profile were assessed as a function of PSS removal. Reducing the amount of PSS prior to preparation of the final conductive elastomer material was demonstrated to markedly improve the cytocompatibility of the material while retaining a degree of electrochemical functionality. These findings represent a key step in facilitating the translation of PEDOT:PSS-based materials to clinical applications.

www.liu.se/en/research/soft-electronics
The detection of bacteria requires full-fledged qualified employees to prepare individual samples for corresponding machine-based analysis. This process is highly time-consuming and cost-intensive. Therefore, there is a great demand for more rapid, portable, and cost-effective sensors for the detection of bacteria.

For this, well-established electrical measurement methods might be transferred to the investigation of biological systems. Our approach is the development of an extended-gate field-effect transistor (EGFET) as a biosensor. The EGFET is composed of a standard metal-oxide semiconductor field-effect transistor (MOSFET) and a periodically patterned and replicated across a thin stack of Polyimide/Platinum/Polyimide of 1/0.1/1 µm thicknesses program stretchability within interconnect tracks as well as hermetic encapsulation of conductive components within electrode arrays is required for long-term protection against the moisture and ions from the physiological environment to avoid electrical failure over time.

Further investigations focus on the increase of trapped bacteria to improve the sensitivity of the biosensor. Here, one of our approaches is the integration of dielectrophoresis (DEP) to the electrodes of the sensor unit. DEP is a highly flexible and multifunctional method to immobilize, separate, and concentrate biological particles such as whole cells but also dissolved molecules in a liquid. In addition, an optimized measurement setup or different functional layers based on e.g. boron-dipyromethene (BODIPY) might also improve the sensitivity. The synthesis of BODIPY's compared to the A₂BC-type porphyrins are less complex which fulfills the requirement of a lean device.

Recording or modulating neural activity using implanted electrode arrays has enabled advancements in the restoration of sensory-motor pathways and brain-computer interfaces. Long-term reliability of these interfaces (>6 months) is paramount to their deployment in neuroprosthetic medicine. Furthermore, hermetic encapsulation of conductive components within electrode arrays is required for long-term protection against the moisture and ions from the physiological environment to avoid electrical failure over time.

We have developed a kirigami-based technology to engineer elasticity within thin films of metal and thermoplastic polymer. The periodic cuts (kirigami) patterned and replicated across a thin stack of Polyimide/Platinum/Polyimide of 1/0.1/1 µm thicknesses program stretchability within interconnect tracks as narrow as 52 µm width. The Polyimide layer is patterned with a 1 µm width offset to that of the Platinum layer, such that the metallization is fully encapsulated, top, bottom, and sideways with Polyimide, thereby providing a built-in long-term hermetic barrier.

We assessed the robustness of the kirigami-based interconnects through a set of in vitro accelerated aging tests and repeated mechanical loading tests. We monitored the evolution of leakage current between two interdigitated tracks (IDE) biased at 5 V and soaked in phosphate-buffered saline (PBS) at 67 °C for 20 days. The elastic regime and plastic onset of the interconnects were measured during incremental uniaxial tensile stretching cycles. The electro-mechanical fatigue was assessed through uniaxially stretching linear interconnects for 1 million cycles at 10% strain, within the elastic regime.

The results of the accelerated aging showed that the leakage current remained below 0.2 µA after 20 days. These findings indicate that the interconnects maintain a high level of hermeticity, equivalent to >25 MΩ after 160 days at 37 °C, in accordance with Arrhenius law. The electro-mechanical characterization demonstrated that the Polyimide-encapsulated kirigami interconnects can deform reversibly up to 15% of applied strain. Moreover, cyclic stretching for 1 million cycles at 10% strain resulted in a slight increase of 5% in relative resistance, indicating minimal mechanical fatigue.

The in vitro characterization demonstrated that the kirigami micro-patternning strategy used to fabricate stretchable interconnects can achieve a high level of hermeticity and exhibit low mechanical fatigue. Ongoing research efforts are focused on integrating materials with superior moisture barrier properties, such as silicon carbide, and further tuning the kirigami geometry to achieve a higher range of stretchability. These advancements aim to design functionally stable and longer-lasting neural interfaces that can withstand the mechanical challenges associated with chronic applications.
Combining two modalities, optical imaging and electrical recordings of neural cells, can shed light on a more profound understanding of neural circuits. Microelectrode arrays with high optical transparency in the near-infrared (NIR) and high electrical conductivity are required to enable simultaneous 2-photon imaging and electrical recording. A transparent microelectrode array allows us to perform imaging and electrical recording at the exact location for improved correlation between the two modalities, with imaging having a better spatial resolution and electrical recording having a better temporal resolution. We present an ITO-based transparent microelectrode array’s design, fabrication, and testing. The microelectrode array has 16 recording sites, with each electrode size of 20 µm x 20 µm. The microelectrode array uses 3 µm parylene-C as a substrate and encapsulation layer maintaining excellent flexibility. Bending tests for different radii are performed to characterize the array’s flexibility. The 2-photon imaging through the electrode array shows optical transparency at the desired wavelength of 920 nm. Electrochemical impedance spectroscopy (EIS) is done to characterize the electrical characteristics of the microelectrode array. Finally, the simultaneous 2-photon imaging and electrical recording through the array on a head-fixed animal is underway for the final testing of the microelectrode array. The microelectrode array is connected to a custom PCB using heat seal connectors for further connection to the data acquisition system.

Nanomesh microelectrode Arrays on 10µm-Thick PDMS for Ultrafast Neuroelectronics
Jeahyoon Ryu1,2; Dartmouth College, United States; 2Northeastern University, United States

Ultrafast neuroelectronics are highly interesting because they enable conformal and compliant interfacing with the soft, curvilinear surface of the neural tissue. However, current ultrafast neural interfaces are usually limited by their electrode performance and scalability for neuroelectronic applications. Here, we present multi-functional nanomesh as an approach to achieve ultrafast microelectrode arrays (MEAs) with excellent scalability. By stacking mechanical supporting polymer, metal, and low impedance coating, here we demonstrate an Au/PEDOT:PSS bilayer-nanomesh-based MEAs on ultrathin Polydimethylsiloxane (PDMS) substrate. We have successfully fabricated 32-channel, bilayer-nanomesh-based MEAs on PDMS with total device thickness down to only 10µm. The 32-channel bilayer-nanomesh arrays have demonstrated over 90% yield on average. We also achieved low impedance of 60 kilohms at 1 kHz with site area down to 400 µm², comparable to the size of a single neuron. The performance of this bilayer-nanomesh MEAs has been characterized through bench testing. This MEA achieves excellent and stable electrochemical performance and also demonstrates good optical transparency over a broad wavelength spectrum. Other achievements of this research are hydrophilic surface modification and the MEA surface along its stability and great sterilization compatibility with ethylene oxide (ETO) sterilization which highlights the practical utilization of this novel device for advanced neural interfacing. This multi-functional bilayer-nanomesh approach provides a promising pathway toward ultrafast neural interfaces with excellent electrochemical performance and large throughput for applications ranging from neuroscience to biomedical devices.

8:00 PM SB07.08.05
Optimization of Parylene Coatings for Implantable Neural Devices
Saman Ebrahimisabasi, Layla Khalifehzhadeh and Hamed Arami; Arizona State University, United States

Parylene C is a widely utilized biocompatible thin-film polymer coating for implantable devices, specifically neural implants, due to its ability to cover uniformly complex shapes, protect the implants against corrosive body fluids such as CSF (cerebrospinal fluid), electrical insulation, chemical stability, and durability. However, weak adhesion to the various types of device substrates remains a significant challenge for this promising coating material. Here, we will present the impact of substrate material selection, silanization (as adhesion promoter), different deposition parameters (such as silane concentration) and post-deposition annealing on overall characteristics of the coating layer (such as thickness and adhesion strengths). First, silicon wafers were coated with different thicknesses of Parylene C using SCS coating machine, followed by annealing in Ar atmosphere at temperatures of 150, 200, and 250°C. Additionally, the effect of thickness (1 and 3µm), and silane A-174 concentration (0.5, 1, and 1.5%) on adhesion strength were investigated. To assess long-term adhesion of Parylene, samples were submerged in an in-vitro accelerated aging bath consisting of PBS at 87°C for 7 days, and the properties were compared before and after the aging, to estimate the coating’s stability in body environment after implantation. Coating thickness and molecular structure were investigated using Ellipsometry and FT-IR, respectively. Adhesion strength was determined using ASTM D3359 tape test. Our initial results indicated that 1µm Parylene coating with 1.5% vol% silane as adhesion promoter, and annealed at 150°C can potentially result in optimal adhesion for silicon substrates. We are pursuing follow up studies on silicon and other types of substrates (such as polyimide, which is a common flexible substrate for a variety of brain and neural implants) to further validate these observations. We envision that our results are critical to address unmet challenges for prolonging the lifetime of the implantable neural devices.

8:00 PM SB07.08.06
Frequency-Dependent Mechanism of Magnetic Nanoparticle Re-Laxation
Mingoo Song, Dowoo Kim and Heon-Jin Choi; Yonsei University, Korea (the Republic of)

Magnetic nanoparticles (MNPs) play a central role in magnetogenetics as energy transducers, delivering the external energy in focus to neighboring cell membranes. Especially, magnetothermal heat conversion is held by two major relaxation mechanism: Neél relaxation (spin) and Brownian relaxation (rotative). As of now, efforts have been ongoing to accurately reflect stochastic nano system with refining mathematical model as more sophisticated. Here, our idea is “there is no gold model”. We carefully argue that particle dynamics between forward field alignment and backward thermal randomization is clearly different. By coining the very field-dependent alignment mechanism as “laxation”, we differentiate alignment and relaxation, also integrate suitable expressions that have been examined so far. Then we compute and visualize theoretical boundaries of Neél & Brownian movement. This approach allows us to decode the frequency sensitivity of heat conversion of magnetic nanoparticles based on relaxation mechanism. Relatively small, less anisotropic particles tend to spin-relax; thus, they efficiently convert high frequency field (~MHz). On the other hand, big, anisotropic particles are inclined to rotative-relax so that they could react only low frequency field (~few kHz). Moreover, we illuminate the enigmatic mixed mechanism, optimistic waveform, field amplitude dependency, and shape factors of MNPs. We support our arguments through experiments. Finally, we propose a simple fabrication method for transition of relaxation mechanism to regulate activation frequency. This frequency tuning may provide a range of possibilities for magnetogenetics, such as multi-channel activation of noninvasive deep brain stimulation (NIDBS).

8:00 PM SB07.08.07
3D-Microelectrode Arrays (MEAs) for In Vitro Applications
Inola Konig1, Hu Peng1, Sebastian Schmidt1, Annika Weisse1, Richard Miu George2, Gil Westmeier1, Christian Mayr2 and Bernhard Wolfrum2; 1Technische Universität München, Germany; 2Technische Universität Dresden, Germany

Abstract:
In the realm of 3D cell cultures and organoids, capturing electrical activity across multiple planes is essential for a comprehensive understanding of their behavior. Conventional microelectrode arrays (MEAs) with surface recordings fall short in addressing this requirement. The limitations of clean-room methods restrict electrode design possibilities and can impede effective cell-electrode coupling. To tackle this challenge, we present a novel approach that
leverages rapid prototyping processes to enhance electrode fabrication. Our laser-patterned MEA incorporates printed 3D-electrode structures, enabling precise recording and stimulation within cell tissues. This advancement improves signal quality through enhanced cell-electrode coupling and provides greater flexibility in electrode placement. We believe this innovative approach will significantly contribute to improvements in 3D cell cultures and organoids, opening new avenues for understanding complex biological systems and developing targeted therapeutic interventions.

Introduction:
Standard planar MEAs can only record electrophysiological signals in 2D, making them unsuitable for capturing the complexity of emerging 3D cell cultures or organoids [1]. To overcome this limitation, we design and fabricate 3D MEAs using additive manufacturing techniques [2]. These 3D MEAs hold promise for studying neuronal functions and diseases using neurally differentiated human-induced pluripotent stem cells (hiPSC) in vitro.

Results and Discussion:
Here, we present the microfabrication of our 3D MEAs. In the first step, silver ink pillars are printed on suitable substrates, followed by sputtering with gold to create a biocompatible electrode interface. Individual electrodes and feedlines are then generated through laser ablation, with feedline structures patterned within minutes, representing a significant improvement over conventional lift-off techniques. The chips are fully passivated with a parylene C layer deposited via vapor deposition. Laser ablation at different angles is used to open the tips of the pillars precisely, and partial etching is employed to create tubular structures. In the final step, individual pillars undergo stepwise electroplating with gold and PEDOT:PSS to prevent silver contamination during long-term cell culture. Our fabrication method offers a fast and easily adjustable approach compared to traditional clean-room techniques. Using the inkjet printing process with laser ablation and electroplating, the height of each pillar can be accurately determined. This enables the realization of multiple pillars with various heights on a single chip. Moreover, the design of the MEA aligns the electrodes in a manner that simplifies their insertion into organoids or 3D cell models. With this highly flexible approach, we aim to record cellular signals from various planes within the targeted tissue.

Conclusion:
This work demonstrates a process for fabricating MEAs with integrated 3D electrodes, providing a platform that facilitates recording and stimulation within 3D cell aggregates or organoid models.

Brain-Machine Interfaces—Taking the Next Step Towards Translational Devices
Santiago Velasco Bosom and George G. Malliaras; University of Cambridge, United Kingdom

Aphasia is defined as the impairment of speech as a result of acquired brain injury, rapidly hindering communication skills in the patient. Current therapeutic approaches are complex and rely on compensatory strategies to regain the lost communicating abilities.

Based on the concept proved by Khodagoly et al, multielectrode arrays (MEA) using electrodes as small as 10x10 µm² are sufficient to capture both local field potential and putative single neuron activity when used for electrocorticography, causing minimal tissue damage. To date, MEAs have predominately been used for investigating human neural network mechanisms and better understanding of brain disorders. Nonetheless, better interpreting these mechanisms carries the potential to open an entire new medical field to use brain signal recordings for healthcare applications and personalized medicine.

In this work, we present the first translational Neurogrid (ultraconformal ECoG multielectrode array) that will be used for the chronic study of cortical neural signals and its decodification into conversation. By complying with European medical regulation in the development of the device, we aim to increase the duration of the implantation in awake human studies, to better understand the potential of this technology with respect to long-term human-machine interfaces. Integrating state-of-the-art machine learning algorithms to the brain signals recorded by the Neurogrid, we aim to decode neural activity in patients suffering from aphasia and translate it into speech.

The combination of these powerful technologies can pave the way for brain-machine interfaces to become powerful clinical tools that increase the wellbeing of patients with neurological disorders. However, to champion the way of this technology into a final clinical product, it should still undergo multiple intermediate steps to prove its safety and reliability.

Flexible Printed Circuit Board (IPCB) Neural Probes for Monitoring Neural Signals
Daerl Park1, Hyeonyeong Jeong1 and Jungsik Choi2; 1Yonsei University, Korea (the Republic of); 2Nformare, Korea (the Republic of)

Neural activity monitoring in the central nervous system often utilizes silicon-based micro electro mechanical systems (MEMS) probes. Despite their strength in monitoring ant stimulating capabilities, these probes are fragile due to the brittle nature of silicon materials limiting their application in various fields. Here, we introduce flexible printed circuit board (IPCB) neural probes that have robust mechanical and electrical properties. The probes fabricated via a roll-to-roll process on films with thickness of 3.5 µm and 10 µm line width of electrodes exhibit an impedance of approximately 1.5 MΩ, reducing to about 120 KΩ after typical platinum colloidal coating. This impedance range is suitable for multunit recordings, enabling simultaneous monitoring of a large population of neurons in the brain. The probes are mechanically very flexible and thus shows no fracture or mechanical/electrical failure under repeated bending test of up to 500 times, and also in the course of handling and monitoring. Furthermore, it is thermally stable that can endure the properties up to 175 degree Celsius and also chemically stable under acidic/alkaline condition that make possible to modify the electrodes easily under harsh conditions such as CVD (chemical vapor deposition) or electro-deposition. In fact, any mechanical failures, or degradation of monitoring capabilities has not been observed in the courses of modification. It indicates that the IPCB probes can be used as a “DO IT YOURSELF” type chronic, tailorable neural probes for chronic neural signal monitoring.

Fully 3D Printed Bio-Electronic Devices for Nerve Regeneration
Ju-Yong Lee, Jooik Jeon, Joo-Hyeon Park, Yea-Seul Park, Se-Hun Kang, Min-Sung Chae, Kang-Sik Lee, Jung Kean Hyun and Seung-Kyun Kang; 1Seoul National University, Korea (the Republic of); 2Korea (the Republic of); 3Asan Medical Center, Korea (the Republic of); 4Soft Foundry Nano Systems Institute (NSI), Seoul National University, Korea (the Republic of); 5Research Institute of Advanced Materials (RIAM), Seoul National University, Korea (the Republic of)

Advancements in miniaturization, wireless technology, and flexible electronic components have led to the development of diverse bio-interfaced
electronics for medical devices. Excessive research has focused on implantable electronic components that can be precisely positioned within the body to record or stimulate specific areas. A significant challenge in this field is achieving a seamless interface between the inserted electronic component and the complex surface or irregular structure of the body. To overcome this challenge, customization of the electrode part and the main body of the device is necessary to adapt to the intricate body surface. Moreover, optimizing space utilization is essential to enable smooth packaging of components in limited spaces, requiring a compact form factor. Therefore, the utilization of additive manufacturing for configuring data-driven voxelated electronic materials within a three-dimensional space holds great potential for integrating electronic components in customized forms. Additionally, it is crucial to prevent infections or internal damage caused by permanent implantation or removal surgery in implantable electronic components. Ultimately, addressing these concerns necessitates biodegradation after the device's operational lifespan. In this study, a fully printed wireless electroceutical tube was developed, capable of treating injuries by inserting it as a tube into peripheral nerves. This achievement was based on the use of biodegradable voxelated electronic ink. Notably, the integration of biodegradable voxelated semiconductors with conductors and dielectrics enabled the creation of a device that generates wireless-controlled monophasic pulses, demonstrating its significant potential for biomedical applications. The suitability for in vivo application was evaluated in small and large animals, and the validity of the findings was confirmed through biological verification, which involved confirming therapeutic effects and assessing their impact on actual functional recovery.

Using Digital Image Speckle Correlation (DISC) to Identify Micro Emotions Shirley Xiong, Hyeonji Ahn, Elaina Heghes, Anusha Misra, Elaine Zhang, Jessica Hofflich, Shi Fu, Pawel Polak and Miraam Rafailovich, 1Ward Melville High School, United States; 2St. Mark’s School, United States; 3South Side High School, United States; 4Dana Hills High School, United States; 5Jericho Senior High School, United States; 6Stony Brook University, The State University of New York, United States

Facial expressions are one of the most basic and natural forms of communication between humans. Alongside general facial expressions, micro-emotions are spontaneous changes in facial muscles that indicate hidden emotions. Micro-emotions become apparent in response to specific emotion-inducing stimuli, such as pictures and videos. These fleeting expressions are low in intensity and are, therefore, significantly more difficult to identify than visible facial expressions and emotions. This study uses Digital Image Speckle Correlation (DISC) to identify micro-emotions by analyzing subcutaneous facial muscle displacement through a contact-free, non-invasive method.

To verify the validity of DISC for tracking facial muscle movement, a video was taken of identical twins and a control performing the same facial actions of frowning and smiling. The control was a subject with no relation to the twins. While the twins used similar parts of muscles to perform actions, the control used quite different parts of facial muscles to perform the same actions. For instance, when frowning, the identical twin’s forehead muscles moved downward toward the inside of the face. However, the control’s forehead muscles moved downward toward the outside of the face.

Sets of ten images were obtained from the International Affective Picture System (IAPS) and categorized using a valence and arousal scale. Valence denotes the emotional value, while arousal characterizes its level of stimulation. The analysis of the participants’ faces shows that high-valence images tend to evoke positive emotions, translating to more pronounced movement in the cheeks and mouth region. When the subject saw an image with positive valence and high arousal, large levels of displacement occurred in those areas. The magnitude of facial displacement in four quadrants of the face was represented through a graph. In the graph, visible spikes span approximately a second. These peaks represent fleeting muscle movements that correlate to micro-emotions, which can be detected through displacement. On the other hand, the negative valence images induced significant amounts of micro-emotions in the upper quadrants, specifically in the forehead and eyebrow areas, commonly associated with reactions to sad emotions.

DISC has the potential to be used to analyze the efficacy of treatments for certain psychological disorders. Major Depressive Disorder (MDD) presents with non-verbal indicators such as the lack of or abundance of specific facial movements and reactions. Hence, changes in facial expressions and movements as identified by DISC can be used to diagnose and understand depression and track the progression and regression of depressive symptoms. For example, esketamine is approved by the FDA to treat MDD that cannot be treated through other antidepressants.

In particular, a case study involving an esketamine patient before and after receiving treatment was utilized to analyze the effects of this treatment on patients. Analysis of the video images indicated differences in the intensity of the patient’s reactions before and within an hour after treatment. The time to react to the different images was also measured and could be a measure of the impact on the information processing ability of the patient. These results will be correlated to the known physiological impact of esketamine as a sedative agent and the answers to the self-report questionnaire administered to the patient, such as BDI or HAM-D which are used to assess the severity of depressive symptoms.

Decorating Bioelectronic Surface with Supported Lipid Bilayer to Study Viral Entry and More Zhongmou Chi1, Ekaterina Selivanovitch1, Zixuan Lu2, Konstantinos Kalitisis3, Rosin Owens4 and Susan Daniel5; 1Cornell University, United States; 2University of Cambridge, United Kingdom

There are two pathways for the entry of SARS-CoV-2: early (cell surface) entry and late (endosomal) entry. In both pathways it requires the initial binding of SARS-CoV-2 spike proteins with host cell membrane receptor (ACE2), followed by the cleavage of spike protein by either TMPRSS2 (early entry) or cathepsin L (late entry). We have previously demonstrated a supported lipid bilayer (SLB) containing native membrane component can maintain membrane fluidity and thus its biological functionalities, making SLB a desirable platform to recapitulate the conditions in vitro that support virus infection of a host cell. In this work, by forming SLB containing ACE2 receptors on a conductive polymer-based substrate, we have probed the two entry pathways of SARS-CoV-2 using electrical signal. Our results suggest the specific binding between spike protein containing virus pseudo particles and ACE2 receptors will increase membrane electrical resistance, while the fusion events catalyzed either by TMPRSS2 and cathepsin L will further increase membrane resistance. Our work shows the electrical readout of membrane properties based on SLB platform can be a powerful tool in detecting SARS-CoV-2 virus entry without the complications of working with live cells. Additionally, in viral entry, the versatile SLB based bioelectronic sensors are also applied to investigate the interactions between chemical permeation enhancer (CPD) and lipid bilayers, providing insights in the drug development against otitis media.

Lactate Biosensor Based on Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Real Time Monitoring Yuchen Shao, Paul Lavryshyn, Jiaxin Fan and Manisha Gupta; University of Alberta, Canada

Diabetic patients have an increasing risk of developing the foot ulcers. Diabetic foot ulcer (DFU), as one of the complications for diabetics, has bothered people for many years. Clinical research has shown that real time monitoring of the lactate concentration helps guide therapy and improve patient outcome [1]. To reduce blood tests for lactate level measurements, non-invasive and low-cost reliable biosensors need to be developed for monitoring.

...In this research, we developed a 3D-printed lactate sensor on top of the flexible Kapton substrate. Organic electrochemical transistors (OECTs) are chosen for the biosensors because of its good performance under aqueous environments and signal amplification. Sensors are fabricated using Optomec Aerosol Jet 5X printer with Au as the source and drain electrode, Pt as the gate, poly(3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) as the channel and polyimide as the insulator layer. Layer by layer strategy is applied for functionalization, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX) and bovine serum albumin (BSA) are drop-casted on top of the gate and then both channel and gate are covered by gelatin to further improve the repeatability of the lactate sensor. Functionalized sensors can be stored in 1X PBS solution for over one month without any deterioration in their sensitivity. The device was measured in both PBS and artificial sweat buffer for comparison and obtained a broad sensitivity range between 10μM up to at least 50mM, which is far beyond the desired range. Blood lactate meter was used as the reference to calibrate the lactate sensor. The printed lactate sensor includes the ZIF connector which can be inserted onto a PCB board and will be used for further diabetic model test.

Integration of Soft Materials in Microfabrication for Auditory Neuroprostheses Alix Trouilliet1, Emilie Revol1, Florent-Valery Coen1, Daniel Lee2 and Stephanie P. Lacour1; 1Ecole Polytechnique Federale de Lausanne, Switzerland; 2Harvard University, United States

Implantable neuromodulation systems often rely on macroscopic electrodes to deliver streams of electrical pulses to a small targeted region of the nervous system. Miniaturisation and design of electrode materials can help improving on the spatial selectivity and electrode reliability over time. In the context of auditory neuroprostheses, we are designing, scaling and implementing soft microelectrode arrays to generate resolutive sound percept with minimal off-target effects in a pre-clinical model of auditory brainstem implants (ABI).

Using microfabrication, we manufactured a macaque sized multichannel, MRI compatible, soft auditory brainstem implant (150μm thick silicone carrier, 11 platinum-silicon composite electrodes of 300μm diameter) that delivers selective electrical stimulation. We engineered customised biodegradable implant holder to ease handling and implantable without compromising the ABI compliance, as well as connectors to reliably interface mechanically and electrically the soft implant with flexible cables and a head-mounted pedestal. The ABI is surgically implanted through a retro-sigmoid craniotomy under endoscopic visualisation at the surface of the cochlear nucleus (<5 mm² surface area).

We evaluated the efficacy of the soft ABI by monitoring the animal’s performance in a behavioural task. Using burst of electrical pulses (ranging from 50-100 pulses per second at 0.1-2 mA) applied through the ABI electrodes, we confirmed the resolutive capability of the implant: the animal was able to
differentiate percept generated from different electrode pairs, with distinct activation threshold for each electrode, indicating good spatial resolution. Systematic characterisation of the materials and processes at each step of the manufacturing of the implant enabled the successful deployment of the soft auditory neuroprosthesis.

11:00 AM SB07.10.02
Waveguide-Based Optical Modules for Cochlear Implant Applications Christian Geßler1,2, Michael Ribeiro Stührenberg1,2, Katharina Kunze1, Daniel Keppeler1, Ulrich T. Schwarz2 and Tobias Moser1,2; 1University Medical Center Göttingen, Germany; 2German Primate Center, Germany; 3Technical University of Chemnitz, Germany

Cochlear implants (CIs) enable open speech comprehension in otherwise deaf patients. Potential improvements affect the limited spatial resolution of the electric stimulus. Optogenetic activation promises a better spatial resolution due to high-precision activation with micro-scaled light emitters. Here, we discuss the development of passive optical modules with integrated micro-optics and laser diode arrays. Remote red-emitting laser diodes are placed outside the cochlea and coupled to polymer-based waveguides with lens-based systems. The waveguides, which are directing the light towards and into the cochlea need to be highly flexible to enable precise placement in the scala tympani with a bending radius of down to 2.5 mm for the human cochlea. Ridge waveguide laser diodes are used due to their available power of several tens of milliwatts. Multibeam applications are enabled by emitter chips with a multitude of parallel aligned laser ridges with a lateral spacing in the 100 μm range. The astigmatic emission profiles of the ridge laser diodes has to be addressed in the optics design, as well as the integration of a transparent sapphire window into the beam path. We evaluate different optical systems on the path towards a human optical cochlear implant prototype, including macroscopic aspherical lenses, which enable medium-scaled optics with beam path length in the range of 15 mm. Further miniaturization of the beam path length to less than 2 mm can be achieved via a micro-lens-based approach. Here, we discuss the different optical systems in terms of channel scalability and waveguide coupling.

11:30 AM SB07.10.03
Acousto-Sensitive Ion-Based Transistors and Soft Electronics for Artificial Basilar Membrane Linta Sohail, Sofia Drakopoulou and Georgios D. Spyropoulos; University of Ghent, Belgium

Current solutions for hearing impairment lie vastly in cochlear implants (CIs). However, they are limited by bulky, power-demanding external uncomfortable components that hinder sound localization and suboptimal neural interfaces which negatively impact the efficiency of hearing restoration. To overcome these issues, we exploit novel internal ion-gated electrochemical transistors (IGTs) and piezoelectric (PVDF) nanofibers to establish a soft, biocompatible artificial basilar membrane (ABM) for a fully implantable and self-contained CI. We hypothesized that organic electronics can create all the required components; IGT-based acousto-electrical transducers with a high signal-to-noise ratio (SNR), and low-impedance, stable stimulation electrodes. To achieve that, we created efficient and fast acousto-sensitive IGTs (gm/τ > 106 mSs-1), high capacitance conductive polymer films, overcome stability issues and design smart fabrication routes that allow the development of all components into a single conformable substrate. We tuned materials composition, improved designs, and investigated the geometry and morphology effects on piezoelectric nanofibers. We explored IGT-arrays gated by continuous electrospun PVDF nanofiber (~0.6μm diameter fiber) films with gradually decreasing areas, to provide a deeper understanding of the device physics and elucidate their exact operating principle under various acoustic stimulations (0.1-10kHz). This work lead to an ABM with 8 intracochlear excitation points that conforms to the intact basilar membrane, generates, and amplifies electrical pulses (>103) according to incoming acoustic stimuli, to stimulate the spiral ganglion neurons and restore hearing without external components. We examined the performance of the ABM in-vivo by recording the electrically evoked auditory brain recordings (ABRs) in a rat model.

This project will generate safer, smaller, and more conformable acoustic-sensitive devices and stimulation electrodes that will build an ABM that can modulate electrically the neurophysiological activity of the spiral ganglion neurons. Further, the materials and methods that will be used in this project will lay the foundation for cost-effective and improved neurological devices such as micro-EEG systems and brain stem implants.

SESSION SB07.11: Smart Bioelectronics for Electrophysiological Recordings

Coin-Sized, Fully Integrated and Minimally Invasive Continuous Glucose Monitoring System based on Organic Electrochemical Transistors Jing Bai, Xinyu Tian and Shiming Zhang; The University of Hong Kong, Hong Kong

Continuous glucose monitoring (CGM) systems are currently a major focus of research in advanced diabetes management. The rapid development in this field calls for next-generation CGMs with improved sensitivity, reliability, and wearability. Here, we propose a coin-sized, fully-integrated, wearable CGM system [1] that combines cutting-edge technologies from the intersecting fields of biosensors, minimally invasive tools, and hydrogels. This CGM system includes: 1) an emerging biochemical amplifier, the organic electrochemical transistor (OECT), to improve sensitivity beyond traditional electrochemical modules; 2) a microneedle array for interstitial-fluid (ISF) sampling with reduced pain during skin penetration; and 3) a tough, adhesive enzymatic-hydrogel-membrane to enhance reliability of glucose sensing on skin. Unlike conventional CGMs, the employed OECT amplifier empowers the OECT-CGM with a high anti-noise ability, an on-demand-tunable sensitivity and current regeneration ability, enabling long-term stable glucose sensing within specific clinical ranges (1–20 mM).

This work paves the way for the development of next-generation CGMs that can simultaneously deliver high and adjustable sensitivity, minimal invasiveness, and improved wearability.

Acousto-Sensitive Ion-Based Transistors and Soft Electronics for Artificial Basilar Membrane Linta Sohail, Sofia Drakopoulou and Georgios D. Spyropoulos; University of Ghent, Belgium
Localized illumination areas of light, suggesting the restoration of their vision. Retinal degeneration mouse model demonstrate that the spatiotemporal distribution of neural responses on their retina can be mapped under selective phototransistors directly convert light into electrical stimuli, stimulating the retina through our soft 3D microelectrodes. The flexible ultrathin layer of this characteristics make potentiometric sensing a robust analytical technique that has grown in popularity for analyzing inorganic ions, including potassium.

I am utilizing potentiometric sensing, which offers direct selective measurement by eliminating separation and sample processing. Potentiometric sensors ACh detection, including bulky and rigid neural probes and low selectivity in biofluids. Here, we are developing a sensor for the in-vivo recording of ACh levels in the brain tissue to address current challenges in biological understanding of the role of this neurotransmitter in disease progression, as well as the rational design and testing of therapeutics that interact psychiatric disorders, anxiety, and depression. Therefore, developing instruments for selective sensing of ACh is essential to enhance the fundamental understanding of these diseases.

Flexible Pressure Sensor for Continuous Physiological Monitoring

To eliminate dynamic motion artifacts more efficiently and universally, we demonstrate new noise reduction strategies using advanced noise damping capacitance and sensors even without the conventional signal processing. We presented 1) New hydrogel materials [1], 2) Applications for EEG sensors [2], and 3) liquid metal for strain-insensitive electrodes [3, 4]. The study aims to show sensors that focus on human-interactive devices while showing insensitivity to 75% stretching, 25% compression, and 5mm radius of curvature bending while maintaining the sensing ability of the sensor.

Flexible Electrochemical Sensors for Detection of Neurotransmitter

Acetylcholine (ACh) functions simultaneously as a neuromodulator and neuromuscular transmitter in the brain, thus playing critical roles in learning, recognition, motivation, and muscle control. Alterations in ACh concentration in the cerebral cortex were correlated to dementia and Alzheimer's disease, psychiatric disorders, anxiety, and depression. Therefore, developing instruments for selective sensing of ACh is essential to enhance the fundamental biological understanding of the role of this neurotransmitter in disease progression, as well as the rational design and testing of therapeutics that interact with the cholinergic receptors. Here, we are developing a sensor for the in-vivo recording of ACh levels in the brain tissue to address current challenges in ACh detection, including bulky and rigid neural probes and low selectivity in biofluids.

I am utilizing potentiometric sensing, which offers direct selective measurement by eliminating separation and sample processing. Potentiometric sensors offer detection in a physiologically relevant concentration range and are a passive sensing mechanism that does not consume or perturb the analyte. These characteristics make potentiometric sensing a robust analytical technique that has grown in popularity for analyzing inorganic ions, including potassium.
(K⁺) and sodium (Na⁺) but has sodium (Na⁺), but has remained underutilized for detecting neurotransmitters. We developed a proof-of-concept flexible, potentialometric sensor for detecting ACh with less than one-second temporal resolution based on flexible parylene electrodes via utilizing a calixarene-based ionophore for ACh.

Using parylene as the structural material for developing neuromorphs has been validated and could be compared with technologies based on other materials such as PDMS, polyamide, and silicon. However, we are reporting the first potentialmetric parylene-based ACh-selective neural probe. We are utilizing parylene due to providing a pinhole-free, highly flexible, sturdy mechanical strength, and biocompatible platform to construct implantable ACh-detecting sensors consisting of a working electrode (containing an acetylene organic sensitive membrane) and a reference electrode (having a reference membrane). The parylene C substrate encompasses three 200 nm thick Pt electrodes with a 200 μm radius. The electrical potential (emf or electromotive force) between the ACh sensor and reference electrode correlates to the activity of ACh levels in the biofluid, according to the Nernst Equation (E=–(RT/zF) log a), where E shows the standard potential, R the universal gas constant, T temperature, F the Faraday constant, z the charge of the ion, and a the activity of ACh. A theoretical slope of 61.5 mV/decade is expected at body temperature and is defined as the Nernstian slope. The ACh-sensing membrane will be drop-cased onto the circular area of the platinum contact. To optimize the high signal stability, we will modify the surface of platinum with the variation of carbon nanotubes (CNTs) due to CNTs capability to generate a stable and reliable interfacing potential in potentiometric sensors with an organic sensitive membrane.

References:
Over the last decades, we have produced an unprecedented and exponentially growing amount of information, now approaching the limit that current technology can physically store. Storage demand is in fact likely to exceed the capacity of silicon-based devices within 20 years. Current storage technologies, such as magnetic tapes, have limitations such as large power requirements and cooling systems, as well as only offering limited lifetime that requires periodically transferring data to new devices. As a result, new alternative data storage technologies are required that are space and cost-effective, and able to store large amounts of information in a small contained volume, with minimum power consumption.

As an alternative data storage material, DNA has attracted a lot of attention thanks to several intrinsic properties that make it a desirable data storage medium. First, even very long DNA molecules can be condensed into a small physical space as seen in living organisms, and it can hold 2 bits of information per nucleotide. A single gram of DNA has the potential to store two orders of magnitude more data than the amount of data expected to be produced by 2025. The DNA’s extraordinary capacity is also coupled with an excellent inherent stability. But the most important aspect that makes DNA such a viable material is the large number of biotechnological tools that have been developed for the manipulation of this biopolymer.

Current strategies aiming to use DNA as a data storage material rely on sequencing technologies for data recovery. However, on a DNA-based memory, having to fully sequence all DNA strands for retrieving a specific subset of information would imply very high levels of latency and risking integrity of information. As a result, random access strategies are required.

Here, we present the first stages of an electrochemical Random Access DNA memory (e-RADM), which utilizes DNA origami nanostructures and localized strand displacement reactions (SDRs) for data manipulation. Short DNA hairpins containing toeholds complementary to the sequences of adjacent hairpins are attached to the DNA origami such that cascades of SDRs can occur. When a data retrieval query is submitted in the form of a short oligonucleotide, only those hairpins with toeholds complementary to the oligo will open, potentially triggering a cascade reaction. After the cascade reaction, the loops of the hairpins are exposed, containing the information related to the query. The unzipping of these hairpins can be monitored by electrochemical means (Squarewave Voltammetry, SWV), as opened hairpins increase the average distance to the surface, preventing electrons from a redox active molecule attached to the end of the sequence to be transferred to the electrode. The final aim of this work is to develop a fully functional electrochemical device in which functionalized DNA origami structures are immobilize on a gold microelectrode array.
Poly(alkylene furanoate)s (PAF) are the most credible bioderived alternative to oil-based poly(alkylene terephthalate)s, as they show superior thermomechanical and functional properties and are therefore attractive for applications in the packaging, textile, and biomedical fields. This work summarizes some of the most recent and promising developments in the processing and characterization of PAFs with variable alkyl chain length and PAF/poly(lactic acid) (PLA) blends and nanocomposites, highlighting the advantages and challenges of each processing technique and the main thermomechanical and functional properties of the resulting films, fibers, and nanofibrous mats.

Solvent mixing and casting have been used to prepare PLA/PAF films, and their microstructural and thermomechanical properties were evaluated as a function of PAF concentration (5–30 wt%) and type (4–10 carbon atoms in the alkyl subunit). For neat PAFs, an increase in the alkyl chain length promotes a decrease in Tg and Tm and an increasing tendency to crystallize. However, the latter is true only for PAFs with an even number of methylene groups in the alkyl subunit, while crystallization is generally hindered for the odd-numbered ones. For PLA/PAF blends, the added PAFs are effective in minimizing one of the most important drawbacks of PLA, i.e., its brittleness, as the strain at break of the resulting blends is up to 30 times higher than that of neat PLA. Adding PAFs to PLA also increases its gas- and UV-shielding properties while keeping good transparency in the visible range, which is very desirable for packaging applications. The permeability and diffusivity to N2, O2, and CO2 further decreases with the addition of reduced graphene oxide (rGO), which also promotes blend compatibilization and microstructural refinement [1-3].

The same PLA/PAF blends were also processed to produce fibers, both through solutions spinning and through melt spinning, and a detailed statistical analysis was performed to establish the optimal drawing conditions for each composition. Also in this case, the addition of a small (5-10 wt%) fraction of PAFs (with either short- or long alkyl subunits) promotes a remarkable increase in the strain at break compared to neat PLA [4] and, in some cases, also a simultaneous enhancement in the mechanical strength and elastic modulus. Following SEM observations, this effect has been attributed to the orientation and possible crystallization of the PAF phase and a plastic-rubber transition of PAF domains in the strain-hardening phase of the stress-strain curve.

Finally, we explored, for the first time, the production of nanofibrous mats made of poly(ethylene 2,5-furanoate) (PBF) and poly(pentamethylene 2,5-furanoate) (PPeF), which have very similar chemical structures but remarkably different physical and mechanical properties [5]. A detailed morphological analysis of the resulting non-woven mats, carried out through SEM analysis, allowed the screening of the best processing conditions for PBF and PPeF. The resulting mats are not cytotoxic, promote cell adhesion without any surface treatment, and allow the retention and controlled release of model drugs (e.g., dexamethasone), thus being promising for biomedical applications, for example as patches for transdermal drug delivery.

A Green Conformable Thermoformed Printed Circuit Board Sourced from Renewable Materials
Pietro Cataldi; Italian Institute of Technology, Italy
Printed Circuit Boards (PCBs) physically support and connect electronic components to implement complex circuits. The most widespread insulating substrate that also acts as a mechanical support in PCBs is commercially known as FR4 and is a glass fiber-reinforced epoxy resin laminate. FR4 has exceptional dielectric, mechanical, and thermal properties. However, it was designed without considering sustainability and end-of-life aspects, heavily contributing to electronic waste accumulation in the environment. Thus, greener alternatives are needed that can be reprocessed, reused, or biodegraded/composted at the end of their function. This work introduces diverse PCB substrates based on biobased and/or biodegradable polymers and fibers, a sustainable alternative to the conventional FR4. The substrates have been developed by compression molding, a process compatible with the polymer industry. We demonstrate that conductive silver ink can be additively printed on the substrate's surfaces, as their morphology and wettability are similar to those of FR4. The PCBs have tunable mechanical properties depending on the polymer-fiber combination, ranging from Young moduli of tens of MPa to GPa, and are thus flexible or rigid. Furthermore, they can be thermoformed to curved surfaces at low temperatures while preserving the conductivity of the silver tracks. The green substrates have a dielectric constant comparable to the standard FR4, while they are suitable for micro-drilling, a fundamental process for integrating electronic components into the PCB. The substrate's biodegradability is tested both in seawater and in soil. We implemented a proof-of-principle circuit to control the blinking of LEDs on top of the PCB, comprising resistors, capacitors, LEDs, and a dual in-line package circuit timer. The developed PCB substrate represents a sustainable alternative to standard FR4 and could reduce the overwhelming load of electronic waste in landfills.

Sustainable Photoluminescent Materials Based on Bio-Based Photocurable Functional Inks for Digital Light Processing
Cristian Mendez-Felipe1; Bárbara Cruz1, Daniela M. Correia1, Veronica de Zea-Bermudez2, Marco Sangermano2 and Senentxu Lanceros-Mendez1; 1BCMaterials - Basque Center for Materials, Applications and Nanostructures, Spain; 2Politecnico di Torino, Italy; 3University of Minho, Portugal; 4University of Trás-os-Montes e Alto Douro, Portugal
The increasing demand for additive manufacturing, particularly digital light processing (DLP) printing, has raised concerns regarding its environmental impact. Conventional materials used in DLP printing, such as petroleum-based resins, often pose challenges in terms of sustainability, resource depletion, and waste generation. To address these issues, it is required to explore sustainable alternatives derived from natural sources. Natural polymers have gained significant attention as potential ink materials due to their availability, low cost, biodegradability, and compatibility with various printing techniques. The formulation of natural polymer-based inks involves careful consideration of their rheological properties, stability, and printability, while maintaining biocompatibility and environmental sustainability. This work highlights the key factors influencing ink development, including material selection, ink formulation, and process parameters optimization, to achieve reliable and high-quality 3D printed objects. Thus, different reactive diluents have been tested in soybean oil-based ink in order to optimize the ink viscosity with the aim to produce a completely DLP printable formulation. Furthermore, photopolymerization process of obtained materials denotes to be comparable with commercially available resins maintaining high biorenewable carbon content and presenting high quality in printing parts. Furthermore, the incorporation of fillers into natural polymer-based inks has opened up new possibilities for functionalizing printed objects. By incorporating photoluminescent materials into the ink formulation, printed objects have been fabricated that exhibit luminescent characteristics, making them suitable for applications such as signalling, identification, security features, or decorative elements.
photoluminescent salts are used, three of them that emit efficiently in the visible spectral region based on Eu³⁺ (red, 612 nm), Tb³⁺ (green, 544 nm) or Tm³⁺ (blue, 440 nm), and two more emitting in the near infrared spectral region, the Yb³⁺ (1000 nm) and the Nd³⁺ (808 nm). The impact of filler type and dispersion on the optical properties and overall performance of printed structures will be discussed, showing quantitative signal even at low concentration of 5 wt.%, together with a high quality of printing parts. In addition, the challenges associated with natural polymer-based ink development, such as achieving sufficient mechanical strength due to the negative impact of the addition of fillers into the polymer, optimizing print conditions ascribed to the light absorption of the fillers that difficult the photopolymerization process during printing, and ensuring good photoluminescent properties will be addressed.

Overall, this work sheds light on the advancements in natural polymer-based ink development for additive manufacturing, specifically targeting DLP technology, and emphasizes the potential of integrating photoluminescent fillers to expand the functional capabilities of 3D printed objects. The findings presented in this abstract contribute to the broader understanding of materials development in additive manufacturing.

11:15 AM SB08.01.04
Stretchable and Biodegradable Plant-Based Organic Batteries Aiman Rahmanudin, Mohsen Mohammadi, Nara Kim and Klas Tybrandt; Linkopings University, Sweden

Next-generation electronics will interface intimately with the human body. This requires devices with high degrees of conformability and autonomy, where integrated soft and stretchable batteries are an essential component. However, existing stretchable batteries are predominantly based on unsustainable transition metal-based active materials and use non-biodegradable petroleum-based elastomers. Such batteries cause environmental issues like waste generation upon disposal and the use of finite resources during manufacturing. To address this, we present a stretchable and biodegradable organic battery employing sustainable plant-based materials with cellulose as a structural component in the electrode, separator, and current collector, and with redox-active biomaterials for energy storage and a biomass-derived biodegradable elastomer for encapsulation. Our 3D porous scaffold design allows for high mass loadings of redox-active biomolecules, in combination with a low Young’s modulus. The full cell showed reversible electrochemical performance under stretching and is biodegradable.

11:30 AM SB08.01.05
Lignin-Based Thermosets via Direct Functionalization using an Efficient and Solvent-Free Valorization Method Dean C. Webster, Alexander Hart and Eric Krall; North Dakota State University, United States

Since lignin is the most abundant aromatic biopolymer, there has been significant interest in identifying ways to convert lignin into useful materials. Degradation of lignin into oligomers and monomers has been a potential approach, however, involves additional processing steps and creates waste. Lignin has abundant hydroxyl groups which can be used for further functionalization to enable crosslinking via a variety of mechanisms. To enable functionalization, lignin—which is a solid material—needs to be converted into a homogeneous mixture for the functionalization reaction. Most commonly, lignin is dissolved in a solvent, functionalized, and then the solvent removed. This process creates waste. We have discovered that lignin is soluble in polyols—such as ethylene glycol, butane diol, glycerol—and the mixture of lignin and polyol can be functionalized together creating a 100% solids crosslinkable liquid resin without creating solvent waste. This approach has been demonstrated with two functionalization chemistries. First, lignin/polyol was functionalized with acetoacetate groups which can be cured using multifunctional amines at ambient conditions. This approach also lends itself to the formation of rigid foams without the use of isocyanates. Lignin/polyol can also be functionalized using methacrylate groups. These can then be cured via free radical initiated crosslinking either thermally or using UV. Due to the aromatic content of the lignin as well as the high functionality of the resins, the thermosets are very hard, with high modulus.
In this study, we propose a lignin as a dopant for tuning the electrical properties of carbon nanotubes (CNTs) by functionalization. This can be achieved by employing electron-withdrawing groups (EWWGs) and electron-donating groups (EDGs) via functionalization and amination, respectively, using a simple and eco-friendly synthetic method, microwave-assisted synthesis. The fluorinated lignin acts as a p-dopant and the aminated one acts as an n-dopant. Furthermore, the thermoelectric properties of lignin-doped CNTs and their devices are demonstrated for their applications in flexible energy harvesting systems. The fluorinated lignin exhibits the high Seebeck coefficient and electrical conductivity, increasing the power factor by 117% compared to the pristine CNT films. The aminated lignin shows the Seebeck coefficient of ~48 μV/K with good electrical conductivity of 246 S/cm and the high power factor. It should be mentioned that the n-type characteristics of aminated lignin-doped CNTs are valuable due to the inherent p-type properties of pristine CNTs. We also demonstrated a thermoelectric generator (TEG) only with lignin-doped CNT films of 10 pm pairs in series, exhibiting an output voltage of 7.86 mV and an output power of 247.3 nW at a temperature difference of 15 K. This study promises the realization of nature-derived n- and p-dopants by an easy modification to improve the thermoelectric performance of CNTs, which performs similar to or superior to those of commercial dopants.

2:15 PM SB08.02.03
Computationally Developed Bio-Based Pressure-Sensitive Adhesives for Healthcare Applications Manjinder Singh1,2, Alessio Alexiadis2, Michael J. Adams2 and Gaurav Manik1; 1Indian Institute of Technology Roorkee, India; 2University of Birmingham, United Kingdom

The adhesive materials used in healthcare sectors for developing adhesive bandages and transdermal patches have been using petro-based components, which cause contact allergy and allergic contact disease, such as dermatitis and stomatitis. In this investigation, linseed oil has been modified to acrylated epoxidized linseed oil (AELO) and acrylated epoxidized methyl ester (AEME) and further used as a low Tg component to develop bio-based pressure-sensitive adhesives (PSAs) computationally using molecular dynamics simulations. The bulk polymer adhesive properties such as density, solubility parameter, and glass transition temperature have been estimated and compared with previously reported literature. The values for density and solubility parameters for the control system have been closely related to the experimental as well as simulated values reported earlier. The glass transition temperature was observed to be in close proximity to the Fox equation values as well as the reported literature, verifying the simulation protocols adopted. Further, surface properties were evaluated in order to understand the adhesive behavior and estimate the interfacial strength with the substrate. The human skin has been considered as a substrate for analysis to understand the interfacial behavior of PSAs and suitability in healthcare industries. The surface energy of human skin was found to be in range with the experimental value, verifying the human skin model adopted for this study. The surface energy for all the developed systems has been estimated, and the AELO-based PSA surface energy value was found to be the highest among all the PSAs. Moreover, the interfacial adhesion strength of AELO-based PSA with human skin was found to be superior to that of AEME-based and control PSAs. An in-depth analysis suggests that the addition of polar groups in AELO and AEME was governing factor affecting the surface properties positively. This study paves the way for exploring the potential of AELO and AEME to formulate novel PSAs with desirable properties for the healthcare industries.

Biomimetic Multifunctional Nanocomposites from Naturally Derived Materials: Exploring the Functionalities of Conductive Melanin and Crystalline Nanocellulose Bong Sup Shim; Inha University, Korea (the Republic of)

Emulating the sophistication and functionality inherent in natural systems, we have designed multifunctional nanocomposites from naturally derived materials such as conductive melanin-like polydopamine (PDA) and crystalline nanocellulose. Nature employs a bottom-up assembly of nanoparticles to create multifaceted structures with hierarchical organization, providing inspiration for our work. PDA, despite its historical limitation due to low electrical conductivity and limited material functionalities, has been restructured in our laboratory to possess tunable electrochemical conductivities, optical reactivity, and casting shape stability, while maintaining inherent biocompatibility. This presentation will highlight these innovative modifications, focusing on the unique functional features of PDA in the realm of biosensors and bionic interfaces. Additionally, our research has expanded to include crystalline nanocellulose, another naturally derived material with promising potential in the creation of multifunctional nanocomposites. Its exceptional strength, biocompatibility, and eco-friendly nature make it a promising candidate for applications alongside conductive melanin. We will also share insights on our newly developed process for creating electrically conductive PDA, setting the stage for its role in emerging bioelectronic applications such as biotic-abiotic interfaces, edible sensors and actuators, and sustainable electronics. This presentation ultimately bridges the gap between nature-inspired designs and cutting-edge material sciences, pointing to an exciting future in multifunctional biomimetic nanocomposites.

3:15 PM SB08.02.05
Nature’s Way: Hierarchical Manufacturing with Biotic Composites Sabrina Shen and Markus J. Buehler; Massachusetts Institute of Technology, United States

Industrial material production is responsible for over half of greenhouse gas emissions from industry which, coupled with biodiversity decline and depletion of critical resources, threatens the livelihood of current and future generations of both humans and non-human species. Conversely, the natural world manufactures enormous quantities of materials that can dramatically outperform human engineering while empowering, rather than degrading, the environment, by architecting simple and common building blocks in creative ways, tuning molecular composition, then nanoscale and macroscale geometries to derive highly specialized products. This work proposes a new paradigm for materials design that achieves goals of sustainability by aligning and integrating models of material production with natural systems, utilizing modern computation and additive manufacturing technology while drawing source and inspiration from nature. We develop a library of 3D-printable functional composites from fully biotic and non-toxic building blocks, and characterize their mechanical, surface, and biodegradation characteristics. We moreover investigate the advantages afforded by additive manufacturing, including fabrication of hierarchical architectures similar to those found in nature. Finally, we explore strategies to further functionalize similar material platforms with computation-guided bioisomorphic optimization, generative microstructure design, and incorporation of living components for novel hybrid-living materials.

3:30 PM SB08.02.06
Alternatives to Traditional Plastic: PHB-Based Biodegradable Polymer Composite Films and Disposable Tableware Jihyeon Kim and Kwan-Soo Lee; Los Alamos National Laboratory, United States

Nowadays, plastic materials are taking an important place in our everyday life. Plastic production has soared since it became commercially produced more than 50 years ago. This growth has seen plastic become one of the biggest environmental issues worldwide, with plastic waste polluting land, oceans, air, and even food and human blood. The majority of U.S. plastic waste is landfilled. Of the estimated 40 million tons of municipal plastic waste generated in the U.S. in 2021, at least 85% was sent to landfill sites. Biodegradable polymers have emerged as an alternative. However, certain types of biodegradable polymers, such as PLA, PBAT, Bio-PP, and Bio-PE, require specific environmental conditions or microbial activity to initiate the degradation process. In
natural environments where these conditions are not present, such as in landfills or marine environments, the biodegradable polymers may persist for extended periods without undergoing significant degradation. This leads to the accumulation of non-degraded biodegradable polymers, which can contribute to environmental pollution and waste management challenges. Polyhydroxybutyrate (PHB) is a class of polymers naturally created by living microorganisms or synthetically produced from biorenewable feedstocks. They’re biodegradable in the ambient environment, including oceans and soil. However, the PHB has a long-standing problem, due mainly to its inherent brittleness ($\varepsilon = 3-5\%$) and poor melt-processability. In this study, we have developed new compositions of PHB-based polymer ($\geq 90$ wt.$\%$) film/tableware bearing green additives (i.e. FDA approved) to overcome the mechanical instability of PHB and optimize their processability. Furthermore, various formulations developed not only increased the elongation properties of the films but also improved processability by lowering the melt temperature of the plasticware. This result has important implications for disposable plastic applications, as it removes the often-cited inferior mechanical properties of currently available bioplastics.

3:45 PM  SB08.02.07
Rhizobium Tropici-Produced Biopolymer: Chemical Characterization and Modeling its Interactions with Clay
Tae Kim1, Brinley Dau2, Jerry Guo1, Tony Guo Feng Tung1, Ashritha Kalakuntla1, Haaris Alam3, Elise Ngo4, Isana Alicea4, Aaron Sloutski5, Yiwei Fang6, Marcia Simon6, Yi Gao7, Miriam Rafailovich1, Steve Larson8 and Fengxiang Han9; 1Stanford Online High School, United States; 2Experimental High School Attached to Beijing Normal University, China; 3Beijing No. 80 High School, China; 4Shanghai High School International Division, China; 5Ed W. Clark High School, United States; 6Portola High School, United States; 7Patchogue Medford High School, United States; 8Stony Brook University, The State University of New York, United States; 9US Army Corps of Engineers Research and Development Center, United States

Preventing soil erosion is important in areas vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is extracellular polymeric substances (EPS), which can increase and maintain the structural stability of soil by increasing resistance to environmental stresses. EPS can improve subterranean root growth, which can stabilize topsoil and help in erosion control. Furthermore, much research in the last decade has focused on explaining EPS-clay/soil interaction in order to improve its applicability. This project aims to investigate the chemical properties of Rhizobium tropici bacteria-derived EPS (RT-EPS) and its interactions with clay to model the on-site interactions with soil. EPS produced from the bacteria was used to generate an Ethanol Precipitate Material, RT-EPM, whose chemistry was researched in depth.

First, the chemical composition of RT-EPM was analyzed with thermogravimetric analysis (TGA) and high-performance liquid chromatography (HPLC). TGA results indicated that most of the RT-EPM was organic matter, and HPLC results demonstrated a significant presence of polysaccharides, with glucose being the main component (73%) and a significant presence of galactose (25%). Moreover, the chromatography also showed a dispersity of 1.013, indicating uniformity of the polysaccharides obtained from the RT bacteria.

The interactions between RT-EPM and clay was explored through rheology. To examine the deformability of RT-EPM-clay interactions in aqueous medium, an amplitude sweep, an angular frequency test, and a shear rate test were conducted. Comparing the viscosity values across the three freeze-dry and hydration cycles of the EPM, a negligible change in the mechanical properties was identified, indicating the reversible nature of the dynamic cross-linking. To examine the anchoring properties of the EPM to the soil, the rheological properties of the EPM mixed with various concentrations of clay were tested. An overall increasing soil shear strength as the clay concentration increased was found, demonstrating the anchoring capabilities of the EPM to clay. Rheology displayed the mixture’s desirable mechanical properties, which simulate RT-EPM’s on-site reinforcement of soil via shear strength enhancement.

In conclusion, beside a significant polysaccharide presence, a small fraction of proteins was also found by running respective BSA-assays. It was also determined that the EPM, due to its adhesive properties, once mixed with clay forms interactions that are reversible, significant, and are environmentally-influenced.

Future directions include in-depth research on the protein fraction RT-EPM contains, with a focus on their influence on the interactions with clay. In order to study the EPM-production influence on the interactions with clay, different dialysis cutoff standards will be applied to treat the EPM. Then, HPLC and rheology tests will be run separately for each cutoff (2K and 14K dialysis). C-NMR and H-NMR will also be applied to further shed light on the chemical composition of the EPM and interactions with clay. Zeta potential of the RT-EPM and clay solution will be used to measure the electrochemical potential and the stability of the particle interactions.

The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-0054) in this research.

SESSION SB08.03: Poster Session: Sustainable Polymers and Composites

Study of Vitrimerization of Thermosetting Liquid Crystal Epoxy Resin via Chemical Reprocessing and Recycling
Kyeoun Ku and Hyeonuk Yeo; Kyungpook National University, Korea (the Republic of)

Thermosetting polymers are applied in various industrial fields due to their excellent physical properties, high thermal and mechanical stability. In particular, epoxy materials are attracting attention as next-generation electronic materials due to their bio-friendliness, electronic insulation, and thermal mechanical stability. However, most thermosetting polymers including epoxy resins, still face challenges from insoluble and non-recyclability. In this study, Liquid Crystal Epoxy Resin (LCER) are synthesized which can be reproduced to overcome the limitations of thermosetting polymers. Also, for application as an electronic material, high thermal conductivity are realized. These results suggest the applicability as electronic materials.

8:00 PM  SB08.03.02
Interfacial Assembly of Cellulose Nanofibers at Oil/Water Interface via Tailored Electrostatic Attraction to Establish Surfactant-Free Emulsion Stabilization
Jaewon Shin, Bokgi Seo and Jin Woong Kim; Sungkyunkwan University, Korea (the Republic of)

The pervasive utilization of petroleum-based cationic surfactants has led to significant pollution of aquatic environments, emphasizing the urgent need to explore sustainable alternatives. Aligned with this concern, this study introduces a novel bio-friendly natural cellulose nanofiber system for surfactant-free emulsion stabilization. To achieve this, glycidyltrimethylammonium chloride was incorporated into bacterial cellulose fibers to enable cationization and nanofibrillation. The newly developed ammonium-functionalized bacterial cellulose (ABC) exhibited electrostatic adsorption at the oil/water interface, facilitated by the spontaneous negative charge present on interfacial hydrocarbon oil drops. Through theoretical considerations that employed the Young’s equation and contact angle measurements of three-phase sessile droplets, we observed that current ABC-based solid interface displayed approximately 10-fold higher adsorption energy compared to hydroxylated solid interface. This unique interfacial adsorption behavior of ABC not only reduced interfacial tension but also promoted the formation of a robust interfacial membrane. Importantly, these interfacial properties are corresponding to the high aspect
ratio of nanofibers, which provide a larger surface area and, consequently, an increased adsorption energy. Furthermore, our rheological studies revealed that the addition of a fibril network formed by the isolated ABC nanofibers facilitated the dissociation of droplets and gelting of the continuous phase, thereby improving the durability of emulsion drops against applied shear stress. Collectively, our findings highlight that our innovative surfactant-free emulsion system would pave the way for development of environment-friendly complex fluids.

8:00 PM SB08.03.03 Scalable R2R Processing of Regenerated Silk Fibroin Film Jeff Roshko and Fiorenzo Omenetto; Tufts University, United States

Owing to its tunable physical, chemical, and biological properties, regenerated silk fibroin (RSF) has been studied extensively in the film format for potential use in many applications, namely drug delivery, medical/environmental diagnostics, electronics, optics, and tissue engineering. Methods such as spin coating and drop casting are routinely employed to create films from RSF solution in the laboratory for research sample production. However, these techniques do not necessarily translate to larger scales without considerable waste or inconsistency, potentially limiting widespread adoption of useful engineered devices developed from RSF. Meanwhile, techniques developed to produce films industrially such as roll-to-roll (R2R) processing are utilized to manufacture large areas of sensitive coatings and intricate devices, such as microfluidics and flexible solar panels. Herein, we present the development of a scalable means of producing RSF films employing techniques from R2R manufacturing using aqueous processing of RSF. This includes the optimization of RSF-inks that are conducive to solution coating and the comparison of knife-blade sheet-coating at the laboratory scale and slot die R2R coating at multi-meter production scale. This work demonstrates that scalable production is possible for widespread adoption of RSF-based functional devices.

8:00 PM SB08.03.04 Tensile and Compressive Properties of PLA-Based Polymeric Blends Depending on PBS, PBAT and TPS Content and Testing Temperature Anna Dmitruk, Joanna M. Ludwiczak, Mateusz Skwarski, Piotr Makałka and Paweł Kaczynski; Wroclaw University of Science and Technology, Poland

Environmentally friendly biopolymers materials can be utilized to replace commonly used plastics, what leads to a noticeable reduction of the pollution level, caused by their processing and exploitation. Nevertheless, in comparison with their non-biodegradable precursors, they suffer from some severe limitations, such as their capability to be untimely decomposed during long-term work, lowered mechanical properties and impaired thermal resistance. Therefore, it is crucial to make efforts to surpass the mentioned constraints by modification of the properties of biodegradable polymers. Among the possible solutions to advance their development a preparation of variously composed biopolymeric blends seems to be a promising route. Poly(lactic acid) (PLA), being widely applied, is one of the most popular biodegradable plastics, characterized with rather high mechanical properties, but with reduced deformability at the same time. To overcome its brittleness, it can be joined together with more ductile additives, namely: polycaprolactone (PCL), poly(propylene carbonate) (PPC), poly (butylene succinate) (PBS), poly(butylene-succinate-co-adipate) (PBSA), poly(butylenecaprate-co-terephthalate) (PBAT), thermoplastic starch (TPS) and polyamide 11(PA11) [1-5]. This work was focused on PLA-based compositions doped with different ratios of PBS, PBAT and TPS to evaluate their mechanical (tensile and compressive) properties in various temperatures (-20°C, 0°C, 20°C, 40°C). Specimens for testing were obtained by preliminary extrusion, subsequent injection molding and final cutting into the intended dimensions. Mechanical properties e.g. tensile strength, elongation at break, Young’s modulus, yield strength and compressive strength for the deformation of 0.4 were investigated. No additional modification step, as for example, addition of compatibilizers was necessary to be involved in the manufacturing method, what significantly simplified this process without impairing the properties exhibited by the obtained blends. Each of the tested plasticizing secondary compounds positively influenced the elongation at break of PLA – increasing it especially in the case of PBAT and TPS. Simultaneously, together with the increasing content of a ductile component, other mechanical properties i.e. tensile and compressive strength were decreased. The stability of the mechanical performance of thus fabricated mixtures was assessed taking into account also the test conditions (strain rate and temperature), aiming to understand its dependence on these parameters. To gain a deeper insight into the potential applicability of the hereby proposed materials also some selected processing parameters were investigated, namely: melt flow ratio (MFR), melt volume ratio (MVR), heat deflection temperatures for 1.8 MPa and 8 MPa (HDT A and HDT C) and Vicat softening temperatures for two loadings of 10 N and 50 N (VST A and VST B). Finally, the DSC test results were used to complement the study, proving information on the softening, glass transition, cold crystallization and crystallization temperatures of the developed mixtures. It can be concluded that the elaborated biodegradable blends provide a desired compromise between the mechanical properties, in terms of both tensile and compressive characteristics, and deformability of durable and brittle PLA and ductile PBS, PBAT and TPS additives. Hereby described biomaterials aim to find their use in energy absorption applications, as for the manufacturing of thin-walled, cellular inserts filling sports helmets, acting as energy absorbers and replacing regularly utilized foamed materials in protection of their users during an accident.

Funding: This work was supported by the project BIKASK “Development of innovative, replaceable, energy-absorbing structures based on biodegradable plastics for protective helmets” (0223/L-11/2019, LIDER, NCBR).

8:00 PM SB08.03.05 Evaluation of Mechanical Properties of Wood, Changed by Structural Changes in Alkali Treatment and Liquid Impregnation Rika Takenaka and Daisuke Ishii; Nagoya Institute of Technology, Japan

One of the increasingly serious environmental problems is plastic waste disposal. In addition to direct solutions such as reducing the amount of plastic used, there are indirect solutions such as using less environmentally hazardous materials as substitutes for plastic materials. Familiar examples include the widespread use of paper bags and straws. In this research, we focused on wood, whose main component is cellulose, as a natural polymeric material with the potential to have the same properties as light and strong plastic. In order to increase its versatility and make it an excellent substitute for plastic, we aimed to investigate novel mechanical properties, such as controlled flexibility, by treating it with alkaline solutions and impregnating it with various liquids.

Commercially available balsa wood was used as the experiment material. Alkaline mixture solutions of NaOH 2.5 mol/L and Na2SO3 0.4 mol/L were prepared, and the balsa wood was immersed in the prepared alkaline mixture solutions on a hot stirrer set at 212 °F. Duration times of alkali treatment were 0 h (untreated) and 6 h. The alkali-treated balsa wood was washed with pure water and freeze-dried. Structural observation and mechanical strength measurements were performed on these two types of samples. Scanning electron microscopy (SEM) was used to observe the cross-sectional structure in each cellulose fiber direction. In particular, cross-sectional observation in the vertical fiber direction showed that the cell wall thickness increased in the alkali-treated samples. This is thought that the cellulose fibers unraveled and swelled by dissolving some of the hemicellulose and lignin that bind the cellulose fibers together. It is expected that this structural change affects the novel mechanical properties.

In the compression test, dry samples before liquid impregnation and liquid-impregnated samples of pure water, ethanol, ethylene glycol, and silicone oil of various kinematic viscosities up to equilibrium were prepared. All measurements were performed in the direction parallel to the cellulose fiber. The results showed that strength varied significantly depending on the alkali treatment and the liquid impregnation. The samples without alkali treatment showed no significant difference in strength depending on the type of impregnating liquid. On the other hand, the alkali-treated samples were softer in water and ethylene glycol and harder in ethanol. This led us to believe that the ratio of hydrophilic to hydrophobic groups was a factor in determining whether the
liquid acted as a cushion between the cellulose fibers. With silicone oil, the smaller the viscosity, the stiffer the sample. This is expected to be due to the degree of penetration of the liquid, i.e., the degree to which the molecular chains of the silicone fluid entangle with the loosened cellulose fibers. In the bending test and the falling-ball impact test, two types of samples were prepared, one in a dry state before liquid impregnation and the other in a liquid-impregnated state after absorption of pure water. Measurements were performed in the direction parallel and vertical to the cellulose fiber. As a result, it was found that the tenacity against bending and the tendency of the force to receive impact differed depending on the fiber direction. We believe that this is due to the effect of structural changes identified by SEM.

As described above, it is possible to control the physical properties of wood using a relatively simple method, and it is hoped that this research will contribute to the development of highly functional sustainable materials that can replace plastics in the future.

8:00 PM SB08.03.06
Lignin-Silica Bio-Composite: A Sustainable Solution for Wastewater Purification
Nataliia Smyk1,2, Oleg Tkachenko1, Tetjiana Budnyak1 and Olena Sevastyanova2; Taras Schyevchenko National University of Kyiv, Ukraine; KTH Royal Institute of Technology, Sweden; Uppsala University, Sweden

The proper purification of wastewater is a pressing environmental concern, given the wide range of pollutants it can contain. In this study, a groundbreaking approach utilizing lignin-silica bio-composite as an effective and sustainable sorbent for removing cationic-type contaminants from wastewater is presented. The research team conducted a comprehensive characterization of the proposed sorbent using SEM, FTIR, XPS, and adsorption methods, ensuring its structural integrity and functionality. This attention to detail instills confidence in the efficacy and reliability of the lignin-silica bio-composite. One of the key strengths of this sorbent is its high sorption capacity. The lignin-silica bio-composite demonstrates an impressive ability to attract and retain heavy metal cations, dyes, and cationic medicines, thereby effectively reducing their presence in wastewater. This feature is particularly noteworthy as it addresses a diverse array of cationic pollutants commonly found in both industrial and domestic wastewater.

Furthermore, the sorption kinetics of the lignin-silica bio-composite are commendably rapid. Its efficient adsorption process allows for the removal of contaminants within a short period, ensuring swift and effective treatment of wastewater. This attribute is of utmost importance when considering large-scale implementation and practical application. At room temperature and near-neutral pH, the sorbent exhibited an adsorption capacity of 0.98 mmol Cu(II) and 1.21 mmol Cr(III) per gram of dry adsorbent. These values were three times higher than those achieved by using lignin or silica alone as starting materials. The kinetics study further demonstrated the efficiency of the composite sorbent. Within a short span of 20 minutes, it was able to effectively extract copper(II) and chromium(III) from the solution. Additionally, the adsorption capacity of the immobilized lignin towards brilliant green dye was found to be relatively high. Furthermore, the capacity of the initial silicas and lignin significantly increased when combined in the bio-composite. This enhancement can be attributed to the "extended" conformation of lignin, which allows for better accessibility of various functional groups when adsorbed onto the charged silica surface. By utilizing lignin, a byproduct of the pulp and paper industry, as a key component of the sorbent, the researchers have showcased a valuable and eco-friendly approach to wastewater treatment. This not only provides an innovative solution but also contributes to the broader goal of promoting a circular economy and reducing waste. The robust characterization methods employed, combined with the sorbent's impressive sorption capacity and rapid kinetics, make it a promising candidate for large-scale wastewater purification. Moreover, its sustainable nature aligns with the increasing need for eco-friendly solutions.

Scalable and Sustainable Valorization of Lignin using Single-Step Aerosol Method
Sujit Modi1, Onochie C. Okonkwo1, Sulay Saha1, Hao Zhou1, Shalinee Kavadiya2, Marcus Foston1 and Pratim Biswas2; 1Washington University in Saint Louis, United States; 2University of Miami, United States

Growing demand for energy and materials has led to increased greenhouse gas emissions from the use of fossil resources. Lignocellulose biomass, one of the few renewable resources of carbon, has an abundance and geographical distribution to displace fossil resources. However, the under-utilization of by-products (i.e., lignin fraction) remains one of the challenges to the rapid growth of biorefinery. Thus, developing technologies that can valorize lignin to high-value products is crucial. Lignin could be used as a precursor for the synthesis of a diverse range of high-value nanomaterials, including lignin nanoparticles (NPs), carbon NPs, and functionalized carbons. However, conventional synthesis methods of these nanomaterials are limited by multistep and batch processes or large volumes of solvents/activating agents. To overcome these challenges of conventional synthesis methods, the present work explores the synthesis of high-value nanomaterials from lignin using a novel and simple furnace aerosol reactor (FuAR) technique.

First, the FuAR is demonstrated for controlled synthesis of lignin NPs of mean sizes between 50 and 68 nm. The as-synthesized lignin NPs are analyzed for their size and functional groups. The mean size of lignin NPs showed an increasing trend with lignin solution concentration. Based on the changes in functional groups, the maximum temperature in FuAR to obtain lignin NPs without significant chemical degradation was found to be around 300°C (at a residence time of 5.8 s). Furthermore, the bulk and as-synthesized LNPs were tested for UV protection applications. The observed improvement in UV protection with a decrease in lignin particle size is systematically investigated using the optical absorption parameter [1]. Next, temperature and residence time are expected to have a key impact on products obtained from the pyrolysis of lignin. With the systematic understanding of the role of these parameters, carbon nanoparticles with high surface area (up to 925 m²/g) are synthesized in FuAR without the use of activating/templating chemicals. This one-step approach requires significantly less time for synthesis: an order of seconds in comparison to hours for conventional methods. Furthermore, the as-obtained carbon nanoparticles are tested for specific capacitance which showed a linear trend with surface area. The best-performing material (with the highest surface area) exhibited a specific capacitance of 247 F/g at 0.5 A/g with excellent capacity retention of over 98% after 10,000 cycles [2,3]. Finally, the FuAR is used for in-situ nitrogen functionalization to synthesize nitrogen-functionalized porous carbons. Urea is added to the lignin solution as a precursor for nitrogen functional groups. Furthermore, the as-obtained carbon nanoparticles are tested for CO₂ adsorption and the material with a maximum surface area of 1051 m²/g exhibited a CO₂ adsorption capacity of 62 mg/g of carbon) and excellent cyclability.

Overall, these studies demonstrate the unexplored potential of FuAR for the scalable valorization of lignin as well as the excellent performance of obtained nanomaterials in respective applications, which will help advance displacing the fossils with renewable resources.

Bacterial Factories for the Production of Functional Lubricants Stephen F. Bartolucci, Cameron M. Longo, Erica Richael and Joshua A. Maurer; U.S. Army DEVCOM Armaments Center, United States

The use of bacteria to produce novel materials is a rapidly expanding arena across many sectors of industry. These “bacterial factories” can be engineered to produce a wide variety of moderately valuable materials. This has been demonstrated both in academia and industry, with the production of such resources as biofuels, natural products, and pharmaceuticals. The use of bacterial factories offers several advantages to other means of production, namely that production can occur at the point of use, and can be fed waste products as feedstock, which otherwise would have little to no value. These two factors make bacterial factories an attractive method for production of kilogram scale quantities of various supplies. One such material which serves as a useful resource as biofuels, natural products, and pharmaceuticals. The use of bacterial factories offers several advantages to other means of production, namely that production can occur at the point of use, and can be fed waste products as feedstock, which otherwise would have little to no value. Relationship Between the Structure and Properties of Recycled High-Density Polyethylene Reinforced with Rice Husk Biochar Hussein S. Alrobei; Prince Sattam Bin Abdulaziz, Saudi Arabia

The focus of this investigation is on how recycled High Density Polyethylene (HDPE) is affected by rice husk biochar in terms of its structural, thermal, flammable, and mechanical characteristics. The different ratios of recycled HDPE to rice husk biochar were prepared and the best ratios were discovered for different kinds of features. Tensile, flexural, and impact properties were considered when evaluating mechanical features. In order to expound on this fluctuation in attributes, Scanning Electron Microscopy and Fourier Transform Infrared Spectroscopy were carried out. All of these experiments demonstrated the importance of rice husk biochar as an additive for improving the mechanical properties of recycled HDPE.

Improving Water Resistance and Film Forming Ability of Cellulose Based Film with Lotus Leaf Extract and Gelatin Behrokh Shams, Evan K. Wujcik and Douglas Bousfield; University of Maine, United States

Cellulose is extensively employed in food packaging to enhance moisture barrier properties. However, cellulose nanofibers face challenges such as low flexibility and high water vapor permeability. Utilizing hydrophobic materials, like lotus leaves, is a promising approach to improve water vapor transmission rates. Gelatin can help with film forming and flexibility. In this research, cellulose nanofibers are combined with a natural hydrophobic extract and gelatin to enhance moisture resistance and film forming ability.

Algae-Powered Sustainability via Hydrothermal Liquefaction: Revolutionizing Epoxy Resins Keshan Lighty, Phillip Agbo, Abhijet Mali, Lijun Wang and Lifeng Zhang; North Carolina A&T State University, United States

In the growing field of materials science, our study establishes a revolutionary creative approach in the area of bio-composites for sustainable manufacturing. We present research using the hydrothermal liquefaction process used to produce eco-friendly epoxy resins from algae. The materials science community will be interested in this study since it has the potential to alter how epoxy resin is made in the future.

Traditional epoxy resins come from petroleum sources and are necessary but have a significant environmental impact. Through the use of algae, a plentiful, quickly expanding, and underutilized resource, we reimagined these resins. We unlock the potential of algae using hydrothermal liquefaction to produce a bio-binder that is not only competitive with conventional components in terms of performance but also a champion of sustainability. The biomass is subsequently transformed into a versatile bio-binder by the state-of-the-art conversion method known as hydrothermal liquefaction, which is prepared to give epoxy resin compositions new life.

The incorporation of bio-binders made from algae not only improves the performance of epoxy resins but also tells a captivating story of ethical material development. Our discovery also changes the paradigm by decreasing reliance on limited fossil fuel resources, which helps lessen the carbon load on our world. The size of the world’s epoxy resin market was approximately USD 8.70 billion in 2020, and it is anticipated that it will increase from USD 11.59 billion in 2021 to USD 17.10 billion by 2028. When it comes to these widely utilized composite materials, our capacity to reduce the consumption of fossil fuels while incorporating sustainable production will have an enormous impact on society as a whole for the better.

With the help of this scientific development, we are encouraging researchers, thinkers, and proponents of sustainable materials to set off on an exploration that will not only enhance the study of materials but also fundamentally alter the way that Epoxy Resin can be manufactured. This research can make an impact in the areas of painting/coatings, electronics, wind turbines & composites, construction, and adhesive/sealants.

We look to encourage creativity, foster teamwork, and bring in a new era of sustainable materials for a more promising, responsible future. I want to assist society in both self-healing and improving the quality of life through sustainable manufacturing and this research assists with that but this is only the beginning. The goal is to help build a better tomorrow starting today.

In-Situ Treatment of Flexible Polylactic Acid (PLA) using Non-Thermal Plasma and Various Electrode Geometries: Towards Developing Advanced Analytical and Machine Learning based Hybrid Methodologies to Study The Wettability Characteristics using Surface Topography, Contact Angle Characteristics and Electrical Impedance Spectroscopy Derek Xiong1, Kaiyu Vang1, Prakhayat Gautam1, Parshwa Khane1, David Ryman1, Harshkumar Bhate1, Edbertho Leal-Quiros1, Saquib Ahmed1,3 and Sankha Banerjee1,3; 1California State University, Fresno, United States; 2University of California, Merced, United States; 3Buffalo State College, United States; 4University of California, Davis, United States

Polymer and polymer composite-based 3D printing processes allow users to fabricate multiple prototypes and proofs of concept, making it an excellent method for testing concepts in the early stages of development. However, the layer-by-layer printing procedure can result in issues with surface properties and the strength of the finished printed geometry, making the product an inaccurate representation of the design. The current work involves the in-situ treatment of biocompatible and flexible-PLA, with non-thermal and room-temperature microplasma-based corona discharge to address this problem and try to optimize the surface properties. This work also involves the evaluation of the effects of plasma-treated 3D printed polymer materials as compared to non-
treated samples. This will involve tailoring the polymer properties in the layer-by-layer process to create stronger and more cohesive bonds between each layer through the modification of the surface characteristics of each of the printed layers. Advanced hybrid machine learning models will be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring surface properties of these materials. Additionally, the work involves the characterization of the surface electrical properties using impedance spectroscopy, surface energy and topographical properties using profilometry, and hydrophobic or hydrophilic properties using water contact angle measurements. This will provide valuable insights into the effects of room temperature-based plasma-based surface modification of the printed layers towards enhancement of surface properties of the samples and which electrode will be the most effective.

SESSION SB08.04: Lignocellulosic Technologies

Nanocellulose as a Sustainable Alternative to Improve the Performance of Resins for Additive Manufacturing Maria Soledad S. Peresin, Laura Alvarez and Zahra Naghizadeh; Auburn University, United States

In a plea to become more sustainable, the construction industry is increasing the demand for research on partially replacing synthetic resins with renewable and more environmentally friendly resources, such as biomass. Having good properties, epoxy resins have been an excellent candidate in composites for construction applications. However, it is a relatively brittle material, with a poor resistance to crack initiation and growth. Reinforcing epoxy composites with renewable and mechanically strong materials like nanocellulose is progressively considered recently. In this research, different percentage of bleached and unbleached cellulose nanofibers (BCNF/LCNF) were used to reinforce and partially replace epoxy resin in composites containing Epon 828 and Jeffamine d-400 catalyst. The chemical interaction between cellulose nanofiber and epoxy resin was investigated by quartz crystal microbalance with dissipation monitoring (QCM-D). Mechanical and thermal performances of the reinforced resin were studied using tensile test and thermal gravimetric analysis (TGA) method, and the elemental analysis, Fourier transform infrared spectroscopy (FTIR), was employed on the cured reinforced resin in order to understand the composition of the mixtures after nanocellulose addition. The results proved that the nanocellulose addition changes the chemical composition of epoxy resin, and based on the QCM-D data, BCNF showed favorable chemical interactions with the resin. The mechanical tests indicated the promising results and they proved that the BCNF can be used as a biodegradable and sustainable additive and partially replacement for epoxy resin in composite materials. BCNF reinforced epoxy showed better tensile performance compare to LCNF one. For both LCNF and BCNF dispersed epoxy, the maximum enhancement in tensile properties occurred with 1 wt.% nanomaterial added. It should be noted that the moisture stability of the wood composites was not significantly affected by the nanocellulose content, however, the thermal stability decreased slightly.

Cellulose Nanocrystals-Based Membrane: Enhancing Dimensional Stability and Water Uptake for Alkaline Fuel Cells Yuan Lu1 and Soydan Ozcan2; 1L.I. products, United States; 2Oak Ridge National Laboratory, United States

The design of anion-conducting polymeric materials has been an active field of research, driven by their application in alkaline fuel cells. These membranes offer advantages such as higher cell efficiencies and cost-effectiveness. However, a major challenge lies in balancing high conductivity with excessive water uptake, which can lead to uncontrolled dimensional swelling or membrane disintegration. In this study, we present a unique approach to address this challenge by utilizing cellulose nanocrystals as the basis for a membrane design. Cellulose nanocrystals, derived from cellulose-rich sources through acid or base hydrolysis, possess exceptional mechanical properties and are known for their high water absorption capabilities while maintaining excellent dimensional stability. By incorporating cellulose nanocrystals with various commercially available polymeric binder systems, we prepared an electrolyte membrane for alkaline fuel cells. We systematically investigated the impact of cellulose nanocrystal content, binder formulations, and temperature on water absorption, swelling, and hydroxide conductivity. Our results demonstrate that the resulting membrane exhibits improved dimensional stability, with less than 10% swelling, and excellent water uptake exceeding 100% compared to membranes solely based on polymer binders. Importantly, the presence of cellulose nanocrystals does not compromise the hydroxide conductivity of the polymer binder system. This approach offers a facile and renewable strategy for preparing solid electrolytes with exceptional dimensional stability and high hydroxide conductivity. It represents a promising avenue for the development of solid electrolytes in alkaline fuel cells, offering a simpler alternative to complex polymer synthesis routes.

Highly Filled Short Banana Fiber-Polypropylene Composites: Fiber Concentration and Interfacial Adhesion Effects on Damping and Mechanical Performance Caitlyn Clarkson1, Sanjita Wasti2, Amber M. Hubbard1, Soydan Ozcan2,3 and Uday Vaidya1,2; 1Oak Ridge National Laboratory, United States; 2The University of Tennessee, Knoxville, United States

Natural fiber-hybrid composites are gaining significant interest from automotive applications because these composites meet performance requirements but are often lighter and lower cost than other fiber composites, thereby reducing the environmental burden of the vehicle during its use phase. In the case of natural fibers, the inherent hydrophilicity of natural fibers is one of the biggest challenges to overcome as these materials take up moisture at a significantly higher rate and most thermoplastic matrices are hydrophobic, resulting in poor interfacial bonding between the dissimilar fiber and matrix. In this work, composites are prepared by first creating a non-woven fiber mat of polymer fiber and natural fiber in a wet-lay process, drying, and then compression molding to the final desired shape. A water-based sizing agent is added directly to the process to size fibers in situ during wet-lay. The composite properties are evaluated including the tensile strength and impact resistance, damping, heat distortion temperature and water uptake. Finally, demonstration parts will be shown that are compression molded from the wet-laid non-woven process.

Ultra-Strong and Tough Bacterial Nanocellulose Sheets and Fibers via Rotational Fluid Flow Assisted Shear Alignment Md Abid Shahriar Rahman Saud1, Yufei Cui2, Shyam Bhakta1, Matthew Bennet1, Pulicieka Ayajan1 and Muhammad M. Rahman1; 1Rice University, United States; 2Massachusetts Institute of Technology, United States
Bacterial nanocellulose (BC) has emerged as an excellent alternative candidate to non-biodegradable polymers due to the remarkable mechanical properties of its basic nano-fibrillar building blocks. However, full utilization of the mechanical properties in BC structures is yet to be achieved due to the challenge of alignment of the nanofibrils. Herein, we report a facile bottom-up fabrication technique for producing ultra-strong BC sheets by using shear alignment from fluid flow in a rotational culture device, which enables in-situ layer-by-layer deposition of anisotropic cellulose nanofibrils. Specifically, we introduce a custom-designed culture device where the cellulose-producing bacteria are cultured in a cylindrical oxygen-permeable incubator that is continuously spun using a central shaft to produce a directional fluid flow. This flow results in consistent directional motion of the bacteria that significantly improves nanofibril alignment in the bulk BC sheets. The BC sheets produced from the rotation culture device after stretching displayed specific tensile strength (up to ~ 1 GPa/g-cm$^2$) and are comparable to the highest tensile strength of BC sheet ever reported yet showing excellent flexibility that allows forming into desired shapes. We show that the BC sheets can be twisted and stretched to make BC micro-fibers of ~200 µm diameter with tensile strength of 1.3 GPa, the highest reported to date among strong natural fibers. We also compare the mechanical, environmental, and cost-effective aspects of the BC fiber with widely used structural fibers such as E-glass and lightweight steel, showing the superiority of BC fiber. This fabrication technique yielding highly aligned, ultra-strong BC sheets and fibers would pave the way toward extensive applications of BC in a range of bio-degradable structural and functional materials.

10:30 AM SB08.04.10
Self-Organized Mycelium-Based Bio-composites for Sustainable Buildings: From Structure to Fracture and Toughening Mechanics Precious O. Etimnoy1, Ali Salifu2, Sarah Osufo3, John Obayemi4 and Winston O. Soboyejo1; 1Worcester Polytechnic Institute, United States; 2Boston College, United States

This work presents the results of a combined experimental and analytical study of the structure and fracture/toughening of bioprocessed mycelium composites. The mycelium composites are reinforced with self-organized cellulose/hemicellulose hemp ducts and varying laterite proportions. In-situ studies of crack growth are used to provide insights into the underlying toughening mechanism that gives rise to resistance-curve behavior. The crack-tip shielding contributions from the observed crack bridging and crack deflection mechanisms are then quantified using fracture mechanics models. The results show that toughening is dominated by crack-bridging at low volume fractions of laterite (≤ 20%), while a combination of crack-bridging and crack deflection is observed to occur at increased laterite volume fractions (20 – 60%). Finally, toughening is shown to occur predominantly by crack deflection at higher volume fractions (≥ 60%). The implications of the results are discussed for the microstructural design of mycelium and mycelium-laterite composites for potential applications in sustainable buildings.

SESSION SB08.05: Novel Bio-Based Materials
Session Chairs: Katherine Copenhaver and Heli Kangas

1:30 PM SB08.05.01
High Specific Surface Areas and Interconnected Pore Networks of Porous Pectin Particles for Enhancement of Protein Adsorption Capacity Tue Tri Nguyen and Takashi Ogi; Hiroshima University, Japan

The aging population is leading to an increasing demand for nutritional supplements, including functional foods. Functional foods aim to provide essential nutrients and proteins to the human body. Porous particles, specifically macroporous particles with pores size larger than 50 nm, have emerged as promising carrier materials for efficient delivery of bioactive compounds. While macroporous particles have been developed from various inorganic and organic materials, their application to natural polymer-derived materials remains unexplored. This study focuses on the synthesis and characterization of porous pectin particles, utilizing a template-assisted spray drying method combined with a chemical etching process to prevent thermal decomposition of the natural polymer. Calcium carbonate (CaCO$_3$) was used as templates to investigate the formation of porous structures. The incorporation of CaCO$_3$ significantly increased the specific surface area and pore volume, with the porous pectin particles offering interconnected pore networks for penetration and binding. The porous particles had the large specific surface area (171.2 m$^2$ g$^{-1}$), and 114 times compared with non-porous particles prepared without CaCO$_3$ particles (1.5 m$^2$ g$^{-1}$). The study also explored the application of porous pectin particles in protein adsorption using lysozyme as a model protein, providing insights into the adsorption kinetics and isotherm parameters. By comparing the adsorption kinetics of different materials, it was found that increasing CaCO$_3$ concentrations led to enhanced specific surface areas and total pore volumes, thereby promoting protein adsorption capacity. All porous pectin particles performed rapid adsorption and high uptake capacity on lysozyme, in which PPT-C has the highest adsorption capacity of 2621 mg lysozyme/g adsorbent for the same amount of adsorbent particles. The adsorption isotherm analysis confirmed the formation of a monolayer following the Langmuir model.

In summary, this report highlights the synthesis of porous pectin particles using a template-assisted spray drying method with CaCO$_3$ templates. Since this technique is rapid, continuous, reproducible, and one-step, it is attractive both in laboratories and in the industrial setting. Thus, it shows significant promise for developing materials on a large-scale in the future. The porous pectin particles exhibited increased specific surface areas compared to pure pectin particles. Notably, the porous pectin particles utilizing CaCO$_3$ templates displayed excellent lysozyme adsorption capacity, making them promising adsorbents for various applications such as protein and antibodies purification, virus capture, and micro- and nanoplastic recovery from the environment.

1:45 PM SB08.05.02
Unleashing Nature’s Potential: Mycelium-Based Innovation in Bio-Composites Chiara Dogmini and Laura Eleonora Depero; Università degli Studi di Brescia, Italy

Mycelium-based composites are groundbreaking biomaterials that are attracting considerable attention in the European Union and the United States. They have tremendous potential for commercializing sustainable products and offer numerous advantages over traditional materials in industrial sectors like construction, packaging, and textiles. These composites are derived from the vegetative part of fungi, which grows on a substrate, often made from agricultural or other renewable waste materials. They can be utilized in the production of various goods, ranging from furniture to insulation panels and eco-friendly leather, aligning with the principles of the circular economy.

Compared to conventional building materials, mycelium-based composites are more environmentally friendly as their production requires fewer resources and generates less waste and pollution. Moreover, they possess superior technical characteristics and can be molded into different shapes and sizes, opening new design possibilities. These adaptable biomaterials possess physical and mechanical properties that can be customized to meet specific requirements. This unique characteristic holds the potential to make a substantial impact on reducing the construction industry’s carbon footprint, which currently...
contributes to around 40% of the total CO₂ emissions.

Building materials contribute to various forms of pollution during their life cycle, caused by production, transport, installation, use, and disposal procedures. Addressing the pollution associated with building materials requires sustainable practices throughout the construction industry. Developing solutions without exploiting natural resources whilst safeguarding the environment is crucial for the ecological transition and the future of a green building market.

In recent years, microorganisms have been validated as a promising alternative to highly polluting products, such as foam insulation boards, particle boards, packaging materials, concrete, non-structural furniture elements, textiles, automotive and aerospace materials, and even medical applications.

Mycelium-based composites consist of a lightweight material developed by an interwoven three-dimensional filamentous network of hyphae able to bind the feedstock. The use of biomass may have seemed like a utopian concept less than a decade ago, but today, they are gaining increased attention due to their customizable properties achieved through specific cultivation procedures.

Key factors that influence the mechanical behavior of mycelium-based composites include the selection of fungal strains, substrates, and cultivation conditions. Despite the exciting opportunity presented by the development of mycelium-based composites to create sustainable and environmentally friendly materials for the manufacturing industry, their widespread adoption has been limited by the lack of efficient manufacturing processes at the industrial level. The presentation discusses and compares various protocols to standardize an efficient manufacturing process for potential industrial scale-up.

2:00 PM SB08.05.03
Design of Novel Chitosan Nanoparticles for Antimicrobial Applications
Magdalena Hudek, Karina Kubiak-Ossowska, Karen Johnston, Valerie A. Ferro and Paul A. Mulheran; University of Strathclyde, United Kingdom

Chitin and chitosan (de-acetylated chitin) are biopolymers derived mainly from langoustine shell waste and are considered potential candidates for novel antimicrobial applications. Chitosan is soluble in weakly acidic aqueous solutions and is polycationic, which gives rise to its antimicrobial properties. We have employed computational simulations to study the binding of chitosan to two different substrates to design new composite nanoparticles with antimicrobial properties. The model substrates studied are chitin nanocrystals and silica nanoparticles. Chitin nanocrystals are stable, biocompatible and biodegradable, and silica nanoparticles have been used for medical applications for a long time and are readily available. Using fully atomistic molecular dynamics and enhanced sampling methods, we evaluated the binding energies of chitosan to the substrates and studied the dynamics of the adsorption process. We show that the adsorption of chitosan to the chitin nanocrystal surface is driven by dispersion forces and hydrogen bonding, while the adsorption to the silica surface is driven by electrostatics. Furthermore, we have simulated the development of a biopolymer film with the substrates, providing insight into the loading capacity of the nanoparticles and the availability of the chitosan to interact with its environment. Our work therefore shows how computational simulations can be used to guide the design of novel composite materials for antimicrobial applications.

2:15 PM SB08.05.04
Data-Driven Representative Models of Bio-Oils for Atomistic Simulations of Biobased Asphalt Rejuvenators
Daniel J. York¹, Isaac Vidal-Daza²,³, Cristina Segura³, Jose Norambuena-Contreras³ and Francisco Martin-Martinez¹; ¹Swansea University, United Kingdom; ²University of Granada, Spain; ³Universidad de Concepción, Chile; ⁴Universidad del Bío Bío, Chile

A large variety of waste can be transformed into bio-oils and biocrude oils via processing techniques such as pyrolysis and hydrothermal liquefaction (HTL), respectively.¹ These techniques provide a waste valorization route with applications such as the production of biofuel precursors, asphalt additives and other carbon-based materials, which can be derived from plastics, lignocellulosic biomass, chitin, etc. However, there are challenges in the fundamental understanding of the structure-property relationships within these bio-based oils, which are exasperated with difficulty in experimental characterisation of these complex biorefinery-like materials. To address this lack of understanding, the development of molecular models for density functional theory and molecular dynamics (MD) studies is key and has potential to identify applications for oils produced by the pyrolysis or HTL of plastics and bio-based polymers (i.e, shopping bags, food utensils, packaging) at the end of their life cycle. Computational studies have been carried out to elucidate the mechanisms occurring during production of bio-based oils during hydrothermal liquefaction² but there are few of these studies investigating the properties and behaviours of the produced bio-based oils with only one comprehensive atomistic model having currently been developed for algae-derived biocrude³. This model is based on existing models for crude oil and asphaltene⁴,⁵ which are based off years of development and research but are tailored to a specific material. In this work, we present a methodology to generate data-driven representative models from pyrolysis gas-chromatography (py-GC-MS) experimental characterization of any complex organic fluid, e.g., bio-oil, biocrude oil, or asphalt samples by generating a selection of statistically representative models that simplify the complexity of the fluid into a limited group of molecules. A variety of different molecular models have generated using a range of different approaches to evaluate the best method for capturing the key chemical features a complex organic fluid that are required for further computational chemistry calculations and large scale molecular dynamic simulations. These atomistic models are key to understanding and implementing waste valorization routes to sustainable, added-value products with potential to accelerate material development from waste. A computational framework has been developed to automate model creation from py-GC-MS data, which could enable future high-throughput MD simulations; ultimately helping to shape future waste-to-materials strategies.

Subterranean Termites produce a cellulose-based composite called Carton that is used as a construction material during nest formation. Carton is a sponge-like material that consists of bioencrusted fecal matter, soil, and saliva. Despite relatively weak microconstituents, Carton is light, resistant to weathering, and multi-functional, adapting macroscopic composition and architecture according to function. Although the macroscopic features of nests have been evaluated in existing literature, there are few studies on material structure, and those that exist are limited by species, variable and test type. Elucidating the compositional properties of cartons at the microscale may yield learning about interfacial interactions between cellulose polymer and its matrix and solvents for solubilizing cellulose.

Samples of carton from Coptotermes Gestroi were obtained from 4 yr-old laboratory reared colonies. After termite extraction and drying, carton was cut and sectioned according to distinct morphological characteristics, correlated with functional architectural features. These features are referred to in this study as nursery, high-cellulose and high-soil regions. Duplicates of samples were taken from each region and embedded in resin. The embedded media was sanded then polished to prepare for material characterization.

Here we perform imaging, Raman Spectroscopy, and Nanoindentation to determine the underlying structure-function-compositional characteristics of the carton and use that to elucidate design principles for cellulose-based structural composite design. The above-proposed research area remains largely unexplored, and this study represents the first of its kind for biogenic structures produced by subterranean termites.

Peptide Nanowire Coated Jute as Hydrophobic Bio-Based Filter for Oil Water Separation Noah Hans-Deschaing, Jeiko J. Pujols and Ramesh Adhikari; Colgate University, United States

Solutions to oil-water separation have received a great deal of attention recently in an attempt to address the environmental damage of oil spills. However, many of these separation methods are materially expensive, environmentally hazardous, require elaborate fabrication, or rely on large amounts of energy to function. Herein we provide an effective, low-cost, and environmentally sustainable method for oil-water separation based on the hydrophobicity of self-assembling diphenylalanine nanowires grown on jute fabric. This modified jute fabric exhibits high levels of both hydrophobicity and oleophilicity due to the nanoscale surface roughness created by the growth of the self-assembling peptides on the jute fibers. The treated jute fabric also achieves consistent oil separation efficiencies of 98% via filtration and high levels of efficiency in a novel boat method of separation. Due to the high efficiency and low environmental impact of this method, we believe our diphenylalanine treated jute fabric has a promising potential in the field of oil-water separation.

Novel Recyclable Bio-Based Materials and Technologies for Sustainable Biocomposite Applications Katarina Torvinen and Kirsi Immonen; VTT Technical Research Centre of Finland Ltd, Finland

Due to challenges in global climate change and related regulations of EU Green Deal, there is a growing need in markets to have sustainable and low carbon footprint materials and products, which are recyclable and utilize bio-based additives. In this paper, we will present novel results in terms of biocomposite material development as well as manufacturing point of view. In addition, we will discuss possibilities to upscale solutions in different end-use sectors, e.g. automotive, construction and packaging.

An optimization of composition and structure of thermoplastic biocomposites having improved functionalities (e.g. fire resistance) is crucial. We have studied sustainable solutions using PLA (polylactic acid) and cellulose esters, and show characteristics of those composites regarding of density, strength and structural properties. We will also address 3D-printable cellulose-based composite material solution, which can be recycled several times without to deteriorate mechanical properties of it.

We will introduce an innovative up-scalable web-forming manufacturing method to produce thermoplastic composites with raw materials like long fibers (natural and synthetic ones), bio-based polymers and additives. Thermoformed products are lightweight, strong and sustainable. The target is to enable the full reinforcing potential of long fibres in thermoplastic composites for high performance applications. In this paper, the selected applications will be highlighted and discussed.

8:30 AM *SB08.06.01
Trojan Horse PET Counits for Facile Chemical Recycling Eric Cochran, Ting-Han Lee, George Kraus, Dhananjay Dileep, Michael Forrester and Nacu Hernandez; Iowa State University of Science and Technology, United States

In this talk I will review our efforts to develop PET copolymers designed for low-energy chemical recycling. For example, PET copolymers with diethyl 2,5-dihydroxyterephthalate (DHTTE) undergo selective hydrolysis at DHTTE sites, autocatalyzed by neighboring group participation (NGP). Liberated oligomeric subchains further hydrolyze until as manufacturing point of view. In addition, we will discuss possibilities to upscale solutions in different end-use sectors, e.g. automotive, construction and packaging.

Additive Manufacturing of Hybrid Cellulose Fibers Reinforced Polymer Nanocomposites Bivek Bista1, Xianhui Zhao2, Lu Wang1, Douglas Gardner1 and Soydan Ozcan1; 1University of Maine, United States; 2Oak Ridge National Laboratory, United States
Hybrid reinforced polymer composites are materials in which a particular polymer matrix is reinforced with more than one reinforcing materials, or one type of reinforcing material is incorporated into two similar or different polymer matrix mixtures. Hybrid reinforced polymer composites are among multifunctional materials when more than one characteristic benefit (e.g., mechanical strength, conductivity) is needed. In this study, pulp and nanocellulose fibers were used for reinforcing polyactic acid (PLA) because of their relatively low cost, abundance, and biodegradability. The hybrid nanocomposites were produced with nanocellulose loading between 0 and 20 wt% to investigate the effect of fiber loading on the composite tensile performance. The hybrid nanocomposites obtained were characterized using tensile testing, differential scanning calorimetry (DSC), and scanning electron microscopy (SEM). In addition, a demonstration of additive manufacturing (i.e., 3D printing) of hybrid nanocomposites was carried out. Results show that cellulose fibers can provide PLA with a higher tensile performance.

Using Waste Organic Matter from Landfills to Create Lignocellulosic Filler Materials for Biocomposite Plastic Products Roger B. Tipton1,2; 1University of North Carolina at Charlotte, United States; 2Newell Brands, United States

Utilization of waste materials in the production of new materials is a fundamental component of the circular economy. We experimentally evaluated four different levels of upcycled organic trash material as filler material in a polyethylene wastebasket. We found that we could include up to 7% upcycled organic waste material into existing wastebasket designs as a filler before product requirements were out of tolerance. Upcycled trash, at production volumes, can be a usable filler in low concentrations in industrial plastic products which has the potential reduce landfill waste and reduce virgin resin requirements.

Understanding the Fragmentation and Transformation Behavior of Plastics in Marine Environments under the Weathering Effect via Ultrasonication-Assisted Mimicking Kyranatae Park and Jinkee Hong; Yonsei University, Korea (the Republic of)

As the amount of plastic use increases, environmentally exposed plastics rapidly accumulate, with a significant portion eventually ending up in the ocean. The fragmentation of plastics has raised considerable concerns regarding microplastics (MPs) as pollutants and potentially toxic substances to ecosystems and human beings. Previous research has highlighted the threat of fragmentation and surface changes caused by eco-corona or weathering, which can result in severe damage to human beings.

Despite the importance of understanding plastic fragmentation, the influence of weathering and the prediction of fragmentation behavior have not been thoroughly investigated. Therefore, it is important to establish an analytical model that can simulate the behavior of environmentally weathered plastics and their transformation. In this study, we focused on the ocean environment, which is considered the ultimate destination for discarded plastics, as our target environment. Our aim is to conduct a comprehensive study on the effects of weathering and the potential threats posed by weathered plastics.

To understand the weathering effect in marine environments, we employed focused ultrasonic irradiation. As the cavitation and collapse process repeated during ultrasonic irradiation, sonooluminescence emitted ultraviolet (UV) energy to the microplastics. We analyzed the morphological and functional group changes on the surface of particles, comparing manufactured plastic with fragmented nano plastics. Our results showed an oxidation process occurring around the microplastics' surfaces, which we detected through FT-IR and XPS analysis. By comparing the oxidation rate of ultrasound-irradiated microplastics with aged microplastics, we aimed to establish an analytical model for mimicking weathered plastics in marine environments.

While increasing research has highlighted the toxicity of microplastics to the human body, the potential toxicity of naturally fragmented and weathered nano plastics has not been clearly investigated. However, microplastics can transform into nano plastics and undergo changes in surface characteristics due to external physical and biological stresses in the ocean. In this study, we focused on manufactured polyethylene plastic particles and used ultrasound to simulate the natural fragmentation of nano plastic particles caused by weathering in the ocean. We examined the potential threats posed by fragmented nano plastic particles to the human body through immune-cytokine analysis, cytotoxicity tests, and co-culture with human umbilical vein endothelial cells. Our study implemented naturally transformed nano plastics through weathering and evaluated their potential toxicity.

Bioinspired Biomaterial Composite for All-Water-Based High-Performance Adhesives Marco Lo Presti1, Nicholas Ostrovsky-Snider1, Giorgio Rizzo2, Davide Blasi2, Marina Portoghese2, Gianluca Maria Farinola2 and Fiorenzo Omenetto1; 1Tufts University, United States; 2Università degli Studi di Bart Aldo Moro, Italy

Nature has ingeniously developed adaptable adhesive materials by utilizing versatile chemistry centered around two fundamental components: catechols and polypeptides. This chemistry enables adhesive processes even in underwater environments using water-soluble biological substances, presenting a technological challenge that current synthetic adhesives are unable to meet. In this study, we present a bioinspired adhesive composite that aims to integrate the adhesive mechanisms observed in mussels and barnacles. The composite formulation comprises silk, polydopamine, and Fe3+ ions, all derived from organic and non-toxic sources in a water-based medium. By combining the adhesive properties exhibited by Mytilus sp. (mussels) and Cirripedia sp. (barnacles), which rely on proteinaceous filaments and proteic cement, respectively, the composite demonstrates remarkable adhesion capabilities in both dry and wet conditions. In lap-shear tests, it outperforms synthetic commercial glues and other adhesives based on natural polymers, rivaling the effectiveness of leading underwater adhesives. It is worth noting that the composite is entirely biologically sourced, eliminating the necessity for synthetic processes. Moreover, the adhesive production method can be extended to utilize proteins beyond silk by fine-tuning the tyrosine-catechol molar ratio to optimize bonding strength. These findings present a cost-effective and sustainable approach that leverages easily accessible raw materials to develop high-performance adhesives suitable for underwater applications.

10:30 AM SB08.06.08
Scalable Synthesis of Biodegradable Polymers Based on Interfacial Polymerization Cecile Chazot and Sara E. Johnson; Northwestern University, United States

Biodegradable polymers have gained increasing attention as environmentally friendly alternatives to polyolefins, due to their attractive mechanical properties and thermal processability through thermoforming and melt processing. State-of-the-art synthetic routes for aliphatic and aliphatic-aromatic polymers employ reaction conditions that are not conducive to industrial scale production, such as inert gas environments, high reaction temperatures, long reaction times, and applied vacuum. These complex reaction conditions are a result of oxidation and slow reaction rates due to limited functional group reactivity of the monomers. Here we discuss the development of an open-air, room temperature and scalable synthesis of polymers based on interfacial polymerization (IP). We investigate the suitability of environmentally friendly solvents and solvent blends in inducing simultaneous fast polycondensation and polymer precipitation in IP and characterize how reaction conditions depend on the backbone chemistry of the synthesized polymers. This IP route has the potential to enable large-scale production of biodegradable polymers for applications in consumer products such as packaging and textiles.

Hybrid Polyactic Acid (PLA) Composites: Impact of Varying the Cellulose Material (CM) Source  
Amber M. Hubbard, Katherine E. Copenhaver, Caitlyn Clarkson, Meghan Lamm and Soydan Ozcan; Oak Ridge National Laboratory, United States

Thermoplastic composites are of significant interest in a variety of industries ranging from automotive to construction as they present a recyclable, low-cost, and lightweight alternative material without sacrificing performance. Additionally, hybrid composites which contain more than one type of reinforcement (e.g., natural fibers and cellulose materials (CM)) have gained increasing attention where target properties are enhanced via composite formulations. Herein, three different fibers (i.e., creafill, flax, and wheat straw) are mixed with three different CM and incorporated into polyactic acid (PLA) via melt compounding. PLA was chosen as the matrix material for all hybrid composites due to its industrial compostability and its demonstrated applicability in 3D printing. The mechanical and thermomechanical properties of the resulting thermoplastic, hybrid composites are reported where the composite strength and modulus exhibit marked increases compared to the non-hybrid composites. In addition, by matching the fiber and CM, the material demonstrates further improvements; the mechanism for property enhancement is explored as a function of CM. Finally, these hybrid composites are formulated and targeted for automotive and tooling applications.

Renewable Fiber-Based Prepregs for Composite Laminates  
Vikram Yadama, Avishek Chanda, Muhammad Bakri and Lloyd Smith; Washington State University, United States

Forming bio-based materials into complex three dimensional shapes can be enhanced using a “prepreg” like material. Adapting bio-based materials into material forms that have successfully been used with synthetic composites allows downstream manufacturing of compression molded panels for a variety of higher value applications. This presentation will discuss the development of a natural fiber prepreg for a variety of applications including automotive interior and exterior panels. Wood strands produced from small diameter trees were stitched to make a preform, which was then injected with a liquid thermoplastic resin, Elium® (produced by Arkema), using a vacuum assisted resin transfer molding (VARTM) technique. The outcome was a thin and flexible thermoplastic wood prepreg with an average thickness of 0.017-in.

Lumens of wood strands were completely filled with the thermoplastic resin resulting in 38% and 124% higher Young’s modulus and strength, respectively, of the saturated wood strands compared to wood strands prior to being infused with resin. A temperature and pressure for the thermoforming process were determined, and these thin and flexible thermoplastic wood-strand prepregs were then laminated by compression molding into panels that are flat or profiled with three-dimensional cross-sections. Compared to wood-strand panels produced using compression resin transfer molding (CRTM) and epoxy resin, Young’s modulus and strength of a flat laminate, made of 12 layers of wood prepreg, were 73% and 20% higher, respectively. Prepreg laminates are resistant to moisture uptake and are dimensionally stable as reflected in the water absorption and thickness swelling results. The ability to recycle these thermoplastic composites reinforced with renewable fibers at the end of their service life fits within the circular economy model.

These new applications and opportunities for wood strands would also contribute to sustainable forest management.

2:00 PM SB08.07.02  
Economic and Environmental Viability of Mixed Polyester Chemical Recycling for a Circular and Sustainable Plastic Economy  
Taylor Uekert, Jason DesVeaux and Katrina Knauer; National Renewable Energy Laboratory, United States

Biodegradable polyesters offer an attractive solution to the plastic pollution problem, as they can biodegrade in composting facilities and specific natural environments. However, these valuable materials should ideally be kept in circulation rather than permitted to degrade. While biodegradable plastics subjected to mechanical recycling often exhibit sub-optimal properties, chemical recycling techniques could potentially retain quality while keeping these materials in a circular economy. Here, we conduct a comprehensive techno-economic analysis and life cycle assessment of three chemical recycling methods: methanolysis, glycolysis, and acid hydrolysis. Our analysis focuses on mixed polyester feedstocks containing polyactic acid (PLA), polybutylene adipate terephthalate (PBAT), and polyethylene terephthalate (PET). We demonstrate that methanolysis economically and environmentally outperforms the other chemical recycling strategies as well as virgin manufacturing of the assessed polymers. The costs and life cycle impacts of methanolysis also tend to decrease with increasing biodegradable polyester content, indicating the suitability of this technology for emerging plastic materials. We conclude by highlighting the challenges and opportunities facing chemical recycling of mixed polyesters and its role in a more sustainable, circular, and pollution-free plastics system.

2:30 PM SB08.07.04  
Surface Functionalized Approaches of Dry Mycelium Membranes for Enhanced Lead Removal  
Mruganka Parasnis, Yu Fu, Erda Deng, Fei Yao, Haiqing Lin and Prathima Nalam; University at Buffalo, The State University of New York, New York, United States

Mycelium hyphae are biomannfactured to grow into 3-dimensional porous networks, which presents a promise for developing sustainable filtration membranes. The hyphal surface is decorated with various biomacromolecules and enzymes that facilitate the remediation of toxic contaminants from the surrounding environments. In this study, we explore various approaches to enhance the filtration efficacy of membranes for lead removal by surface functionalization of dried mycelium hyphae. Firstly, we aim to present the biosorption capacity of untreated, dry mycelium membranes as a function of environmental parameters such as lead concentration, pH, and the duration of Pb(II) exposure to mycelium. A thermodynamic investigation for lead adsorption is conducted to estimate the adsorption capacities and the kinetic rate constants of Pb(II) adsorption onto the mycelium network. Secondly, hyphal surfaces’ surface-functionalization using phosphate is explored to remediate lead via pH-dependent biomimneralization pathways. Stable lead-based salt crystals formed at the hyphal cell wall (biomineralization), synergistically assisted with the biosorption of lead ions, especially at high lead concentrations (1500 ppm), showed 42% enhancement in lead remediation efficiency compared to sole biosorption. Moreover, crossflow filtration demonstrated a 90% removal of Pb(II) within 30 minutes of filtration, offering the potential for permeate reuse and metal recovery from the retentate.

Lastly, we achieve the uniform functionalization of the hyphal surface in the mycelium network through electrochemical deposition using low-dimensional
layered MXene structures. This innovative approach amplifies the surface-to-volume functional area and permeability of filtrate via mycelium membrane. The preliminary results show an 83% increase in the kinetic rate of Pb(II) removal for the hybrid membrane compared to the unfunctionalized mycelium membrane. Ongoing studies aim to determine the mechanisms underpinning Pb(II) adsorption within the hybrid membrane. Harnessing the intrinsic chemical functionalities of mycelium hyphae presents a promising approach for advancing mycelium-based biomaterials. This research explores novel, sustainable alternatives to synthetic microporous filter membranes exhibiting comparable or higher remediation efficiencies.

Keywords: mycelium membrane, biomineralization, biosorption, MXene

Functional Polyurathane Foams with Sustainable Micro- and Nanoscale Reinforcing Agents Zeynep Işıl gündoeğdu, Adana Science and Technology University, Turkey

Incorporating additives and structural fillers into polyurethane foams can provide improved mechanical, thermal, electrical properties to create higher performance components made from such nanoscale and can provide improved noise vibration harshness (NVH) and antimicrobial properties. This study explores the effect of adding micro and nanoscale fillers (nanocellulose, biocarbon, graphite, etc.) from sustainable sources as reinforcing agent on thermal stability and mechanical, physical, and sound absorption and antimicrobial properties of flexible polyurethane foam. The incorporation of sustainable micro-and nanoscale reinforcing agents increased the compression modulus and Young's Modulus significantly compared to the control. The addition of reinforcing agents at low concentration (less than 0.25wt.%) showed improvement in sound absorption of plane waves at low frequency range. Minimum inhibitory concentration values were determined by the lowest concentration of the graphite that inhibits the growth of microorganisms. Adding sustainable micro and nanoscale reinforcing agents from the natural sources or recycling products into polyurethane foam reduced waste to landfill and created a superior foam product. This presentation also exemplifies the benefits of creating a closed-loop plastic industry to improve polymer materials and protect the mother earth

Sustainable Manufacturing of Acrylonitrile Liesl Schindler; Trillium Renewable Chemicals, United States

Trillium Renewable Chemicals is scaling a two-step thermochemical process that converts a biobased feedstock (glycerol) into valuable chemicals (acrylonitrile and acetonitrile). Acrylonitrile (ACN) is used to manufacture a wide-range of materials (e.g., acrylonitrile-butadiene-styrene (ABS) plastic, carbon fiber, acrylic fiber, nitrile butadiene rubber (NBR), acrylamide, specialty amines) with a wide range of end uses including aerospace, automotive, apparel, toys, energy, personal care products, pharmaceuticals, consumer electronics, and wastewater treatment. The presentation will focus on the progress toward the ultimate goal: de-risking Trillium’s bio-ACN™ technology for commercialization while achieving stretch targets for sustainability through a combination of low carbon raw materials and innovative process intensification concepts as well as meeting unit cost economics at parity or below the incumbent process to produce acrylonitrile.

11:00 AM SB08.08.02
Industry–Academic Partnerships: Valorizing Lignin Through De-Aromatization and COOH Functionalization Mitra Ganewatta1, Qi Wang1, Thomas Sisson1, Mariola Beresmiewicz-Kopcinski1, Daniella Martinez2, Jay Salinas2, Michael Kent2, JiHyuan Hwang2 and Chunbing Tang3; Ingevity Corporation, United States; 1Sandia National Laboratories, United States; 2University of South Carolina, United States

Lignin is a valuable biomass feedstock that has the potential to produce advanced chemicals and materials. Lignin comprises 15-30% of lignocellulosic biomass and is mostly burned for its heating value within the paper pulping industry. Generating greater value out of this renewable and abundant material is critical for the establishment of a sustainable bioeconomy. We report an industry-academic partnership established to develop high-performance polymeric products from lignin. A near-room temperature aqueous oxidative process was developed to open the aromatic rings within the lignin structure and resulting in carboxylic acid-functionalized lignins. These lignin polyacid materials were evaluated as commercial agricultural dispersants, micronutrient complexation agents, or water-absorbent materials.

11:30 AM SB08.08.04
Lignin/PBS Filaments for 3D Fused Deposition Modeling of Medical Orthoses Adnan Memic; King AbdulAziz University, Saudi Arabia

There is a technological need for materials with improved functionalities to propel new biomedical applications. Some of the outstanding challenges could be solved using three dimensional (3D) printing. However, there is a pressing need for new generation of biomaterials that have unique properties. Combining nanomaterials with bio-based and synthetic polymers could yield biomaterials with improved properties. We developed filaments using bio-based waste polymer (lignin) and synthetic polymer (polybutylene succinate (PBS)). Next we coated these scaffolds that could provide antioxidant and antifouling properties while improving the rheological and physical properties of the composites filaments and easy of extrusion and 3D printing. Taken together these nanocoated filaments could propel several biomedical applications including aiding design of medical orthoses and bracing materials.

11:45 AM SB08.08.05
Mussel Byssus as a Green Fiber Manufacturing Platform David U. Zamora Cisneros, Alejandro D. Rey, Noemie-Manuelle Dorval Courchesne and Matthew J. Harrington; McGill University, Canada

Biological materials and Nature’s manufacturing processes offer inspiration to move towards more green manufacturing of structural and functional materials. Functionality in Natures’ materials is strongly correlated with structure, such as chirality, orientation, and layering. In this Ph D. thesis, I will focus on the mussel byssus, a thread fabricated by marine mussels from a pretransition liquid crystal organization within vesicles, which offers rich store principles and mechanisms to create green tough functional materials and composites used to remain attached to surfaces under continuous flowing states. The material organization of the mussel byssus precursor is a smectic liquid layered semisolid with oriented elements between layers.

This work is divided into three sequential stages: (i) thermodynamic-geometric modeling to ascertain the energy landscape and the stable, unstable, and
metastable states of this material under changing thermodynamic driving forces, (ii) colloidal organization including the shape, size, and structural organization to attain for the vesicle-vesicle interactions during the transitional state, and (iii) fiber formation under flow conditions. In this work, I will focus on the progress so far in the area of thermodynamic-geometric model and will shed light on how geometric tools are powerful and useful to detect, control, and optimize equilibrium states of smectic liquid crystals, their organization, and thus, its application for the tuning of material properties.

In particular, we use level set lines of steepest decent, bifurcation methods, lines of curvature and geodesic to provide a multidimensional view of the evolution of stable, unstable states that appear when decreasing the phase transition parameter, here taken as temperature. Overall, it is found that the emergence of smectic order favors the increase of the orientational alignment, yielding in the enhancement of the elasticity modulus of the solid state. Understanding the evolution and behavior of the hierarchical organization will provide a pathway for the development of green engineering principles, storage technologies, biocompatible materials such as tissue scaffolds, and advances in the processing of such materials involving scalable biomedical and technical applications like extrusion molding, and injection molding to address crucial public health and environmental concerns.

11:50 AM 5SB08.08.06
Feasibility of Hot-Melt Extrusion of Simvastatin-Based Amorphous Solid Dispersions with PVP-VA and HPMC-AS
Charima Lampai1, Scott Smith2, Xiaoling Li3 and Bhuskara Jasti1; 1University of the Pacific, United States; 2Gilead Sciences, United States

Purpose:
Poor aqueous solubility is among the primary causes of low or variable oral bioavailability in pharmaceutical development, with ~45% of new drugs considered very slightly soluble or practically insoluble. Preparation of amorphous solid dispersions (ASDs) is one approach to address the challenge. An ASD is composed of an amorphous drug stabilized in a polymeric excipient matrix. Amorphous forms have higher free energy and thus, higher aqueous solubility and/or faster dissolution compared to crystalline forms. However, their thermodynamic instability means it has a propensity to degrade or crystallize during processing and storage. Hot-melt extrusion (HME) is an emerging technology for ASDs due to its advantages as a scalable and efficient process. It is also attractive due to its sustainability as it does not require the use of solvents as other manufacturing practices like spray-drying. Key challenges with HME are poor physical stability of the amorphous drug and thermal degradation during processing. Simvastatin (SIM), which belongs to an important class of lipid-lowering drugs, was selected as a model drug. Poly(vinylpyrrolidone) vinyl acetate (PVP-VA), a neutral, aprotic polymer, and hydroxypropyl methylcellulose acetate succinate (HPMC-AS), an anionic, protic polymer were selected as the excipients. The objective of this study is to prepare and characterize HME ASDs with varying SIM/polymer ratios.

Methods:
ASD Preparation. ASDs of SIM/PVP-VA and SIM/HPMC-AS were prepared at varying ratios of 0/100, 25/75, 50/50, 75/25, 100/0 % w/w SIM/polymer using twin-screw hot melt extrusion. Physical blends of SIM and polymer were prepared by a 1-min trituration, followed by a 10-min blending step. Each blend was fed into the hot-melt extruder with a thin-slit die at 150°C. The extrudate was collected and milled to a powder using a tube mill at 15,000 RPM for 1 min.

Physical form characterization. The physical form of the ASDs in the SIM was identified using powder X-ray diffraction (PXRD). Samples were scanned in reflection mode over a 2.0000 – 39.9990 °2θ range with a Cu Kα1 radiation source and a detector at 45 kV and 40 mA. Step size was 0.0131 °2θ and scan rate was 0.08 sec/step. Modulated differential scanning calorimetry (mDSC) was used to determine the glass transition temperature Tg, with a nitrogen purge flow of 50 mL/min and a 3°C/min ramp rate and a modulation cycle of ±1°C every 60 sec.

Water content. Thermogravimetric analysis (TGA) was performed on the ASDs, with a nitrogen purge flow of 50 mL/min and a 10°C/min ramp rate from 25°C to 150°C. Weight loss was attributed to water content.

Chemical purity. Chemical purity was evaluated using ultra performance liquid chromatography (UPLC). A gradient method using water with 0.1% trifluoroacetic acid (TFA) and acetonitrile with 0.1% TFA was employed for separation, and the chromatogram at 236 nm was used for analysis.

Results
This study determined the suitability of preparing SIM/polymer ASDs with HME. All extrudates passed through the extruder with a residence time of 5-10 minutes. Subsequent milling of the ribbons yielded free-flowing powders that can be used for further processing. All ASDs demonstrated the amorphous nature of the drug, indicated by an amorphous halo using PXRD. A single glass transition temperature was observed, indicating a homogenous solid solution. The composite Tg of the ASDs decreased as the SIM-loading was increased. Weight loss by TGA was relatively low across all ASDs, indicating moisture content ranging from 0.3% to 3.8%. Thermal degradation was minimal, with purity >97% across all ASDs relative to starting SIM purity, although purity seemed slightly higher with PVP-VA.

Conclusions
ASDs of simvastatin/PVP-VA and simvastatin/HPMC-AS were successfully prepared by hot melt extrusion. Simvastatin was demonstrated to be in an amorphous form with both polymeric excipients, and exhibited good chemical stability during the hot melt extrusion process.

11:55 AM 5SB08.08.07
Naturally Derived Photoluminescent Composite Inks for Advanced Applications
Daniela Correia1, Bárbara Cruz1,3,1, Rita Policía1, Nelson Pereira1, Paulo Nunes2, Mariana Fernandes2, Carmen R. Tubio1, Gabriela Botelho1, Veronica de Zea-Bermudez2,4 and Senentxu Lanceros-Mendez3,5; 1University of Minho, Portugal; 2University of Trás-os-Montes e Alto Douro, Portugal; 3Basque Center on Materials, Applications and Nanostructures, Spain; 4University of Trás-os-Montes e Alto Douro, Portugal; 5Ikerbasque, Basque Foundation for Science, Spain

Naturally derived polymers have been increasingly explored by different fields of knowledge to be applied in different areas. The high interest devoted to natural polymers mainly relies on their natural abundance, unique properties, and sustainability attributes. The interesting advantages of this type of polymer allow the development of smart and multifunctional materials with a strong potential for sensors and actuators, biomedicine, and environmental remediation applications [1], among others. Particularly, photoluminescent materials are of high interest for sensors in anti-counterfeiting systems and actuators [2]. This type of material can be obtained by incorporating different luminescent compounds, such as rare-earth elements, quantum dots, fluorescent compounds, and inorganic phosphors. Lanthanide ions (Ln3+), have gained a special interest in recent times due to their fine emission bands, wide diversity of colours, large pseudo-Stokes shifts, and difficult replication of the fingerprint emission profiles [3].

The present work presents the development of photoluminescent materials based on the natural polymer sodium alginate (SA), a linear polysaccharide derivative of alginic acid comprised of 1,4-β-d-mannuronic (M) and α-l-guluronic (G) acids [1], incorporating different contents of the compounds sodium tetra(2-thienyltrifluoroacetonate) europate (III) [Na(Eu(tta))3] (5, 10 and 20% wt.) and 1-butyl-3-methylimidazolium tetra(2-thienyltrifluoroacetonate) europate (III) [Bmm][Eu(tta)]2 (20% wt.) have been developed by a solvent casting method [4]. The influence of both compounds in the morphology of all the developed materials was evaluated by SEM and their physical-chemical properties by FTIR-ATR and DSC analysis. Independently of the luminescent compound, a non-porous material was obtained, however, a surface roughness increase was observed. Both Na[Eu(tta)]3 and [Bmm][Eu(tta)]2 induce a thermal stability behavior on SA and an improvement of the mechanical properties.
The highest luminescence was observed for SA/[Bmim][Eu(tta)₄] films, exhibiting an intense red/orange emission when irradiated with ultraviolet (UV) light at 388 nm, and in this context a strong potential to be applied in anticounterfeiting applications. The developed materials are also suitable to be applied as electromechanical actuators.

Silk Proteins as Functional Biomaterials for Regenerative Medicine  
David L. Kaplan; Tufts University, United States

Biomaterials that provide versatility in terms of control of structure, chemistry, morphology, mechanics, degradation lifetime, and material form factor, while biocompatible, are useful in meeting regenerative medicine goals. Silk, as one of the oldest biomaterials utilized as sutures for centuries, is undergoing a rebirth into new biomaterial formats and applications for regenerative engineering for the medical field. Key to this emergence has been fundamental insight into mechanisms of self-assembly and control or tunability of material features achievable with silk. As a unique, high molecular weight, amphiphilic protein, new modes to modify the native protein using processing methods, chemistries and bioengineering approaches are emerging from the laboratory. Some of these recent strategies will be discussed related to fundamental aspects of controlling biomaterial structure and function, leading to new silk-based biomaterials for regenerative medicine.

9:00 AM SB09.01.02  
Unconventional Biomaterials for Regenerative Engineering  
Gulden Camci-Unal; University of Massachusetts Lowell, United States

Across different areas of regenerative engineering, there are limitations with controlling cell adhesion, viability, growth, differentiation, biocompatibility. Conversion of simple and abundant items to advanced cell culture substrates addresses some of the limitations in regenerative engineering. Departure from complex fabrication processes to the applications of unusual materials provides another dimension to the engineering of viable multifunctional tissue constructs and regenerative can increase access to regenerative engineering technologies on a global scale. In this work, we used unconventional biomaterials such as eggshells and paper for tissue regeneration.

We fabricated eggshell micro/nanoparticle (ESP) reinforced protein-based scaffolds to produce mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells into osteoblasts. The ESP-reinforced constructs were then implanted in a rat model to determine their biocompatibility and degradation behaviors. In addition, these composite scaffolds were used to regenerate critical sized cranial defects in a rat model. We also used mineralized paper scaffolds with hydrogels through an origami-inspired approach to test their osteoinductivity and potential for tissue repair in *in vitro* and *in vivo* studies.²,³

The ESP-reinforced scaffolds enabled the differentiation of stem cells into osteogenic lineage. The constructs showed significant enhancement in mineralization by the cells. The ESP composites demonstrated superior mechanical properties and showed favorable *in vivo* responses by subcutaneous implantation in a rat model. The scaffolds were responsive to cells and did not elicit inflammatory responses *in vivo*. The implants were easily accepted by...
The tensile modulus of the scaffolds increased significantly after the mineralization process. Gene expression results for the osteogenic differentiation markers revealed the osteoinductivity of the mineralized paper scaffolds. Subcutaneous implantation of the samples in rats demonstrated biocompatibility, vascularization, and integration in vivo.

Unconventional scaffolds that are readily available and adapted from nature demonstrated biomimetic characteristics including porosity, structure, and bioactivity resulting in physiologically relevant constructs. The use of existing naturally derived materials in combination with hydrogels for regenerative engineering provides an inexpensive and sustainable approach that benefits the economy and environment while providing unique solutions to unmet clinical needs. Many of the unconventional biomaterials are overlooked and under-studied for biomedical applications, partly for their simplicity as mundane items.

Development of Tissue-Safe, Shape Memory Polymer Scaffolds
Courtney Roberts, Sarah K. Beck, Caitlyn M. Prejean and Melissa Grunlan, Texas AM University, United States

Thermoresponsive shape memory polymers (SMPs) were developed as self-fitting scaffolds to heal cranial bone defects. Exposure to temperatures above the melt transition temperature (Tm) causes scaffolds to undergo shape recovery, driving its expansion to the tissue perimeter for improved osseointegration and healing. SMP scaffolds were originally prepared from semi-crystalline, biodegradable linear poly(ε-caprolactone)-diacrylate (PCL-DA; 10k g mol⁻¹). However, a major limitation of scaffolds based on linear-PCL-DA is a Tm of ~55 °C. Such a scaffold could be submerged into saline at this temperature and pressed into a bone defect for self-fitting. However, to extend the working time, post-implantation irrigation with ~55 °C saline would induce thermal damage to the surrounding tissues. Ideally, a SMP self-fitting bone scaffold would have a reduced Tm, but still be ~37 °C in order to ultimately return to its rigid state for mechanical support. Other devices prepared from SMP scaffolds could also be envisioned if the Tm was reduced to ~37 °C, affording shape recovery (expansion) upon implantation. For instance, this would enable the development upon implanting gynecological stents. Thus, in this work, a Tm of ~39 - 45 °C (bone scaffolds) and ~37 °C (stents) was targeted for tissue safety and functionality. We sought to lower the Tm of PCL by altering the architecture, creating star-PCL-tetracrylate (star-PCL-TA), and by also decreasing molecular weight (Mₙ). This yielded scaffolds with Tm of ~45 °C (10k g mol⁻¹), ~40 °C (7.5k g mol⁻¹), and ~29 °C (5k g mol⁻¹). Owing to reduced crystallinity, scaffolds based on star-PCL-TA degraded faster than linear-PCL-DA of the same Mₙ and also exhibited decreased compressive moduli. Scaffold degradation rates increased as the Mₙ of star-PCL-TA was decreased. Overall, by altering the architecture of the PCL macromer from a linear to a star architecture and reducing the Mₙ, more tissue-safe SMP scaffolds were created. Specifically, scaffolds with Tm values ideal for self-fitting bone scaffolds and self-expanding stents were obtained.

Cancer in bone presents a formidable challenge, particularly for terminally ill patients. Addressing this issue, our research focuses on the development of a pipeline for ultra-high-resolution 3D printed metamaterial-based bone replacements. Unlike traditional implants or conventional 3D printed bone scaffolds, our approach aims to improve patients' quality of life during end-of-life care by offering bio-compatible, bioinert implants with sophisticated functionality that closely match the mechanical behaviour of native bone. The challenge arises in meeting the custom requirements of patient specific implants such as size, shape and native mechanical properties, along with the fabrication technology required to 3D print them.

The presentation introduces the fabrication process and material for a Metamaterial implant, where the mechanical properties are not derived from the properties of the base material but from its smartly designed architecture. The chosen technology is vat-polymerisation 3D printing which offers the opportunity to produce complex, multiscale, geometries from a suitable bio-compatible material at the required specifications. The final implant will be a computationally derived hierarchical lattice with an intricate multiscale structure. It will need to span several orders of length scale (cm > mm > μm) to create the desired properties. However, commercially available 3D printers face limitations with delivering the required high-resolution and small build size print specifications for such designs. These limitations stem from resolution constraints, curing inconsistencies, and challenges in balancing speed and precision. Therefore, a challenge remains in the development of a printer capable of producing bio-compatible photopolymer objects with the desired feature resolution at the required build size.

To overcome the limitations faced by commercial 3D printers at the macro scale, we developed an in-house projection micro-stereolithography (Pµ-SL) 3D printer capable of achieving ultra-high resolutions. This achievement is essential for fabricating implants with intricate designs that exhibit metamaterial properties at resolutions of 1-5 μm. Further, we successfully developed a photoresin suitable for 3D printing our desired implants. An integral challenge lies in formulating a bio-compatible photoresin that can achieve the desired feature resolution when printing at small build volumes. This was achieved by optimising photoresin chemistry, rheological properties, and light penetration depth. Ultimately, a base formulation suited for ultra-high-resolution 3D printing was produced and iteratively tailored to meet the application requirements. Our study identifies a range of photoactive monomers and cross-linkers that demonstrate bio-compatibility and compatibility with sterilization protocols.

In conclusion, our work focuses on developing an in-house Pµ-SL 3D printer and compatible ultra-high-resolution photoresin to address the micro-to-macro scale challenge in 3D printing. Achieving close to 1μm print resolutions, our printer enables the fabrication of novel implant bone replacements. Leveraging metamaterial design and computational frameworks, we aim to produce bio-compatible implants emulating native bone properties, advancing additive manufacturing for patient-specific solutions and improving quality of life for individuals with bone cancer.

Over one million surgical procedures are performed each year to treat bone defects with an associated medical cost over 5 billion dollars. Current procedures are fraught with problems that limit clinical success from fixation challenges in osteoporotic bone to replicating form factor in

Polymer Strategies in Musculoskeletal Tissue Engineering
Elizabeth Cosgriff-Hernandez, The University of Texas at Austin, United States
Injectable Colloidal Hydrogels of N-Vinylformamide Microgels Dispersed in Covalently Interlinked pH-Responsive Methacrylic Acid-Based Microgels  
Brian Saunders; University of Manchester, United Kingdom

Injectable hydrogels offer great potential to augment damaged or degenerated soft tissue. A key criterion for such gels is that their modulus is as close as possible to that of the target tissue. The majority of synthetic hydrogels have used low molecular weight polymer chains which may cause problems if they diffuse away from the injection site and/or increase the local osmotic pressure. We previously introduced a different approach of injecting preformed ultra-high molecular weight pH-responsive microgels (MGs) that interlink to form hydrogels. MGs are crosslinked polymer colloid particles that swell when the pH approaches the particle pKa. These colloidal hydrogels are termed doubly crosslinked microgels (DX MGs). The gel moduli of previous DX MGs were much greater than that reported for human nucleus pulposus (NP) tissue of the spinal intervertebral disk. Here, we replace some of the pH-responsive poly(ethylacrylate-co-methacrylic acid) (PEA-MAA) MGs with hydrophilic non-ionic MGs based on poly(N-vinylformamide) (NVF). We investigate the morphology and mechanical properties of these new injectable DX MG composite gels and show that the mechanical properties can be tuned by systematically varying the NVF MG content. Using this approach, gel moduli close to that for NP tissue are achieved. These injectable new pH-responsive gels exhibit low cytotoxicity. Our work provides a potential new system for minimally-invasive intervertebral disk augmentation.

Regenerative Engineering Through Biomaterial Design  
Brendan A. Harley; University of Illinois-Urban-Champ, United States

Advances in the field regenerative medicine require biomaterials that instruct, rather than simply permit, a desired cellular response. A major contemporary motivator in biomaterial design is the complex organization of the tissues in our bodies, which are hierarchical, vary in space and time, and can differ person-to-person. However, the future success of regenerative medicine requires more deeply considering aspects of human variation and heterogeneity. For example, considering the role of sex-specific differences in tissue engineering technologies motivates innovative lines of investigation that will become central dogma in the future.

Defects in craniofacial bones of the skull occur congenitally, after high-energy impacts, and during the course of treatment for stroke and cancer. They affect a broad segment of the US population, are large and irregularly shaped, and heal poorly. Contemporary tissue engineering efforts that combine exogenous mesenchymal stem cells (MSCs), morphogens, and biomaterials face challenges due to the cost and time for in vitro MSC expansion and MSC-biomaterial culture as well as the need for supraphysiological morphogen doses. We are developing porous biomaterials that can be shaped precisely and quickly like an alloplastic implant but that work in a regenerative fashion like autologous bone. Specifically, I will describe a class of mineralized collagen scaffold that promotes MSC recruitment and osteogenicity in the absence of osteogenic supplements. We have refined these materials to study MSC-macrophage crosstalk and to promote MSC-osteoprogenitors to secrete osteoprotegerin, a soluble glycoprotein and endogenous inhibitor of osteoclast activity. We showed polymeric meshes can be integrated into the scaffold, a la rebar in concrete, to create composites that can be shaped intraoperatively to aid surgical-practicality and accelerate regeneration. I will also describe scaffold processing approaches to create spatially-graded collagen biomaterials that direct MSC differentiation down multiple musculoskeletal lineages in a spatially-selective manner, along with methods to develop continuous hydrogel zones that link dissimilar musculoskeleton tissue zones (e.g., tendon and bone) to provide mechanical and trophic advantages to accelerate regenerative healing. I will conclude by describing recent efforts to address barriers preventing regeneration, notably the role of sex-differences in regenerative activity. These initiatives demonstrate that understanding sex-specific differences in cell activity is essential in the design of biomaterial system to improve regenerative potential as well as to study disease progression and therapy.

Injectable and Biodegradable Piezoelectric Hydrogel for Medical Applications  
Thanh D. Nguyen and Tra Vinikoor; University of Connecticut, United States

Osteoarthritis (OA), a painful joint disease manifested by cartilage damage, affects 654 million people worldwide every year. Currently, there is no cure for OA; available medicines only alleviate the disease symptoms (e.g. pain and inflammation) while surgical approaches including the use of replacement auto- or allo- graft cartilage suffer from the problems of donor-site morbidity, infection, immune-rejection, and especially, limited tissue supply. Herein, we present a novel injectable and biodegradable piezoelectric hydrogel with ultrasound (US) activation to offer a minimally invasive regenerative engineering approach for OA treatment. The piezoelectric hydrogel can be injected into the joints and self-produce localized electrical cues under US activation to drive cartilage healing. In vitro data shows the hydrogel with US activation attracts host cells, enhances cell migration, and induces stem cells to secrete endogenous growth factors like TGF-β1 which facilitates COL2A1, ACAN, and SOX9 expression to promote chondrogenesis and extracellular matrix (ECM) deposition. Significantly, the piezoelectric hydrogel enables the healing of hyaline cartilage in rabbits with critical size osteochondral defects. After two months of the piezoelectric hydrogel and US treatment, the animals had more subchondral bone formation, well-organized hyaline cartilage structure, and improved mechanical properties, close to those of healthy native cartilages and superior to the other control/sham groups either without US activation or piezoelectricity. This injectable piezoelectric hydrogel is not only applicable for cartilage healing but potentially other tissue regeneration and could serve as a minimally-invasive material platform for important medical devices such as injectable piezoelectric pressure sensors, actuators, energy-harvesters, and transducers, thus offering a significant impact on medicine.
Biomaterials are an integral component of tissue engineering and regenerative medicine. The selection and biophysical properties of the materials are instrumental in guiding the behavior of transplanted or invading host cells. We will highlight our recent work in two areas to create building blocks for tissue engineering: 1) manufacturing cellular spheroids with instructive cues to guide cell fate; and 2) production of instructive microgel scaffolds to dictate macrophage phenotype, instruct cell differentiation, and promote tissue formation.

Our group has developed key advances in generating and guiding cell spheroids as building blocks for tissue formation. The bioactivity and function of spheroids is dictated by the selected cell population(s) (both homotypic and heterotypic), culture conditions such as local oxygen tension or inflammatory stimuli, and the association of spheroids with instructive biomaterials. Our group engineered a decellularized extracellular matrix (ECM) secreted by bone marrow-derived mesenchymal stromal cells (MSCs). After characterizing its composition, we demonstrated that MSC spheroids loaded with cell-secreted ECM exhibited markedly increased osteogenic potential and survival in harsh conditions. We have iterated on this ECM to retain endogenous growth factors more effectively. We examined the composition and bioactivity of ECM produced by MSCs differentiated from induced pluripotent stem cells as an alternative cell population that addresses shortcomings of MSCs. Finally, we identified key biophysical properties of hydrogels that regulate cell migration, proangiogenic potential, and tissue formation by MSC spheroids.

Tunable scaffolds that direct cell fate are desirable in many tissue engineering applications such as wound healing, organoids, systems, and drug delivery. As our understanding of tissue complexity increases, so does the demand for heterogeneous biomaterials. Microgels are an emerging tool that fulfill this role given their modularity, injectability, and range of fabrication techniques. Unlike bulk hydrogels, microparticle-based scaffolds possess tunable void space which inherently exists between the particles. Such void space permits cells to migrate and proliferate readily without first remodeling their surrounding environment. While the effects of pore size on cell penetration and proliferation have been studied in bulk hydrogels, it has yet to be thoroughly investigated in a microgel platform.

We employed the ability to readily alter porosity in photoanneable microgel scaffolds to influence macrophage polarization, alter cell spreading and aggregation, and influence cell function. We generated microgels with compressive moduli ranging from ~10-80 kPa, which demonstrates their ability to match a range of tissue stiffnesses. The compressive modulus and bioactivity of the microgels remained constant after cryopreservation at -20°C, which facilitates high-throughput production, storage, off-the-shelf availability, and expands their potential for clinical translation. Void volume was a key stimulus to instruct macrophage polarization toward a pre-regenerative M2 phenotype.

In another example, we created bilayer constructs of microgels with distinct compressive moduli and pro-osteogenic and chondrogenic peptides. Using light to anneal the gels, we produced constructs that did not delaminate, as is common for many bilayer materials. When cultured in mixed media, we observed upregulation of osteogenic and chondrogenic markers that were primarily restricted to the designated layer. The ease of loading cells, cryopreservability, and short annealing time make this a promising platform for translation to the clinic.

Osteochondral defects (OCDs), areas of localized joint damage to articular cartilage and underlying subchondral bone, often lead to pain, loss of joint function, and osteoarthritis. Clinical repair is focused on biological grafting procedures, which are innately limited by graft availability and donor site morbidity. We have developed a bioprosthetic implant, combining articular cartilage resurfacing and osseous tissue regeneration, as a new method for OCD repair. These implants – “cartilage-capped, regenerative osteochondral plugs (CC-ROPs)” - combine a multi-network hydrogel (cartilage cap) and osseous scaffold (base). The cartilage cap is prepared from a multi-network, electrostatic hydrogel that gives rise to articular cartilage-like mechanical, hydration, and tribological properties. The osseous scaffold base is prepared from a semi-interpenetrating polymer network (semi-IPN) of poly(e-caprolactone)-diacrylate (PCL-DA) and poly(L-lactic acid) (PLLA). The scaffold is intrinsically osteoinductive and has a trabecular bone-like modulus as well as robust degradation rates to facilitate bone ingrowth. Formed as cylindrical plugs, CC-ROPs are able to be implanted using existing grafting techniques and be fabricated at a wide range of sizes. CC-ROPs were successfully implanted into rabbit OCDs using an osteochondral graft delivery device with a custom tip to help alignment on the small rabbit condyles. At 10 days, MRI images illustrated the cartilage cap remained intact with the osseous scaffold (i.e., no delamination). It was also confirmed that CC-ROPs did not become displaced post implantation. Formation of new tissue around the periphery of the osseous scaffold was illustrated in microCT and histological analyses. At 12 weeks post-implantation, there were likewise no signs of delamination or fracture of the CC-ROP. Furthermore, no migration of the implant was seen (e.g., cartilage cap surface congruent with surrounding cartilage). Extensive bone tissue formation was seen around the edges and throughout the pores of the osseous scaffold. Performance in rabbit OCDs illustrated the ability of CC-ROPs to immediately provide an articulating surface as well as promote regeneration of osseous tissue, exemplifying the potential to improve the treatment of OCDs.

Heart disease is currently the leading cause of death in the United States, and is most often caused by myocardial infarction (MI). There is a desire to create novel therapies and treatments. However, due to a lack of fundamental understanding of the heart’s inflammatory response to infarction, the development of new therapies is both time consuming and costly. In this work, we report a novel biomaterial platform to mimic dynamic changes in the heart tissue during MI. We believe that our platform enables dynamic control of cardiac cell alignment and matrix stiffness (from healthy to fibrotic tissue) to investigate cardiac tissue development and disease.

In this study, we report a novel dynamic hydrogel platform enabling spatiotemporal control of cellular alignment and matrix stiffness (from healthy to fibrotic tissue stiffness). Our approach involves: (i) fabrication of polydimethylsiloxane (PDMS) based elastomeric film displaying lamellar wrinkling...
patterns with user defined and spatiotemporally controlled pattern amplitude and wavelength, and (ii) chemically grafting a hydrogel film allowing light-induced stiffening from healthy to fibrotic stiffness, matching values reported in the literature. In our approach, methacrylated alginate (McAlg) hydrogel films are first fabricated using Michael-type addition crosslinking using dithiothreitol (DTT) to form hydrogels with healthy stiffness (~15 kPa), during which it is also chemically tethered to the PDMS substrate. When needed, hydrogels can be stiffened in situ when exposed to UV or blue light in the presence of a photo initiator to reach to fibrotic stiffness (~55 kPa). Using this platform, we first investigate the effect of pattern size (amplitude and wavelength) on cardiac cell alignment. We then report the effect of matrix stiffness on cardiac cell function. Human cardiac fibroblasts (hCFs), Normal Human Ventricular Cardiac Fibroblasts, NHCF-V, CC-2904, Lonza, United States, human cardiomyocytes (hCMs), AC16 Human Cardiomyocyte Cell, and human induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs) (iCell Cardiomyocytes 01434, FUJIFILM Cellular Dynamics, Inc.) were used in this study.

In the first part, we show that the degree of cellular alignment for hCMs and hCFs is controlled by the pattern dimensions, such that higher degree of alignment is obtained for higher pattern amplitudes or smaller wavelengths. Spatial control of lamellar patterns allows us to create distinct regions with tunable patterns or continuous patterns with gradient dimensions. In the second part, we show that hydrogels are capable of being stiffened dynamically during the culture (confirmed by AFM and rheology), and gel integrity can be maintained for up to 21 days of culture. In addition, iPSC-CMs cultured for up to 21 days show distinct changes in their sarcomere expression and beating frequency in response to changes in stiffness and alignment. We plan to conclude with our approach to use this platform to mimic the dynamic changes in the ECM post-MI to develop a drug screening platform.

Engineered Biomaterials for In Situ Tissue Regeneration Akhilesh K. Gaharwar; Texas A&M University, United States

Engineered biomaterials have emerged as powerful tools for a range of biomedical applications, including tissue engineering, drug delivery, and additive manufacturing (3D bioprinting). These biomaterials possess tunable biophysical properties, specific biochemical cues, and complex architecture, enabling precise control over cellular behavior. In this talk, I will outline three biomaterials-based approaches developed in our lab for biomedical applications. Firstly, I will highlight how engineered biomaterials can harness the body's regenerative potential to control and direct cell functions for in situ tissue regeneration. Our work has resulted in a new class of biomaterials for bone regeneration, osteoarthritis treatment, angiogenesis, hemostasis, and wound healing. The second approach focuses on designing nanomaterials for bone regeneration for sustained and controlled release of therapeutics. We have developed a range of nano-tool kits for the delivery of small molecules drugs and large proteins, which have high loading efficacy and tunable delivery properties. These approaches can be used for targeted delivery of cancer therapeutics. Lastly, I will demonstrate the design of a new class of biomaterials for 3D printing anatomical-size tissue constructs. These tissue structures can be used to develop physiologically relevant tissue models, mimicking disease conditions such as vascular pathophysiology and vascularized glioblastoma models.

Peptides with Polyproline II Helix Secondary Structure and Their Potential Role in Biomaterials Engineering Julie Ronner; Case Western Reserve University, United States

Bound peptide monolayers are a promising way to control surface properties because peptides are biocompatible, easily tunable, and can be designed to have, or not have, interactions with cells. Our lab is especially interested in establishing new engineering models and assembly techniques to control and understand the behavior of surface-bound peptides for use as biomaterials. Peptides with a polyproline II helix secondary structure (PPII helix peptides) have recently emerged as promising tools for biomaterials due to their unique antifouling properties and ability to form dense monolayers. Using a variety of characterization techniques, we uncover new details about the assembly mechanisms of PPII helix peptides and explore their antifouling capacity. In addition, we explore the interactions of these peptides with human mesenchymal stem cells and 3T3 cells with and without bioactive peptides attached. Collectively, these results reveal greater understanding of the mechanisms behind PPII helix peptide assembly and antifouling and provide insight into their potential use as biomaterials for regenerative engineering.

Stiffness Assisted Cell-Matrix Remodeling to Induce Stem Cell Differentiation Akhilesh K. Gaharwar; Texas A&M University, United States

Engineered matrices provide a valuable platform to understand the impact of biophysical factors on cellular behavior such as migration, proliferation, differentiation, and tissue remodeling, through mechanotransduction. While recent studies have identified some mechanisms of 3D mechanotransduction, there is still a critical knowledge gap in comprehending the interplay between 3D confinement, ECM properties, and cell behavior. Specifically, the role of matrix stiffness in directing cellular fate in 3D microenvironment, independent of viscoelasticity, microstructure, and ligand density remains poorly understood. To address this gap, we designed a nanoparticle crosslinker to reinforce collagen-based hydrogels without altering their chemical composition, microstructure, viscoelasticity, and density of cell-adhesion ligand and utilized it to understand cellular response. This crosslinking mechanism utilizes nanoparticles as crosslink epicenter, resulting in 10-fold increase in mechanical stiffness, without other changes. Human mesenchymal stem cells (hMSCs) encapsulated in 3D responded to mechanical stiffness by displaying circular morphology on soft hydrogels (5kPa) and elongated morphology on stiff hydrogels (30kPa). Stiff hydrogels facilitated the production and remodeling of nascent extracellular matrix (ECM) and activated mechanotransduction cascade. These changes were driven through intracellular PI3AKT signaling, regulation of epigenetic modifiers and activation of YAP/TAZ signaling. Overall, our study introduces a unique biomaterials platform to understand cell-ECM mechanotransduction in 3D.

Development of an iPSC Loaded Biomimetic Biomaterial Scaffold for Spinal Cord Repair Applications Cian O'Connor1,2,1, Ian Woods1,2,1, Sarah F. McComish1, Mavee A. Caldwell1, Adrian G. Dervan1,2,1 and Fergal J. O'Brien1,2,1; 1Royal College of Surgeons in Ireland, Ireland; 2Trinity College Dublin, The University of Dublin, Ireland

Introduction: Following spinal cord injury, a lesion cavity develops preventing axonal regrowth. Biomaterial implants that bridge the cavity and encourage axonal growth while delivering trophic cells to restore lost tissue may have potential for repair. Therefore, by identifying neurotrophic extracellular matrix proteins to incorporate into biomimetic hyaluronic acid biomaterial scaffolds and by tuning the biomaterial stiffness, we aimed to develop a novel platform for spinal cord repair. Furthermore, we wished to determine if the developed biomimetic biomaterial scaffolds were capable of delivering and modulating the trophic capacity of induced pluripotent stem cell (iPSC)-derived progenitors for spinal cord repair applications.

Methods: Spinal cord astrocytes and neurons were cultured on a range of extracellular matrix-proteins to identify the optimal neurotrophic substrate combination. Following the incorporation of the neurotrophic substrate into freeze-dried 3D hyaluronic acid scaffolds of varying stiffnesses, scaffold properties were characterized. Next, spinal cord astrocytes, neurons, dorsal root ganglia (DRG) and iPSC-derived astrocyte progenitors were cultured in the...
scaffolds for up to 21 days and the effect of scaffold physicochemical properties was assessed. Thereafter, the impact of scaffold properties on the trophic capacity of iPSC-derived progenitors was assessed in vitro and ex vivo using neurons, DRG and spinal cord explants.

**Results:** A combination of collagen-IV (CIV) and fibronectin (FN) synergistically enhanced neurite outgrowth by 203% while also promoting astrocyte process extension. Subsequently, hyaluronic acid biomaterial scaffolds functionalized with CIV/FN were successfully manufactured with different stiffnesses ranging from soft/biomimetic to stiff/supraphysiological (0.8-3.5 kPa). Spinal cord astrocytes cultured in soft-CIV/FN functionalized biomaterial scaffolds matching cord stiffness, displayed positive stellate morphologies and increased pro-regenerative IL-10 release. Furthermore, soft scaffolds significantly enhanced neurite outgrowth from neurons and adult mouse DRG explant cultures compared to stiffer scaffolds. Soft-CIV/FN scaffolds also enhanced iPSC-progenitor neurotrophic and functional capacity while encouraging the growth of iPSC-derived spheroids that subsequently formed extensive neuronal/astrocytic cellular tracts, colonizing the biomaterial scaffold. Conditioned media from soft-CIV/FN but not other, iPSC-loaded scaffolds, and applied to growing neurons enhanced neurite outgrowth by over 280%. Super-resolution microscopy also confirmed similar neurite enhancement (170%) in mouse primary spinal cord neurons treated with media from soft-CIV/FN scaffolds only without eliciting negative inflammatory and/or reactive responses from healthy and injured astrocytes. Furthermore, analysis of media from stiffer or non-CIV/FN-containing scaffolds showed increased pro-inflammatory IL-1β release compared to soft CIV/FN scaffolds. Finally, when ex vivo DRGs or spinal cord explants were cultured directly on CIV/FN iPSC-loaded biomaterial scaffolds up to 21 days, only soft biomaterials enhanced cellular infiltration, astrocytic process extension and directed axonal outgrowth between DRG and iPSC-spheroids.

**Conclusion:** Overall, this research describes the development and utilization of a novel, biomimetic biomaterial scaffold-based platform for spinal cord repair and demonstrates that biomimetically inspired biomaterials can enhance the growth of cord resident neurons and astrocytes and promote the neurotrophic potential of implanted progenitor cells to act as a novel, therapeutic platform for spinal cord injury repair applications.

**Acknowledgements:** This work is funded by the Anatomical Society, Irish Rugby Football Union Charitable Trust, and the Science Foundation Ireland Advanced Materials for Bioengineering Research (AMBER) centre.

**Protein-Derived Jammed Microgels as Inks for Extrusion 3D Printing of Bioactive Scaffolds**

**Lucas Ribeiro**1, 2, Rita Sobreiro-Almeida2, Vitor Gaspar2, Emerson Camargo1 and João Mano2. 1Federal University of São Carlos, Brazil, 2University of Aveiro, Portugal

Extrusion 3D printing has emerged as a promising technique in tissue engineering, enabling the creation of personalized scaffolds for individual patients. Typically, natural hydrogels are utilized as inks due to their resemblance to the extracellular matrix (ECM), as well as their biodegradability and biocompatibility, making them ideal for tissue engineering applications. One such biomaterial is human platelet lysates (PL) derived from whole blood, which carries a rich assortment of growth factors, cytokines, and proteins that can stimulate cell proliferation and differentiation, and tissue regeneration. However, the use of PL as ink for printing scaffolds is limited by its liquid nature even at high concentrations, preventing the formation of a solid and stable filament upon deposition.

To address this challenge, granular hydrogels of methacylated PL (PLMA) were developed through chemical coupling. These granular hydrogels consist of jammed microgels that exhibit viscoelastic solid properties at low levels of strain while flowing under high levels of strain. This unique characteristic enables filament formation and facilitates their application as injectable biomaterials. Additionally, a granular ink of methacylated bovine serum albumin (BSAMA) was prepared for comparison, leveraging the high albumin content of PL. The microgels were generated by extruding bulk hydrogels through a series of nozzles with progressively higher gauges (18G, 21G, and 23G), followed by centrifugation to remove excess liquid phase and obtain granular hydrogels. Both materials displayed irregular microgels and a wide size distribution. Moreover, the process resulted in albumin microgels with a larger average size, leading to increased porosity compared to the PLMA hydrogel.

Rheological analysis revealed that both inks exhibited shear-thinning, yield-strain, and self-healing properties—essential characteristics for materials used in 3D printing. Additionally, a time sweep test utilizing UV light demonstrated a rapid increase in the storage modulus of the hydrogels due to photocrosslinking, indicating rapid stabilization of the printed scaffolds. The study of filament formation using different nozzles allowed an evaluation of the printing fidelity of BSAMA and PLMA inks. In all cases, the filament diameter closely matched the internal diameter of the needles, and thus the smallest nozzle tested (22G) was selected for printing the scaffolds. Due to its larger microgels, the printing of the BSAMA presented some clogging, requiring higher pressure for constant extrusion compared to the PLMA ink. Nevertheless, stable scaffolds with varying geometries and layer numbers were successfully printed, confirming the efficacy of this strategy in producing protein inks with the necessary printing properties.

Finally, the bioactivity of the granular hydrogels was assessed by seeding human adipose-derived stem cells (hASCs) for a period of 7 days. Metabolic activity increased at each time point, being consistently higher in PLMA hydrogels. This can be attributed to cell proliferation in the spaces between the microgels, with cells adhering around them from the first day, as indicated by the Live/Dead assay. Furthermore, only a small number of dead cells were detected, indicating the non-cytotoxic nature and biocompatibility of the inks. The DAPI/Phalloidin assay confirmed a higher cell count in the PLMA scaffolds from day 1, highlighting the superior bioactivity of this material. In summary, bioactive granular hydrogels of protein sources with microporosity were successfully created, demonstrating their potential for 3D printing stable scaffolds with excellent resolution for use in tissue engineering applications.

**Enhanced Therapeutic and Immunomodulatory Effect of Stem Cell Spheroid with Transition Metal-Based Nanoparticles in Rat Myocardial Infarction Model**

**Yeong Hwan Kim and Suk Ho Bhang. Sungkyunkwan University, Korea (the Republic of)

Myocardial infarction (MI) which accompanies decrease in myocardium function and destruction of millions of cardiomyocytes is a leading cause of mortality worldwide. In this study, we demonstrated advanced stem cell therapy to treat cardiovascular disease with enhanced therapeutic efficacy of stem cell spheroids by upregulating angiogenesis-related paracrine factors secretion and inducing immunomodulatory ability with transition metal based nanoparticles (TMNs). Stem cell spheroids treated with TMNs (spheroids-TMNs) had wider hypoxia inducible factor (HIF) expression area in core with mild reactive oxygen species (ROS) generation. According to increased HIF expression of spheroids-TMNs, the secretion of angiogenesis-related paracrine factors was enhanced compared to untreated spheroids. Immunomodulatory effect of spheroids-TMNs was verified with Raw cell; suppression of pro-inflammatory responses and promotion of anti-inflammatory responses. Enhanced therapeutic effect and immunomodulatory effect of spheroids-TMNs were verified in vivo rat MI model. An advanced stem cell therapy we provided can be a promising therapeutic strategy for cardiovascular disease treatment.
Dental infections affect millions of people globally with a burden of $298 billion annually associated with direct costs to treat oral diseases. Injectable hydrogels incorporated with antimicrobial and antioxidant agents can be used to treat dental pulp infections. Herein, injectable hydrogels of chitosan (CH) and liposomes loaded with curcumin and α-tocopherol have been developed to provide antimicrobial and antioxidant action for dental pulp regeneration. Hydrogels are prepared with high (HCH), and low (LCH) molecular weight chitosan to investigate the impact of molecular weight on injectability, biodegradability, controlled release, and antimicrobial activity. The diameters of liposomes are mostly uniform, in the range of 152 - 162 nm, making them suitable for controlled release and injectability. Zeta potential values of hydrogels are negative, which could lead to a homogenous distribution of liposomes in the positively charged hydrogels. Approximately 80% of curcumin and α-tocopherol are released from liposomes within 21 days in a controlled manner. Therefore, the antimicrobial and antioxidant activity of the hydrogels could be sustained during the healing process. TGA results showed that the thermal stability of the hydrogels decreased with respect to the solution volume and the sonication time while preparing the hydrogels (i.e., the mass loss values of LCH and HCH at 500 °C increased from 79 to 96 % and 90 to 95 %, respectively). DSC findings are consistent with the TGA results for LCH groups, where a shift in Tc from a higher (347 °C) to a lower (326 °C) temperature is observed in response to the increase in volume and sonication time. Nevertheless, the Tc values of HCH are not influenced (366 °C). Rheological analysis revealed that the viscosity of hydrogels decreases as the shear rate increases, signifying the shear-thinning behavior and injectability of the hydrogels. In vitro biocompatibility and antimicrobial features are investigated using dental pulp stem cells and gram-negative as well as gram-positive bacteria. Finally, the antimicrobial mechanism of LCH and HCH on Escherichia coli and Staphylococcus aureus is evaluated theoretically by density functional theory.
and Staphylococcus aureus growth of two major pathogens that typically grow during wound healing: in situ microbial invasion. The rapid and easy application of calcium peroxide microparticles were incorporated into the hydrogel precursor solution at 0-12 mg/mL concentrations to protect the dressing from precursors. The bioactive GelMA component was evaluated at 5-15% w/v while HAMA was used as the anti-inflammatory component at 1% w/v. Solid calcium peroxide microparticles were incorporated into the hydrogel precursor solution at 0-12 mg/mL concentrations to protect the dressing from microbial invasion. The rapid and easy application of in situ photocrosslinkable hydrogels were demonstrated by spraying the composite gel precursor on the surface of the ex vivo pig skin model. The physical properties of the composite hydrogel dressings were analyzed by measuring the mechanical strength, swelling, degradation, and porosity characteristics at the macro scale. The antimicrobial properties of the composite hydrogels were evaluated against the growth of two major pathogens that typically grow during wound healing: Staphylococcus aureus and Pseudomonas aeruginosa. The oxygenation kinetics was measured using an oxygen sensing probe under hypoxic condition (2-5% O₂). The cytocompatibility of the composite hydrogels were assessed by testing their effects on metabolic activity and viability of the primary human dermal fibroblasts. We successfully demonstrated the practical and convenient application of our sprayable composite hydrogels on ex vivo pig skin tissue by an in situ crosslinking strategy. The optimum sprayable concentration for GelMA was found to be 10% w/v in the dressing. The gelatin, hyaluronic acid, and peroxide containing composite hydrogels showed high tunability in their physical and biological properties. The peroxide microparticles provided antimicrobial properties in this sprayable wound dressing. The composite hydrogels were able to provide oxygen up to all two weeks in the in vitro cell culture. The metabolic stress from human dermal fibroblast cells was relieved by the release of oxygen from the peroxide microparticles.

High-Throughput Mass Spectrometry Imaging of Biomaterials for Regenerative Medicine using Three-Dimensional Biomimetic Models (Spheroids and Organoids) Sohee Yoon; Korea Research Institute of Standards and Science, Korea (the Republic of)

Three-dimensional spheroids and organoids are the next generation of biomimetic models that can mimic tissues and organs, as well as diseases and cellular microenvironments such as microtumors. This biomimetic model can be used to elucidate the mechanisms of various biomaterial changes or to rapidly screen cellular responses to drug treatments, and is therefore actively being applied in disease treatment and regenerative medicine. Imaging-based assays are important for a holistic understanding of tumor cell formation and behavior based on organ mimics. Cell viability in three-dimensional biomimetic models is primarily characterized by fluorescence-based imaging techniques. While fluorescence analysis can confirm cell viability, it is difficult to quickly identify chemical changes occurring in high-throughput cells simultaneously. Mass spectrometry imaging is a label-free, high-throughput imaging technique that can simultaneously obtain spatial and chemical information about analytes. We applied mass spectrometry imaging techniques to a three-dimensional biomimetic model to investigate changes in the cellular microenvironment and drug penetration upon drug application.

To this end, we applied drugs and nanoparticles to three-dimensional colon cancer spheroids and liver organoids to investigate chemical changes in the cellular environment by mass spectrometry imaging. In the case of three-dimensional spheroids, the extent of drug penetration into each proliferating, quiescent, and necrotic layer within the spheroid and the accompanying metabolites were investigated, confirming its potential for expansion as a nanomedicine that can be applied to regenerative medicine. To investigate these changes following nanoparticle-based drug delivery in the liver organoid model, we developed and optimized a high-throughput chemical imaging assay that provides a global view of chemical changes within the organoid.

Disulfiram-Encapsulated PLGA Nanoparticles for Liver Injury Treatment Wei Xu1, Waliul Islam1, Hisaaki Hirose2, Shiroh Futaki2, Yukio Fujiwara1, Yoshihiro Komohara1 and Takuro Niidome1; 1Kumamoto University, Japan; 2Kyoto University, Japan

Liver macrophages, Kupffer cells, the most abundant immune cells in the liver, play important roles in innate immunity and contribute to many liver diseases. Disulfiram (DSF), a drug used to treat alcohol abuse, has attracted much attention because it has anti-cancer and anti-inflammatory activities. However, DSF distribute in several cell types, and few studies have examined its utility as a potential treatment for liver injury. In this study, we prepared DSF-encapsulated PLGA nanoparticles (DSF@PLGA NPs) and examined anti-inflammatory effect in vitro and in vivo experiments. Size of DSF@PLGA NPs was about 250 nm and zeta-potential was negative. The encapsulated DSF was slowly released from the nanoparticles over a couple of weeks. DSF@PLGA NPs had low cytotoxicity, selectively taken up by human macrophage cell line THP-1 via macrophagocytosis, and inhibited lipopolysaccharide-induced proinflammatory cytokine production by THP-1 cells. Intravenously administered PLGA NPs predominantly localized to the liver, specifically CD68-positive Kupffer cells, and DSF@PLGA NPs significantly alleviated thioacetamide-induced proinflammatory cytokine production and liver injury. These results indicate that encapsulation in PLGA NPs promotes specific delivery of DSF to Kupffer cells and reduces liver injury and inflammation, suggesting that DSF@PLGA NPs may be a promising treatment for liver disease.

8:00 PM SB09.03.07
Drug-Loaded Decellularized Tissue for Suppression of Anastomotic Stenosis after Artificial Vascular Grafting Kaito Shimizu1,2, Yoshiaki Hirano2,3, Tetsuji Yamaoka4 and Atsushi Mahara1; 1The National Cerebral, and Cardiovascular Center Research Institute, Japan; 2The Kansai University, Japan; 3The National Cerebral, and Cardiovascular Center Research Institute, Japan; 4The Komatsu University, Japan

[Literature Cited]...

Introduction

The suppression of thrombus formation and anastomotic stenosis is required for long-term patency of small-diameter vascular grafts [1]. Surface modification techniques for an anti-thrombus surface are reported [2], while no effective strategy has been developed to prevent anastomotic stenosis. It is well known that anastomotic stenosis causes to the hyperproliferation of transformed smooth muscle cells (SMCs) [3]. SMC phenotype is altered from contractile to synthetic type, resulting in hyperproliferation. Drug eluted stent is a famous device in the clinical site, and the stent is coated with a biodegradable polymer loaded with rapamycin. The drug is released over a month after application to the arteriosclerosis site. If this concept can be applied to artificial blood grafting, we assumed that stable graft patency would be achieved over the medium to long term by local releasing of the drug at the anastomotic site. In this study, we focused on cilostazol as the anti-proliferative drug for SMC and developed a cilostazol-loaded acellular tissue (CLZ-Graft). After grafting the vessel, CLZ-Graft was implanted into the periarterial anastomotic site. When the tissue was degraded during the time...
regeneration, anastomotic stenosis would be suppressed by releasing CLZ. Here, we developed the CLZ-loaded acellular tissue, and inhibition of in vitro SMC growth and in vivo stenosis would be discussed.

[Experiment] The decellularized carotid artery was freeze-dried, and the artery was immersed in 100 mg/ml of CLZ/DMSO solution for 1 hour. As the control, the artery immersed with only DMSO were also prepared (FD-Graft). After that, the sample was washed with water to remove the solvent. The cistostazol loading in the CLZ-Graft was evaluated by FT-IR. The total amount of cistostazol in CLZ-Graft was quantified by using collagenase digestion. Enzymatically degraded CLZ-Graft was added to SMCs, and suppression of the SMCs proliferation was evaluated. In vivo experiments, CLZ-Graft was implanted into the periarterial area of the carotid artery in a stenosis model rat. The vascular stenosis was evaluated after 4 weeks by histostaining.

[Result and Discussion] IR spectrum derived from CLZ was detected in CLZ-Graft by FT-IR analysis, and approximately 110 μg of CLZ was loaded in 10 mg of the graft. When the graft was incubated with the collagenase solution, the weight of the CLZ-Graft was reduced to 19 % for 8 hrs, and 82% of the loaded CLZ was gradually released during this time. When the lysate was added to the SMCs, the cell number was decreased, suggesting that the SMCs proliferation was suppressed by the degradation of the CLZ-Graft. In vivo experiment, the carotid artery with abraded lumen was wrapped with the grafts. As the result of this, the lumen area in the case of CLZ-Graft was maintained to 60% after 4 weeks while the area was largely reduced to 35% in the case of FD-Graft. These results indicate that CLZ-Graft would suppress adverse LV remodeling by CLZ release.

Prevention of Adverse Ventricular Remodeling Post-Mycardial Infarction by Sorbitol-Responsive In-Situ Gelling Material [Hue T. Le1, Atsushi Mahara2, Takeshi Nagasaki3, and Tetsuji Yamaoka1;2;1 The National Cerebral and Cardiovascular Center Research Institute, Japan; 2The Osaka Metropolitan University, Japan; 3The Komatsu University, Japan

Introduction: The loss of myocardium after myocardial infarction (MI) leads to a thinned left ventricular (LV) wall and the exacerbated dilation of the LV cavity, eventually leading to heart failure. Intramyocardial hydrogel injection has gained attention as a therapeutic approach in MI treatment. Various materials have been tested in preclinical and clinical studies; however, the difficulties in control of their gelation cause inadequate distribution and retention of the hydrogel within the myocardium. We recently developed a sorbitol-responsive in-situ gelling material composed of poly (3-acylamidophenylboronic acid-co-acrylamide) (BAAm), poly(vinyl alcohol) (PVA), and sorbitol. This mixture exists in a sol state because the phenolboronic acid group of BAAm is bound to the sorbitol. The BAAm and PVA are quickly conjugated by a non-covalent bond to form a gel when the sorbitol is released from the BAAm. We previously reported the proof-of-concept for the sol-gel transition of sorbitol-containing BAAm/PVA (S-BAVA) solution in the heart tissue by diffusing the sorbitol out of the sol. In this study, we investigated the distribution and retention of the injected S-BAVA in the infarct myocardium and its therapeutic effect on post-infarct adverse LV remodeling in a rat model.

Method: S-BAVA solution was prepared from 25 mg/ml BAAm, 10 mg/mL PVA, and 10 mg/mL sorbitol. To examine S-BAVA hydrogel formation in vivo, 1 mL of the S-BAVA containing 100 mg/mL of iopamidol was intramyocardially injected in the porcine heart and tracked by computer tomography (CT) 30 min after injection. A rat subacute MI model was prepared by surgically ligating the left anterior descending (LAD) artery. The LV wall motion of MI rats was assessed by MRI at 21d after administration. The saline was set as a negative control.

Result: The CT images showed the presence of iopamidol-containing S-BAVA in the porcine myocardium 30min after injection, suggesting the occurrence of its hydrogel formation. The rho-labeled S-BAVA was fully distributed in the infarct myocardium and stably remained up to 21d after injection. The MRI images showed the dyskinetic wall motion and thickness in all rats operated with LAD ligation. A gradual reduction of the LV function of the LV morphology was assessed by histological staining at 21d after administration. The saline was set as a negative control.

8:00 PM SB09.03.09
3D Printed Polymer Scaffolds for Bone Regeneration [Shreya Madhavarapu and Joseph Freeman; Rutgers, The State University of New Jersey, United States

Significant bone loss can occur due to trauma or disease, resulting in large bone defects. Typically, autografts and allografts are used as bone grafts but these are associated with disadvantages like limited availability, and the risk of disease transmission with allografts. In recent time, synthetic bone graft substitutes have come up as alternatives, but they fail short in one or more aspects as well. Tissue engineered bone grafts are viable alternatives. In order for these to be successful, we must first address two important issues - lack of cell infiltration throughout their structure and a lack of vasculature formation. We have developed a 3D printed polylactic acid (PLA) scaffold with distinct cortical and trabecular geometries. These are highly porous structures promoting capillary inflow of blood and bone marrow. They are also mineralized and prevascularized to promote regeneration of both bone and its vascularization. These scaffolds are evaluated in a load-bearing, rabbit critical-sized radial defect model and show promise.

Scaffolds were designed using Solidworks and 3D printed using the Ultimaker 2+/S3 3D printers. They were tested under compression and their mechanical properties were compared to the previous iterations of scaffolds developed in our lab. The new design displayed superior mechanical properties when compared to the previous design. Our previous design displayed Ultimate Compressive Stress and Compressive Modulus which fall within the limits for trabecular bone (0.2-10MPa and 7-200MPa) but fall short of those required for native whole bone i.e. 200 MPa and 1 GPa respectively. With our new design, we have been able to achieve a mean Ultimate Compressive Stress of approximately 40 MPa and a mean Compressive Modulus of approximately 600 MPa. Glyceral-water mixtures were used to mimic the viscosities of blood and bone marrow and study scaffolds’ ability to promote capillary inflow. Slow capillary rise of fluids mimicking viscosities of blood and bone marrow was observed in the 3D printed scaffolds. In order to improve their ability to which these fluids, polymer surface was pretreated with oxygen plasma prior to mineralization using concentrated simulated body fluid. Presence of mineral resulted in them quickly wicking up fluid followed by a more gradual rise. Scaffolds were prevascularized by allowing vascular endothelial cells to grow within the cortical structure. They were decellularized after 2 weeks leaving behind a pro-angiogenic matrix. Scaffolds with and without autologous bone marrow were implanted in a rabbit critical-sized radial defect model, with allografts serving as controls. X-Ray and CT imaging was used to track bone regeneration over the course of 20 weeks. X-ray images showed progressive bone regeneration from 2 to 10 weeks, originating first from the ulna ridge just below where the radius was removed and from the two ends where the radius meets the implant. The CT images taken at 12 weeks post-op showed significant bone regeneration. At the end of the study, histology will be performed to analyze regenerated bone and vasculature.
We have developed load bearing scaffolds that promote infiltration of bone marrow into and throughout the scaffold, reducing the need to add stem cells prior to implantation in vivo. Using endothelial cells to prevascularize our scaffolds, we have created decellularized lamens within our cortical geometry to promote growth of vasculature upon implantation. Our ongoing in vivo evaluation has shown that our scaffolds can maintain their structural integrity while promoting bone remodeling and show promise as bone graft alternatives.

8:00 PM SB09.03.11
Eggshell Reinforced Scaffolds for Bone Repair
Mert Gezek1,2 and Gulden Camci-Unal1,2; 1University of Massachusetts Lowell, United States; 2University of Massachusetts Medical School, United States

More than two million bone graft procedures are performed to treat patient defects annually.1,2 The main drawbacks of some of the existing bone graft materials are their complex fabrication steps, inflexibility, lack of porosity and biofunctionality, and requirement of costly reagents. Bone regeneration can be achieved using mineral-based materials, such as calcium carbonate, which is a major component of eggshells. Global waste of discarded eggshells typically amounts to millions of tons annually from household and commercial cooking. Innovative repurposing of eggshells can impact the economy and environment while providing unique solutions to unmet clinical needs. Due to the superior biophysical properties of calcium carbonate over other calcium-based minerals, the incorporation of chicken eggshell microparticles (ESP) into polymers can enhance osteogenic differentiation and bone regeneration.

In this work, we developed ESP-reinforced polymeric scaffolds to obtain mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells or preosteoblasts into osteoblasts.1 We generated ESP-reinforced 5-50% (w/v) polymeric scaffolds. The concentrations of the ESP were 5, 15, 30, and 50% (w/v) in the scaffolds. We characterized the mechanical properties, porosity, swelling, and degradation of these biomaterials. The cellular response was then evaluated against the ESP-reinforced scaffolds via, cytotoxicity, growth, and proliferation assays as well as gene expression analyses. Implantation of ESP-reinforced scaffolds was performed in vivo using a rat model and histology was carried out to evaluate the inflammatory response. In addition, near full regeneration of critical-size calvaria defects was achieved using our ESP-reinforced scaffolds in vivo.2 These composite materials demonstrated significant bone formation as well as bone remodeling.

This work demonstrates that eggshell microparticles can be used in a composite 3D polymeric construct for bone regenerative engineering. We successfully fabricated ESP microparticle-reinforced biomaterials and evaluated their suitability for osteogenic cell cultures in vitro, and biocompatibility and bone regeneration in vivo. Pre-osteoblasts were encapsulated within the ESP-reinforced scaffolds at 5 million cells/mL density which underwent osteogenesis as determined by RT-qPCR for osteocalcin and BMP-7. The ESP-reinforced composite scaffolds were osteoinductive and enabled the differentiation of stem cells without the use of a specialized osteogenic growth medium. The ESP-reinforced constructs were then subcutaneously implanted in Wistar rats and found to be biocompatible without inflammatory response and they were biodegradable. The implants were easily accepted by the host, allowed for cellular migration and infiltration in 3D, and were highly vascularized. To study the regenerative capability of the ESP-reinforced scaffolds, they were implanted into critical-size calvaria defects. The in vivo model demonstrated a near full regeneration of the critical-size defects in 12 weeks. The newly formed bone had similar bone density compared to the native bone and it was capable of producing bone marrow. Furthermore, in addition to vascularized bone formation, bone remodeling also took place as determined by immunohistochemistry for TRAP. We anticipate that the ESP-reinforced scaffolds will serve as promising implants for the treatment of bone defects in the body.

Simultaneous Anti fouling and Selective Adsorption in a Poly(dimethyl siloxane) (PDMS) Based Microfluidic Device using a Functional Surface Segregating Zwitterionic Copolymer Additive
Ryan O’Hara1, Luca Mazzaferro1, Aslihan Gokaltun2,3, Berk Usta2,3 and Ayse Asatekin1; 1Tufts University, United States; 2Harvard Medical School, United States; 3Massachusetts General Hospital, United States

Non-specific protein adsorption and small molecule absorption have been a persistent challenge in the use of poly(dimethyl siloxane) (PDMS)-based microfluidic devices due to PDMS’s hydrophobicity. This issue has led to the development of various post-processing techniques to make the surface fouling resistant, such as plasma treatment and surface grafting of hydrophilic polymers. However, these approaches often have limited stability, with the surface becoming hydrophobic again within days. Additionally, for many applications, it is of interest to selectively adsorb only specific analytes while preventing the adhesion of others, specifically for use in protein capture for diagnostics, biochemical assays, and cell capture for organ-on-a-chip models. Achieving both selective adsorption and fouling resistance is particularly challenging. To address these challenges, we have synthesized a surface spontaneously segregating copolymer additive to create a hydrophilic, anti fouling zwitterionic surface interspersed with functionalizable groups that can be easily blended into pre-cured PDMS during the traditional manufacturing method of microfluidic devices. Using this approach, we have been able to decrease the non-specific adsorption of Bovine Serum Albumin (BSA) on PDMS surfaces by at least 95%. We have also shown that we can utilize the functionality of this polymer additive to attach desired functional groups to mediate the adsorption of specific analytes using isocyanate or EDC/NHS coupling chemistry. We expect this novel method for simultaneous fouling prevention and surface functionalization of PDMS surfaces to enable the development of better-performing biomicrofluidic devices.

Decoupling of Adhesive and Repulsive Domains of Microstructured Stimuli-Responsive Polymer Film for the Refining of Particulates and the Non-Enzymatic Harvesting of Cells
Yongwook Kim1,2, Ummay M. Jahan3,2, Alexander P. Deltchev2, Nickolay Lavrik4, Vladimir Reukov2 and Sergiy Minko2; 1Lawrence Livermore National Laboratory, United States; 2University of Georgia, United States; 3North Carolina State University, United States; 4Oak Ridge National Laboratory, United States

Sorting colloidal particles such as protein complexes, cells, and viruses presents a challenge due to their strong and quasi-irreversible adsorption to interfaces, which hampers their efficient separation. To overcome this limitation, a microstructured stimuli-responsive polymer interface has been developed to generate a controlled local oscillating repulsive mechanical force. This force facilitates the transition between particle adsorption and facilitated desorption, allowing for the separation of colloidal mixtures based on their affinity to the particle-polymer interface. The microstructured films consist of adhesive domains and disjoining thermoresponsive poly(N-isopropylacrylamide) brush domains. This dynamic regime holds significant potential for various applications in research, diagnostics, and large scale label-free sorting of highly asymmetric mixtures of colloids and cells. Furthermore, this novel polymeric interface can be applied to non-enzymatic cell harvesting. By utilizing microstructured patterns, the areas responsible for solid cell adhesion serve as cell growing scaffolds, while the repulsive areas are employed to collect proliferated cells from the surface. This surface design
effectively addresses the limitations associated with thermostressive coatings, such as the need for precise coating thickness, grafting or cross-linking density, and specific substrate materials. This innovative architecture enables efficient cell harvesting and selective sorting of particulates by separating the adhesion and detachment processes.

Part of this research was conducted as a user project at the Center for Nanophase Materials Sciences (CNMS), which is a US Department of Energy, Office of Science User Facility at Oak Ridge National Laboratory.

8:00 PM SB09.03.15
O-Carboxymethyl Chitosan-Based Nanostructured Surface using Poly(Ethylene Glycol) for Multi-Functionalization of Vascular Catheters Min Yeong Jeong1, Se Kye Park2, Kibeom Nam3 and Dong Yun Lee4; 1Kyoungpook National University, Korea (the Republic of); 2Korea Institute of Industrial Technology, Korea (the Republic of)

Vascular catheters (VCs) are essential medical devices used for diagnostic purposes, drug administration, and surgical interventions. However, using VCs can lead to severe complications, including bloodstream infections, thrombosis, and blood vessel damage, posing a risk to patient safety. To address these critical issues, it is crucial to incorporate antimicrobial agents, such as o-cym, antithrombotic, and low-friction properties into the surface of ICs. One approach for achieving multifunctionality in ICs involves coating them with a hydrogel that embeds antimicrobial and antithrombotic agents. However, catheters with such hydrogel coatings have effectively prevented these issues, they can have unwanted side effects such as cytotoxicity and tolerance. Additionally, the performance of hydrogel-coated ICs tends to degrade over time due to the leaching of functional agents from the coating layer. O-carboxymethyl chitosan (O-CMC) is a promising material for multi-functionalizing VCs due to its exceptional material properties, including biocompatibility, biodegradability, antimicrobial activity, and hemocompatibility. However, the antithrombotic activity of O-CMC remains uncertain due to incomplete thrombosis reduction and limited clinical use cases [5]. Although O-CMC has sufficient hemocompatibility, the antithrombotic activity is questionable due to its incomplete performance of thrombosis reduction and lack of clinical use cases[5]. Furthermore, there is a lack of studies on the multifunctionalization of VCs using chitosan derivatives like O-CMC. Consequently, the verification of multi-functional performance, including antithrombotic activity, remains a challenge in the application of actual VCs. In this study, we introduce a novel strategy to achieve surface multi-functionalization of ICs using O-CMC. To enhance the inherent performance of O-CMC, we fabricated a nanoscale rough surface for the coating layer. This is accomplished by fabricating a nanoscale porous O-CMC coating layer on pre-treated ICs through the selective leaching of water-soluble polyethylene glycol (PEG) from a heterogeneous O-CMC/PEG composite. The resulting coated layer exhibits superhydrophilicity due to increased surface roughness. Notably, the antifouling effect by superhydrophilicity of the coating layer effectively prevented the adhesion of bacteria and platelets, synergizing with the inherent properties of O-CMC. Additionally, the porous O-CMC coating layer exhibits sufficient low-friction properties even with its rough surface. Moreover, we have successfully demonstrated that the practical VC with the proposed coating method exhibits excellent trackability in a curved artificial blood vessel. This proposed coating strategy shows great potential not only for VCs but also for a wide range of polymer-based vascular devices, including vascular filters, grafts, pacemakers, and soft robots.

8:00 PM SB09.03.16
Cationic Material-Free mRNA Delivery Carrier Naoki Taguchi1,2, Akihisa Hirano1, Yoshiaki Hirano12 and Tetsuo Yamaoka1;1 The National Cerebral and Cardiovascular Center Research Institute, Japan; 2The Kansei University, Japan; 3The Komatsu University, Japan

[Introduction] Since mRNA is easily degraded in our body, it requires a delivery carrier to be delivered to target cells. Cationic carriers are often used for mRNA delivery because it electrostatically interacts with the phosphate groups of mRNA. However, cationic feature often causes cytotoxicity and nonspecific protein adsorption in the blood, thus decreasing the therapeutic efficiency. To solve this problem, we focused on zwitterionic arginine methacrylamide (ArgMA), in which the alpha-amino group of arginine is conjugated with methacrylic acid as a carrier component. The guanidyl group of arginine has affinity to nucleic acid3 and retains mRNA despite its zwitterionic and nonionic structure. Furthermore, previous papers have reported several attractive features of ArgMA as a delivery carrier, such as lower cytotoxicity than cationic arginine3 and antifouling properties4. In this study, ArgMA-containing polymers were synthesized and verified whether the polymer can retain and protect mRNA and induce protein expression.

[Synthesis and Method] ArgMA was synthesized according to a previous report4. Since ArgMA homopolymer is insoluble in water, ArgMA was copolymerized with 2-methacryloyloxyethyl phosphorylcholine (PMR) at the ArgMA composition ranging from 0 to 70 mol%. Free radical polymerization and reversible addition-division chain transfer (RAFT) polymerization were performed using 2,2'-azobis(isobutyronitrile) as initiator and water/ethanol as solvent. PMR was mixed with mRNA, encoding a near-infrared red fluorescent protein (iRFP), with a guanidyl/phosphate group ratio from 0 to 200, and the polypeptide formation was confirmed by agarose gel electrophoresis. The mRNA protection by PMR was evaluated after incubation with 10% fetal bovine serum (FBS) at 37°C for 10 min. The transfection efficiency of fibroblast cells (HEK293) was evaluated using flow cytometry analysis.

[Results and Discussion] Agarose gel electrophoresis showed that the more mRNA formed polyplex with PMR synthesized by free radical polymerization (Mw = 100,000) with an increase in the ArgMA composition, while the polymer without ArgMA failed to form polyplex. This suggests that ArgMA is the major mRNA binding domain of PMR. As a result, in the mRNA protection assay, the PMR with an increasing composition of ArgMA inhibited mRNA degradation. However, naked mRNA was completely degraded. Similar results were observed using PMR synthesized by RAFT polymerization (Mw ranging from 7,400 to 27,000) in the agarose gel electrophoresis and the mRNA protection assay. Finally, transfection experiments were performed using iRFP fluorescence expression as an indicator. HEK293 cells expressed the highest iRFP expression by culturing in the medium containing the polypeptide core transfection with 30 mol% ArgMA. ArgMA will be a promising motif for designing cationic moiety-free mRNA delivery carriers.

Lyophilized Porous Gelatin Microgels Ziqiang Guan; University of New Hampshire, United States

Injectable hydrogels are useful for wound healing and tissue engineering due to their ability to conform to the topography of target tissues and provide a natural hydrated 3D environment for cells. However, most injectable hydrogels are nonporous, resulting in a delayed cellular response. Previously, our group developed an injectable microporous hydrogel made of gelatin microgels, which are cured to form a bulk hydrogel using microbial transglutaminase (mTG). This novel hydrogel allowed efficient migration of surrounding cells into the hydrogel phase as well as rapid spreading and proliferation of encapsulated cells. These characteristics indicate its potential use in wound healing and stem cell delivery. In this research, we demonstrate the development of porous gelatin microgels and their assembly for cell encapsulation. The porous microgels are produced by swelling and lyophilization of nonporous gelatin microgels. The microstructure of the microgels was confirmed using scanning electron microscopy (SEM). The pores in the microgels enabled more rapid diffusion of a model protein (bovine serum albumin) into the microgels, demonstrating that these porous microgels will facilitate the transfer of nutrients and gas molecules in and out of the hydrogel. When these porous microgels were used for the encapsulation of human dermal fibroblasts (hDFs), hDFs were found to exhibit more widespread morphologies. Taken together, these novel microgels will prove useful for stem cell delivery for tissue repair.
8:00 PM SB09.03.13 Novel Nanoscale 3D Mapping of Mechanical Heterogeneities in Hydrogels for Tissue Engineering Fei Wang, Kevin Grassie, Fayekah Assanah, Yusuf Khan and Bryan D. Huey; University of Connecticut, United States

We are developing a platform to investigate the forces experienced by cells in tissue engineering hydrogels when exposed to external loading by ultrasound, mimicking clinical procedures for bone tissue regeneration. A high density of embedded fluorescent microbeads, which serve as fiduciary markers for deformation tracking, is dispersed within the hydrogel. A series of optical images are first acquired over a range of focal planes, spanning thicknesses of tens of micrometers, to map the bead positions in 3D. Such optical stacks are then repeatedly collected as a function of time before, during, and after uniform acoustic loading. Post processing identifies the displacements of the several thousand beads in the field of view. This allows local distortions within the hydrogel, and even incorporated cells, to be volumetrically mapped. Variations in the magnitude and direction imply mechanical heterogeneities due to local differences in hydrogel cross-linking, density, hydration, and/or cellular mechanical structures and active adhesion. This approach will help to investigate the cellular response to clinically applied, but still not well understood, low-intensity pulsed ultrasound (LIPUS) with the potential to be translated to enhance soft tissue formation and healing, and ultimately this approach may enable rapid 3D Traction Force Microscopy, with broader applications to other 3-dimensionally heterogenous systems including individual cells, tissue, and block copolymers, and nanocomposites.

8:00 PM SB09.03.20 Biomimetic Scaffolds from Biopolymer Ionogels: Elucidating Processing Parameter Dependence on Cell Proliferation Evan McDowell, Liberty Yoder and Letti Frenadez; North Carolina A&T, United States

Novel tissue engineering approaches are imperative to address the increasing prevalence of replacing damaged or lost organs due to congenital defects, traumas, or disease. Current methods for developing functional tissue miniaturizing the potential to improve patient outcomes, alleviate healthcare burdens, and improve quality of life globally. Recently, research developments in stem cells, biomimetics, biochemistry, and material science have been undertaken to pioneer these new paths for researchers, in some cases allowing them to circumvent traditional methods altogether. Most regenerative medicine/techniques that have emerged are centered around infusing a cell’s natural mechanisms with manufactured processes, but realizing a functional biomimetic synthetic tissue is an intricate process. Synthetic tissue must aim to mimic the heterogeneity, complexity, structural integrity, mechanical function, and biocompatibility of indigenous tissue. Additive manufacturing, hydrogel cell cultures, and electrospinning have been used to produce tissue that equates to or enhances the regenerative properties of the human body. Here in this study, we follow established ionic liquid protocols, synthesizing BmimCl from conventional precursors to be used in various dissolutions, forming ionogels. These ionogels are composed of cellulose, silk, or a blend of both, and in combination with our regenerating solution, served as the material for 3D printing the scaffolds. Here we show that via standard additive manufacturing processes, we were able to design and manufacture biomimetic ionogel scaffolds with tailored nanostructured features that facilitated enhanced cellular activity and proliferation.

8:00 PM SB09.03.21 Actuating Extracellular Matrices Mechanically Program Anisotropy in Engineered Muscle Tissues Brandon Rios, Angel Bu and Ritu Raman; Massachusetts Institute of Technology, United States

Introduction: Multicellularity is the key to the dynamic functionality of biological tissues. Cells embedded in an extracellular matrix communicate with each other, and with their surrounding scaffold, through a combination of chemical, electrical, mechanical, and signaling. A soft actuating substrate that is capable of controlling cell-cell mechanical interaction with high spatiotemporal precision, while also allowing for the generation of forces in the biologically relevant range, would enable probing the impact of external forces on intercellular communication and measuring downstream impact on morphology and function. We have developed a magnetically actuated extracellular matrix capable of modular, programmable, and tunable deformation. We test this platform as a mechanically active substrate for skeletal muscle and show that we can control the directional fusion of myoblasts into aligned fibers. By leveraging computational tools to track substrate deformation in response to muscle contraction, we further demonstrate that mechanically programmed anisotropy in muscle improves synchrony of tissue-wide coordinated twitch. This study sets the stage for deploying actuating extracellular matrices to map and modulate mechanical signaling and control a variety of complex biological processes.

8:00 PM SB09.03.22
Laminin-Decorated Gelatin Microporous Injectable Hydrogel for the Encapsulation and Differentiation of Neural Progenitor Cells Seth Edwards; University of New Hampshire, United States

Nervous tissues have limited capacity to regenerate, and damage to these tissues, due to neural injuries or neurological disorders, is often debilitating to the affected patients. The delivery of neural progenitor cells (NPCs), with biomaterials as a delivery vehicle is a promising strategy to promote neural tissue repair. Neural differentiation of NPCs is facilitated by cell spreading and morphological changes, as well as cell-cell interactions. An effective delivery vehicle for the nervous tissue regeneration should promote such cell-matrix and cell-cell interactions. In this report, we investigated the potential for a microporous injectable hydrogel, formed by annealing of gelatin microgels to promote the differentiation of encapsulated NPCs. In addition, we demonstrate a novel method of improving NPC adhesion in the microgel matrix by a facile covalent incorporation of laminin by microbial transglutaminase (mTG) during the microgel annealing process. We found that cell organization, morphology, and differentiation were dependent on the 3D microenvironment, as examined through live/dead assay, immunofluorescence staining for neural markers, mitochondrial activity, and by investigating functional neuronal network formation through monitoring calcium flux of encapsulated cells in response to neurotransmitter. In summary, our results investigate and demonstrate the potential for microporous injectable hydrogels to serve as a vehicle for the encapsulation and differentiation of NPCs.

8:00 PM SB09.03.23
Guanyidine-Based Hydrophilic Antimicrobial Polymer as a Textile Coating Urmilingual Process using a Microfluidic Reaction System Jun-Won Ko; Ajou University Medical Center, Korea (the Republic of)

With the increase in infection transmission and resistance to antibiotics, using clothing as the first of defense can reduce transmission rates and contain disease spread. We report a guanidine-based cationic hydrophilic antimicrobial polymer (GAMS) that can selectively lyse bacterial cells. Antibacterial activity, hydrophilicity, haemolytic and thermal properties of the crosslinked siloxane-based cationic polymer are tested post-functionalization with guanidine groups at 10%, 30%, 50%, and 70% loading relative to the amine groups on the polymer. It is concluded that guanidine functionalized polymer is selective for bacterial cell lysis with complete elimination of class 2 pathogens (E. coli and MRSA) using a contact killing mechanism. GAMS polymers show high thermal stability. Structural characterization of GAMS polymers is performed using NMR (1H, 13C, COSY, HMQC), FTIR, elemental analysis, TGA, (E. Coli/MRSA). Bacterial colony counting assays are performed to evaluate the efficiency of GAMS compared to hydrophobic antibacterial polymers that have been previously reported.

8:00 PM SB09.03.24
Synthesis of Curcumin-Loaded LNP-Based Sarcopenia Treatment using Microfluidic Reaction System Jun-Won Ko; Ajou University Medical Center, Korea (the Republic of)

Sarcopenia, characterized by progressive loss of skeletal muscle mass and function, is a prevalent condition associated with aging. Currently, there is a growing interest in developing effective therapeutic strategies to combat sarcopenia and improve the quality of life for affected individuals. In this study, we propose a novel approach for the synthesis of curcumin-loaded lipid nanoparticle (LNP)-based sarcopenia treatment using a microfluidic reaction system.

The microfluidic reaction system offers several advantages over traditional bulk synthesis methods, including precise control over reaction conditions, enhanced mass transfer, and reduced reaction times. These characteristics make it a promising tool for the synthesis of drug-loaded nanoparticles with improved physicochemical properties and therapeutic efficacy.

Curcumin, a naturally occurring polyphenol found in turmeric, has demonstrated potential as a therapeutic agent for sarcopenia due to its anti-inflammatory and antioxidant properties. However, its poor aqueous solubility and low bioavailability limit its clinical application. By encapsulating curcumin within LNPs, we aim to enhance its stability, solubility, and targeted delivery to skeletal muscle tissues.

The microfluidic reaction system enables the efficient production of curcumin-loaded LNPs by facilitating the rapid mixing of lipid precursors and curcumin in a continuous flow. This allows for the formation of uniform nanoparticles with controlled size and composition. Furthermore, the microscale dimensions of the system enable the precise tuning of reaction parameters, such as temperature, flow rates, and residence times, to optimize the encapsulation efficiency and loading capacity of curcumin within the LNPs.

To evaluate the potential of the synthesized curcumin-loaded LNPs as a sarcopenia treatment, in vitro and in vivo studies will be conducted. The nanoparticles will be characterized for their physicochemical properties, including size, zeta potential, and drug release kinetics. In vitro assays will assess the cellular uptake and cytotoxicity of the LNPs using skeletal muscle cells. In vivo studies will involve the administration of the curcumin-loaded LNPs to animal models of sarcopenia, followed by the evaluation of muscle mass, strength, and markers of inflammation and oxidative stress.

In conclusion, this study proposes a microfluidic-based approach for the synthesis of curcumin-loaded LNPs as a potential sarcopenia treatment. The use of a microfluidic reaction system offers unique advantages in terms of control, scalability, and reproducibility. If successful, this approach could provide a promising therapeutic strategy for the management of sarcopenia, addressing the unmet need for effective treatments for this age-related condition.

Noninvasive and Longitudinal Study of Multi-Contrast 3D Bioprinted Tissue Constructs via Photon Counting Computed Tomography Carmen J. Qi; Connor Evans; Lan Li; Alexander Allphin; Martin Tomov; Liqun Ning; Ming Shen; Jarred M. Kaiser; Luz Restrepo; Victor Putaturo; Gabriella Kabboul; Anjum Alam; Travis Fulton; Remi Veneziano; Nick Willet; Hicham Drissi; Cristian Badea; Holly Bausner-Heaton; Ryan Roeder; and Vahid Serpouhian; 1Emory University, United States; 2Georgia Institute of Technology, United States; 3University of Notre Dame, United States; 4Duke University, United States; 5George Mason University, United States

3D bioprinting has revolutionized the fields of personalized and precision medicine by offering the unique possibility of designing patient-specific tissue engineered constructs and therapies. For cardiovascular disease, patient-specific bioprinted cardiac patch devices have emerged as novel therapeutics, demonstrating promising results in restoring and/or improving cardiac function, reducing the infarct size, and enhanced angiogenesis in animal models of myocardial infarction (MI). However, current 3D bioprinted cardiac patch designs primarily lack the ability of noninvasive, longitudinal, and quantitative monitoring of their function following the implantation in vivo. Computed tomography (CT) is widely used in clinical settings to monitor cardiac function and anatomy. A recent advancement in CT imaging, i.e., photon-counting CT (PCCT), has enabled simultaneous imaging of multiple contrast agents at higher spatial resolution while potentially reducing the radiation dose. Through integrating advanced multi-material bioprinting and PCCT imaging, this research aimed at design and creation of novel 3D cardiac patch structures, incorporated with multiple CT imaging probes, which can be monitored noninvasively and longitudinally in both in vitro and in vivo applications.
In this study, distinct k-edge CT imaging probes were incorporated in different bioinks and used to print patch structures. To determine the feasibility of our approach, release profiles of various imaging probes from the constructs were investigated to optimize the production of bioinks with adequate and stable concentrations of imaging probes. Subsequently, imaging properties of bioprinted contrast agent-laden constructs were evaluated by CT/PCCT both \textit{in vitro} and \textit{in vivo}, in a subcutaneous mouse model. Imaging probes added to distinct bioink formulations included gadolinium (Gd) chelate, iodine (Iod), GdO₂, gold nanoparticles (Au NPs), and methacrylated Au (AuMA) NPs. Printed patches with single and multiple imaging probes were able to be discriminated and quantified by PCCT, offering the ability to perform longitudinal and noninvasive monitoring of the implanted patch. In the final path design, AuMA and GdO₂ NPs were used to label different components of the patch structure, and Iod was used to visualize and quantify perfusion through the printed vasculature in the patch. Future studies aim to further control the stability and release behavior of imaging probes, incorporate advanced drug delivery tools within the patch (e.g., co-encapsulation of therapeutic molecules and imaging probes), and development of novel imaging probes (e.g., via chemical conjugation of probes to the polymer matrix). In addition, we work on improving the functionality of cardiac patch by incorporating various molecular therapeutics and cardiovascular cells, together with the CT imaging probes. In summary, this study demonstrates the feasibility of designing a novel theranostic platform to treat cardiovascular disease using a new generation of bioprinted patch devices.

Compressive Modulus and Charge Dictate Surface Protein Adsorption on Injectable Cellulosic Hydrogels \textit{In Vitro} Adam Weisel and Steven Nicoll,
The City College of New York, United States

Cellulose is a natural polysaccharide that can be modified to meet many physical, biological, and chemical requirements, making it an attractive candidate for tissue engineering\(^1\). Specifically, its inherent sustainability and the potential for \textit{in situ} gelling by functionalization with methacrylate groups, makes this system appealing for stable, minimally invasive implants\(^2\). Water-soluble cellulosic derivatives, such as methylcellulose (MC), which contains hydrophobic methoxy groups that afford thermogelation properties at body temperature, and carboxymethylcellulose (CMC), which provides polyanionic character analogous to native tissue glycosaminoglycans, allow for further tuning of the hydrogel features. The biological response to these materials is dependent on serum protein adsorption, which has not been examined for such cellulosic hydrogels. Thus, this study investigated the effect of hydrogel compressive modulus and charge on surface protein adsorption \textit{in vitro} by varying MC and CMC fractional composition, macromer concentration, and molecular weight.

MC and CMC were functionalized by esterification of hydroxyl groups with methacrylic anhydride and gels were fabricated via free radical polymerization using ammonium persulfate and ascorbic acid redox initiators\(^2\). Hydrogel hydrophobicity/charge was varied by mixing combinations of MC and CMC, while the modulus was altered by changing the macromer concentration (3\% & 6\%, w/v) and molecular weight (90, 250 KDa CMC). Generally, concentration was the largest driver of gel stiffness as indicated by compressive moduli ranging from 5.8±1 kPa to 19.3±3 kPa for the 3\% group and 59.3±3 kPa to 90.6±32 kPa for the 6\%. Relatedly, stiffer gels exhibited less swelling as measured by the equilibrium weight swelling ratio (W_s/W_o), with the 6\% gels yielding lower values on average. Within a concentration group, charge played a clear role on swelling. For the 3\% gels, the CMC only (negatively charged) gels yielded the highest ratio of 41±9, the MC only (hydrophobic) gels the lowest at 22±0.7, and a 1:1 mix of the two polymers was in between (ratio of 36±7). Interestingly, there was an inverse relationship between serum protein adsorption and gel modulus where every 3\% gel formulation promoted more adsorption than its 6\% macromer counterpart. Adsorption was also affected by charge, as no more than 63±11 µg/mL of protein was measured on MC gels, whereas the CMC only gel values ranged from 138±24 to 568±155 µg/mL.

Tailoring an injectable device is crucial for successful tissue incorporation. Long-term implants often suffer from sustained foreign body responses that may result in dense fibrous tissue encapsulation, and surface protein adsorption is a precursor to this adverse outcome\(^3\). Thus, the effects of biomaterial stiffness and charge on adsorption are often investigated and are material specific\(^4,5\). These findings represent an improved understanding of cellulosic materials and are currently being investigated for correlations to \textit{in vivo} foreign body reaction and potential fibrous encapsulation.

A Fillable Scaffold Mimicking Extracellular Matrix for \textit{Chronic} Tunnelling Wound Healing Xiaoyu Wang\(^1\), Sigen A\(^2\), Hongyuan Tai\(^1\) and Wenxin Wang\(^1\), \textit{Charles Institute of Dermatology, School of Medicine, University College Dublin, Ireland}; \textit{2School of Medicine, Anhui University of Science and Technology, China}; \textit{3Biflar Ltd, Ireland}

Chronic wounds impose significant social and financial costs for patients and healthcare systems. Pathogenic abnormalities and hostile wound environments, such as inflammation, and augmented levels of Matrix metalloproteinases (MMPs) render the healing of chronic wounds a major and long-term challenge. Most commercial wound dressings are aimed to target a single non-healing factor, only a few are tailored to the multiple pathological abnormalities of chronic wounds and even fewer are suitable for tunnelling chronic wounds due to the difficulty in making adequate contact with wound beds. Herein, a novel fillable wound matrix mimicking extracellular matrix was fabricated by crosslinking gelatin and glycosaminoglycan via Schiff’s base reaction to inhibit the inflammatory response, and inactivate excessive MMPs, ultimately promoting chronic wound healing. The degradation rates, pore size, swelling profile, cytotoxicity, cell proliferation and migration were investigated. Highly promoted cell adhesion and proliferation, and significantly improved migration of fibroblasts demonstrated that this fillable scaffold could provide a scaffold for cellular invasion and promote wound healing. It is easy to apply in difficult-to-access tunnelling wounds, indicating the promising potential in treating chronic tunnelling wounds. Moreover, the validation of reaction to inhibit the inflammatory response, and inactivate excessive MMPs, ultimately promoting chronic wound healing. The degradation rates, pore size, swelling profile, cytotoxicity, cell proliferation and migration were investigated. Highly promoted cell adhesion and proliferation, and significantly improved migration of fibroblasts demonstrated that this fillable scaffold could provide a scaffold for cellular invasion and promote wound healing. It is easy to apply in difficult-to-access tunnelling wounds, indicating the promising potential in treating chronic tunnelling wounds. Moreover, the validation of sterilisation and virus inactivation laid the foundations for the commercialization of this fillable wound matrix.

Anderson\(^1,2\), \textit{1Massachusetts Institute of Technology, United States}; \textit{2Boston Children's Hospital, United States}; \textit{3Wellesley College, United States}
The transplantation of cells engineered to secrete therapeutic proteins presents a promising method to address a range of chronic diseases including diabetes, cancer, and blood disorders. However, clinical translation faces several challenges regarding immune rejection, adequate nutrient supply to therapeutic cells, and the mechanical integrity of delivery constructs. Typically, non-degradable hydrogels are used to encase and protect therapeutic cells from immune rejection while still permitting the exchange of nutrients and therapeutics. However, a critical tradeoff exists wherein improving hydrogel mechanics (e.g., by increased crosslinking or molecular weight) often compromises biocompatibility and diffusion. Consequently, the design of macroscale, retrievable hydrogel devices often must balance the risks of mechanical failure and poor viability of encapsulated cells.

We address this challenge through a composite materials system centered around an oxygen-permeable silicone cryogel, which acts as an internal skeletal support for conventional hydrogel matrices coated by an anti-inflammatory polyelectrolyte for alleviating immunological responses towards foreign objects. We show that integration of the skeletal structure dramatically improves mechanical properties and effectively mitigates fracturing of implanted devices. Notably, our approach forgoes the use of commonly employed external housings, which can impede both the transport of nutrients to cells and the release of therapeutics to the host. By contrast, the skeleton leverages the superior oxygen diffusivity of silicone elastomers and a judiciously designed microstructure to improve the oxygenation of encapsulated cells. Fluorescence microscopy reveals that the skeleton acts as an internal scaffold that guides cellular proliferation and results in favorable changes in cell morphology. Pre-clinical studies demonstrate that these functionalities translate to significantly enhanced protein secretion from genetically engineered, xenogenic cells in immunocompetent animals over 4 weeks, without the need for immunosuppression.

The resulting technology drives important improvements in the efficacy and practicality of implantable cell therapies. Namely, superior materials mechanics translates to easier device handling and reduces risk of mechanical failure, while the ability to sustain denser cell populations enables miniaturization of therapeutic implants. With the capability to modify encapsulated transgenic cells to secrete different biologics, the presented platform promises to support a broad spectrum of protein replacement therapies.

Voxelated Bioprinting of Double-Network Hydrogel Scaffolds
Liheng Cai; University of Virginia, United States

Analogous of pixels to two-dimensional pictures, voxels — in the form of either small cubes or spheres — are the basic building blocks of three-dimensional (3D) objects. Here, we present a voxelated bioprinting technology that enables the digital assembly of interpenetrating alginate and polyacrylamide (PAM) double-network (DN) hydrogel droplets. The hydrogel is crosslinked via additive-free bioorthogonal chemistry involving a pair of stoichiometrically matched polymers. We develop theoretical frameworks to describe the crosslinking kinetics and stiffness of the hydrogels, and construct a diagram-of-state to delineate their mechanical properties. Multi-channel print nozzles are developed to allow on-demand mixing of highly viscoelastic bio-inks without significantly impairing cell viability. Further, we showcase the distinctive capability of voxelated bioprinting by creating highly complex 3D structures such as a hollow sphere composed of interconnected yet distinguishable hydrogel particles. Finally, we validate the cytocompatibility and in vivo stability of the printed DN scaffolds through cell encapsulation and animal transplantation.

Conductive Biodegradable Elastomeric Scaffolds for Bladder Regeneration
Rebecca Keate1, Matthew Bury2, Jonathan Rivnay1, Arun Sharma2 and Guillermo Ameer1; 1Northwestern University, United States; 2Lurie Children's Hospital of Chicago, United States

Electrically conductive polymers are a unique class of materials that have demonstrated promising potential to enhance regeneration in several systems including muscle, skin, and neural tissue. The capability to bolster repair in a variety of tissue systems makes conductive polymers a promising material for advanced tissue engineering applications, such as organ regeneration, that require synergistic repair with various cell lineages. One such organ that could benefit from advanced repair solutions is the bladder, the function of which is impaired in cases such as neurodegenerative disorders, cancer or injury. Conductive polymers have not been used for bladder regeneration, in part due to the difficulties of incorporating conductive polymers in a mechanically robust tissue engineering solution. One reason for this loss of material integrity is the inherent phase mismatch between hydrophobic conductive polymers and the primarily hydrophilic biomatrices they are integrated within. Furthermore, we sought to mitigate these shortcomings by adopting a phase-functionalization approach wherein the hydrophobic conductive polymer is embedded within a similarly hydrophobic biomaterial. Citrate-based materials are one such class of hydrophobic biomaterials with excellent bioactivity, morphological versatility, and degradability. By utilizing an in situ polymerization of the conductive polymer poly(3,4-ethylenedioxythiophene) in conjunction with citrate-based elastomers, we are able to preserve the intrinsic benefits of the base material including its powerful antioxidant activity, biocompatibility, and mechanical durability. We further demonstrate the applicability of this material in a bladder augmentation model, comparing our PEDOT-citrate based films to cell-seeded citrate-based counterparts. Analyzing regenerated bladder function through urodynamics studies, we find that PEDOT-incorporated films facilitate repair significantly compared to the cell-seeded films and significantly better than the pristine citrate-based film. Furthermore, this work demonstrates (1) advantages of a phase-compatible functionalization approach from a materials-perspective, (2) application of conductive polymer-based materials in a novel regenerative system, and (3) the capabilities for conductive polymers to promote regeneration as effectively as a cell-seeded material.
(SonoScaffolds) for noninvasive and spatiotemporally-controlled genetic manipulation of cells in 3D scaffolds. Here, focused ultrasound interacts with integrated echogenic particles within hydrogel matrices to locally deliver nucleic acids to cells to manipulate protein expression and secretion. Ultrasound has distinct advantages as a triggering stimulus as it can be focused to small volumes with multi-centimeter tissue penetration depth [1-2].

Using this approach, we have successfully demonstrated ultrasound-induced transfection of cells embedded in SonoScaffolds, including localized expression of vascular endothelial growth factor (VEGF). A dual expression VEGF-GFP fusion plasmid was coupled to lipid-based ultrasound-responsive microparticles and incorporated into a cell-seeded collagen hydrogel. Focused ultrasound (1 mm² focal zone) was applied noninvasively within the hydrogel matrix. Transfection of matrix-embedded cells was localized to the ultrasound-exposed region. The cells showed a punctate distribution of VEGF-GFP consistent with packaging of VEGF into secretory vesicles. Creating user-defined 3D spatiotemporal patterns of growth factor expression can be leveraged to elucidate how spatial presentation and timing of protein expression affect 3D cell migration and to inform therapeutic strategies for tissue repair.

Pushing the boundaries even further, we are creating ultrasound stimuli-responsive scaffolds with complex 3D architectures by integrating our echogenic gene delivery particles into 3D-bioprintable inks. Transfection was selectively activated by ultrasound within printed constructs, demonstrating the first cell-seeded bioprinted structure designed for ultrasound-controlled gene delivery. We are further extending this technique to 3D-printed spheroids and organoid cultures. Together, this work demonstrates a new class of 3D-programmable cell culture materials that enable remote, spatiotemporally-defined genetic perturbation of embedded cells and multicellular structures. These systems will provide new insights into coordinated cell processes and how growth factor presentation can be leveraged to direct healing in implantable biomaterials, with important applications in tissue construct maturation, vascularization, and tissue regeneration.

8:45 AM SB09.04.03 Shape Memory Polymer Bioglass Composite Scaffolds to Heal Complex Bone Defects Brandon M. Nitschke, Alexander E. Konz, Elizabeth A. Butchko, MaryGrace N. Wahby and Melissa Grunlan; Texas A&M University, United States

Cranio-maxillo-facial (CMF) defects are generally treated with autografts, but difficulty achieving a conformal fit with lead to premature graft resorption. Thus, we have developed shape memory polymer (SMP) scaffolds that can “self-fit” into irregularly shaped CMF defects. These are formed from biodegradable linear-poly-(ε-caprolactone) diacrylate (linear-PCL-DA), with crystalline lamellae serving as switching segments (Tm = −55 deg C) and crosslinks acting as netpoints. After exposure to warm saline (~55 deg C), the scaffold becomes malleable, allowing press-fitting into an irregular defect before cooling to body temperature restores its rigid state. Herein, SMP scaffold composition was systematically tailored to enhance thermal tissue safety, degradation rate, modulus, and bioactivity. Star-architectures of constituent polymers and inclusion of bioactive Bioglass (BG) were utilized to achieve these properties. To reduce the self-fitting temperature, SMP scaffolds were be formed from star-PCL-tetraacrylate (star-PCL-TA; Tm = −45 deg C). Furthermore, to accelerate degradation and tune modulus, semi-interpenetrating networks (semi-IPNs) were formed by including linear- or star-poly(ε-caprolactone) (PLLA). 45S5 BG is known to induce hydroxyapatite (HAp) mineralization that subsequently promotes osteogenic differentiation (i.e., osteoinductivity) as well as osseointegration. Scaffolds were prepared from linear-PCL-DA or star-PCL-DA, as well as each with linear- or star-PPLA (75:25 wt% ratio). BG was incorporated at varying levels into scaffolds (up to 30 wt%) during fabrication. The BG content was confirmed using thermal gravimetric analysis (TGA). The compressive mechanical properties of the scaffolds were evaluated, as well as the in vitro degradation behavior. Notably, composite scaffolds exhibited rapid formation (24 hours) of HAp when exposed to simulated body fluid (SBF) as confirmed by SEM/EDS. Overall, these composite SMP scaffolds are expected to provide enhanced healing of complex bone defects.

9:00 AM **SB09.04.04 In Vitro Engineered Tissue Screens for Cardiac Regeneration Nenad Bursac; Duke University, United States

Cell and gene therapies for heart regeneration represent a promising approach to remuscularize the heart following myocardial injury. These regenerative therapies can benefit from in vitro chemical and genetic screens in engineered heart tissues to identify and study novel inducers of cardiomyoctye (CM) proliferation. Our recent screens in neonatal rat and human iPSC-derived CMs have identified activations of the mitogen activated protein kinase (MAPK) pathway and pentose phosphate pathway (PPP) as two promising strategies with pro-proliferative effects in engineered cardiac tissues (ECTs). Specifically, a doxycyclin-inducible, CM-specific expression of constitutively-active mutant of BRAF (BRAF-V600E), a major kinase in the MAPK pathway, was sufficient to induce CM cycling in ECTs, but resulted in functional decline and tissue stiffening. These adverse functional effects were associated with broad transcriptional changes, a shift to glycolytic metabolism, and induction of a pro-migratory CM phenotype. While ERK activation was required for the initial establishment of the caBRAF-induced phenotype, inhibition of ERK after the phenotype had been established was insufficient to restore the loss of tissue function.Transient caBRAF expression in ECTs rapidly induced CM cycling that preceded functional decline, which was reversible only if MAPK activation was brief (~3 days). Notably, the increase in ECT stiffness resulting from sustained caBRAF expression was dispensable for induction of CM cycling, as transient caBRAF expression yielded increased CM cycling without altered stiffness. Furthermore, in an independent in vitro CRISPR/Cas9 knockout screen, we identified adenosine deaminase knockout (ADA-KO) as the most effective inducer of CM cycle activity in neonatal rat ECTs and long-term cultured hiPSC-CMs. RNA sequencing of ADA-KO vs. control ECTs and measurements of metabolite abundance and enzyme activity suggested lactate generation and PPP upregulation as potential drivers of CM proliferation. Inhibition of the PPP rate-limiting enzyme glucose-6-phosphate dehydrogenase (G6PD) via the small molecule inhibitor 6-aminonicotinamide prevented ADA-KO induced CM cycling, while increased PPP activity via doxycycline-inducible lentiviral G6PD overexpression yielded a significant increase in CM cycling. Overall, our studies demonstrate the utility of in vitro engineered cardiac tissues as a testbed for identification of novel CM mitogens with potential for use in cardiac regenerative therapies.

9:30 AM SB09.04.05 3D Bioprinting of Dense Cellular Structures within Functional Hydrogels with User-Defined Heterogeneity Alperen Abaci and Murat Guvendiren; New Jersey Institute of Technology, United States

3D bioprinting has a strong potential to address tissue and organ shortage for transplantation. Successful fabrication of a functional tissue requires bioprinting strategies that can replicate the biological and structural features of the native tissue. 3D bioprinting advances extrusion-based bioprinting technology for fabrication of architecturally and biologically complex structures, yet this technology requires the use of support baths which generally hinders the relevant bioactivity and heterogeneity. In this study, we developed a new method to create dense cellular structures where cell-only bioinks could be deposited into photocurable support hydrogels with tunable stiffness, degradation and bioactivity. Our approach can utilize multiple cell types or functional hydrogels to create highly heterogeneous and complex structures that could potentially be used to fabricate functional tissue models, as well as tissue interfaces, with relevant biochemical and physical complexities.
In this study, we demonstrate bioprinting of dense cellular structures using fibroblasts (NIH 3T3), human umbilical vein endothelial cells (HUVECs), and human mesenchymal stem cells (hMSCs) within support or functional hydrogels. To demonstrate the potential of our approach and importance of matrix functionalization, we investigate the osteogenic differentiation of hMSCs bioprinted within MeHA hydrogels with controlled stiffness and bioactivity. To control stem cell aspect ratio initial concentration of the MeHA hydrogel is varied (5-15%). Bioactivity is varied by tethering RGD and BMP-2. Dense hMSC scaffolds show even overall cell viability (>80%) and inclusion of RGD and then BMP-2 significantly enhanced osteogenic differentiation. This is confirmed with ALP assay, Alizarin Red staining and osteocalcin immunostaining. Finally, we fabricated dense cellular structures with spatially controlled cellular composition and matrix composition towards creating tissue interfaces.

Conflict of Interest: New Jersey Institute of Technology has a financial interest in the bioprinting approach reported in this manuscript and has already filed a patent application for the technology described in this paper (U.S. Application No. 17/588,998).

Materials for Engineering Cartilage Integration Helen Lu; Columbia University, United States

Muscloskeletal joint motion is facilitated by synchronized interactions between multiple tissue types and the seamless integration of bone with soft tissues such as tendons, ligaments or cartilage. Many of these soft tissues transit into bone through a multi-region interface that minimizes the formation of stress concentrations while enabling load transfer between soft and hard tissues. Given its functional significance, re-establishment of multi-tissue interface is thus critical for promoting the integrative repair of biological as well as tissue engineering cartilage grafts. To this end, interface regeneration and formation of composite tissue units have become a design consideration in tissue engineering. Using the classic osteochondral interface as an example and inspired by current understandings of the native interface structure-function relationship, strategies for interface regeneration and homeostasis will be discussed, with the focus on strategic biomimicry and functional multi-tissue integration.

Development of a Biomimetic Multi-Layered Functionalised Antimicrobial Biomaterial Scaffold for Healing of Complex Wounds Matthew McGrath1,2, Juan Carlos Palomeque-Chávez3, Shane Browne3 and Fergal J. O’Brien1,2, 3Royal College of Surgeons in Ireland, Ireland; 1Advanced Materials and Bioengineering Research Centre (AMBER), RCSI and TCD, Ireland; 3Trinity Centre for Biomedical Engineering, TCD, Ireland

Diabetic foot ulcers (DFUs) are chronic non-healing wounds that constitute one of the most devastating complications of diabetes. Dysfunctional angiogenesis plays a key role in DFU, limiting tissue repair leaving wounds open and prone to infection. Biomaterial approaches, and in particular the use of collagen-glycosaminoglycan (CG) scaffolds, have shown promise to promote tissue regeneration and burn wound healing. These biomaterial scaffolds provide a platform for infiltrating cells into the wound environment but do not directly deal with the underlying pathology of diabetic wounds, so further functionalisation is needed for these complex wounds. The aim of this project was to engineer a biomimetic bi-layered biomaterial scaffold designed to replicate the anatomical structure of the native skin with an epidermal antimicrobial collagen/chitosan film to prevent wound infection and a pro-angiogenic, matrix molecule functionalised dermal porous CG scaffold layer to heal complex wounds.

A bi-layered scaffold was developed by combining an antimicrobial collagen/chitosan film (0.5%, 1% / 0.75%) with a type I collagen, chondroitin-6-sulfate slurry by lyophilisation. Mechanical properties, including interlayer adhesion, were optimised through the film’s collagen content and crosslinking treatment (non-crosslinked (NXL)/dehydrothermal/carbodiimide EDAC crosslinking). The CG layer was then functionalised with either fibronectin, collagen IV, or laminin-1 to enhance its angiogenic and regenerative potential. The film’s antimicrobial potential was tested versus staphylococcus aureus, and the ability of the film to support re-epithelialisation was verified through seeding of human epidermal keratinocytes (HuCkTs). The vascularisation potential of the scaffold was investigated through the culture of human umbilical vein endothelial cells (HUVECs), and human dermal fibroblasts (HDFs) on the functionalised CG scaffold layer.

The bi-layered scaffolds had enhanced mechanical properties suitable for implantation following EDAC crosslinking (compressive modulus = 1.83 ± 0.0035 kPa (EDAC), 0.72 ± 0.15 kPa (NXL)) adhesion strength between layers = 32.3 ± 4.5 kPa (EDAC), 22.5 ± 8.8 kPa (NXL)). Biological characterisation showed that all collagen/chitosan films had antimicrobial activity versus staphylococcus aureus regardless of crosslinking regime and collagen composition and supported the metabolic activity of human epidermal keratinocytes. However, crosslinked scaffolds showed enhanced infiltration and growth of vascular cells. Functionalisation of the CG layer with laminin-1 significant increased production of vascular endothelial growth factor (VEGF) by HDFs over 7 days (1044 ± 112 pg/ml). In addition, HUVECs seeded on these scaffolds formed tubular structures.

This study has led to the development of a novel biomimetic multi-layered functionalised antimicrobial biomaterial scaffold for complex wound healing. The collagen/chitosan film layer demonstrated the ability to inhibit growth and infiltration of staphylococcus aureus, the most common bacterial isolate found in infected wounds and supported metabolic activity of epidermal cells, demonstrating significant potential as a protective cover to the wound and as a surface for re-epithelialisation. Functionalisation of the CG scaffold layer with laminin-1 enhanced the pro-angiogenic regenerative potential of the dermal CG scaffold layer, with increased growth factor production and vascular cell tube formation. Taken together, these results demonstrate the promise of this scaffold as a biomaterial-based solution to treat DFUs.

A Versatile, Bioengineered Skin Reconstruction Device Designed for Austere Environments Joachim G. Veit, Morgan Weidow and Monica Serban; University of Montana, United States

Austere environments in which access to modern medical facilities, medical personnel, or even water and electricity is limited or unavailable pose unique
challenges for medical device product design. Currently existing skin substitutes are severely inadequate for the treatment of severe burns, chronic wounds, battlefield injuries, or work-related injuries in resource-limited settings. For such cases, an ideal device should be biocompatible, bioresorbable, promote tissue healing, not require trained medical personnel for deployment and use, and should enable topical drug delivery. As proof of concept for such a device, silk fibroin and an antioxidant hyaluronic acid derivative were chosen as primary constituents. The final formulation was selected to optimize tensile strength while retaining mechanical compliance and protection from reactive oxygen species (ROS). The ultimate tensile strength of the device was 438.0 KPa. Viability of dermal fibroblasts challenged with ROS-generating menadione decreased to 49.7% of control, which was rescued by pre-treatment with the hyaluronic acid derivative to 85.0% of control. The final device formulation was also tested in a standardized, validated, *in vitro* skin irritation test which revealed no tissue damage or statistical difference from control. Improved topical drug delivery was achieved via an integrated silk fibroin microneedle array and selective device processing to generate crosslinked/through pores. The final device including these features showed a 223% increase in small molecule epidermal permeation relative to the control. Scaffold porosity and microneedle integrity before and after application were confirmed by electron microscopy. Next, the device was designed to be self-adherent to enable deployment without the need of traditional fixation methods. Device tissue adhesive strength (12.0 MPa) was evaluated and shown to be comparable to a commercial adhesive surgical drapes (12.9 MPa) and superior to an over-the-counter liquid bandage (4.1 MPa). Finally, the device’s wound healing potential was assessed in an *in vitro* full-thickness skin wound model which showed promising device integration into the tissue and cellular migration into and above the device. Overall, these results suggest that this prototype, specifically designed for use in austere environments, is mechanically robust, is cytocompatible, protects from ROS damage, is self-adherent without traditional fixation methods, and promotes tissue repair.

1:10 AM SB09.04.09 Development of Antibiotic-Free Antimicrobial Scaffolds for Effective Delivery of Osteogenic & Angiogenic MicroRNAs to Simultaneously Treat and Repair Infected Bone Tissue Joanna Sadowska1, Katelyn Genoud1, Rachael Power1, Austyn Matheson1, Arlyng González-Vázquez1, Lara Costard1, Tanguy Hallegouet2, Gang Chen1, Brenton Cavanagh1, Huijun Zhang2, Aldo Boccaccini3 and Fergal O’Brien1; 1Royal College of Surgeons in Ireland; 2University of Strasbourg, France; 3Friedrich–Alexander University Erlangen–Nuremberg, Germany

**INTRODUCTION:** The treatment of bacterial infection of bone while regenerating bone at the same time is extraordinarily challenging in clinical settings (1). The escalating problem of antimicrobial resistance necessitates the development of novel antibiotic-free strategies to eradicate bacteria. One such approach is the use of metal-doped nanoparticles (2). To address bone regeneration, the approaches include the local delivery of gene therapies, such as microRNA in scaffold systems. A scaffold provides structural support while microRNA induces host cells to produce multiple angiogenic and osteogenic proteins essential for bone healing (3). The present study combines these two promising approaches to develop a multifunctional biomaterial-based platform with angiogenic, osteogenic and antimicrobial properties. The scaffold delivers osteogenic genes (by delivering antagomiR-138, a microRNA targeting ERK pathway) (4) and antibiotic-free antimicrobial nanoparticles (copper-doped bioactive glass, CuBG) (2), leading to a novel platform with superior therapeutic potential and angiogenic, osteogenic and antimicrobial features.

**METHODS:** Freeze-dried collagen-based scaffolds, previously optimized in our lab for bone regeneration (3), were enriched with antagomiR-138 and CuBG nanoparticles and assessed *in vitro* using human mesenchymal stem cells (transfection efficacy, osteogenic and angiogenic gene expression, metabolic activity, DNA content, alkaline phosphatase activity, calcium deposition). The antimicrobial properties of the scaffolds were assessed using gram-positive (*S. aureus*) and gram-negative (*E. coli*). The anionic and osteogenic properties of the scaffolds were assessed in *two in vivo* models: a load-bearing 5 mm femoral defect in female Sprague Dawley rats and a chick chorioallantoic membrane model (CAM).

**RESULTS SECTION:** The CuBG and antagomiR-138 particles were effectively incorporated into collagen scaffolds without affecting the mechanical and structural properties of the scaffolds. The CuBG scaffolds reduced the adhesion of *S. aureus* and *E. coli* 5-fold and 2-fold, respectively. The antagomiR138 and CuBG functionalized scaffolds effectively transferred functionalized hMSCs *in vitro*, enhancing the osteogenic (COLL1A2, NOCH4, SMAD5) and angiogenic genes (VEGFA) and calcium deposition. The *in vivo* assessment showed that antagomiR-138 scaffolds promoted enhanced healing in the femoral defect model by producing endothelial cell outgrowth. The antagomiR138-CuBG scaffold promoted vasculogenesis, improving the number of branches and the length of blood vessels in *in vivo* CAM model.

**DISCUSSION:** The study demonstrated the therapeutic potential of a multifunctional, antagomiR138 antimicrobial scaffold system. The system delivered antagomiR138 to hMSCs *in vitro*, enhancing the osteogenic genes and mineralisation. The incorporation of CuBG nanoparticles enhanced antimicrobial mechanisms (production of ROS) in *S. aureus* and *E. coli*, inhibiting the attachment to the scaffold. The antagomiR138 scaffolds improved osteogenesis and vasculogenesis *in vivo* in a femoral defect model and a chick chorioallantoic membrane model, respectively. Our work demonstrates, for the first time, the feasibility of combining non-antibiotic biomaterial-based approaches with gene therapeutics for developing a platform which not only regenerates bone but also fights rising problems of antimicrobial resistance. This approach opens the door to new possibilities in a myriad of indications beyond bone repair.

**SESSION SB09.05: Cellular Approaches for Regenerative Engineering**

**Wednesday Afternoon, November 29, 2023**

**Hynes, Level 1, Room 104**

**1:45 PM SB09.05.01**

A Decellularized Cartilage Biomaterials Approach to Pediatric Airway Reconstruction Paul Gehret1,2, Soheila Ali Akbari Ghavimi1, Alexandra Dumas2,3, Ryan Borek2,3, Ian Jacobs2 and Riccardo Gottardi1,2; 1University of Pennsylvania, United States; 2Children's Hospital of Philadelphia, United States

**Introduction:** Severe subglottic stenosis (SGS), the narrowing of the airway just below the vocal folds, develops in 8.3% of ICU neonates and directly leads to debilitating comorbidities [1,2]. Pediatric SGS is the result of prolonged intubation and dramatically lowers the child’s long-term quality of life, as they often suffer speech and cognitive delays. In the most severe cases, laryngotracheal reconstruction (LTR) surgery is required to expand the airway and...
restore airflow [1,2]. During LTR, autologous costal cartilage is harvested, shaped, and implanted into the child’s airway. However, a major obstacle is that young children often lack sufficient costal cartilage to ensure a successful graft surgery, leading to donor site morbidity and high risk for restenosis, necessitating revision surgery. Our objective is to utilize xenogeneic decellularized meniscal cartilage (MEND) to engineer a cartilage implant populated with patients’ cells to circumvent the limitations of pediatric autologous cartilage.

**Materials and Methods:** 
*Meniscus decellularization and channel formation:* Meniscus cross-sections were devitalized with 4 freeze/thaw cycles then subjected to pepsin and acetic followed by treatment with elastase. 6 mm cylinders were created with a biopsy punch from the posterior half of the digested cross-sections to ensure the maximum number of channels. Decellularized Meniscus Reinnovation: Sterile decellularized, digested meniscus (MEND) cylinders were placed on top of a transwell plate and cartilage progenitor cells (CPC) were seeded on top of the MEND cylinders. After 3 days, the MEND cylinders were fixed, sectioned, and stained. In Vitro Differentiation: CPC-invaded MEND were cultured in chondrogenic medium for 3 weeks and media was renewed twice/week. The differentiated construct were examined for gene expression, compression testing, and histology. Rabbit Laryngotracheal Reconstructions: Acellular, re-cellularized, or differentiated decellularized cartilage was implanted in an anterior cricoid split LTR. After 3 months, the rabbits were euthanized and the construct phenotype, airway expansion, and histomorphometry were assessed.

**Results and Discussion:** After enzymatic treatment, H&E images of circumferential sections showed that clearly aligned channels are visible post-treatment. Following a serum gradient (transwell) migration, cartilage progenitor cells (blue DAPI nuclei) penetrated in 3 days through the channels the entire depth of the construct (collagen red auto-fluorescence) reaching a density similar to that of native cartilage. After 3 weeks of differentiation, cells were arranged into lacunae with columnar structures resembling the organization of native cartilage and secreted a substantial amount of glycosaminoglycans (GAGs). Importantly, the constructs increased in both bulk mechanical strength and GAG content. Finally, a 38 rabbit study was conducted and MEND was implanted in a rabbit LTR, MEND successfully expanded the airway over the course of the 3 months and integrated with the existing cartilage as shown by the increase of GAGs within the construct and the neo-chondrification protruding from the cartilage rings. We established how decellularized meniscal cartilage reinimated with progenitor cells can significantly improve outcomes for pediatric LTR.

**Ethical Statement:** All animal studies were conducted with IACUC approval.

**Magnetic-Responsive Silk Microfibers for Neuroregeneration**

**Jeanine Coburn and Melissa Wojnowski; Worcester Polytechnic Institute, United States**

Magneto-responsive fiber-based architectures represent an exciting prospect in the development of hierarchically ordered tissue engineering scaffolds, facilitating non-invasive, in situ spatiotemporal manipulation and organization of regenerative cues via an externally applied magnetic field. [1] While magneto-responsive fiber architectures are typically fabricated from magnetic nanoparticle (MNP)-doped polymeric solutions, risks of MNP leaching and subsequent toxic intracellular accumulation remain unaddressed. To this end, chelation of paramagnetic ferric iron ions (Fe3+) is a promising alternative to MNP-doping. [2] Given its innate fibrous structure, notable capacity for heavy metal chelation, and FDA approval as a biocompatible, biodegradable, naturally derived biomaterial [3, 4], silk fibroin extracted from Bombyx mori silkworm cocoons offers a unique, unexplored opportunity to fabricate MNP-free magneto-responsive fiber architectures. In this work, passive chelation of ferric iron is explored as an MNP-free alternative in the magnetic functionalization of silk-based biomaterials. Silk fibroin microfibers (mSF) treated with aqueous ferric chloride (FeCl3) exhibit significantly increased iron content relative to the nascent protein as determined by x-ray photoelectron spectroscopy (XPS). Coupled with the absence of detectable chlorine traces and iron oxide species, the predominantly ferric oxidation state of iron within FeCl3-treated mSF (Fe3+-mSF) suggest incorporation of iron, without reduction, at innate oxygen-containing ligands of mSF. On exposure to an external magnetic field, Fe3+-mSF displays paramagnetic magnetization behaviors that facilitate field-parallel alignment. Both magnetization and directional uniformity increased concomitantly with iron exposure during FeCl3 treatment, suggesting the observed magnetic response of Fe3+-mSF is derived from the chelated iron. In vitro biocompatibility of the Fe3+-mSF has been confirmed using human dermal fibroblasts and neuroprogenitor cells (NPCs). This work is the first to investigate the magneto-responsive properties and biocompatibility of ferric iron chelated SF, demonstrating a novel, MNP-free alternative approach to magnetic functionalization of TE scaffolds. Ongoing work is underway to evaluate NPC alignment and axonal growth, differentiation, and function in response to the aligned guidance architecture.

**Microvascular Imaging in Brain Tumors by Supramolecular MR Contrast Agents**

**Atsushi Mahara1, Soni Raghav1, Shigeysoshi Saito2 and Tetsuji Yamaoka3,4; 1National Cerebral and Cardiovascular Center, Japan; 2Osaka University Graduate School of Medicine, Japan; 3Komatsu University, Japan**

**[Introduction]** Magnetic resonance angiography (MRA) is used clinically to diagnose brain diseases. Although the MRA visualizes the main cerebral artery such as Willis arterial circle and middle cerebral artery without any contrast agents, it is hard to imagine the microvasculature and entire vascular network due to low MR signals. In our previous study, we developed the fluorescein and Gd-chelate conjugated 8-arm PEGs (8-arm PEG-Gd3) as the MRA contrast agents, and microvascular structure was enhanced on MRA scan by the administration of these contrast agents2,3. Here, we discuss the structural feature of the 8-arm PEG-Gd3 and its blood circulating profile. Furthermore, the microvascular formation in the brain tumor would be presented.

**[Methods]** The 8-arm PEG conjugated with one fluorescein and three Gd-chelates (8-arm PEG-Gd3) was synthesized by the reported procedure2. Briefly, fluorescein isothiocyanate and 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) mono-N-hydroxysuccinimide ester were added into the 8-arm PEG with 15 kDa of the molecular weight. The polymers were purified by a dialysis membrane. After the addition of gadolinium, 8-arm PEG-FGd3 was acquired. The products in each step were confirmed by 1H-NMR. As the control, 8-arm PEG conjugated with one fluorescein (8-arm PEG-F) was also prepared. Structural features were estimated by dynamic light scattering analysis (DLS) and atomic force microscopy (AFM), and the molecular...
environment of fluorescein was analyzed by fluorescence spectroscopy and 1H-NMR measurements. The brain tumor in the SD-rat was scanned by 7T-MRI with or without contrast agents.

[Results and Discussion] The hydrodynamic radius of the 8-arm PEG was 6 to 8 nm within the concentration range from 0.5 to 100 mg/mL. On the other hand, the hydrodynamic radius of 8-arm PEG-FGd was largely dependent on the polymer concentration. When the concentration of the 8-arm PEG-FGd was 1 to 5 mg/mL, the radius was approximately 7 nm. At the concentration ranges higher than 100 mg/mL, the radius was increased to over 1000 nm. As the results of AFM observation, nanoparticles, and fiber structure were observed at the concentration ranges from more than 100 mg/mL. The fiber was formed by the stacking of the nanoparticles. Spectroscopic analysis revealed that fluorescein groups of 8-arm PEG-FGd were in the center part of the particle and stacked with the π-stacking interactions. The brain microvessel and tumors in rats were scanned on MRI. Microvasculature with a minimum diameter of 45 μm was clearly visualized on MR images only when the 8-arm PEG-FGd at the concentration of 200 mg/mL was administrated. The microvessel structure in the tumors was also visualized with the supra-high resolution, and these data provided information on vascular permeability.

Rapamycin-Loaded Boronic Acid-Based Hydrogel as Artificial Perivascular Tissue for Prevention of Vascular Graft Failure
Hue T. Le1, Atsushi Mahara1, Takeshi Nagasaki1 and Tetsuji Yamaoka1,2; 1The National Cerebral and Cardiovascular Center Research Institute, Japan; 2The Osaka Metropolitan University, Japan; 3The Komatsu University, Japan

Introduction: Excessive proliferation of subendothelial smooth muscle cells (SMC) leads to anastomotic stenosis, resulting in an increase in graft failure rate, a big issue of vascular graft transplantation. Perivascular adipose tissue (PVAT), an adipose tissue adherent on the vessel’s external surface, has been shown to inhibit the excessive proliferation of SMC via releasing biomolecules1. However, the PVAT is mostly absent in vascular grafts involving native and artificial ones. Phenylboronic acid (PBA)-based polymer has been reported to form a hydrogel with synthetic polyvinyl alcohol (PVA) and bind to cell membranes and tissue surfaces via PBA-sialic acid integration2. Rapamycin (RPM) has been clinically approved as an anti-stenosis drug because of its cell anti-proliferative ability3. Recently, we synthesized poly (3-acrylamidophenylboronic acid-co-acrylamide) (BAAm) polymer. In this study, we proposed RPM-loaded BAAm/PVA (BAVA) hydrogel serving as an artificial PVAT4, thus its tissue adhesive and drug release characterization and anti-SMC proliferative function were investigated. Furthermore, we tested its effectiveness on graft patency in a porcine model.

Method: Two hydrogels with 25 and 50 mg/mL of BAAm (named BAVA25 and BAVA50, respectively) were prepared. A decellularized vascular graft with 2.5mm in inner diameter was selected as the graft model1. To examine the tissue adhesive ability, the lap-shear test was done after loading the hydrogel on the graft’s external surface. To assess drug release ability, the RPM-loaded BAVA hydrogel was immersed in PBS solution, and the released RPM was measured every day of 6d after incubation. To test the anti-cell proliferative function, the BAVA hydrogel with or without RPM was co-cultured with porcine SMC cells, then the cell viability was examined at 1d and 3d. Finally, a porcine carotid artery interposition grafting was performed. The external surface of the transplanted graft was then coated with the RPM-loaded BAVA hydrogel, and its graft patency was followed for six months by computer tomography.

Result: The BAVA25 and BAVA50 hydrogels could adhere to the graft surface, and their adhesive force was stable for 15d after immersion in PBS solution. In the lap shear adhesion test, initial loading slope (1.5) of the BAVA25 hydrogels was similar to that (1.3) of the BAVA50 hydrogels, and the displacement at fraction point of the BAVA25 hydrogels was approximately two-fold higher than that of the BAVA50 hydrogels. As incubated in PBS solution, the BAVA25 and BAVA50 hydrogels released 83 and 73% of the initial loaded RPM within the first day. As co-cultured with SMC cells, the RPM-loaded BAVA25 and RPM-loaded BAVA50 hydrogels significantly reduced cell proliferation after one day and three days of incubation, respectively. In porcine experiments, the graft without any treatment or with RPM-loaded BAVA50 hydrogel was occluded within three days after transplantation. However, in three cases treated with RPM-loaded BAVA25 hydrogel, two grafts were patent for 10 and 17d and one graft was patent for at least 180d.

Conclusion: The BAVA25 hydrogel had a higher tissue adhesive and more rapid drug release potential than the BAVA50 hydrogel. By loading with RPM, the BAVA25 and the BAVA50 hydrogel showed the in-vitro anti-SMC proliferative function. In the porcine model, the RPM-loaded BAVA25 hydrogel effectively maintained the patency of small-diameter decellularized vascular grafts. The RPM-loaded BAVA25 hydrogel, as an artificial PVAT, might be a therapeutic approach for preventing graft occlusion by suppressing SMC proliferation.

Design of High Throughput Techniques for Functional Medical Devices
Victor M. Villapun Puzas, Luke N. Carter, Daisy Rabbitt, Xue Cao, Billy Plant and Sophie Cox; University of Birmingham, United Kingdom

Since the early designs of medical devices, it has become apparent that implants should act as modulators of specific biological processes to ensure short- and long-term benefits1. Nevertheless, standard alloys used in orthopaedics have been repurposed from other industries (e.g. aerospace) as a consequence of their mechanical behaviour, corrosion resistance and biocompatibility. With increased life expectancy requiring longer service life of implantable devices and common alloying elements (e.g. aluminium or vanadium) demonstrated to negatively impact biological processes beyond cytotoxicity, it is clear that novel medical alloys should be developed to modulate clinical outcomes2. In this work, the difficulties of designing alloys for implantable devices will be contextualised, providing case studies focused on generating high throughput methods for their use in alloy development with especial attention on the advantages posed by metal additive manufacturing (AM) platforms.

When metallic elements are considered, there exist a plethora of materials with reported effects on biocompatibility, antimicrobial, angiogenic, osteogenic properties and/or their ability to modulate the innate and adaptive immune response3 Nevertheless, most effects have been reported for single element compounds, reducing their direct correlation to complex alloys and calling for methods to rapidly evaluate biological properties. The first case study will showcase the development of high throughput techniques for both material processing and biological evaluation. The use of AM and novel Reduce Build Volume designs for Powder Bed fusion coupled with powder blending will be shown as a tool to enable the rapid evaluation of alloy systems for antimicrobial applications with conventional and AM Ti-Cu samples used to highlight their benefits over traditional casting. Microstructural variations were assessed through SEM imaging, X-ray diffraction and Vickers microhardness evaluation which were complemented with antimicrobial assays in model strains of S. aureus and P. aeruginosa. In addition, the power of powder compaction and HIP technologies will be harnessed to enable the rapid analysis of bacterial behaviour and antibiotic synergistic/antagonistic effects through the agar diffuse method and metabolic assays in model strains of Gram-positive and Gram-negative species to enable novel databases in the healthcare industry.

Besides combinations of different metallic elements, alloy design should consider the effect of microstructure and the manufacturing of complex alloys with significantly different processing parameters. Copper and Molybdenum are two elements that have shown promise to tackle antibiotic infection, nevertheless, their disparity in reflectivity or melting point has made their incorporation in titanium alloys a challenge from a manufacturing perspective. Herein, the use of AM, powder compaction and sintering will be used to demonstrate the possibility of providing novel alloys with highly different elemental properties and their use in multicomponent alloys. Through variations in composition and heat treatment, we successfully produced a blended
powder of two dissimilar elements which can be used to manufacture SLM parts with reduced input energies (1333/m instead of 3003/m). Similarly, the effect of microstructural variations with antimicrobial properties and eukaryotic cell line responses will be shown for the rapid optimisation of novel alloys.

Therapeutic Mesoporous Cerium Oxide Nanoparticles for Modulating Excessive Oxidative Stress as a Treatment for Age-Related Macular Degeneration Seung Woo Choi1 and Jaeyun Kim2,3,4; 1Seoul National University Bundang Hospital, Korea (the Republic of); 2Sungkyunkwan University, Korea (the Republic of); 3Samsung Advanced Institute for Health Sciences & Technology, Korea (the Republic of)

Age-related macular degeneration (AMD), the leading cause of vision loss in the elderly, is characterized by progressive visual impairment caused by destructive changes in the photoreceptor and retinal pigment epithelial cells (RPEs). Since reactive oxygen species (ROS) and chronic inflammation in the retina are believed to be essential contributors to AMD pathogenesis, the regulation of the ROS and inflammation levels may be effective therapeutic targets. As cerium oxide nanoparticles (CeNPs) have attracted attention due to good ROS scavenging properties, suitable biocompatibility for human RPEs and Rau264.7 cells (murine macrophage cells), and cytoprotective effect on RPEs against the harmful effect of high H2O2, as well as additional anti-inflammatory effects. In addition, the CeNPs were intravitreally administrated to a NaIO3-induced AMD mouse model, and the mCeNP-treated group showed a partial salvage effect of at least 14% in outer nuclear layer (ONL) thickness, indicating that CeNPs protected RPEs from NaIO3 injury by exerting a disease-preventive effect. In addition, the drug-carrying capacity of CeNPs was demonstrated by loading indomethacin (IDM) as a model drug, and IDM-loaded mCeNPs exhibited an additional 17.3% reduction in intravitaminin-6 levels in vitro compared to the group treated with mCeNPs alone, suggesting that a synergistic anti-inflammatory effect when an additional drug is loaded onto mCeNPs, thereby enhancing their therapeutic potential. These findings suggest that mCeNP can be a therapeutic alternative or adjuvant for the treatment of AMD.

Glycoprotein Hydrogel-Based Implantable Nerve Guidance Conduits for Peripheral Nerve Regeneration Melis Ozkan1,2, Sujeet Pawar1, Xavier Navarro3,4, Francesco Stallacci1,4 and Silvestro Micera5,6,7; 1Institute of Materials, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland; 2Bertarelli Foundation Chair in Translational Neural Engineering, Center for Neuroprosthetics and Institute of Bioengineering, Ecole Polytechnique Federale de Lausanne, Switzerland; 3Department of Cell Biology, Physiology and Immunology, Institute of Neurosciences, Universitat Autònoma de Barcelona (UAB), Spain; 4Institute Guttman Foundation, Hospital of Neurorehabilitation, Badalona, Spain, Spain; 5Centro de Investigación Biomédica en Red sobre Enfermedades Neurodegenerativas (CIBERNED), Spain; 6Institute of Materials, Department of Bioengineering and Global Health Institute, École Polytechnique Fédérale de Lausanne (EPFL), Station 12, CH-1015 Lausanne, Switzerland, Switzerland; 7Department of Excellence in Robotics & AI, Scuola Superiore Sant’Anna, Piazza Martiri della Libertà, Italy

Peripheral nerve injuries (PNIs) beyond the critical gap length pose a serious problem in neural tissue engineering and regenerative medicine. Research on effective therapeutic strategies has centered primarily on implantable nerve guidance conduits (INGCs) over the past several decades. A significant amount of progress has been made in INGC development. Still, the field has remained stagnant due to the lack of an optimal solution for ensuring target reinnervation accuracy, which requires a delicate balance of biochemical cues, including growth factors that govern tissue formation and regeneration throughout the regeneration process. In recent years, researchers have utilized heparin-based materials for sustained growth factor delivery owing to the intrinsic characteristic of heparin to bind and stabilize the growth factors through electrostatic interactions to afford more efficient regenerative outcomes. However, several shortcomings of heparin, such as immunogenicity, could hinder the successful clinical translation of heparin-based INGCs. For this reason, structurally well-defined synthetic mimics fulfilling the same function without triggering immune response are in demand. In this work, we introduce a silk fibroin-modified gelatin tyramine hydrogel matrix fabricated through enzymatic crosslinking. Both 2D-shaped (planar film) and 3D-shaped (tubular INGC) protein hydrogel scaffolds with the same composition were produced for in vitro and in vivo investigations, respectively. On the macroscale, silk fibroin modification facilitated enhanced mechanical strength to provide the native nerve tissue-like mechanical properties and prolonged the degradation time of the hydrogel implant. It acted as a biocompatible scaffold for Sprague Dawley rat Schwann cells (SCs). Then, we directed our efforts toward creating a small library of synthetic small-molecule heparin glycomimetics to address the limitations of native heparin. We synthesized monosaccharides and disaccharides with different sulfation patterns to conjugate to the hydrogel matrix covalently via a PEG linker for cellular-level nerve regeneration. The binding affinities of these synthetic heparin glycomimetics to nerve regeneration-promoting biochemical cues, namely, brain-derived neurotrophic factor (BDNF), nerve growth factor (NGF), and fibroblast growth factor 2 (FGF2), were screened using isothermal titration calorimetry (ITC) and surface plasmon resonance (SPR) techniques and our findings showed sulfation pattern-dependent binding affinity. The best-performing molecule was able to bind to NGF and FGF2 with acceptable affinity. We covalently conjugated this compound to the hydrogel matrix. Fluorescence assays and gel permeation chromatography (GPC) confirmed small molecule sugar conjugation to the hydrogel. Hydrogel scaffold, which bears small molecule heparin glycomimetic complexed with NGF, referred to as glycoprotein-based hydrogel, accelerated the neurite growth of Sprague Dawley rat dorsal root ganglion (DRG) neurons and extended retention time of NGF.

Inspirèd by in vitro evaluations, we currently fabricated 3D tubular glycoprotein hydrogel-based INGCs (heavily grafted with our small molecule heparin glycomimetic and with native heparin having the same degree of grafting for comparison) to assess in vivo nerve regeneration in Sprague Dawley rat sciatic nerve defect model. Our final goal is long-term monitoring of INGC to unveil how heparin glycomimetics affect the cumulative release of NGF in vivo compared to native heparin and as well as to analyze the immunogenicity of both INGCs at the same degree of grafting. To the best of our knowledge, it is the first report systematically investigating the structure-activity relationship of small molecule heparin glycomimetics for in vivo nerve regeneration applications. This approach could be further extended to related regenerative medicine and tissue engineering disciplines.

8:00 PM SB09.06.06
Direct Delivery of Nanobeads into Cells with Nanoinjector Kazuhiro Oyama, Bowen Zhang, Bingfu Liu and Takeo Miyake; Waseda University, Japan

Delivering biomolecules into living organisms is an important challenge in medical and biological fields. Conventional techniques such as virus vector and electroporation are utilized commonly for small molecule delivery, but still remain several problems of low efficiency and low viability for large molecules such as biological proteins and organelles. To overcome this problem, we demonstrate the macromolecular delivery into adhesive cells with...
metallurgical nanotube ducts, which is called as nanoinjector. The metallic nanotubes were developed by an electroless plating of gold onto track-etched polycarbonate template and wet/dry etching [1-2]. To insert Au nanotubes into the cells (such as HeLa and NIH3T3), we have developed a nanoinjector stamping system that can be integrated with the microscope. Here we demonstrated the delivery of macro molecules (a few hundred nanobeads) into the cells and compare it with the endocytosis delivery. The nanoinjector system provide the high efficient delivery of 200nm diameter beads for 10min injection, while the endocytosis was at low efficiency, which takes for 24h to deliver the nanobeads. Furthermore, our nanoinjector can deliver the nanobeads uniformly into the cells.

Light-Degradable Nanocomposite Hydrogels for Antibacterial Wound Dressing Applications Changhao Fang, Yingnan Zhang, Qiming Shen and Michael J. Serpe; University of Alberta, Canada

Bacterial infections in skin injuries can lead to life-threatening human diseases if not treated appropriately. Wound dressings can function as a barrier that can cover the infected sites and inhibit further bacterial infection, thus promoting wound healing processes. In recent years, hydrogel-based materials have emerged as ideal candidates for wound dressing applications due to their biocompatibility, mechanical, and biological similarity to human tissues. With high biocompatibility, adaptive capability, and unique drug release profile, however, there are still many limitations associated with current hydrogel-based wound dressings, such as the on-demand release of antibacterial agents and triggered degradation. Therefore, the focus of my research project is to address these limitations by developing a light-degradable nanocomposite hydrogel that can achieve both of these goals using light (365 nm) as the single stimulus.

The approach we are taking involves incorporating triclosan-loaded, poly(V-isopropylacrylamide)-based nanogels (TCS-NGs) into a light-degradable poly(ethylene glycol)-based hydrogel matrix via a simple physical entrapment method. Upon exposure to 365 nm light, the hydrogel matrix can rapidly degrade, which subsequently releases the entrapped TCS-NGs into the surrounding environment.

Our results have first demonstrated that TCS-NGs possessed potent antibacterial activities. Moreover, TCS-NGs could be entrapped in light-degradable hydrogel matrix with high encapsulation efficiency. Upon exposure to light (365 nm), TCS-NGs can be released from light-degradable nanocomposite hydrogels, which still possess remarkable antibacterial efficacy in terms of inhibiting the growth of Staphylococcus aureus both in solution and on bacteria-infected porcine skins. Next, based on Alamar Blue assay on human dermal fibroblasts, each component of the nanocomposite hydrogel exhibited excellent biocompatibility and would not cause significant cytotoxicity. Finally, we showed that the nanocomposite hydrogel could be rapidly degraded by exposure of light, and the extent of degradation was dependent on exposure time. The results here indicate that the fabricated light-degradable nanocomposite hydrogels could serve as novel materials for antibacterial wound dressing applications.

8:00 PM SB09.06.09
The Role of Discoidin Domain Receptor 2 (DDR2) and Collagen on Neuroblastoma Cellular Mechanosensing Theadora Vessella, Steven Xiang, Madelyn Stilwell, QI Wen and Susan Zhou; Worcester Polytechnic Institute, United States

Increased extracellular matrix (ECM) stiffness is a characteristic commonly observed in tumors. Cancer cells can sense changes in substrate stiffness and adjust their migration, proliferation, and differentiation accordingly. Cell-ECM adhesion is crucial for cells to sense substrate stiffness. Discoidin Domain Receptor 2 (DDR2) is a collagen receptor and has been shown to play a role cell-ECM adhesion. Elevated levels of DDR2 in tumor cells have been associated with unfavorable outcomes and metastatic disease. In this study, we aim to investigate the significance of DDR2-collagen interaction in substrate stiffness sensing by studying how DDR2 downregulation affects the responses of SHY5Y cells, a neuroblastoma cell line that expresses DDR2, to substrate stiffness changes. Cells were cultured on collagen-coated polyacrylamide gels with stiffness ranging from 800 Pa to 20 kPa. On stiffer substrates, we observed cells with larger spreading area, more polarized shape, stronger traction force, greater cytoskeletal stiffness, and upregulated neuroblastoma-associated gene expression. These suggest that SHY5Y cells are sensitive to sense ECM stiffness. In contrast, the sh-DDR2 SHY5Y cell line, in which DDR2 expression was downregulated by sh-RNA mediated depletion, did not demonstrate substrate stiffness sensitivity. Our results indicate that DDR2 plays an important role in cellular substrate stiffness sensing. This highlights the potential significance of DDR2 as a target for cancer treatment, as modulation of DDR2-collagen interactions could potentially impact cancer cell behavior and invasion.

8:00 PM SB09.06.13
Elucidating the Mechanism of Gelation for Decellularized Extracellular Matrix Hydrogels Alexander Chen and Karen Christman; UCSD, United States

Naturally derived, decellularized extracellular matrix-based hydrogels (ECM hydrogels) have been increasingly investigated as biomaterial scaffolds for tissue repair and regeneration in a variety of disease models due to their injectability through minimally invasive methods, tunable properties, ability to assemble and form a hydrogel in situ, and intrinsic regenerative properties. Most commonly, their rheological, mechanical, optical properties, and protein composition have been studied to understand the gel’s stability, gel formation kinetics and the extracellular matrix protein component type and distribution. Natively within mammals, type I collagen is the most abundant structural fibrillar protein and forms a hydrogel through fibril self-assembly and crosslinking when it is pure and has been assumed to be the main driver for hydrogel formation within heterogeneous ECM hydrogels. The goal of this study was to provide more fundamental materials characterization of ECM hydrogels and determine whether type I collagen is in fact the driver for ECM hydrogel formation.

Using three batches of a porcine derived decellularized myocardial ECM hydrogel, we first ensured batch consistency by quantifying residual dsDNA, quantifying sGAG concentration and rheological measurements. We also employ Fourier transform infrared spectroscopy (FTIR) to analyze the bonds within our ECM hydrogels, thermal gravimetric analysis (TGA) from 30 to 700°C to analyze degradation temperatures, and turbidimetry analysis to observe gelation kinetics. Finally, using cryogenic transmission electron microscopy and two photon microscopy, we analyze the fibril structures within our ECM hydrogel and quantify the differences in fibril diameters before and after incubation at 37°C.

All batches contained less than 1 ng DNA per mg of ECM showing adequate decellularization and 10 µg of sGAGs per mg of ECM. We observed
consistent complex viscosity across all samples that had not been incubated, and similar storage and loss moduli values for gels after 24 hours of incubation. The FTIR revealed the same peptide-related peaks (amides I, II and III) at similar peak intensity ratios also seen in mature type I collagen control. TGA of our ECM hydrogel revealed degradation onset temperatures around 304.6±1.7°C and 624.9±16.8°C [KC1] C, consistent with literature reported values for collagen. Turbidimetry analysis revealed similar kinetics of gelation evidenced through similar times to achieve 50% of maximum equilibrium absorbance at around 15 minutes. ECM hydrogel batches were imaged before and after incubation at 37°C for 24 hours using two photon microscopy through second harmonics generation and two photon fluorescence, which leveraged the intrinsic property that only fibrillar, helical collagens produce signal. Incubated samples revealed distributed linear fibers in a grid-like conformation signifying the formation of a hydrogel network. Using cryogenic transmission electron microscopy, we analyzed fiber diameters within our samples for fresh, uncubated samples and samples incubated at 37°C for 24 hours. Fibers in fresh samples averaged 45.6 ± 21.7 nm, 48.7 ± 10.8 nm, and 128.9±56.8 nm, respectively, where all measured fibers within the incubated group revealed a distinct 67 nm D-periodicity unique to fibrillar collagens.

Incubated samples averaged significantly higher fiber diameters when compared to their fresh counterparts at 113.1±48.2 nm, 156.1±79.3 nm and 128.9±56.8 nm, respectively, where all measured fibers within the incubated group revealed a distinct 67 nm D-periodicity unique to fibrillar collagens. Combined, these data reveal batch to batch consistency using more sensitive materials characterization techniques for the ECM hydrogel while also providing visual evidence, through two microscopy techniques, that type I collagen self-assembly occurs during incubation at 37°C and is one of the main drivers of ECM hydrogel formation.

8:00 PM SB09.06.14
A High-Throughput Micropatterning Platform for Screening of Nanoparticles in Regenerative Engineering Cheryl Koh, Liu Ying Chen, Lingyan Gong, Shao Jie Tan, Han Wei Hou and Chor Yong Tay; Nanyang Technological University, Singapore

Engineered nanoparticles (ENPs) have been gaining traction in the field of regenerative engineering due to their unique physical, chemical and biological properties that are able to modulate cellular behaviour by influencing cell adhesion, migration, and proliferation. These nanomaterial-cellular interactions are important in directing tissue regeneration processes at the cellular level. However, the usage of nanoparticles brings about safety concerns with regards to imputation of cellular dynamics. In this context, micropatterning platform has emerged as a high-throughput tool for assessing stress response of ENPs. This platform not only allow the analysis of biological responses to nanoparticles in a controlled and reproducible environment, but also provides the identification of subtle effects that may not be discernible using traditional methods. This abstract discusses how two commonly incorporated engineered nanoparticles in regenerative engineering, specifically zinc oxide (ZnO) and titanium dioxide (TiO2) have an influence on collective epithelial rotation via the use of micropatterned platform. The confinement of cells in geometrical constraints were achievable through the precise control over the geometry and size of the adhesive fibronectin islands which aids in cell attachment. Collective rotation is essential in tissue morphogenesis and wound healing, and disruption to this collective behaviour could lead to a wide range of biological dysregulations. Through this approach, it was observed that the micropatterned human keratinocytes clusters exhibited spontaneous rotation without external stimulus, at relatively constant uniform speeds of 10 µm/h. However, acute (6 h) exposure to non-cytotoxic doses of ZnO and TiO2 NPs (≤100 nm) resulted in a loss of directionality and slowing down of cell rotation, respectively. The loss in collective cell rotation (CCR) was determined to be attributed to reactive oxygen species (ROS)-induced proliferation by ZnO. While cell proliferation is desired in regenerative engineering, the generation of new, heterogeneous localised velocity fields by the increased cell density led to cell jamming within the epithelial units. On the other hand, the retardation of the velocity of TiO2-treated units was most likely as a result of degradation of membrane recycling integrins that are necessary for continued cell migration. This is because TiO2-treated units were found to induce autophagy, which has been reported to correlate with endocytosis-driven recycling. Taken together, our findings offer nano-biological insights into the distinct signalling pathways exerted by different nanoparticles - ZnO NPs promoting cell proliferation, yet disrupting cell migration, and TiO2 NPs decreasing cell migration. This suggests that when it comes to the usage of ENPs in regenerative engineering, further studies have to be done to ensure that cellular dynamics are not compromised.

Directing Phase Separation to Harness Biomaterial Microstructures for Controlled Cellular Behavior Samiva Yesmin Bubi, Jennifer Sidhwa and Linqing Li; University of New Hampshire, United States

The compositional heterogeneity and structural diversity of native extracellular matrix are essential in regulating cell behavior and promoting tissue regeneration. Thermo-responsive polysaccharide-based materials with tunable transition temperatures and phase-separated microstructures offer substantial opportunities in tissue engineering, drug delivery, and wound healing applications. To develop novel synthetic thermoresponsive polysaccharides, we employed versatile chemical routes to attach intrinsically hydrophobic adducts to the backbone of hydrophilic dextran and developed protocols to form hydrogels with defined microstructures. Systematically conjugating methacrylate moieties to the dextran backbone yielded a continuous increase in macromolecular hydrophobicity that induced a reversible phase transition whose lower critical solution temperature can be systematically modulated via variations in polysaccharides concentration, molecular weight, degree of methacyrrlation, ionic strengths, and Hofmeister salts. Photo-initiated radical polymerization permits facile chemical crosslinking and kinetic capture of phase separation, enabling the formation of hydrogels with defined microdomains. The resulting heterogeneous hydrogels feature tunable microstructures and exhibited both microphores and continuous phases that promoted enhanced cell adhesion in 2D and interfacial-driven cell migration in 3D. Engineering macromolecular hydrophobicity with temperature-triggered phase separation of conventional hydrophilic, non-phase separating polysaccharides to generate heterogeneous hydrogels with controlled microstructures will find potential applications in chronic wound healing.

Study of The Senescence Progress of Human Skin Fibroblast on Silica Nanobeads Array Yerin Choi, Soojin Roh and Jin Seok Lee; Hanyang University, Korea (the republic of)

Senescence is a physiological process that progresses with age. Cellular senescence is induced by stimuli such as telomere shortening and oxidative stress. In particular, it refers to the cell cycle arrest state. Senescence cells are characterized by reduced cell proliferation, migration, and speed. In addition, aging proteins p16, p21, and p53 are expressed.

We study the adhesion changes of senescent cells on silica nanobeads (SiNBs) of various sizes. In particular, it analyzes how senescence changes due to different adhesion. We induced aging by adding Paclitaxel (PTX) to WS1 cells, which are human skin fibroblasts. PTX causes cellular senescence due to damage from ROS. The optimal PTX concentration was fixed, and the cell survival rate was confirmed by MTT assay. In particular, we have identified different adhesion on SiNB arrays of various sizes. In addition, changes in cell proliferation, migration, speed, and aging proteins were analyzed. As a result, we observed the correlation between the topographic factors of SiNB arrays and cellular senescence.

Tensile Testing of Two Anniotic Membrane Products: Artentac Wound® and Artentac AC® Abbigail Poland, Olivia Logan, Mora Melican and Isabella Sledge; Tides Medical, United States

Anniotic membrane is a promising biomaterial for regenerative medicine and a plethora of placental membrane products products exist in the market today
and are used for varying applications. When assessing and characterizing the multitude of amniotic products on the market, it is important to ensure that each product meets user need for handling capabilities so that the membrane can be properly applied to the wound. One way this characterization can be achieved is via tensile testing using an Instron 5544. The process of tensile testing amniotic products with the Instron 5544 has not previously been well-standardized or optimized for this material. With this study, a standardized test method for tensile testing of dehydrated amniotic membrane has been established. In this study, the established tensile testing procedure is used to distinguish differences in the handling capabilities of Artacent Wound, a dual layer amniotic scaffold, and Artacent AC, a tri-layer amniotic scaffold composed of a layer of chorion between two layers of amnion. In addition, this repeatable test method is also used to assess a modified version of Artacent AC where one of the tissue processing steps has been altered.

Methods:

Tensile Testing
1. Nonslip material is cut to size and applied to Instron Jaw Faces.
2. ASTM D1708 dog bone die cutter is used to cut samples to the proper size and shape.
3. Width and thickness measurements of the sample are taken in triplicate and averaged.
3. The force sensor is calibrated.
4. Tare load of 0.5N is applied to the sample prior to test start.
5. Length measurements of the product are taken.
6. Length, width, and thickness measurements are entered into Bluehill Software.
7. Strain Rate of 0.40mm/min. is entered into software.
8. "Zero displacement" is selected.
9. Test is started until full sample break is achieved.
10. Test is stopped and data is collected.

Data Analysis:
One – Way ANOVA Multicomparison Tukey Tests were used to compare each test group.

Results:
Comparative graphs summarize the failure stress (MPa), failure strain (%) and Young's Modulus (Mpa) of the following test groups:
- Artacent Wound
- Artacent AC
- Modified Artacent AC

Discussion:
There are no significant differences between the measured biomechanical properties of Artacent Wound and Artacent AC, although Artacent Wound has slightly increased strength when compared to Artacent AC. The modified version of Artacent AC did not show any significant difference when compared to original Artacent AC. However, the modified Artacent AC is shown to have higher Young’s Modulus and failure stress when compared to original Artacent AC. This demonstrates that modifying certain tissue processing steps could be advantageous for improving material handling properties.

Conclusion:
Artacent Wound has increased failure stress and Young’s Modulus when compared to Artacent AC. Modifying certain steps of the Artacent AC tissue processing procedure is shown to be beneficial for improving handling properties of the scaffold, as it demonstrates increased Young’s Modulus and failure stress when compared to that of original Artacent AC.
undergoes this deformation in a fraction of the time required in experiment. This allows for a time-effective solution to enable understanding of both the deformation of different scaffold designs and the deformation of scaffolds with different material additives incorporated, like those utilized to enable visibility of the BVS when imaged in vivo. Here, we utilize a finite element crimping simulation in ABAQUS to rapidly reproduce experimentally validated qualitative design comparisons between several designs of 3D printed bioresorbable vascular scaffolds made of a previously developed citrate-based polymer, taking into consideration both the properties of the base polymeric material and the properties of the polymeric material with a radiopaque additive. By doing so, it is possible to harness the advantages of additive manufacturing to allow for more optimal bioresorbable vascular scaffold design and production, simultaneously elucidating the relationship between material, structure, and mechanical response of scaffolds.

**In-Vitro Human Cell Behavior: Using Cell Culture to Assess Biocompatibility and Cell Proliferation on Artacent Products**  
Olivia Logan, Sadhana Joshi, Babak Safavieh, Mora Melican and Isabella Sledge; Tides Medical, United States

**Introduction:**  
Cell culture is a useful method of determining cell interactions and assessing product safety in-vitro before completing in-vivo testing, such as animal models. In this study, cell culture is utilized to assess the proliferation and attachment of various cell types on amniotic scaffolds. The selected cell types represent cells that are known to play a part in the wound healing process and include Human Umbilical Vein Endothelial Cells (HUVEC), Neonatal Human Dermal Fibroblasts (NHDF), Normal Human Epidermal Keratinocytes (NHEK) and L929 cells (an adherent type of mouse fibroblast cell line).

**Methods:**  

**Cell Culture**

All cell lines are maintained in appropriate culture media supplemented with necessary growth factors, antibiotics, and serum per manufacturer’s protocol. These cells were incubated at optimal conditions in a humidified cell culture incubator.

**Cell Treatment**

Optimal seeding density for each cell type was determined from preliminary testing. Determined seeding densities were then used to seed each cell type on circular 6mm diameter samples from each test group. Cells were seeded for 2, 3, 7 and 9 days in 96 well Low cluster microplates.

**Alamer Blue Assay**

After the treatment period, the culture medium was removed from each well or plate and Alamar blue was added to the wells. The cells were treated with the Alamar Blue reagent for 6 hours and under appropriate conditions. The absorbance of these wells was measured using a microplate reader at 570nm and 600nm.

**Microscopy**

To validate the Alamer Blue Assay results, the cells seeded on Artacent product were labelled with DAPI and Vimentin 647 and observed under Zeiss LSM 800 with Airyscan.

**Results:**

Graphs summarize the Alamer Blue reduction (%) for the following test groups at the following time points. Chosen time points reflect when the most Alamer Blue reduction was observed for each cell type.  
- HDF at 7 day time point  
- NHEK at 7 day time point  
- HUVEC at 9 day time point

**Discussion:**

HDF cells showed improved proliferation and attachment on Artacent AC compared to other test groups. NHEK cells showed improved proliferation and attachment on Artacent Wound compared to other test groups. NHEK cells showed improved proliferation and attachment on Artacent Wound compared to other test groups.

**Conclusion:**

Different types of amniotic scaffolds are shown to be optimal for the proliferation and attachment of different cell types.  
- HDF cells showed improved proliferation and attachment on Artacent AC.  
- NHEK cells showed improved proliferation and attachment on Artacent Wound.  
- NHEK cells showed improved proliferation and attachment on Artacent Wound.

8:00 PM SB09.06.22  
**Comparison of Amniotic Products in Full Thickness Rat Wound Model: Artacent Wound and Artacent AC**  
Olivia Logan, Isabella Sledge and Mora Melican; Tides Medical, United States

**Introduction:**

It is well understood that human placental tissue contains a multitude of factors that play a part in the healing process [1]. Placental membrane is an attractive biomaterial for regenerative medicine applications due to its natural factors that aid in wound healing, angiogenetic and regenerative remodeling, as well as immunomodulation. However, the processing methods used to create final product have an impact on the growth factors that are retained [2]. A plethora of placental tissue processing methods has led to the creation of an array of placental product compositions and applications. Two products currently being used in the field are Artacent Wound®, a dehydrated dual layer amniotic graft and Artacent AC®, a tri-layer graft composed of a chorion sandwiched between two layers of amnion. In this study, we assessed these wound coverings in Sprague Dawley rats to elucidate the influence these scaffolds have on a healing wound. Additionally, this test is used to assess a modified version of Artacent AC to see if modifying certain tissue processing steps has implications on wound healing.

**Methods:**

Two full thickness wounds were created on the dorsal side of each rat using a 2 cm x 2 cm square stencil and scalpel. Implant dimensions were
approximately 2.5 x 2.5 cm. Samples were randomized into implantation sites across the animals. Implants were harvested at 7 days and grossly assessed for healed wound geometry, remodeling and re-epithelialization. Implants were fixed in neutral buffered solution (NBS). Samples were stained with H&E and stained cross sections were evaluated for surface re-epithelialization, cellular infiltration, and remodeling. A numerical scoring system was utilized to quantify re-epithelialization and granulation tissue formation based on histological images.

Results:
Initial and final wound measurements were used to calculate the percentage of wound closure for each test group. Re-epithelialization and granulation tissue formation ratings are used to calculate average values for each test group.

Discussion:
No adverse effects were noted during this 7 day study. Partial wound healing is observed during the 7 day study, and healing is accelerated by the addition of a placental scaffold. Modified Artacent AC shows increased wound closure, equivalent re-epithelialization, and increased granulation tissue formation when compared to positive control (original Artacent AC).

Conclusion:
No adverse effects were noted.
The 2x2 Challenge Full Thickness Wound model in the rat shows partial healing at 7 days that is accelerated by the addition of a human placental membrane product to the wound bed.
Modified version of Artacent AC shows improved wound healing when compared to original Artacent AC.
- Increased wound closure
- Equivalent re-epithelialization
- Increased granulation tissue formation

8:00 PM SB09.06.23
Protein Characterization of Placental Membrane Products: Artacent Wound and Artacent AC Olivia Logan, Babak Safavieh, Isabella Sledge and Mora Melican; Tides Medical, United States

Introduction:
Placental membrane is a highly biocompatible natural scaffold and is a source of several native factors that may aid in wound healing. Some of the many factors that make placental membrane such an attractive material are the natural anti-inflammatory, angiogenic, and antibacterial properties of the membrane. These properties are mostly dictated by released growth factors and cytokines. The angiogenic properties are attributed mostly to its capacity to produce VEGF and platelet-derived growth factor (PDGF), both of which mediate wound healing. The anti-inflammatory and immune-modulatory effects are largely attributed to the secretion of IL-10 and IL-6 [1]. Here, we characterize the protein content in Artacent Wound (a dual layer amniotic product) and Artacent AC (a tri-layer composed of a layer of chorion in between layers of amnion) using a Microarray assay. In addition, immunohistochemistry (IHC) was used to quantify protein composition of extracellular matrix (ECM), growth factors, and immune modulating cytokines. This analysis provides further insight into the protein composition and cell interactions of hAM scaffolds currently on the market.

Methods:
The chosen assay for testing is Quantibody® Human Cytokine Antibody Array 1000 assay from RayBiotech Inc., a multiplexed ELISA that enables the detection and quantification of up to 1000 human cytokines in a single experiment. To prepare samples for testing, they were first incubated on captured antibody for 2 hours. The biotinylated antibody cocktail was then added, followed by another 2 hour incubation. After the final incubation, streptavidin labeled dye was added. The results were then analyzed using fluorescent microarray reader.

Results:
The various cytokines and growth factors observed in each test group were categorized based on Angiogenetic cues, immune modulating cytokines and Regenerative growth factors.

Discussion:
Protein microarray analysis reveals that Artacent AC and Artacent Wound have various factors that are attributed to angiogenetic and regenerative remodeling as well as immunomodulation. The Artacent Wound protein distribution shows that factors are uniformly distributed amongst the angiogenetic (28%), regenerative (34.1%), and immunomodulatory (37.8%) categories. In contrast, the protein distribution for Artacent AC shows that a large portion of the observed factors are regenerative growth factors (78.4%), with a smaller portion of results falling into the angiogenetic (8.3%) and immunomodulatory (13.2%) categories.

Conclusion:
The varying products are each shown to contain a unique profile of proteins that play a role in angiogenetic and regenerative remodeling as well as immunomodulation.
- Artacent Wound proteins are evenly distributed amongst the angiogenetic, regenerative, and immunomodulatory categories.
- Artacent AC protein distribution largely falls in the regenerative category, with smaller percentages of proteins falling into angiogenetic and immunomodulatory categories.

8:00 PM SB09.06.24
Subcutaneous Implantation of Amniotic Products in Sprague Dawley Rats: Artacent Wound and Artacent AC Olivia Logan, Isabella Sledge and Mora Melican; Tides Medical, United States

Introduction:
Although there are numerous placental membrane products currently being used in wound healing applications, it is not yet well-understood how these products interact with the wound bed as the wound heals. In this study, we assess subcutaneous implantation of varying amniotic membranes to better understand how these products support the wound healing process.

Methods:
Four incisions were made on the back of each rat—two incisions left of the spine and two incisions to the right with each incision measuring approximately 2 cm. Four individual pouches were created by bluntly dissecting laterally at each incision site with scissors. A 1 x 1 cm implant was placed in each implantation site and samples were randomized in location. Implants were fixed in neutral buffered solution (NBS). Samples were stained with H&E and stained cross sections were evaluated for surface re-epithelialization, cellular infiltration, and remodeling. A numerical scoring system was utilized to quantify re-epithelialization and granulation tissue formation based on histological images.
that HS-RGNs can hybridize with miR-200c, impact of miRNA on cell behavior.

When treated with HS-RGNs, miR-200c was effectively consumed, resulting in a higher survival rate in both SK-BR-3 and MCF-7 cells. This result suggested the effective binding of HS-RGNs to miR-200c. Additionally, when assessing the SK-BR-3 cells. When treated with HS-RGNs, increased expression levels of Zinc finger E-box binding homeobox 1 (Zeb1) and Tropomyosin receptor kinase B (TrkB), which were inhibited by miR-200c, indicated the effective binding of HS-RGNs to miR-200c. The higher expression level of miR-200c in SK-BR-3 compared to MCF-7 led to the observation of a higher Raman signal in stained cross sections. The higher expression level of miR-200c in SK-BR-3 compared to MCF-7 led to the observation of a higher Raman signal in stained cross sections.

The design of stimulus-responsive smart hydrogel actuators for tissue engineering holds great promise, as they enable the creation of 3D structures mimicking the functionality of natural tissues, responding in a controlled manner to changes in temperature, light, or pH. To achieve near-infrared (NIR) light-induced responses in smart hydrogels, molybdenum disulfide (MoS2) nanosheets have gained recent attention due to their layered structures and strong NIR absorbance, making them promising photothermal agents. Among various hydrogels, we focus on double-network hydrogels (DN) composed of chitosan (C) and polyvinyl alcohol (P), known for providing a robust and flexible matrix for cell growth and tissue regeneration. In this study, we developed C-P DN hydrogels with MoS2 nanoparticles to create 3D printed scaffolds (3D C-P) and evaluated their mechanical properties, water content, NIR light irradiation response, and cell viability.

By adjusting manufacturing parameters like freezing temperature, chitosan cross-linking time, and lyophilization, we tailored the mechanical properties of C-P DN hydrogels. These hydrogels were successfully extruded using a fourth-generation 3D BioplotterTM (Envisiontec, Germany), enabling precise scaffold production. After 2 hours of crosslinking, the 3D C-P scaffold exhibited high toughness and mechanical stiffness resembling native heart tissue, with a stiffness value of 0.78 MPa. Interestingly, DN C-P MoS2 hydrogels with 0.5% w/w MoS2 incorporation did not show improved mechanical stiffness compared to pure DN, maintaining material structural stability. Furthermore, MoS2 incorporation led to a slight decrease in water content, attributed to its hydrophobic nature.

The material’s responsiveness was evident through rapid contraction and bending upon NIR light irradiation due to dehydration, and this response was 40% faster than that of DN C-P hydrogels. This confirmed their potential as candidates for generating light-stimulated smart DN hydrogels. Additionally, MoS2-incorporated hydrogels exhibited mechanical self-healing under NIR light exposure, enhancing their tissue engineering applications. These multifunctional behaviors arise from MoS2’s ability to convert light energy into thermal energy, triggering NIR light-induced contraction. Furthermore, NIR-induced heat facilitates polymer chain diffusion, enabling a self-healing process through hydrogen bond reformation in MoS2-incorporated hydrogels. MoS2 absorbs NIR light, releasing heat, and leading to hydrogel contraction, while reconstituted hydrogen bonds allow the material to ‘heal,’ restoring structural integrity and functionality.

Viability studies on umbilical cord-derived mesenchymal stem cells (UC-MSCs) cultured on MoS2 hydrogels showed improvement from day 1 to day 7, suggesting that DN and DN C-P MoS2 hydrogels offer a conducive environment for UC-MSC growth and survival, serving as a three-dimensional support and suitable substrate matrix.

The results demonstrate that the incorporation of MoS2 nanosheets into C-P DN hydrogels achieves a rapid actuation response to NIR light irradiation and a mechanical self-healing behavior, making them ideal for light-stimulated flexible hydrogels. Additionally, cell viability studies indicate MoS2-containing hydrogels’ suitability as three-dimensional support in regenerative medicine and tissue engineering.

Stimulus-Responsive Double Network Hydrogels with MoS2 Nanosheets for High Toughness and Self-Healing Smart Biomaterials for Tissue Engineering

8:00 PM SB09.06.25

Stimulus-Responsive Double Network Hydrogels with MoS2 Nanosheets for High Toughness and Self-Healing Smart Biomaterials for Tissue Engineering

Acknowledgement: This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (RS-2023-00211360) and Biomaterials Specialized Graduate Program through the Korea Environmental Industry & Technology Institute (KEITI) funded by the Ministry of Environment (MOE).
The Influence of Donor Age and Cholesterol Inhibition on Fibroblast Mechanical Properties and Susceptibility to Bacterial Infection

Shahriar Hui1, Pia V. Sodhi2, Avi Talsania3, Samuel D. Coopersmith4, Richard A. Wong5, Sai Pranav Kota6, Adam Hansen7 and Miriam Rafailovich7; 1Valley Christian High School, United States; 2The Brearley School, United States; 3Sachem High School North, United States; 4Casa Grande High School, United States; 5Plainview-Old Bethpage John F. Kennedy High School, United States; 6Cedar Falls High School, United States; 7Stony Brook University, The State University of New York, United States

Cell mechanics depend upon cell membrane mechanics (which, in part, depends upon cholesterol content) and the rigidity and organization of the cytoskeleton. The latter was shown to depend on the properties of the substrate upon which cells are cultured, where tensile modulus models were used to explain reorientation of the scaffold. With aging, measurements of the viscoelastic properties of cells were shown to stiffen, but these measurements were performed on individual cells without mechanical cues from surrounding tissue or the substrate. We report on experiments performed on dermal fibroblasts, which were obtained from female donors: “young” (ages 28 and 29 years) and “old” (ages 69 and 71 years), where we applied the technique of scanning force modulation microscopy (SFMFM) which allows for measurements of cell modulus that account for the underlying substrate mechanics. The results represent an average of n=9 measurements.

Cells were cultured on polybutadiene thin films whose moduli were varied (ratio of 3:1) by adjusting the film thickness without additional chemical additives. On both substrates the moduli of the cells became significantly harder with age, consistently 40±1.6%, in agreement with previous work. For both young and old cells the cell modulus responded to changes in the substrate, where the moduli between cells plated on the hard and soft substrates differed significantly: 50±2% and 60±2.8% for the old and young cells, respectively. These results indicate that even though cells become harder as they age their ability to adjust to mechanical changes in their environment is not diminished. We were also able to image the actin filaments and we found that the moduli of the filaments in the older cells were consistently 20±0.8% higher than those of the younger cells independent of substrate.

Cholesterol is the most dominant sterol found in mammalian tissue and is a major structural component of the cell membrane. We investigated the impact of cholesterol on the mechanical properties of fibroblasts. To prevent uptake of cholesterol, we cultured cells in lipid-free media. We then added AY9944, a known disruptor of cholesterol synthesis, which has been shown to cause a shift to 7-dehydrocholesterol (7DHC), a precursor to cholesterol, and mechanical stiffness. Comparing both Pluronics, the data collected showed that F88 had a higher swelling ratio than F127. Elastic modulus measurements confirmed that F127 was inherently stronger, and its cross-linking efficiency was superior due to its lower swelling ratio. Aiming at imparting degradability, the Pluronic were end capped with L-Lactide prior to methacrylation and similar studies were conducted throughout prolonged time incubated in aqueous medium at 37 degrees. The lactide-containing matrixed exhibited elevated swelling until full degradation after several weeks, demonstrating the rapid degradability. Furthermore, aiming at exploring drug release capabilities, release profiles of Clindamycin, Metronidazole and Ciprofloxacin (Triple paste antibiotic) were researched. In conclusion, while F127’s stiffness and effective crosslinking make it a promising candidate in terms of mechanical features and F88’s hydrophilic properties and favorable degradation profile also make it a favorable option in regards to hydrophilic affinity and mass loss, further research is required to assess the biocompatibility of photoinitiators and their concentrations in terms of cell viability. Thus, further studies will be conducted on the hydrogels’ bio-printability, cell viability, cytotoxicity, antibacterial efficiency of drugs added and osteogenic differentiation or the ability of stem cells to differentiate into bone cells. The gels developed will present multiple potential endodontic applications: it could be placed on the top of the pulp cavity to induce dentin regeneration or disinfect the canal area. Thus, these hydrogels will ultimately pave the way for more potent dental treatment approaches.
Osteogenic differentiation of dental pulp stem cells (DPSCs) offers potential treatments for bone-related diseases such as osteoporosis. DPSCs are preferred over other stem cells due to their ease of preservation and relative ease to obtain. Previous literature has shown that continuous exposure to a static magnetic field (SMF) induces osteogenic differentiation in rat DPSCs [1]. Past studies also suggest titanium-treated surfaces improve the rate of differentiation of DPSCs. [2] We report the degree of osteogenic differentiation with the combined effects of titanium deposition and an SMF, and compare each treatment individually. Investigating these factors will provide crucial insight to the differentiation of DPSCs and the discovery of a stem cell-based treatment for endemic bone diseases.

DPSCs of strain 13 were isolated from third molar teeth and prepared via trypsinization every 4 days for 16 days. 4x104 cells were plated on each sample with agarose, along with MEM-a, 10% fetal bovine serum, and 1% glutaMAX. After 1 day, the media was changed to ascorbic acid and β-glycerophosphate, which has been shown to induce cell biomineralization. [2] 4 groups contained 2-inch x 2-inch silicon wafers while 2 others were in tissue culture plastic (TCP). All wafers were coated with Polyactic Acid (PLA). Half the wafers were further treated with titanium via atomic layer deposition (ALD). Half of all groups were placed in an SMF parallel to the surface for the duration of their incubation period of 28 days. Images produced by atomic force microscopy for ALD and PLA groups were analyzed via NanoScope Analysis to quantify the roughness of the wafers. Roughness did not play a role in the rate of collagen triple helix formation, allowing us to understand the role of an SMF on the rate of collagen triple helix formation and thus osteogenic differentiation. Raman spectroscopy will be used to determine the nature of mineralization.

8:00 PM SB09.06.30

Mechanical Characterization of Poly(vinyl alcohol) and Resorcinol Diphenyl Phosphate Clay Blend Vascular Grafts Hannah Oh, Leora Stochel, Haoyu Xu, Megha Gopal, Robert Wong, Aaron Sloutski, Adam Hansen, Reza Dashiti, Chander Sadasivan and Miriam Rafailovich; Stony Brook University, The State University of New York, United States

Poly(vinyl alcohol) is suitable for vascular grafts in patients due to its biocompatibility and tunable mechanical properties, but its documented bioinert nature limits cell-adhesiveness, which is critical for the long-term patency of grafts in vivo [1]. We have previously found that Resorcinol Diphenyl Phosphate (RDP)-clay, a phosphate ester flame retardant, can enhance mechanical and cell-adhesive properties when blended with other polymers[2]. Here, we report on the effect of RDP-clay on the mechanical properties of PVA hydrogels towards manufacture of small-diameter vascular grafts. Poly(vinyl alcohol) (PVA/RDP-clay blend solutions were synthesized by combining 10% PVA (w/w) solution with RDP-clay at 0%, 1%, 5%, and 10% (w/w), respectively. These solutions were crosslinked with 15% (w/w) sodium trimetaphosphate (STMP) and 35% (w/w) sodium hydroxide (NaOH). This solution was poured into 26mm diameter molds and allowed to dry overnight, after which the resulting discs were rehydrated in Dulbecco’s Phosphate Buffered Saline (DPBS) for about 24 hours. Rheology of these discs was characterized using a Kinexus Pro+ rheometer (Netzsch), with oscillatory amplitude sweeps with parameters 0.1 to 100 Pa range, 1 Hz frequency, and 25 C temperature. To create small-diameter grafts from this polymer blend, we devised a 3-step process. Melted wax was injected into a metal tube and allowed to harden, into 26mm diameter molds and allowed to dry overnight, after which the resulting discs were rehydrated in Dulbecco’s Phosphate Buffered Saline (DPBS) for about 24 hours. Rheology of these discs was characterized using a Kinexus Pro+ rheometer (Netzsch), with oscillatory amplitude sweeps with parameters 0.1 to 100 Pa range, 1 Hz frequency, and 25 C temperature. To create small-diameter grafts from this polymer blend, we devised a 3-step process. Melted wax was injected into a metal tube and allowed to harden, creating a 2mm diameter wax rod. For all RDP-clay concentrations, these rods were affixed to a single-axis spinner and dipped 10 times in PVA blend, with 15 minutes of spin-drying between dips. After the final dip, all rods were allowed to spin-dry overnight, rehydrated the next day, and the wax rods were removed to obtain patent vascular grafts. These grafts were orthogonally cut into thin rings, allowing wall thickness measurements to be found using a Keyence VHX-7000 microscope. 2 cm lengths of vascular graft tubes were also orthogonal cut, then attached to a PGI-5 Digital Pressure Gauge and pressurized until rupture to determine vessel burst pressure. Blend characterization through rheology indicated an average modulus of 35 kPa, with a slight increase as RDP-clay concentration increased. The 10% RDP-clay vessels were more prone to pin-prick bursts. As such, we posit that 10% RDP-clay may be an upper limit for organoclay additive described manufacture method for these small-diameter grafts was successful at creating patent vessels at all RDP-clay concentrations tested. Vessels pressurized until rupture to determine vessel burst pressure. To create small-diameter grafts from this polymer blend, we devised a 3-step process. Melted wax was injected into a metal tube and allowed to harden, into 26mm diameter molds and allowed to dry overnight, after which the resulting discs were rehydrated in Dulbecco’s Phosphate Buffered Saline (DPBS) for about 24 hours. Rheology of these discs was characterized using a Kinexus Pro+ rheometer (Netzsch), with oscillatory amplitude sweeps with parameters 0.1 to 100 Pa range, 1 Hz frequency, and 25 C temperature. To create small-diameter grafts from this polymer blend, we devised a 3-step process. Melted wax was injected into a metal tube and allowed to harden, creating a 2mm diameter wax rod. For all RDP-clay concentrations, these rods were affixed to a single-axis spinner and dipped 10 times in PVA blend, with 15 minutes of spin-drying between dips. After the final dip, all rods were allowed to spin-dry overnight, rehydrated the next day, and the wax rods were removed to obtain patent vascular grafts. These grafts were orthogonally cut into thin rings, allowing wall thickness measurements to be found using a Keyence VHX-7000 microscope. 2 cm lengths of vascular graft tubes were also orthogonal cut, then attached to a PGI-5 Digital Pressure Gauge and pressurized until rupture to determine vessel burst pressure.

Blend characterization through rheology indicated an average modulus of 35 kPa, with a slight increase as RDP-clay concentration increased. The 10% RDP-clay vessels were more prone to pin-prick bursts. As such, we posit that 10% RDP-clay may be an upper limit for organoclay additive described manufacture method for these small-diameter grafts was successful at creating patent vessels at all RDP-clay concentrations tested. Vessels pressurized until rupture to determine vessel burst pressure.
phosphate (RDP)-clay can improve cell adhesion within polymer blends [3]. We aim here to characterize the thrombogenic and cell-adhesive properties of PVA/RDP-clay blends on both thin films and hydrogels. 2% PVA (w/w) solutions with each of 0%, 0.1%, 0.5%, 1%, 2%, 3%, 5%, 7% and 10% (w/w) RDP-clay added were spun cast onto silicon wafers. Human umbilical vein endothelial cells expressing green fluorescent protein (HUVEC-EGFP) were plated on the spun-cast wafers at a concentration of 20,000 cells/cm², then imaged on an EVOS M7000 fluorescent microscope. Good HUVEC cell adhesion with notable elongated cell morphology and cell-to-cell connections were observed on all spun cast films regardless of RDP-Clay concentration, indicating that in the absence of cross linker, PVA polymer is biocompatible, supporting cell adhesion and proliferation. Potential thrombogenicity of the spun cast films was assayed by placing the substrate in a 4mg/ml solution of human fibrinogen. When fibrinogen contacts a hydrophobic surface, protein unfolding has been reported [3], which frees the alpha-C domains and exposes interior of the molecule in the absence of thrombin. Soluble fibrin is then recruited, forming large fibers which have been shown [3] to initiate clots in the presence of plasma. While multiple large fibers were observed here on the unfilled PVA films via Atomic Force Microscopy, the number of fibers and their diameters decreased with increasing RDP clay concentration, disappearing completely at a maximum loading of 5% RDP clay. This correlated with a continuous decrease in water contact angle with increasing RDP-Clay concentration, with a critical value between 1% and 2% RDP-clay. Formation of the PVA hydrogels for the grafts, though, require cross linking with NaOH followed by rehydration of the PVA. In this case, samples with different clay concentrations were produced by dissolving 10% PVA with 0% and 10% RDP-clay, then crosslinking the solution with 15% sodium trimetaphosphate (STMP) and 30% sodium hydroxide (NaOH). The crosslinked solution was poured into 35 mm diameter molds and dried, creating hydrogel discs for cell plating. Discs were sterilized in isopropyl alcohol for 5 minutes, then rehydrated in media. Fibroblasts expressing Green Fluorescent Protein were plated atop the discs at a concentration of 2000 cells/cm², then imaged after 12 hours with the EVOS microscope. Without extensive washing of the discs, cells were unable to adhere to the hydrogel due to leaching NaOH from the polymer matrix. However, after hydrogel discs were subjected to daily DI exchanges for 5 days and placed under constant agitation from a magnetic stirrer, high fibroblast adhesion to both 0% and 10% RDP-clay gels was observed. This finding contradicts previous studies that show little endothelial cell adhesion to pure PVA [1], which we believe can be attributed to a lack of extensive hydrogel washing.

Our novel processing method of PVA hydrogels as well as the hemocompatibility of PVA/RDP-clay blend thin films show great promise towards using this material for long-term, implanted vascular grafts in humans.

Developing a Skin Construct for Wound Healing Associated with Endothelial Cell Network  
Caitlyn Limbert1, Sahana Dhama2, Michael Lotwin1, Jacqueline Han3, Grace Wang4, Chunuo Chu5, Annika Joshi6, Rachel Na7, Shi Fu8 and Miriam Rafaollowich9; 1British School Jakarta, Indonesia; 2The Wheatley School, United States; 3Rambam Mesivta, United States; 4Great Neck South High School, United States; 5Detroit Country Day School, United States; 6Shenzhen Middle School, China; 7Johns Creek High School, United States; 8Washington University in St. Louis, United States, 9Stony Brook University, The State University of New York, New York, United States

Researchers have recently engineered skin constructs incorporating epidermal and dermal layers from the collagen matrix. A significant disadvantage in designing this organotypic culture for wound healing applications is the lack of a vascular network that promotes anastomosis of the graft-host vasculature. Meanwhile, relying on the additive growth factor to promote vascularization and angiogenesis is not sustainable and could be costly. Mesenchymal cells like fibroblasts and dental pulp stem cells are known to secrete several pro-angiogenic growth factors. Hence, our objective in this research is to (a) establish a microvascular network by co-culturing human umbilical vein endothelial cells (HUVECs) with mesenchymal cells in vitro without additional growth factors, (b) develop a series of altered mediums where both the endothelial and the epithelial cells can be co-cultured, (c) determine the role of an endothelial cell network in predicting vascularization and anastomosis response in vivo and (d) evaluating the impact of these constructs on wound healing.

Living skin equivalents were prepared for 17 days according to the procedures from our previous work [1], modified with the HUVECs-EGFP and mesenchymal cells co-culture layer on the bottom of skin constructs, cultured in the altered mediums to enhance both vascularization and epithelial differentiations. The non-vascularized skin equivalents with the same bottom layer without HUVECs were prepared similarly for comparison. Three SCID Hairless Outbred mice were used as hosts for wound healing experiments. 8mm diameter wound beds were created on the back of the mice. The harvested skin equivalents were then placed on the wound beds and bandaged with silicone film to prevent dehydration during healing.

Following a 7-day period of postoperative recovery, skin tissue samples were collected for histological analysis. Hematoxylin and eosin (H&E) staining revealed a seamless integration between the graft and the surrounding epithelium and dermis. Additionally, lumens were scattered throughout the grafted skin. Following a 7-day period of postoperative recovery, skin tissue samples were collected for histological analysis. Hematoxylin and eosin (H&E) staining revealed a seamless integration between the graft and the surrounding epithelium and dermis. Additionally, lumens were scattered throughout the grafted skin.

In conclusion, we have designed a highly effective scaffold that enables the simultaneous culture of HUVECs with skin organotypes, promoting anastomosis and accelerating wound healing.

Promoting Angiogenesis via HGF Upregulation using Titanium Dioxide Nanoparticles  
Grace Wang1, Michael Lotwin2, Caitlyn Limbert3, Jacqueline Han4, Annika Joshi5, Chunuo Chu6, Sahana Dhama2, Rachel Na7, Shi Fu8 and Miriam Rafaollowich9; 1Detroit Country Day School, United States; 2Great Neck South High School, United States; 3Shenzhen Middle School, China; 4The Wheatley School, United States; 5Johns Creek High School, United States; 6Washington University in St. Louis, United States, 7Stony Brook University, The State University of New York, New York, United States

Titanium dioxide (TiO2) nanoparticles (NPs) have high biocompatibility, antimicrobial properties, and light-scattering abilities, making them a valuable tool across various industries. As such, TiO2 NPs have become strong points of interest in the modern biomedical field. Previous research has demonstrated that TiO2 NPs induce the activation of human umbilical vein endothelial cells (HUVECs) due to increased expression of adhesion and other molecules associated with inflammatory response [1]. Such NPs may be linked to promoting angiogenesis, the process by which new capillaries are formed from existing vascular structures in the human body. Hence, this study examines the effects of TiO2 NPs on HUVECs angiogenesis through flow
cytometry and cell sorting based on TiO2 uptake, imaging time lapses of vascular development using EVOS microscopy, network quantification with Celleste Image Analysis software, scanning electron microscopy (SEM), and Reverse Transcription Polymerase Chain Reaction (RT-PCR).

HUVECs were cultured with and without 0.1mg/ml Rutile TiO2 particles for 24 hours. The cultures were then sorted using FACS, where cells were sorted by a low and high scattering angle window, and it was assumed that the high scattering fraction would increase with TiO2 uptake. The results showed that 91% of the treated cells contained TiO2 particles.

The high scattering fraction and the control untreated cells were then plated on a 1mg/ml matrigel substrate, and the progress of angiogenesis was recorded using an EVOS microscope with a CO2 onsetage incubator. Images of triplicate cell cultures were captured every 20 minutes over 18 hours. The images were then analyzed using Celleste Image Analysis software. From the images, it was found that the culture with TiO2 nanoparticles nucleated a network, and the network was more robust and persisted longer than the control. SEM analysis of the networks indicated that TiO2 particles were present in the cells, which constituted the nodes, splines, and all aspects of the network.

RT-PCR was performed on the cultures, and the results of the treated cultures were compared to those of the control. The data showed that while the housekeeping gene, GAPDH, was significantly upregulated by the particles, no difference with the control group was observed for the other housekeeping gene, Actin Beta. Hence, only the latter was used for normalization.

The data demonstrated that TiO2 exposure upregulated the hepatocyte growth factor (HGF) expression by more than an order of magnitude. In contrast, Vascular endothelial growth factor A (VEGFA) expression, which was previously observed to be upregulated in tumors with HGF, did not occur. These results indicate that despite no evidence of TiO2 nanoparticle penetration into the nucleus, exposure to TiO2 can result in upregulation of multiple genes. Further research into the precise mechanism is underway to determine whether the findings can serve as a beneficial factor in promoting wound healing.

We acknowledge the Morin Charitable Trust for funding.

Thrombosis: An Analysis of Pseudo-Thrombi to Understand Collagen-Fibrin Interaction
Sripradhu Manikanthan1, Huiting Luo2, Shi Fu2, Robert Wong2, Shifloni Sukhla1 and Miriam Rafailovich1; 1James Logan High School, United States; 2Stony Brook University, The State University of New York, United States

When vascular injury occurs, the exposed tissue factor initiates thrombosis through a cascade of events including the aggregation of platelets and their coagulation, which in turn triggers the formation of fibrin and collagen to wrap around the coagulated platelets. Clinical treatment of thrombosis in patients with deep vein thrombosis or pulmonary embolism uses fibrinolitics in low fibrinolytics [1]. However, for arterial thrombi, fibrinolitics do not often respond well. Research shows that collagen plays a dual role in thrombosis [2] by stimulating glycoprotein VI to promote platelet accumulation and by activating factor XII to promote blood coagulation. In this research, we intended to understand the disparity between venous and arterial thrombosis by studying the interaction between collagen and fibrin in thrombi that prevent lysis. A model scaffold was produced where fibrinogen and collagen were mixed at low temperature and then allowed to crosslink at 37 C. The scaffold was submerged in osteogenic media for 21 days and biomineralization was assayed using XRF and Raman spectroscopy. Results show that in-vitro XRF of scaffold revealed that biomineralization is significant in collagen when compared to fibrin. The calcium to phosphate ratio for the mixture of collagen and fibrin samples is 1.67, consistent with the formation of hydroxyapatite in the sample. Raman spectroscopy confirmed the formation of crystalline HA in the matrix. The spectra showed a greater peak for collagen when compared to fibrin or the collagen/fibrin scaffold mix, consistent with the XRF results. This means that fibrin has very little biomineralization. Also, unique peaks identified in the fibrin-collagen mix graph suggest the possible formation of a new biomaterial. Venous thrombi were analyzed histologically and it was shown that they were predominantly composed of fibrin, while arterial thrombi were shown to contain collagen. XRF confirmed the absence of biomineralization in the venous thrombus, consistent with the in-vitro model. Results on the arterial thrombus will be presented, where the presence of mineral deposits will be investigated, as a function of collagen content and the hypothesis that they interfere with lysis will be investigated.

Neurogenic Differentiation of Micro-Spheric Dental Pulp Stem Cells via Poly-Lactic Acid, Poly-(4-vinylpyridine) and Resorcinol Diphosphate Clay
Polymer Scaffolding
Dvita Bhattacharya1, Catherine Chun2, Anita A. Gienkens1, Alexander C. Wang1, Adam Zaidi1, Ethan Lai1, Michael Wang2, Aman Yarlagadda1, Kuan-Che Fang1 and Miriam Rafailovich1; 1Kent Place School, United States; 2Ardsley High School, United States; 3Huron High School, United States; 4Sewickley Academy Senior School, United States; 5San Francisco University High School, United States; 6Phillips Academy, United States; 7Mounds View High School, United States; 8Newman Smith High School, United States; 9Stony Brook University, The State University of New York, United States

Neurodegenerative diseases such as Alzheimer’s pose a major risk to the central nervous system due to the intrinsic non-dividing nature of neurons. Therefore, it is imperative to find methods of generating functionally and morphologically neuronal-like cells from non-neuronal cells under biominetic conditions. Previously, dental pulp stem cells (DPSCs) have been shown to differentiate into neurons via plating on Poly-lactic Acid (PLA), Poly-(4-vinylpyridine) (P4VP), and Polyacetic Acid with Resorcinol Diphosphate (RDP) Clay. A concentration of 20% RDP-Clay was found to provide the highest extent of differentiation into neurons on rough PLA surfaces [1]. Also, the usage of micro-sphere forming U-bottomed StemFit 3D suspension well plates increased the differentiability of DPSCs [2]. Therefore, in this experiment, we are investigating the effects of PLA, P4VP, and RDP Clay scaffolding on neuronal differentiation of DPSCs plated on 3D micro-sphere forming plates.

DPSC micro-spheres (created using suspension well plates) were plated onto silicon wafers spin-casted with pure PLA, PLA with 20% RDP-Clay, PLA with 30% RDP-Clay, pure P4VP, P4VP with 20% RDP-Clay, and P4VP with 30% RDP-Clay. These spin-coated surfaces were analyzed with Atomic Force Microscopy (AFM) to ensure homogeneous roughness across the samples so that roughness wouldn’t be a confounding factor in the growth and differentiation of the DPSCs. The RDP-Clay particles dispersed throughout the PLA with 20% RDP-Clay sample became nuclei for PLA crystals. Conversely, P4VP does not crystallize around the RDP-Clay. The plated cells were incubated for 28 days with regular media changes. EVOS images of the DPSCs were taken on Day 1, 6 days after the cells were cultured and Day 1 and Day 6 after plating on polymer scaffolds, confirming microsphere formation following suspension well culturing.

On Day 4, the elastic modulus of the DPSCs was measured for each group of polymer scaffolding via AFM. Cells plated on TCP served as a baseline for modulus. Lower modulus values indicate neuronal differentiation, as neurons are softer cells compared to DPSCs. P4VP had lower modulus (half that of...
TCP), which indicates that cells plated on pure P4VP had the highest elasticity and were therefore likely differentiating into neurons at a higher rate. Adding RDP-Clay concentration corresponded to a significant difference in modulus for cells plated on P4VP, but an increasing concentration of RDP-Clay was not consistent with a significant change in modulus for PLA scaffolds.

On Day 28, the expression of early-stage neuronal development markers TUBB3 and NES and late-stage marker NEFM was measured using RT-PCR and compared to expression in undifferentiated DPSCs. In differentiated neuronal cells, expression of TUBB3 and NES is expected to be downregulated, and NEFM is expected to be upregulated. Corresponding to our modulus data's implications, adding RDP-Clay to PLA did not lead to significant downregulation of TUBB3, NES, or upregulation of NEFM. However, an increasing concentration of RDP-Clay in P4VP correlated with significant downregulation of TUBB4, NES, and upregulation of NEFM in comparison to undifferentiated DPSCs, indicating that the cells likely underwent neuronal differentiation. Further data will be collected to analyze the effects of these polymer scaffoldings on the neuronal functionality of these morphologically and genetically differentiated cells.

To address the aforementioned problems present in the current standard of care, our group developed a three-pronged approach consisting of the creation of an elastic biodegradable scaffold to encapsulate the marker, a deployment device for testing on rats that does not utilize forces during in vivo testing in rats, and Nicole Levi; Wake Forest University School of Medicine, United States

SESSION SB09.07: Scaffolds for Regenerative Engineering I

ECM Based Hydrogel Delivery Vehicles and 3D In Vitro Injection Model for Human Retinal Progenitor Cells Transplantation
Rebecca Carrier1, Peng Zhao1, Sidi A. Bencherif1 and Michael J. Young2; 1Northeastern University, United States; 2Schepens Eye Research Institute, an affiliate of Harvard Medical School, United States

Retinal degenerative diseases caused by photoreceptor cell loss and damage are the leading cause of blindness worldwide.1 Treatments, including gene therapy, drug, and neuroprotective approach, mainly focus on slowing down the degeneration process rather than reversing it. Retinal cells implanted into the subretinal space have been shown to integrate within host retina, improving visual function in models of retinal degeneration. One barrier to clinical success is the loss, through efflux and death, of the majority (~99%) of implanted cells. A factor likely contributing to cell death is the host microenvironment of the subretinal space after a high cell density (~105 cells/μl) bolus injection (e.g., lacking oxygen/nutrients, missing physical support, and chemical cues). Recent studies have demonstrated that the delivery of retinal progenitor cells (RPCs) using polymer scaffolds results in improved cell survival and differentiation with associated increases in RPC integration.3-4 However, current polymer scaffolds still result in minimal overall integration (~2%).

We have established an in vitro bolus injection model mimicking clinical subretinal injection to explore the impact of bolus injection on human RPC viability. Studies using this model have revealed that indeed RPCs are damaged during the injection process, leading to cell death. To better understand what cues may improve survival of RPCs in the post-injection bolus microenvironment, inert hydrogel systems (oxidized low viscosity alginate) were employed in conjunction with retinal ECM cues including glycosaminoglycans (GAGs): hyaluronic acid (HA) and chondroitin sulfate (CS), laminin (important component of basement membrane), and RGDS (adhesive peptides). The effects of the stiffness and chemical modifications of the delivery vehicles on cell survival/death mechanisms in the bolus injection environment were investigated using fractional factorial design, revealing advantages of stiffer substrates and laminin in promoting RPC survival. Ultimately, this information can be used to guide design of cell delivery vehicles for human RPCs transplantation with improved post-injection survival.

Poly 1,8-Octanediol Citrate Breast Biopsy Scaffold and Deployment System
Darnell R. Campbell, Marcos Benavides, Jordan Forte, Clifford Howard and Nicole Levi; Wake Forest University School of Medicine, United States

During a breast biopsy, it is crucial to accurately identify regions of concern and deliver markers accurately for subsequent imaging and surgical procedures. If surgical removal is not required, it is essential for the marker to be biocompatible, as it will remain in the tissue for the remainder of the patient's lifetime. Current breast biopsy systems employ a forceful deployment during marker administration leaving a void within the tissue that contributes to marker migration. Furthermore, current marker-encapsulating-meshes are not robust and lack compliance to breast tissue which further contributes to rapid mesh disintegration and marker migration.

To address the aforementioned problems present in the current standard of care, our group developed a three-pronged approach consisting of the creation of an elastic biodegradable scaffold to encapsulate the marker, a deployment device for in vivo testing on rats that does not utilize forces during administration, and a transparent breast tissue phantom to determine real-time expansion of the scaffold.

First, a biodegradable Poly 1,8-Octanediol co-citrate (POC) elastic scaffold capable of securing both metallic and non-metallic markers was developed and characterized. Our initial results indicate that POC's properties can be tuned to user-preference by changing crosslinking time, porogen size and leaching time during fabrication; to ensure elasticity of the scaffold, we optimized the pore size by using 400μm NaCl as a porogen. Next, we optimized POC compression and expansion by testing tensile forces at different crosslinking and porogen leaching times. Interestingly, we encountered that during subsequent crosslinking after leaching, POC develops limited self-healing capabilities which allowed for previously embedded markers to be repositioned within a completed scaffold.

Secondly, we developed a 3D-printed deployment device which releases the encapsulated breast biopsy marker passively in a retractable motion, eliminating the forces that cause an increase in void size within the biopsy incision. The device was subsequently employed during in vivo testing in rats, from which initial results demonstrate little to no marker migration when compared to current standard of care.
Finally, an optically transparent breast phantom was made from Dermasol. This reusable, insensitive to temperature or dehydration phantom allows for POC scaffold deployment and expansion in real time.

Here we presented our solutions to address the challenges associated with breast biopsy marker placement. We achieved this by developing a biodegradable POC scaffold capable of encapsulating markers and expanding to fill the biopsy void, a retractable device to release the scaffold passively, a breast tissue phantom for visualization of sponge expansion, and tested of our approach in vivo. We are currently determining POC’s degradation profile as well as continuing to evaluate our prototype scaffold and deployment system in vivo to measure the reduction in metallic marker migration compared to commercially available devices.

8:45 AM *SB09.07.04 Responsive Antimicrobial Biomaterials for Treatment of Wound Infections Anita Shukla; Brown University, United States

The wound repair and regeneration process is greatly complicated by the presence of infections. Chronic wounds in particular are highly prone to infection. As a prominent example, nearly 60% of individuals with diabetic foot ulcers develop infections. Preventing and treating wound infections is a critical challenge in promoting successful tissue repair. The existence of biofilms and antimicrobial-resistant microorganisms within wound environments further complicates the effective treatment of these infections. In this talk, I will describe recent approaches we have taken to treat wound infections using hydrogel biomaterials and nanoparticle therapeutic formulations. I will discuss the development of a bacteria-responsive hydrogel drug delivery platform that can provide on-demand treatment of wound infections, while facilitating tissue repair. These hydrogels respond to the presence of beta-lactamases, which are bacteria-produced enzymes that are a common cause of antibiotic resistance. Upon exposure to beta-lactamases, the hydrogel backbone undergoes degradation, leading to the release of encapsulated antibacterial liposomes. Our findings using a Pseudomonas aeruginosa-infected murine skin abrasion wound model indicate complete clearance of infection within one day of treatment. Importantly, there were no instances of infection recurrence during the four-day wound monitoring period. Furthermore, timely eradication of the infection helped promote wound healing, as evidenced by histological analysis revealing rapid regeneration of the epidermis. Notably, the hydrogel itself exhibited no signs of toxicity. I will also describe our work on the development of bacteria-responsive gelatin nanoparticles that have demonstrated promising antibiofilm efficacy against prevalent wound infection-causing bacteria, including Vibrio vulnificus and P. aeruginosa. Overall, the technologies described in this talk are biocompatible and effective at eliminating wound infections, thus holding immense potential for promoting effective wound healing.

9:15 AM SB09.07.05 Biomimetic Semi-Flexible Hydrogel with Reduced Inflammation for Bone Defects Jaseo Lee1,2 and Il Keun Kwon1; 1Harvard Medical School, United States; 2Brigham and Women's Hospital, United States; 3Kyung Hee University, Korea (the Republic of)

Engineered 3D scaffolds must be biomechanically capable to substitute injured tissues, and have typically been made of tissue-mimicking stiffness. However, this paradigm is shifting towards the understanding that the stiffness of scaffolds can be directly responded to by cells. Herein, we have designed a soft hydrogel to meet two criteria that can shift from soft to progressively hard tissue, similar to tissue development in nature. First, inspired by clotting blood at the wound site, the goal is to achieve strong bonding with adjacent tissues through physical crosslinking of fibrinogen (FBG). Second, the hydrogel is needed to dissipate energy such as existing collagen (COL) in the body. This scaffold promotes energy dissipation by strengthening the elastic and soft fibers of the FBG through COL to form a dense structure. As a crucial fundamental substrate, soft hydrogels initially induce rapid cell adhesion due to their soft surface. Sequentially, the cells increase to penetrate inner part and make rigid themselves, and leading to bone formation. Furthermore, this hydrogel was composed of ECM-like tissue, which could reduce inflammation in the early stage. Therefore, our dual-function system provides a promising strategy for natural tissue-mimicking bone regeneration by reducing inflammation, and concurrently bridging defect area through harmonizing the newly assemble cells and ECMs.

9:30 AM SB09.07.06 Neuron Viability and Maturation on Electroactive Materials and Effect of Electroactive Stimulation on Neural Cell Response Teresa Marques-Almeida1, Clarisse Ribeiro1, Igor Istrorza2, Patricia Miranda2, Ignacio Torres-Alemán3, Unai Sillan4 and Senentxu Lanceros-Mendez2,1,5; 1University of Minho, Portugal; 2BMCMaterials, Basque Center for Materials, Applications and Nanostructures, Spain; 3University of the Basque Country, Spain; 4Auchucarro Basque Center for Neuroscience, Spain; 5Ikberbasque, Basque Foundation for Science, Spain

Electric cues are intimately related connected to physiological functions of cells and tissues. The ability to control and direct electric signals within tissue-engineered constructs is therefore increasingly important for proper tissue engineering strategies, as they influence cell behaviour and guide tissue development towards more functional and biomimetic outcomes. In this context, smart materials, able to react in a controllable and reversible way to external stimuli by varying a specific physical or chemical quantity, show great potential for the development of advanced biomedical strategies, including biosensing, tissue regeneration and repair, immuno- and cancer therapy. Among the different types of smart materials, piezoelectric ones, that convert mechanical solicitations into electrical potential variations and vice versa, represent as suitable candidates to induce specific cell behaviors through electric cues, mainly by improving biomimicry of the cell microenvironment. The presence of piezoelectric properties in different materials is known and the effect of surface charge and piezoelectric stimulation has been proven to be beneficial in a variety of cells, including mesenchymal stem cells, myoblast and osteoblasts, among others, has been evaluated. Since neurons were first cultured outside a living organism more than a century ago, a number of experimental techniques for their in vitro maintenance have been developed. These methods have been further adapted and refined to study specific neurobiological processes under controlled experimental conditions. Nevertheless, the impact of fundamental properties of the surfaces to which neurons adhere when cultured in vitro has not been sufficiently considered.

In the present work we have analyzed the response of primary neurons when cultured on piezoelectric poly(vinylidene fluoride), PVDF, surfaces with different surface electric charge and electric maturation type, allowing to stabilize the effect of the net charge on neuron behavior. It is shown that PVDF films promote the attachment, viability and maturation of primary neurons. More cells per unit area and longer neurites were already present in neurons cultured for one day on PVDF surfaces. Early neurite outgrowth was induced using polar PVDF as culture substrates, since by day 4 of culture neurons already show significantly increased neural process development, and by day 7, this development is even more obvious in neurons cultured on PVDF-. Negative surface charge promotes particularly increased cell metabolism, being about 3 times higher than in control, and being about 1.7 times higher than in the absence of charge (PVDF NP). When adhering to PVDF-, neurons undergo maturation at a faster rate, as revealed by the higher expression levels of MAP2 and NeuN. Further, the effect of surface charged PVDF films (positive, negative, and non-poled (average neutral surface charge)) on adhesion, proliferation and differentiation of neural-derived cell line, under static and dynamic mechanoelectrical stimulation was assessed. Upon mechanoelectrical stimulation, PVDF with average positive surface charge allows to significantly improve cellular adhesion compared to PVDF with negative or without average surface charges. Independently of the PVDF surface charge type, the applied electrical stimulus throughout the assay improved neurite extension and differentiation.
The obtained results highlight the importance of considering the electric charge of the culture surface for the in vitro maintenance of neurons, demonstrating the suitability of the use of 2D PVDF based surface-charged substrates. Further, these findings highlight the possibility of novel therapeutic strategies for the regeneration of neural tissues based on the dynamically surface charge variation that can be induced in the electroactive films.

Magnetic Hyperthermia Enhances In Vivo Tissue Regeneration Through Intracellular Ros Production Giuseppeppina Tommasini1, Susel Del Sol-Fernández1, Angela Tino1, Claudia Tortiglione2 and Maria Moros1,1; 1Institute of Nanoscience and Materials of Aragon (INMA-CSIC), Spain; 2Institute of Applied Science and Intelligent System (ISASI-CNR), Italy; 3Centro de Investigación Biomédica en red en Bioingeniería, Bionanomateriales y Nanomedicina (CIBER-BBN), Spain

Regenerative medicine is a pioneering field aimed at restoring and regenerating damaged tissues and organs through numerous strategies, including the use of new materials and de novo generated cells. As a dynamic biological process, tissue regeneration requires a variety of intracellular and extracellular molecular mechanisms to facilitate cell division and regeneration. In recent years, multiple studies have demonstrated a central role of reactive oxygen species (ROS) in tissue regeneration, acting as signaling molecules that trigger the activation of molecular pathways involved with cell proliferation and differentiation. Recently, regenerative medicine has found a surge of interest in magnetic nanoparticles, using their magnetomechanical and heating potential to activate different pathways. In this optics, a promising therapeutic approach could be the possibility of manipulating the ROS production to enhance tissue repair using mild magnetic hyperthermia (MH).

Here, we present a novel approach for enhancing tissue regeneration in vivo through mild magnetothermal stimulation using manganese iron oxide nanoparticles (MnxFe3-xO4) with improved heating performance. We evaluated the biological effect of internalized MNPs subjected to an alternating magnetic field on the regeneration process that physiologically occurs in the freshwater invertebrate polyps Hydra vulgaris. To decipher the molecular mechanism underlying this process, we performed gene expression analysis of molecular markers normally modulated in ROS homeostasis in regenerated polyps after the MH stimulation. This innovative approach has not been applied before to improve tissue regeneration and thus could represent a breakthrough in tissue engineering.

The Effects of Varying Ratios of PEGDA:PDMS on the Mechanical Properties of Hydrogels with Differing PEGDA Concentrations for Bone Tissue Engineering Sam Lloyd-Harry1, Ozgul Yasar-Inceoglu1 and Ozlem Yasar2; 1California State University Chico, United States; 2The City College of New York, United States

The mechanical properties of hydrogels play a crucial role in determining their suitability as scaffolds for cell growth. Properties such as biocompatibility, porosity, and mechanical properties dictate the success of a candidate scaffold material. The effects on the mechanical properties of varying ratios of Poly(ethylene glycol) diacrylate (PEGDA) to polydimethylsiloxane (PDMS) have been reported; however, the effects of differing PEGDA:PDMS ratios in varying amounts of water have not been studied. In this work, the effects of varying ratios of PEGDA:PDMS (90:10, 85:15, 80:20) on the mechanical properties of PEGDA concentrations (20%, 40%, 60%, 80%, 100%) were investigated and compared with the embedment of SiO2 nanoparticles (NPs). PEGDA, PDMS, water, and photoinitiator were mixed and cured under a 365 nm UV light for 10-30 minutes (increasing by 5 minutes with increasing PEGDA concentrations). Compressive testing was performed on all samples using a QT/50 Universal Testing Machine at a 5mm/min rate until breaking. Results indicate that introducing silicon and increasing oxygen strengthens PEGDA hydrogels significantly, regardless of concentration. The comparison of SiO2 embedded samples to varying PEGDA:PDMS samples reflects the tunability that makes PEGDA hydrogels ideal candidates for tissue engineering.

Pediatric patients suffering from heart valve disease often require multiple highly invasive valve replacement surgeries throughout their childhood. Building heart valve replacements that remodel and grow alongside the patient could provide a potential solution to avoid these repeat interventions. Here, we present FibraValves as heart valve replacements that mimic the multiscale structure of the native valve, ranging from the nanoscale of the extracellular matrix (ECM) to the macroscale of the native leaflet geometries. Current valve manufacturing processes struggle to recreate these hierarchical structures. With Focused Rotary Jet Spinning (FRJS), we fabricated these valve scaffolds in less than ten minutes. Utilizing centrifugal forces to extrude synthetic polymer fibers and a focused air stream to direct them, FRJS prints micro- and nanofibers onto customizable trileaflet valve shaped collection mandrels. Fiber production and valve formation occur simultaneously. The micro- and nanofibers serve as ECM analogs, interacting with the native tissue at the cellular level, while the macroscale shape of the valve leaflets control unidirectional cardiac flow. We manufactured FibraValves using Poly(L-Lactide-co-ε-Caprolactone) fibers, due to their elastic mechanical properties and ability to facilitate rapid cellular infiltration. To evaluate clinical translatableity, FibraValves were implanted in sheep using a minimally invasive transcatheter approach. The stented valves were deployed successfully and provided one-way cardiac flow control in initial acute studies. This work indicates the potential viability for FRJS to be used for future heart valve manufacturing as well as other medical implants.

Cell-Seeding Promotion of Phages Functionalized Surfaces Grazia M. Messina1, Giovanna Calabrese2, Salvatore Guglielmino3 and Giovanni Marletta4; 1University of Catania, Italy; 2University of Messina, Italy

Regenerative medicine is a developing field of interdisciplinary research that includes a combination of in vitro/ex vivo and in vivo techniques, including the transplantation of stem/progenitor, differentiated, or modified cells, either alone or in biomaterial scaffolds. Many strategies have been developed based on the stimulation of body’s endogenous process to grow and repair.
Microneedle (MN) has been extensively studied for drug delivery with the rapid development of various designs and fabrication methods. Dissolving MN made of fast-dissolving biomaterial such as hyaluronic acid (HA) has shown great potential and has been the most popular MN type. However, dissolving MNs have several unsolved issues: less reliable tissue insertion and inconsistent drug delivery to the tissue. Dissolving MNs are usually fabricated with an aqueous polymer solution, which requires a solvent evaporation step for solidification. However, evaporation deforms MN’s shape and results in air voids trapped in MN. This inevitably affects each MN’s stiffness, insertion ability, and dose distribution. Nevertheless, most of the studies on dissolving MNs have focused on studying their clinical effects and neglected the reliability of MN insertion and drug delivery to the tissue. Multi-drug delivery from MNs trapped in MN. This inevitably affects each MN’s stiffness, insertion ability, and dose distribution. Nevertheless, most of the studies on dissolving MNs have focused on studying their clinical effects and neglected the reliability of MN insertion and drug delivery to the tissue. Multi-drug delivery from MNs have been introduced as an advanced form of MNs when more than one drug needs to be administered for cancer treatment. They are mostly fabricated by micro-molding two drugs together or dip-coating the second drug formulation on dissolving MNs containing the first drug. However, these MNs have unwanted interactions between drug compounds and can have difficulty with accurate dose control at the MN insertion site. A heterogeneous MN (h-MN) device which contains different drugs in different MNs in a single patch can be a great alternative since it can avoid drug interaction. Nevertheless, the fabrication process of the h-MN array is challenging since the traditional micro-molding process produces an array of MNs with a single material. This study established a vacuum-assisted extrusion 3D printing process for high-strength, void-free h-MN flexible patch fabrication. We confirmed reliable tissue penetration and accurate drug delivery to a target tissue. Negative pressure was applied beneath a PDMS mold to remove the air void remaining after molding the polymer solution. For efficient removal, the mold was fabricated with a thickness of less than 1 mm. The mold was located on the customized vacuum jig which was connected to a vacuum pump to apply negative pressure beneath the mold. An array of poly (lactic-co-glycolic acid) (PLGA) and HA MNs were fabricated in a single flexible patch for long-term and short-term drug delivery. For PLGA MN fabrication, PLGA5050 57.14 wt.% solution was prepared using dimethyl sulfoxide (DMSO) with rhodamine b (0.1 w/v %) at 60 °C for 1 h. The solution was extruded single time by an extrusion 3D printer (Nordson Pro4L EFD) with 20 kPa of pneumatic pressure into the cavity. DMSO was evaporated after the extrusion at 130 °C for 60 min. For HA MN fabrication, HA 9.09 wt.% solution was prepared using 0.2 w/v % fluorescein isothiocyanate–dextran (FITC-Dextran) aqueous solution. The solution was extruded 9 times with 90 kPa of pneumatic pressure and a humidifier was applied to maintain relative humidity over 50 %. After the MNs fabrication, the mechanical properties of each MNs were analyzed by the penetration test conducted on porcine skin. The penetration force of each MNs was up to 30 g on the porcine skin which was inserted into tissue to a depth of about 550 μm. Afterward, the drug release rate of h-MNs was estimated by measuring the fluorescence intensity using a plate reader. Drug release test showed that PLGA MN released rhodamine b for 98 h and HA MN released FITC-Dextran for 3 h. Finally, HA solution (13.04 wt.%) was extruded in a mesh pattern over a fabricated 3 x 3 h-MN array to form an h-MN flexible patch. After preparing the h-MN patch, it was again inserted into the porcine skin to identify the penetration ability by confirming the cross-sectional view using a cryo-sectioning machine. Through the development of the fabrication process and analysis result, vacuum-assisted extrusion 3D printed h-MNs patch has demonstrated its mechanical, and clinical feasibility.
growth, cell viability, and cardiomyocyte function were monitored and compared within the three patches. Additionally, the cardiac patch mechanics were examined using nanindentation, tensile testing, and Raman spectroscopy to discuss the overall suitability of the fibrous mat in cardiac tissue engineering applications.

Cancer Testbeds for Bone Metastasis Therapeutics  
Kalpana Katti1, Prereetham Ravi1, Quyen Hoang1, Jiha Kim1, Anu Gaba2, Parth Vyas2 and Dinesh R. Katti1; 1North Dakota State University, United States; 2Sanford Health, United States

Worldwide over a million deaths occur each year from breast and prostate cancer bone metastasis. Majority of the deaths due to breast and prostate cancer are attributed to metastasis, the process of migration of cancers from the primary site to a remote location which happens to be bone for breast and prostate cancer. Bone metastasis of cancer often causes skeletal failures that become the cause of death in patients. The anticancer drugs available are ineffective for bone metastasis treatment. The inefficacy of anticancer drugs and failure of animal models necessitates the need for reliable in vitro models. We have developed a novel nanotube tissue engineering scaffold that enables development of remodeling stage fetal bone, a preferred niche for breast and prostate cancer metastasis. The bone mimetic scaffold utilizes modification of the clay galleries with amino acids to allow biomimetic mineralization of hydroxyapatite inside clay galleries. The bone scaffold is further sequentially seeded with commercial and patient derived cell lines of prostate and breast cancer to generate in vitro models of bone metastasis in breast and prostate cancer. A specially designed horizontal flow bioreactor enables physiologically relevant fluid flow through the scaffolds thus creating a realistic testbed of bone metastasis. The cancer testbed serves as a useful platform to investigate new biomarkers using FTIR spectroscopy, Raman imaging and nanomechanical investigations. We have developed unique mechanics-based biomarkers that use direct nanindentation to evaluate thech change in elastic modulus, mechanical plasticity and viscoelasticity of cancer cells as a measure of metastasis progression. We have developed unique FTIR based spectroscopic biomarkers with the help of the testbed that also demonstrate the use of FTIR in developing markers for progression of metastasis. Since clinical observations indicate extensive skeletal problems and failures in bone metastasis patients, we use the testbed to evaluate the mechanisms of influence of cancer cells on the Wnt b catenin pathway an important osteogenesis pathways. We observe the specific role of cancer cell factors DKK and ET-1 on influence osteogenesis at the bone site. Lastly we demonstrate the use of testbed for screening new drugs and plant-based compounds for efficacy in treatment of bone metastasis. Overall the cancer testbed presented here is a useful in vitro system for development of new metastasis therapies and personized medicine.

2:00 PM SB09.08.03
Lacunar Bone-Inspired Biodegradable Constructs: Towards Mini-Invasive Bone Repair  
Federica Buccino1, Giuliana Tromba2, Sandra Hofmann2 and Laura Maria Vergani1; 1Polytechnic University of Milan, Italy; 2Elettra Synchrotron, Italy; 3Technische Universiteit Eindhoven, Netherlands

Advancements in the field of medicine have resulted in increased life expectancy but have also led to a rise in age-related illnesses, with osteoporosis being one of the most prevalent and widespread diseases. Each year, approximately 9 million fragility fractures occur globally, imposing a significant economic and psychosocial burden for disease management. While accidents and bone tumors directly cause pain and deformity, bone fragility often remains undetected, gradually deteriorating quality of life and creating a pressing need for effective regenerative strategies. Despite notable progress in microsurgical techniques in recent decades, achieving satisfactory functional and structural repair of damaged bone tissue remains challenging. Although bone tissue possesses intrinsic regrowth and self-restoration capabilities to some extent, the injured bones frequently fail to regain their load-bearing function, resulting in fracture nonunion. Current approaches for treating large bone injuries involve the use of autografts, allografts, and scaffolds, but none of these methods are entirely satisfactory due to specific limitations. These limitations include reduced bioactivity, potential spread of pathogens, inflammation, the need for additional surgery, limited availability, inappropriate shape and size, and a lack of monitoring for newly formed bone. In particular, difficulties in detecting bone-scaffold interactions and understanding the complex relationships between bone formation and local scaffold geometry are currently impeding the clinical applicability of minimally invasive constructs for bone healing.

To overcome these challenges, we propose the design of a novel construct for bone healing that has the potential for scalability, while addressing the current geometric, biological, and monitoring issues. The geometry of the construct is inspired by the natural lacunar micro-porosity and interconnectivity found in human bones, facilitating an improved cell seeding process. The constructs are fabricated using silk fibroin and seeded with mesenchymal stem cells. Two different culture media are considered: the state-of-the-art fetal bovine serum (FBS) and the human platelet lysate (hPL). To assess the mechanical response of cellularized constructs, we employ image-guided failure assessment within a synchrotron using a newly developed X-ray and human eye testing equipment, performing micro-compression tests on the seeded constructs. Scans are acquired at various time frames, corresponding to increasing levels of applied displacement to the construct. To evaluate the interplay between bone regeneration and the architecture of the silk fibroin scaffold, we utilize neural networks (NN). With a NN accuracy of 0.92, our findings demonstrate the following: i) there is a statistically significant correlation (p<0.05) between pore density and bone formation; ii) constructs seeded with hPL exhibit enhanced bone regeneration (+26%) compared to those seeded with FBS; iii) pore shape may play a crucial role in modulating bone remodeling.

The unprecedented resolution of synchrotron imaging, coupled with the ability to gain novel insights into the mechanical response of constructs for bone healing, enables us to elucidate the intricate connections between scaffold geometry, woven bone formation, and the restoration of mechanical function. Future endeavors will focus on the utilization of shape-responsive materials in construct design, allowing the shape of the construct to be adapted according to specific requirements and needs.

2:15 PM SB09.08.04
NanoTube Scaffolds: Versatile and Customizable Long-Term Culture Platform for Primary Cells and Adult Tissues  
Astrid Kuengeler1, Sabrina Friebe1,2, Philine Jauch1,2, Sonja Kallendrusch1, Ivonne Neß2, Bahriye Aktas2 and Stefan G. Meyer1,2; 1Leibniz Institute for Surface Engineering, Germany; 2University of Leipzig, Faculty of Physics and Earth Sciences, Division of Surface Physics, Germany; 3HMU Health and Medical University Potsdam, Germany; 4University of Leipzig, Medical Center, Germany

A personalized therapy for each patient is one of the milestones in medicine. Associated with this is the organotypic culture of endogenous tissue. In this context, the extracellular matrix plays a major role, because it is unique for every part of the body. Hence, each tissue requires a specific microenvironment when cultured or grown ex vivo. For instance, topography and prominent chemical characteristics of the surface are crucial for protein adsorption, cell and tissue adhesion. Usually, the discrepancy between tissue demands and culture conditions results in a loss of physiological properties such as structural integrity, function, or viability of healthy tissues and tumors when the culture period exceeds seven days. This indicates that a one-size-fits-all approach of commonly used Teflon membranes is not effective for an organotypic culture. In contrast, the systematic tailoring of titania nanotube scaffolds aims to enable enhanced culture of adult human tissues ex vivo and preserves its structure and viability.

As an example, we present long-term cultured human mamma carcinomas that are highly responsive to the underlying nanostructures. Characteristic structural features as blood vessels, glands and connective tissues that contain for instance adipocytes, fibrocytes, immune cells (like macrophages) and tumor cells show a surface-mediated preservation. In order to maintain a normal degree of proliferation, migration, and apoptosis that corresponds to the endogenous state, to preserve the extracellular matrix overall, glands and bloods vessels in specific, and to observe active immune cells, we designed advanced titania nanotube scaffolds with the desired functionality.
Altogether, we aim to realize a platform for organotypic tissue culture of up to several weeks, where primary cells and adult tissues are maintained in a physiologic condition. In particular, we aim to maintain an intact histomorphology, proper function, infiltration with immune cells and preserved physiological niches. Chemical and physical characteristics of the titania nanotube scaffolds are tunable with regard to e.g. surface morphology and topography, surface functionalization and overall conductivity. In this way, the scaffolds can also serve as a tolerable basis for primary cells and 3D bioprinted organ structures. Hence, we pave the way for reliable drug testing and personalized medicine.

We acknowledge the Heinrich-Böll-Stiftung and the German Federal Ministry of Education and Research, project EYECULTURE, as well as the Saxon State Ministry for Economic Affairs, Labor and Traffic (SMWA), project NanotubeUpscaling, for funding.

2:30 PM SB09.08.05
Advances in Cell Coculture Porous Membranes to Mimic In Vivo Microenvironments Jin Yoo; Korea Institute of Science and Technology, Korea (the Republic of)

In this presentation, we will discuss the advancements in cell coculture platforms that integrate engineered porous membranes to recapitulate in vivo microenvironments and facilitate diverse cell-cell signaling. The utilization of a porous membrane-based coculture platform holds great importance in cell research as it enables the creation of modular interfaces for cells and tissues, while also establishing barrier models for tissue-on-a-chip applications. In vitro coculture systems that incorporate porous membranes are commonly employed to mimic in vivo microenvironments, such as inducing differentiation of stem cells by recapitulating naturally occurring cell-cell communications. Using porous membrane-based coculture to induce stem cell differentiation proves to be a more cost-effective approach compared to relying on growth factors or specific mediums. A widely used commercial coculture membrane, typically a Transwell®, has played a significant role in fundamental and practical studies involving heterogeneous cell coculture systems. However, due to its relatively thick membrane thickness (~10 µm) and low porosity, it has limitations in facilitating sufficient interactions between cocultured cells. To address these limitations, we have developed advanced coculture membranes using polymers. These new membranes have a thinner thickness and higher porosity, resulting in improved cell-cell interactions that more closely mimic native tissue microenvironments. We have successfully applied these newly developed porous coculture membranes to enhance stem cell differentiation efficiency and establish endothelial barrier function.

The Dynamic Interplay Between Tumor Stromal Discoidin Domain Receptor 2 (DDR2) and Collagen on Neuroblastoma Cellular Mechanics Theadora Vessella1, Esteban Rozen2, Jason Shohet2, Qi Wen1 and Susan Zhou1; 1Worcester Polytechnic Institute, United States; 2UMass Chan Medical School, United States

Cancer development, progression, invasion, metastasis, and responses to therapy rely on a permissive tumor microenvironment. The migration invasion of cancer cells through 3D confined extracellular matrices is coupled with cellular mechanics. Abnormal or dysregulated receptor tyrosine kinase (RTK) signaling is common within neuroblastoma. Fibrillar collagen RTK discoidin domain receptor 2 (DDR2) is studied in this project as it is present in both tumor cells and tumor stromal cells, with high DDR2 levels correlated with poor outcomes and metastatic disease. Because DDR2 is upregulated in various cancer cells, we hypothesized that DDR2 binds to collagen within the extracellular matrix (ECM) to promote cellular mechanics during cancer migration. In this work, a comparative study between neuroblastoma cells with normal and down-regulated DDR2 levels is conducted. Downregulated DDR2 cell areas and aspect ratios were significantly decreased when plated on collagen coated substrates. Protrusive speeds were found to be comparable among all cell lines. However, contractile speeds were significantly slower in DDR2 downregulated cells, resulting in decreased detachment of cell edges to participate in migration. Additionally, the depletion of DDR2 was shown to reduce cellular traction forces on collagen coated soft substrates (2kPa), when compared to the control cells. Together, our findings suggests that DDR2 is vital to the role of collagen binding in mediating cellular mechanics and cellular migration in neuroblastoma cells.

3:30 PM SB09.08.07
3D Printed Nanofibrous Multidomain Peptide Hydrogels for Regenerative Medicine Adam Farsheed and Jeffrey Hartgerink; Rice University, United States

Tissues vary in their biological, mechanical, and structural properties. In the field of regenerative medicine, 3D printing has emerged as a powerful technique for producing hydrogel scaffolds that replicate the geometric complexity of tissues. Biologically derived polymers are commonly used as hydrogel inks in 3D printing due to their inherent bioactivity. However, these polymers lack the mechanical flexibility offered by synthetic counterparts. In addition, many biologically derived polymers lack the fibrous composition that naturally exists at the nano and micro scale within the body. This necessitates the development of hydrogel inks that are both bioactive and fibrous in structure to better replicate tissues. Here, we present the use of Multidomain Peptides (MDPs), a class of self-assembling peptides that form a nanofibrous hydrogel, as a novel ink for 3D printing [1]. After optimizing MDPs for 3D printing, we show that they can be used to create complex, overhanging structures, and multi material prints. In addition, we demonstrate how cationic and anionic MDPs can be strategically patterned to influence cell behavior.

Building upon this work, we have developed a novel fabrication method for producing MDP hydrogels with aligned nanofibers, resembling the alignment present in tissues such as skeletal muscle and peripheral nerve. We show that these anisotropic MDP scaffolds can guide cell growth and spreading. Further, by fabricating hydrogel scaffolds with controlled degrees of alignment, we observe that cells exhibit distinct growth patterns in response to nanoscale differences. Leveraging 3D printing, we have scaled this fabrication method to create multilayer hydrogel scaffolds with precise control over the direction of fibrous alignment. The ability to generate aligned hydrogel scaffolds in a scalable manner sets this fabrication technology apart from other techniques. This work highlights the unique potential of using self-assembling multidomain peptides as 3D printable inks, enabling the creation of improved scaffolds for regenerative medicine.

Nature-Inspired Functional Biomaterials to Reduce Biofouling for Medical Implants and Devices Woo Kyung Cho; Chungnam National University, Korea (the Republic of)

The formation of bacterial biofilms on medical implants and devices has been recognized as a major cause of healthcare-acquired infections. These infections not only affect the quality of patient care but can also result in implant or device failure. To address healthcare-acquired infections, we have developed anti-biofouling materials that can suppress bacterial adhesion and biofilm formation. Drawing inspiration from mussel's adhesive foot proteins,
we synthesized a zwitterionic derivative of 3-(3,4-dihydroxyphenyl)-L-alanine (L-DOPA) and catechol-conjugated fucoidan. Robust antibacterial coatings were achieved through oxidative polymerization and the complexation between catechol groups and Fe(III) ions. These synthesized biomaterials can be applied to silicone implants for plastic surgery and various medical-grade substrates. Additionally, we have recently explored polyphenol chemistry to prevent thrombus formation on blood-contacting medical devices in a substrate-independent manner. In this presentation, I will discuss the development of these biomaterials and surface modification methods. The antibacterial and antplatelet properties will be discussed in terms of non-specific protein adsorption, bacterial and platelet adhesion, as well as relevant infections and side effects associated with biomedical implants and tools.

Shear-Responsive Boundary-Lubricated Hydrogels Attenuate Osteoarthritis Yiting Lei; The First Affiliated Hospital of Chongqing Medical University, China

Lipid-based boundary layers formed on liposome-containing hydrogels can facilitate lubrication. However, these boundary layers can be damaged by shear, resulting in decreased lubrication. Here, we designed boundary-lubricated drug-loaded hydrogel by incorporating cellobiox (CLX)-loaded liposomes within dynamic covalent bond-based hyaluronic acid (HA) hydrogels (CLX@Lipo@HA-gel). The dynamic cross-linked network enables the hydrogel to get restructured in response to shear, and the HA matrix allows the accumulation of internal liposome microreservoirs on the sliding surfaces, which results in the formation of boundary layers to provide stable lubrication. Moreover, hydration shells formed surrounding the hydrogel can retard the degradation process, thus helping in sustaining lubrication. Furthermore, in vitro and in vivo experiments found that CLX@Lipo@HA-gels can maintain anabolic-catabolic balance, alleviate cartilage wear, and attenuate osteoarthritis progression by releasing CLX and shear-responsive boundary lubrication. Overall, CLX@Lipo@HA-gels can serve as shear-responsive boundary lubricants and drug-delivery vehicles to alleviate friction-related diseases like osteoarthritis.

10:45 AM SB09.09.02
Application of Degradable Porous Scaffold for Bone Regeneration Ben Zhang; SINOPEC Beijing Research Institute of Chemical Industry, China

Bone defects caused by trauma and disease present severe threat to human health. At present, allografts and autografts are the most utilized methods to repair bone defects. However, these treatments have inherent shortcomings such as high failure rates due to poor graft fixation/tissue integration, potential disease transmission and limited supplies, as well as additional surgical hurt. Synthetic bone grafts, if properly engineered with physical properties enabling stable graft fixation, robust osteoconductive and osteoinductive properties encouraging new bone growth, and safe degradation, could help address these challenges.

We report here degradable scaffolds based on poly(lactic acid) derivatives modified with poly(ethylene glycol), which exhibit high-efficiency shape recovery around body temperature and hydration induced stiffening and swelling effects. Composites of these polymers mixed with nanosized hydroxyapatite were electrospun to fabricate meshes composed of nano/micro fibers with size range from 150 nm to 10 μm. With the help of hydroxyapatite, the morphology of electrospun meshes improved wherein bulk nodules in the fibers reduced and nano/micro fibers become more smooth. As the content of hydroxyapatite increased, the average size of nano/micro fibers decreased and mechanical strength of electrospun mesh lowered. These electrospun meshes showed to support the attachment, proliferation and osteogenesis of osteoprogenitor cells in vitro. However, mouse bone marrow stromal cells (BMSCs) cultured on electrospun meshes exhibited suppressed activity with high hydroxyapatite content of 30 wt% indicated by CCK-8 result. Gene expressions of RUNX2, ALPL, COL1A1 and OCN increased at 14th day shown with q-PCR data, demonstrated potential osteogenic differentiation.

11:00 AM SB09.09.03
3D Printing using Oxygen-Generating Filaments for Bone Scaffolds Tissue Engineering Adnan Memici; King AbdulAziz University, Saudi Arabia

The latest advancements in bone scaffold technology have introduced novel biomaterials that have the ability to generate oxygen when implanted, improving cell viability and tissue maturation. We developed a new oxygen-generating nanocomposite filament that can be used in FDM based 3D printing of bone tissue scaffolds. Initially, the polymer nanocomposites were characterised using an X-ray diffraction analysis, surface morphology assessment, evaluation of filament extrudability, microstructural analysis, and examination of their rheological and mechanical properties in order to optimize filament production. Next, the filaments were optimized in terms of nanocomposite content to control oxygen release, porosity, and antibacterial activities. Our results indicate that an optimized oxygen releasing filament with a holds great promise for improving bone generation through supporting bone cell oxygenation and resistance to bacterial infections.

Multifunctional Patch Systems for Breast Cancer Treatment Jalal Karimzadehkhoei1, Eda Güney1, Beril Ustunkaya1, Buğra Senel2, Ozlem Kutlu2 and Gozde O. Ince3,4; 1Faculty of Engineering and Natural Sciences, Materials Science and Nano Engineering Program, Sabanci University, Turkey; 2Faculty of Engineering and Natural Sciences, Molecular biology, Genetics and Bioengineering Program, Sabanci University, Turkey; 3Nanotechnology Research and Application Center (SUNUM), Sabanci University, Turkey

Breast cancer, although treatable in its early stages with available chemotherapy drugs, remains a significant challenge in the field of oncology due to treatment difficulties, high risk of recurrence, and increased metastasis development, particularly in advanced stages. There is a pressing need in oncology for efficient therapies that provide long-term protection against cancer recurrence. However, the clinical application of chemotherapy drugs is hindered by the lack of efficient drug delivery systems, resulting in diminished treatment success and severe side effects that negatively impact patients' quality of life.

In this study, we present the development of a multi-functional patch system for both short-term and long-term treatment of breast cancer. The patch system comprises two components: drug-loaded nanoparticles dedicated to the therapy and antigen epitope-loaded polymer patches designed to enhance the immune response against potential recurrence. These patches are fabricated using Solution Blow Spinning (SBS), a technique that utilizes a biodegradable polymer for the controlled release of growth factors alongside the drug-loaded nanoparticles. To evaluate the patch's degradation properties, degradation tests are performed by incubating the fabricated patch in phosphate buffered saline (PBS) solution and a lysosome-mimicking solution (LMS). The morphology of the fibers is assessed using scanning electron microscopy (SEM) before and after the spinning process, as well as after the degradation
process. Fourier transform infrared spectroscopy (FTIR) is employed to analyze changes in the chemical composition of the fibers. To monitor the release of antigen epitopes from the patches and drugs from the nanoparticles, enzyme-linked immunosorbent assay (ELISA) is employed. Furthermore, in vitro studies are conducted to assess the effectiveness of the patches in stimulating the immune system. Overall, this study presents a promising approach to address the challenges associated with breast cancer treatment. The development of a multi-functional patch system that combines drug delivery and immune response enhancement may pave the way for more efficient therapies and improved outcomes for patients with breast cancer.

11:30 AM SB09.09.05
Synthesis and Characterization of Carbon-Based Nano-AdSORBent for Dyes Removal from Wastewater
Angeles L. Licona Aguilar1, Aidé Minerva Torres Huerta2, Miguel A. Domínguez Crespo2, María de la Luz X. Negrete Rodríguez1, Eloy Conde Barajas3, Silvia Beatriz Brachetti Sibaja2 and Issis C. Romero Ibarr4; 1 TecNM/ Instituto Tecnológico de Celaya, Mexico; 2 UPIH - Instituto Politécnico Nacional, Mexico; 3 TecnNM/ Instituto Tecnológico de Ciudad Madero, Mexico; 4 UPITHA- Instituto Politécnico Nacional, Mexico

Water pollution is the main part of environmental pollution and it has been increased due to factors such as urbanization and rapid industrialization, considering to human activities in various industrial fields e.g. textile industry, metallurgical, and others. In particular, dyes are hazardous and toxic components, present in trace amounts in wastewater effluents, for its treatment the adsorption method has been the most promising and widely used treatment technique due to its efficient and its flexible operation compared to other methods. Currently, in the nanotechnology field, there are substantial studies researching the potential application of nano-adsorbents for dye removal such as carbon nanotubes (CNTs) and activated carbon (AC) due their physical-chemical properties e.g., large surface area associated with the availability of active binding sites, chemical and thermal properties. These materials can be modified chemically with metallic nanoparticles to increase the surface area and their adsorption capacities through high selectivity and active centers generation. In the present work, multilayered carbon nanotubes (MWCNTs) and activated carbon from orange peel (AC) were modified to obtain absorbent materials. Firstly, a functionalization using a mixing acid (HNO3 and H2SO4) was proposed, to improve groups such as oxygen, nitrogen and sulfur on carbon surface materials. Furthermore, MWCNTs and AC surface were modified with nanoparticles with oxide zinc (ZnO) at different concentration (15 and 30 wt%) by precipitation method. The carbon materials were tests to removal methylene blue (MB) and the optimum adsorption conditions were evaluated. The carbon materials (CM) were analyzed by X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR), thermogravimetric analysis (TGA), scanning electron microscopy (SEM), Nitrogen (N2) adsorption-desorption, zeta potential and UV-VIS technique were used to quantify the concentration of MB. Results revealed that CM developed a large surface area from 200 to 1100 m2g-1 and chemical groups such as OH, C=O and C-O were conserved; adsorption studies reveal that materials with nanoparticles at 30 wt% can removal until 89.5 % of MB considering conditions such as pH 10, time 24 h, adsorbent dose 20 mg, concentration 80 ppm. The overall all results indicated that CM are promising candidates for dye removals.

Keywords: carbon nanotubes, activated carbon, nanoparticles, dyes, adsorption.

11:45 AM SB09.09.07
Development of Metabonegenic Citrate Biomaterials for Orthopedic Engineering
Jian Yang; Westlake University, China

Background: Although significant progress has been made in the development of orthopedic biomaterials, the currently available materials are limited by their inability to mimic the native tissue composition, weak mechanical strength, minimal osteoinductivity, significant inflammatory responses, poor bone integration, and slow bone regeneration. Metabolic factors such as glucose were shown to regulate the energy needs of stem cells during osteoblast differentiation. However, a full picture of the metabolic processes guiding or supporting osteogenic differentiation is far from complete. Citrate is a small molecule participating as the starting metabolite in the TCA cycle, is also a key component of bone. However, very limited information is available on what role the citrate plays in bone development and bone biomaterial design despite of its well-known unusual high abundance in bone.

Methods: In this study, a new class of highly versatile and functional citrate-based biomaterials has been developed by reacting citric acid with various carefully selected compounds including amino acids, diols and other functional molecules. We seek to answer several unexplored questions: 1) Can exogenous soluble citrate be uptaken by MSCs? 2) What is the role of extracellular citrate on the energy metabolism of bone forming cells? 3) Can the citrate-regulated cell energy metabolism crosstalk with MSCs signaling pathways involved in osteogenic differentiation? 4) Can the citrate-presenting materials mediate MSCs differentiation through the same mechanism as the soluble citrate? We also explore how these understandings can be applied to novel citrate-presenting biomaterial design and validate if the use of citrate-presenting analogically similar and mechanically compliant scaffolds can enhance tissue integration and bone regeneration in a critically sized bone defect model.

Results: Our studies showed that extracellular citrate uptake through solute carrier family 13, member 5 (SLC13a5) supported osteogenic differentiation via regulation of energy-producing metabolic pathways, which led to elevated cell energy status to fuel osteo-differentiation of hMSCs with high metabolic demands. We next identified citrate and phosphoserine (Pser) as a synergistic pair in polymeric design, exhibiting concerted action not only in metabonegenic potential for orthopedic regeneration, but also in facile reactivity into a fluorescent system for materials tracking and imaging. We herein designed a novel, citrate/phosphoserine-based photoluminescent biodegradable polymer (BPLP-Pser), which was lastly fabricated into BPLP-Pser/hydroxyapatite composite microparticulate scaffolds, demonstrating significant improvements in bone regeneration and tissue response in rat femoral condyle and cranial defect models.

Discussion and Conclusion: We have revealed a previously unexplored expression pattern of SLC13a5 citrate transporter along osteo-differentiation, and a mechanism focusing on the metabolic regulation of citrate to elevate cell energy status for bone formation, referred to as citrate metabonegenic regulation. These findings not only identify citrate as a new metabolic factor in the stem cell micro-environment favorable for osteo-differentiation, but also suggest that citrate should be considered in bone biomaterials design, providing guidance to develop biomimetic BPLP-Pser/HA for prolonged citrate metabonegenic effect well into late stage of differentiation, which demonstrated therapeutic potential for bone injuries [1-3]. The unprecedented knowledge on the citrate mechanism enables us to design the next generation of biomimetic dynamic orthopedic implants that may present citrate signals in demand during cellular and tissue development.

Designing Biocompatible Hydrogel Nanoparticle Emulsions for Regenerative Engineering
Georgia Papavasiliou, Shadi Motamed, Fernando Borges and Fouad Teymour; Illinois Institute of Technology, United States

Polymeric nanoparticle (NP) emulsions have shown significant promise for regenerative engineering applications as they can be designed as topical and/or
injectable formulations for in vivo administration of therapeutic compounds. Hydrophilic therapeutic delivery often requires water-in-oil-in-water (w/o/w) double emulsions which are difficult to produce and have limited storage life because of their inherent instability. Inverse, water-in-oil (w/o) emulsions for encapsulation of hydrophilic therapeutics are far less common as they involve use of organic solvents. Highly biocompatible and biodegradable crosslinked hydrogel NP are perfectly suited for controlled and sustained diffusive-based release of therapeutics, enhanced tissue-targeted delivery and bioavailability of hydrophilic drugs. Hydrogel NP, however, come in contact with cytotoxic organic solvents and surfactants during emulsion polymerization requiring subsequent purification and isolation before being administered directly in vivo. This leads to limitations, including significant drug loss, dosage uncertainty, compromised drug release kinetics, and loss of particle stability, thereby minimizing in vivo therapeutic efficacy. To address these limitations, we have developed novel biocompatible NP emulsions (BCNE) consisting of stable poly(ethylene glycol) (PEG) crosslinked hydrogel NP dispersed in a naturally-derived consumable organic phase that can be formulated as a liquid (or as an ointment) and administered en masse, directly to target tissues. BCNE are synthesized with biocompatible components including PEG diacrylate (PEGDA) crosslinking macromer, N-vinyl pyrrolidone or ethylene glycol comonomers, polyphosphate (PpI) or NaCl as the lipophobe, soybean oil (SO), as the organic phase, with Polyanhydrol PolyGlycerolate (POLI) emulsifier (FDA recognized as safe for human consumption) and with V50 initiator using inverse phase emulsion polymerization. We synthesized BCNE with varying mesh dimensions to accommodate the encapsulation and sustained release of hydrophilic therapeutics of varying size and conformation including PpI (PpI-BCNE), NaCl (NaCl-BCNE) and the α-helical pro-angiogenic peptide QK (QK-BCNE). BCNE NP size measurements (Nanosight LM10, Malvern) yielded mean NP diameters of 111±7.2nm and 96±3.9nm for PpI-BCNE and NaCl-BCNE, respectively. To define mesh dimensions suitable for encapsulation and release of PpI and QK, experimental measurements of hydrogel mass swelling ratio were coupled with theoretical kinetic and thermodynamic interpretations we recently developed to characterize the network architecture of hydrogel networks comprised of macromeric crosslinkers. Our approach accounts for crosslinker size, and its behavior under swelling, both neglected by the Flory-Rehner theory. This allows for quantification of two new hydrogel mesh dimension variables that establish bounds on the maximum size and aspect ratio of therapeutics that can be encapsulated and released from crosslinked hydrogel NP networks. Using this approach to guide our experimental design, QK-BCNE were designed to release QK for 46 days whereby 90% of the encapsulated peptide was retained for 36 days in vitro. In vitro findings indicate that PpI-BCNE completely disperse PAO1 P. aeruginosa biofilms compared to blank BCNE and no treatment controls. Preliminary experiments conducted with en masse topical application of BCNE in a Staphylococcus aureus C57BL/6 mouse model of burn injury and impaired healing demonstrated incontrovertible evidence that PpI-BCNE improves wound healing compared to blank BCNE. These results highly suggest that BCNE provide a versatile platform whereby hydrogel nanoparticle mesh dimensions can be precisely tuned for encapsulation of hydrophilic therapeutics of varying size and complex conformation (peptides, growth factors and mRNA) to enable sustained tissue-targeted delivery in vivo for regenerative medicine applications.

Panthenol Citrate Biomaterials Accelerate Wound Healing and Restore Tissue Integrity Huifeng Wang, Chongwen Duan, Rebecca Keate and Guillermo Ameer; Northwestern University, United States

The global surge in diabetes has led to diabetic foot ulcers (DFU) becoming a predominant diabetes-related complication, resulting in hospitalizations and, in severe cases, lower limb amputations. A staggering 34% of individuals with diabetes will encounter a DFU during their lifetime, with 15-20% becoming chronic or non-healing wounds. These wounds differ significantly from normal wounds, plagued by persistent oxidative stress, abnormal inflammatory responses, impaired vascularization, and innervation, among other patient-specific challenges. Furthermore, suboptimal physical properties of regenerated tissue often lead to recurrent or reopened wounds, with alarming statistics indicating recurring DFUs may result in amputation in 71-85% of cases. Meeting the pressing need for wound treatments that not only expedite wound closure but also enhance the quality of regenerated tissue is paramount in improving diabetic wound care outcomes. In this study, we present the synthesis and characterization of panthenol citrate (PC), a versatile compound with potential applications in soluble form as a cleansing solution and as a regenerative dressing to address impaired wound healing in diabetes. PC is derived by reacting citric acid with panthenol, offering intriguing optical, chemical, and biological properties conducive to protecting and regenerating skin tissue. With citric acid's established safety record and panthenol's known skin benefits, PC represents a promising candidate. PC demonstrates antioxidant, antibacterial, anti-inflammatory, and proangiogenic properties, facilitating wound closure in diabetes while restoring skin's mechanical and electrophysiological properties. In both solution and hydrogel forms, PC stimulates keratinocyte and dermal fibroblast migration and proliferation, resulting in improved epidermalization, granulation tissue formation, and accelerated wound closure. Remarkably, PC significantly enhances the mechanical strength and electrophysiological properties of regenerated skin. To our knowledge, this is the first study to demonstrate such comprehensive improvements in the histological and physical properties of regenerated skin following treatment with both monomeric and polymeric forms of a compound. Our approach encompasses the utilization of PC as a wound cleansing solution or as a component of a thermoresponsive biomacromolecule for use as a regenerative dressing. In conclusion, PC emerges as a pivotal building block for advanced tissue regeneration therapies, holding the promise of markedly improving wound care management for diabetic patients.

SYMPOSIUM SB10

From Soft Hydrogel Materials to Hard Water Sports Materials—Bridging the Gap with Additive Manufacturing November 27 – November 27, 2023

Symposium Organizers
Preethi Chandran, Howard University Ferenc Horkay, National Institutes of Health Marc In het Panhuis, University of Wollongong Yongfu Li, Dow Chemicals Company

**Nicholas A. Peppas**; The University of Texas at Austin, United States

Soft hydrogel materials are water-swollen polymer networks that can be tuned to mimic the physical and biochemical properties of their surrounding environment. The signaling mechanisms between the hydrogel properties and their environmental behavior are not always clear, especially because hydrogels and exterior matrix serve the dual functions of mechanically supporting other materials (including tissues or cells) and regulating how chemical signals travel between. In hydrogels, stiffness and solute diffusivity are closely associated with the hydrogel’s polymer network structure. The structure-property relationships of hydrogels are summarized by numerous mathematical modeling systems. We present robust, well-tested predictive models that describe how structural changes affect hydrogel properties to make hydrogels into the precise, nuanced tools needed to solve modern engineering problems.

We have coordinated swollen polymer network models based on four structural parameters and demonstrate how those four parameters work together to decouple stiffness and other parameters in hydrogels without changing the chemical properties of the network. The resulting decoupling and associated fundamental models facilitate more nuanced investigations of polymer-environment interactions.

**Influence of Solvent Quality on the Swelling and Deswelling and the Shear Modulus of Semi-Dilute Solution Cross-Linked Poly(vinyl acetate) Gels**

*Jack F. Douglas* and Ferenc Horkay; National Institute of Standards and Technology, United States; National Institutes of Health, United States

We systematically examine the influence of varying temperature (T) over a large range in model poly(vinyl acetate) gels swollen in isopropyl alcohol. The theta temperature \( T_\theta \) of our gels, at which the second virial coefficient \( A_2 \) vanishes, is found to be equal to within numerical uncertainty to the corresponding high molecular mass polymer solution value without cross-links, and we quantify the swelling and deswelling of our model gels relative to \( T = T_\theta \) and compare to the hydrogel swelling factor, \( \alpha \). We find that all our network swelling and deswelling data can be reduced to a scaling equation of the same general form as derived from renormalization group theory for flexible linear polymer chains in solution so that it is not necessary to invoke either the Flory-Huggins mean field theory or the Flory-Rehner hypothesis that the elastic and mixing contributions to the free energy of network swelling are separable to describe our data. We also find that changes of \( G \) relative to \( G(T = \theta) \) are directly related to \( \alpha \). At the same time, we find that classical rubber elasticity theory describes many aspects of these semi-dilute solution cross-linked networks, regardless of the solvent quality, although the perfection clearly reflects the existence of network defects whose concentration depends on the initial polymer concentration of the polymer solution from which the networks were synthesized.

Tunable Surfaces and Interfaces from Responsive Polymers for Biomedical Applications
Namita Choudhury, Nisal Wanasingha, Rajkamal Balu and Naba K. Dutta; RMIT University, Australia

Design of responsive surfaces, interfaces and nanostructures, whose characteristics can be modulated on demand is an important challenge in diverse applications. In this presentation, we discuss the responsive behaviour of soft surfaces, interfaces and solid-liquid interfaces derived from biomimetic polymers. The unique structural features of such polymers and the changes in their characteristics properties and conformation induced by a change in the environment have been evaluated in detail using highly sensitive tools such as quartz crystal microbalance (QCM-D), surface plasmon resonance (SPR), dynamic light scattering, small angle neutron scattering, UV-Vis, and spectroscopy. The talk will illustrate how this responsiveness could be used towards the construction of novel hydrogels, hybrids, conjugates and functional nanoparticles such as high surface area nanoparticles for specific applications. It will also highlight the new classes of multifunctional biomimetic polypeptide synthesis, 3D fabrication of hydrogel and the nano-bioconjugates, that we are developing for biomedical and injury applications, including effective therapeutic, adhesion and repair.

2:30 PM SB10.02.03
Textile Electronics for Long-Term Electrophysiological Signal Recording Application
Chansoo Kim, Junyi Zhao and Chuan Wang; Washington University in St. Louis, United States

Long-term electrophysiological signal collecting is important since it provides a prior warning to people by detecting diseases such as heart failure or arrhythmia before the diseases progress to a more dangerous stage. It also provides fundamental data for training to improve performance by identifying the accurate amount of exercise and muscle usage for athletes. For this purpose, flexible and stretchable sensors have shown great potential for wearable and ambulatory electrocardiography signal monitoring applications. These soft sensors are comfortable, conform to human skin, and daily wearable in contradistinction to rigid metal-based conventional electronic devices. Nevertheless, most of long-term electrophysiologic sensors have focused on sticky dry electrodes for long-term signal collection because conformal contact of electrodes on the human skin can decrease contact impedance. Here, we propose an interesting approach for long-term electrophysiological signal collecting electrode in dry condition by E-textile system. This system consists of textile and microfiber electrode that were coated by Poly(3,4-ethylenedioxythiophene) polystyrenesulfonate (PEDOT:PSS). For the textile electrode, PEDOT:PSS was simply printed on the nylon-based textile through screen printing manner and the stretchability of electrode was enhanced via polyethylene oxide (PEO) crosslinking process. In addition, hydrophobic treatment through 1H,1H,2H,2H-Perfluorooctyl-trichlorosilane (FTOS) effectively prevent water permeation that can cause erosion and dissolving of the electrode. Consequently, the textile electrode shows high durability in water. Moreover, the microfiber electrode offers greatly reduced contact impedance between skin and electrode, and improved signal-to-noise ratio (SNR) through dramatically increasing contact area. These electrodes combined via electrolyte conductive gel pad and build E-Textile system. Therefore, we achieve 1.1×10⁵ Ω×cm⁻¹ contact impedance. In addition, the SNR of the electrocardiogram (ECG) and electromyography (EMG) SNR were 27 dB and 29 dB in dry atmosphere.

Understanding Hydrodynamic Wear in Self-Similar Superhydrophobic Coatings Subjected to Rapid Droplet Impacts
Daniel Bracconieri1, Terence Davidovits2 and Randall M. Erb1; 1Northeastern University, United States; 2Thermobionics LLC, United States

Superhydrophobic materials rely on both chemical apolarity and surface roughness to achieve the high contact angles and the low roll-off angles that lead to self-cleaning and antibacterial properties. Current superhydrophobic coatings tend to be delicate and lose their properties easily when subjected to droplet impact. Such impact quickly deteriorates these coatings through hydrodynamic wear; changing structure, eroding hydrophobic chemistry, and quickly leading to full wet out of the substrate. In fact, hydrodynamic wear is more detrimental to coatings than seemingly more aggressive mechanical wear including scratching with sandpaper - a common approach used to claim both self-similarity of a material and extreme robustness against wear. What makes certain coatings more robust against hydrodynamic wear? To understand this answer, we systematically study ten disparate self-similar superhydrophobic coating approaches from academia to industry by subjecting them to hydrodynamic wear with rapid droplet impacts. We find rapid droplet impact that simulates a medium rain can deteriorate most coatings within seconds or minutes. Meanwhile, the more resilient coatings share specific characteristics that make them resistant to hydrodynamic wear. We will present a phenomenological model that nicely characterizes the hydrophobic lifetimes of these systems.

Characterization of the Network Structures of PEGDA and Dextran Hydrogels by Complementary Methods
Joseph M. Scalet and Stevin H. Gehlke; University of Kansas, United States

The physical properties of hydrogels are directly affected by their network structure; thus, characterization of that structure is a key part of their development for specific applications. There are generally several different characteristic length scales from the molecular to macroscopic dimensions. Additive manufacturing of hydrogel components introduces additional levels of network structures, depending on the manufacturing methods. Thus, many different methods of characterizing network structures have been developed and used to characterize gels. In this presentation, two fundamentally different but complementary methods will be examined for their potential to evaluate the network structure. The first is the most widely used method – mechanical testing, but the data is examined in terms of multi-parameter models. The second is the use of time domain low-field NMR (LF NMR), a method that has not been widely used but has the potential for rapid screening of hydrogel formulations. Two hydrogels with quite different network structures widely used in a variety of applications, including 3D printing, are examined: poly(ethylene glycol diacrylate) (PEGDA) and thiol-ene crosslinked dextran.

PEGDA hydrogels were synthesized from monomers of molecular weight from 575 to 8000 Da by photopolymerization at polymer concentrations ranging from 7% to 50 wt.% in water. Dextran gels were made by functionalization of dextran with pentanoate groups which makes it possible to crosslink them by a photopolymerized thiol-ene reaction with dithioretilol.
Generally, hydrogels are assumed to follow the classic neo-Hookean elastic model under compression or tension, from which network mesh size is estimated. However, not all gels fit this model well, often with deviation increasing with strain. Multiple parameter models can accurately fit data over a broader range of strains and provide further structural information than the standard model. For PEGDA, molecular weights, and concentrations were varied. As the polymer concentration at hydrogel formation increases, the covalent and the entanglement contributions of the modulus both increase. For dextran, a range of molecular weights and polymer concentrations were tested, as well as pentanoate functionalization and thiol:ene ratio. As the thiol:ene ratio was varied, the covalent contributions increased, but the entanglement contributions were less strongly affected. When the polymer concentration at formation was increased, however, both contributions increased.

LF-NMR is an experimentally simple, quick, and non-destructive technique that has the potential to determine a distribution of characteristic length scales in hydrogels. Its speed and experimental simplicity suggest a potential use for the rapid characterization of hydrogel formulations in application development. Proton relaxation times in the time domain (T2) are related to surface-solvent interactions, and theory can be used to convert the T2 distributions into network mesh sizes. PEGDA gels were characterized in solution before polymerization, after polymerization, and after equilibration with water. A noticeable reduction in T2 was observed for PEGDA gels upon cross-linking, indicative of the mobility constraint caused by the formation of the hydrogel network.

4:00 PM SB10.02.06
Effects of Zig-Zag Hydrogen Bonding and Movable Cross-Linking on the Physical Properties of Poly(ether-thioureas)-Based Elastomer Seojung Seo and Ji-Hun Seo, Korea University, Korea (the Republic of)

It is important but challenging to overcome the trade-off in mechanical properties by simultaneously increasing the tensile strength and elongation of elastomers for many applications requiring diverse mechanical properties of polymeric materials. Here, we fabricated an elastomer that forms two types of physical bonds (hydrogen bond and host-guest interaction). The combination of poly(ether-thiourea) (TU/EIC) with zig-zag array of hydrogen bonds and polyrotaxane (PRX) with movable cross-linking junctions simultaneously increased the mechanical strength (tensile stress of 15 MPa) and elongation (tensile strain of 600%) of the elastomer. It was investigated that degradation of mechanical properties of polymer network against repeated deformation (10 times, tensile strain of 150%) was prevented owing to movable cross-linking junction of PRX. Therefore, this work presents a dual physically cross-linked elastomer having a short main chain (3k) with high tensile strength, tensile strain, and resilience.

4:15 PM SB10.02.07
Nonlocal Intrinsic Fracture Energy of Polymer-Like Networks Bolei Deng, Shu Wang, Chase Hartquist and Xuanhe Zhao; Massachusetts Institute of Technology, United States

Connecting the molecular level details of chain scission to the macroscopic fracture of polymer networks remains a long-standing problem. The Lake-Thomas model predicts the intrinsic fracture energy of a polymer network is the energy to scission a layer of polymer chains. However, recent experiments showed that the Lake-Thomas model underestimated the intrinsic fracture energy by about one to two orders of magnitude. We show that the intrinsic fracture energy of polymer-like networks mainly results from nonlocal energy dissipation by relaxing polymer chains far away from the crack tip. Experiments and simulations show that increasing nonlinearity in single chain mechanics amplifies the intrinsic fracture energy in 2D and 3D polymer-like networks and sustains despite varying defects, dispersity, topologies, and length scales. Our findings not only provide new physical insights into the fracture of polymer networks but also offer design guidelines for tough architected materials.

4:30 PM SB10.02.08
Network Materials with Soft Matrix with Extreme Properties Catalin R. Picu and Mithun Dey; Rensselaer Polytechnic Institute, United States

Most biological materials and many engineering materials, including those used in sports equipment, are network materials with matrix. Their mechanical function is conditioned by the presence of a stochastic network of crosslinked fibers. The embedding matrix is typically a hard thermoset (e.g. epoxy) or a soft hydrogel. The interplay of the two constituents is pronounced when the stiffness of the network tested independently is equal to the stiffness of the matrix. We explore the design principles of this type of composite to determine the parametric space in which special properties can be obtained. Matrices with extreme properties, i.e. incompressible and auxetic, lead to the most pronounced effects. Of special interest is the response to indentation/impact, case in which the interplay of the network and matrix is enhanced. The results are relevant for the design of hybrid materials with exceptional properties and with applications in multiple areas, including in sports equipment design.

8:00 PM SB10.03.01
The Role of Hyaluronic Acid in the Organization of Aggrecan in the Extracellular Matrix Ferenc Horkay, Emilios K. Dimitriadias, Iren Horkayne-Szakaly and Peter Basser; National Institutes of Health, United States

Aggrecan is a negatively charged bottlebrush shaped biopolymer molecule. Bottlebrush structures provide excellent lubrication in living systems. Inspired by the lubrication properties of biological systems (e.g., synovial fluid), synthetic bottlebrush polymers have been designed and synthesized. In the extracellular matrix (ECM) aggrecan exists as an aggregate where aggrecan molecules are noncovalently attached to long hyaluronic acid (HA) chains. Aggrecan-HA complexes are important for the mechanical response of cartilage. They exhibit high osmotic modulus, which defines the resistance of the tissue to compressive stress. We studied the hierarchical organization and the scattering properties of hyaluronic acid solutions and aggrecan-hyaluronic acid complexes. Small angle neutron scattering (SANS) and static and dynamic light scattering (SLS and DLS) measurements reveal a domain structure of size greater than several hundred nanometers. At higher values of wave vector, the SANS response corresponds to rod-like structures, of length consistent with the hydrodynamic correlation length associated with the fast diffusion coefficient. Calcium ions do not affect the geometric properties of these domains. DLS is used to investigate the effect of charge valence on the relaxation rates of the concentration fluctuations. The fast diffusion mode in the autocorrelation function becomes slower in the presence of calcium ions relative to sodium counter-ions. The slow mode, however, becomes faster with calcium ions. Reasonable agreement is found between the scattering intensity of the osmotic concentration fluctuations obtained from DLS and from the SANS response. Atomic Force Microscopy is used to determine the morphology of the aggrecan-HA complexes.
8:00 PM SB10.03.02
Surface Function Transformation Through Deformation of 3D Structure using Soft Materials
Seongmin Kang1; 1Chungnam National University, Korea (the Republic of); 2Harvard University, United States

Recently, the study of surface morphology alterations has been extensively studied due to their ability to control material properties by changing surface morphology. As for materials, hydrogels are gaining attention due to structural changes through water penetration into the hydrogel network in a wet environment. And as for technology, there are various processes to fabricate three-dimensional (3D) structures but issues of low throughput or low resolution remain. Therefore, we propose a novel approach that 2D structures, made of conventional lithography, transform into complicated 3D structures using hydrogels. By swelling hydrogels under constrained conditions, we achieved the desired shape transformations. We replicated the swollen pattern because of its moisture transport behavior. To optimize material for replication, we investigated about affinity for water of prepolymer and indentified that the lower the affinity for water compared to hydrogels the better the swollen pattern retained its shape. In this way, we manufactured molds for buckling and inversely tapered structures and noted that replication from complicated 3D shapes was possible due to the softness of swollen hydrogel. In this method, buckling structures made of polydimethylsiloxane (PDMS) can be utilized as protective films due to their ability to disperse forces laterally. Also, the inverse tapered patterns made of perfluoropolyether (PFPE) exhibit oleophobic surfaces, enabling self-cleaning properties for oil. We also identified that as swelling ratio increased, dispersion capability in buckling film and oleophobicity in inversely tapered film were improved. Therefore, this research demonstrated the potential of utilizing surface shape modifications to achieve various properties using desired materials. It is expected that function transformation can be a platform to create unprecedented functions arising from unique shapes morphed from conventional straight shapes.

8:00 PM SB10.03.04
Blood Oxygen and Heart Rate Monitoring by a Flexible Hybrid Electronics Device Fabricated by Multilayer Screen-Printing
Gábor Méhes1,2, Ayako Yoshida3 and Shizuo Tokito4; 1Waseda University, Japan; 2Yamagata University, Japan

Finger-based pulse oximetry (SpO2) and heart rate monitoring are widely used in medical settings and are penetrating the everyday life. However, SpO2 response measured on the peripheral parts of the body (such as fingers and wrists) has a time lag and is less accurate compared to measuring on forehead. In addition, current devices are centimeter-thick, making seamless integration with the body difficult, hindering continuous monitoring and wide adoption. We designed, fabricated, and evaluated an SpO2 and heart rate sensing device based on flexible hybrid electronics (FHE) technology. The marriage of flexible electronics with high performance commercially available IC chips makes it possible to have advanced sensing, data processing and wireless transmission functionalities on a thin (1.5 mm) and flexible form that can be attached to various parts of the body. Differently from most devices using FHE technology, here we describe a cost-efficient and mass production compatible multilayer screen-printing process based on conducting Ag-based and non-conducting inks for making the flexible interconnection circuitry in detail, including advanced topographic analysis. By optimizing the printing steps, we could fabricate interconnecting lines vertically traversing up to five printed layers over several tens of micrometers, increasing the spatial density of functional units. By this, we widen the possibilities to utilize screen-printing for advanced wearable devices. Indeed, our FHE device reliably detects induced hypoxemia, and when applied on forehead, detects changes in SpO2 more than 10 seconds earlier compared to a finger-based medical grade reference device.

8:00 PM SB10.03.05
Highly Entanglement Hydrogel-Coated Sticker for Diverse Surface Applications via Copolymerization Method
Joon Hyung An1, Junsoo Kim2 and Seongmin Kang1; 1Chungnam National University, Korea (the Republic of); 2Harvard University, United States

High entanglement hydrogel has advantages such as low friction and high stiffness. However, its applicability is limited by its tendency to easily delaminate when adhering to a surface, which is caused by its high swelling property. In this study, we propose a simple method for surface coating highly entangled hydrogels. By utilizing the designed copolymerization of polymers with hydrogel, we enable high entanglement hydrogels to adhere strongly to various surfaces, even under high swelling conditions. The copolymerized polymers are fabricated into a bilayer film of hydrogel and hydrophobic polymer, creating a freestanding sticker that can be used. The hydrophobic polymer layer prevents moisture transfer, thereby preventing the delamination of the hydrogel caused by swelling. Through this study, we have expanded the potential applications in various fields by enabling the application of high entanglement hydrogel regardless of the surface material.

8:00 PM SB10.03.06
A Fully Self-Healable, Temperature Tolerant and Stretchable Supercapacitor for Operating Integrated Self-Healing Strain Sensor
Yeon Ji Choi and Jeong Sook Ha; Korea University, Korea (the Republic of)

With the rapid advancement in wearable technology, there has been extensive effort on the development of high performance flexible/stretchable energy storage devices. Among various energy storage devices, supercapacitors are considered to be one of the most promising devices as integrated power supply of wearable electronics owing to many advantages of high power density, high cyclic stability and simple structures. Since the wearable devices are frequently exposed to extreme conditions of environments and/or physical damage, however, durability issue has evolved to be a serious challenge for their practical applications. Thus, addition of novel functionality such as self-healing from mechanical damage and tolerance over dramatic changes in temperature to stretchable supercapacitors can be a solution for that. Up to now, most of the reports showed the self-healing of electrolyte only instead of fully self-healing supercapacitors. Even though many temperature tolerant supercapacitors were reported, there is a few supercapacitors with both self-healing and stability over wide temperature ranges which requires a deliberate design of device structure and materials. In this work, we report on the fabrication of a fully self-healing, temperature tolerant, and stretchable supercapacitor and its application as a powering device for integrated strain sensor. Organohydrogel with a self-healing via the diol-borate bonding as well as the hydrogen bonding, and the stability over wide temperature range via hydrogen bonding between water and ethylene glycol, could be obtained, respectively. As a self-healing encapsulating film as well as a substrate, a polyurethane film based on oxime-carbamate bonding and hydrogen bonding was synthesized. As a self-healing stretchable electrode, CNT/polyaniline spray-coated on Au nanosheets functionalized with a poly(ether-thiourea) triethylene glycol was used. By sandwiching the self-healing and temperature tolerant electrolytes with self-healing electrodes on both sides, the fully self-healing supercapacitor stable over temperature changes from -20 to 100 °C was completed. Such fabricated supercapacitor showed the fully self-healing efficiency of 83% even after 5 repetitive cycles of biscion and thermal healing at 65 °C for 6 hr. Also, the supercapacitor was mechanically stable over stretching by 40%, with a capacitance retention of 99%. Furthermore, the whole supercapacitor recovered the electrochemical performance even after biscion and self-healing. The capacitance of the supercapacitor at room temperature was retained over 85% with the temperature changes between -20 and 100 °C. After attachment of repetitive cycles of bisection and thermal healing at 65 °C for 6 hr. Also, the supercapacitor was mechaically stable over stretching by 40%, with a capacitance rention of 99%. Furthermore, the whole supercapacitor recovered the electrochemical performance even after bisection and self-healing. The supercapacitor as a self-healing energy storage device. This work suggests that our fabricated fully self-healing, temperature-tolerant, and stretchable supercapacitor should be widely applied to future wearable electronics with a longevity.
Vapor-Responsive Impact Energy Absorbing and Dissipating Eutectogel

Youna Kim and Jinkee Hong; Yonsei University, Korea (the Republic of)

Every year 2 million people have experienced sports injuries. Especially, in ball games such as basketball, baseball, and golf, serious injury could be caused by a high-speed ball. To prevent sports injuries, players should wear sports protective equipment. For example, in a baseball game, catchers wear protective equipment such as chest protectors, protective helmets, and shin guards. However, as the total weight of the protective equipment approaches 5 kg, the catchers suffer from extreme physical fatigue during the game. Therefore, it is necessary to develop materials for protective equipment that are lightweight and block impact.

As shock-preventing materials, there are representative viscoelastic hydrogels and organogels. These materials are effective in blocking impact due to their viscosity properties that absorb impact and elastic properties that dissipate impact. However, hydrogels have limited ability to withstand the impact energy of spherical projectiles due to their weak mechanical properties. In addition, it is difficult to apply to sports games due to shrinkage and weakening of physical properties due to water evaporation. Organogels overcome the limitations of hydrogels but use harmful solvents. It is necessary to develop viscoelastic protective materials that are lightweight, non-harmful, and can block impact.

In this study, a shock-preventing viscoelasticomer (SPV) is designed by using non-toxic deep eutectic solvents (DES) and polyvinyl alcohol (PVA). Shock-preventing materials should absorb all impact energy and convert it into kinetic energy, preventing the energy from being transferred to the wearer. SPV could regulate the dissipation and absorption of impact energy through hydrophobic vapor treatment.

The entangled polymer chains within the amorphous phase could dissipate impact energy. PVA is a hydrophilic semi-crystalline polymer. DES is an azeotropic mixture composed of hydrogen bond donors and hydrogen bond acceptors, which hinder hydrogen bonds between PVA chains. For the increment in the amorphous phase, DES is used as an additive. As the amorphous phase increases in SPV, SPV shows viscoelasticity and could dissipate impact energy. Moreover, SPV is stronger than conventional hydrogels.

Hydrophilic SPV has a different chemical affinity with hydrophobic methyl salicylate (MeS), an analgesic and mint flavoring agent. Due to the different affinity, the solvation effect of MeS within SPV increases the chain entanglement density by H-bonding PVA chains. However, as the MeS treatment does not affect the crystallinity of SPV, MeS-treated SPV still maintains the rubbery phase at a high amplitude sweep. That is, MeS-treated SPV could absorb the impact energy to break the H-bonding and dissipate impact energy.

The MeS-treated SPV is restored to its original state after 50 min. It can be used as protective equipment for baseball and hockey within 1 h per inning. In addition, SPV can be applied to sports protective equipment in various forms such as thin film, fiber, and spray coating. We expect that SPV is suitable as an impact protection material to prevent sports injuries.

8:00 PM SB10.03.09
Auxetic Metamaterials with Structurally Programmed Reconfigurability
Josef Jancar, Jan Zidek and Jakub Peroutka; Brno University of Technology, Czechia

Low density engineering materials capable of reacting to mechanical stimuli in a manner programmed by their structural architecture can improve design of shock and impact resistant or tunable acoustic damping structures, robust actuators, and adaptable heat insulators. Similarly to computers, structural programming translates the human developed algorithm into a string of structural commands obeying syntax enabling to perform the desired task. The structural coding of commands converts the materials programming language (MPL) into a low-level language understandable by the executing architectural structure. While constitutive materials capable of carrying the basic structural information already exist, designing the source code, commands compiler, assembler, and linker for the MPL remains a foundational challenge. Here, we outline the strategy for developing the source code for simple MPL commands using functional polymer nanocomposites as the units of structural information (USIs). USIs are spatially organized within simple geometrical elements of the re-entrant auxetic unit cell constituting the basic storage units of structural information (SUSIs). SUSIs are combined in a library of bending eigenmodes and rotations forming the structural source code enabling to program simple MPL commands. Primitive algorithms are developed, and simple commands are structurally coded at the auxetic unit cell array and lattice levels to achieve desired stimuli induced reconfigurations of the auxetic structure. Finally, multi-port FDM fabrication process is employed for physically compiling, assembling, and linking the structural commands into the auxetic structure with structurally pre-programmed system level response.

8:00 PM SB10.03.10
Multi-Responsive 3D Printed Nanocellulose-Based Hydrogels Programmable in Space and Time
Beatriz Arsuffi1,2, Gilberto Siqueira3, Silvia Titotto4, Tommaso Magrini1 and Chiara Daraio2; 1California Institute of Technology, United States; 2Federal University of ABC, Brazil; 3Empa–Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Stimuli-responsive materials are desirable for a variety of functional applications, that range from biomedical devices, sensors and actuators to adaptive surfaces and deployable structures. However, as the natural environment offers multiple stimuli at the same time, current solutions often lack multi-responsiveness and display poor control over their properties over time. Here, I will introduce a new multi-stimuli-responsive material platform, realized via additive manufacturing, that can be precisely programmable to morph both in space and time. In my talk, I will highlight the fabrication steps that led to the development of composite inks for Direct Ink Writing (DIW), formed by double-network hydrogel matrices, reinforced by a high content of cellulose nanofibers and nanocrystals. Thus, I will display how the alignment of the reinforcing particles, induced by intense shear forces during DIW, provides composites with a highly anisotropic microstructure, key to tune the stiffness as well as the swelling/shrinking behavior of printed actuators [1, 2]. Additionally, I will highlight how the reversible shape-morphing capability of bilayer systems, as well as their activity in time, as a fourth dimension, can be tailored through processing parameters and geometrical design [3], in response to multiple stimuli scenarios, such as simultaneous variations in humidity, temperature, pH, and ion concentration. Finally, I will show how the performance of multi-responsive hydrogels can be leveraged to design and fabricate, by additive manufacturing, mechanically versatile architectures and mechanical sensors with outputs structured through the Boolean logic and logic gates, paving the way to multi-logic stimuli-responsive materials.

Insights into Biocompatible and Bioorthogonal Fluorous-Phase Neural Probe for In Vivo Detection of Acetylcholine

Maral Mousavi, Farbod Amirghasemi and Abraham Al-Shami; University of Southern California, United States

Acetylcholine (ACh) is one of the least understood neurotransmitters, mainly due to difficulty in its selective detection in biological matrices. ACh appears in the brain and body of mammals, and is released as a messenger by the nerve cells to communicate with other nerve cells, muscle cells, and gland cells. In the brain, ACh functions both as a neuromuscular transmitter and neuromodulator, and thus plays key roles in learning and memory, motivation, and muscle control. Alterations in ACh concentration in the cerebral cortex was correlated to dementia and Alzheimer's disease, psychiatric disorders such as schizophrenia and major depressive disorder, as well as anxiety and depression. Tools for selective sensing of ACh are crucial for better understanding the role of this neurotransmitter in disease progression, as well as rational design and testing of therapeutics that interact with the cholinergic receptors. For successful in-vivo recording of ACh levels, the neural probe (1) should have high selectivity to enable detection of ACh in the large background of other species in the complex brain environment, (2) should be flexible to minimize tissue scarring during probe insertion, (3) should be resistant to biofouling and remain functional after implantation, and (4) should be non-toxic and safe. This talk will discuss the strategies we have to address these requirements for an ACh in-vivo probe through development of new materials for sensing and for electrode fabrication. We detect ACh using its permanent positive charge and a potentiometric sensing membrane. This membrane is made of a unique fluororous-phase material that provides outstanding selectivity and biocompatibility to the electrode. Fluorous compounds (not to be mistaken with fluorescent compounds) are molecules with high content of fluorine atoms. They are extremely non-polar to the extent that they are NOT miscible with oil and water. In fact, mixing water, hexanes, and perfluorohexane results in formation of three distinct phases. That is, fluorinated compounds are both hydrophobic and lipophobic. This sets apart fluorocarbons for novel neurotechnologies in neuroscience and implantable medical applications, and at the same time to identify the main challenges ahead.

This work has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement N. 881603 (GrapheneCore3); from the European Union’s Horizon Europe research and innovation programme under grant agreement N. 101070865 (MINIGRAPH), that is supported by the Swiss State Secretariat for Education, Research and Innovation (SERI) under contract number 22.00163; and from the Proyecto PCl2021-122095-2A financiado por MCIN/AEI /10.13039/501100011033 y por la Unión Europea NextGenerationEU/PRTR.

SESSION SB11.01: Implantable Neuroelectronics with 2D Functional Devices

Session Chairs: Ertugrul Cübbüce and Duysu Kuzum

Wednesday Morning, November 29, 2023

Hynes, Level 2, Room 209
polymide film using a CO₂ laser. This talk will discuss integration of laser-induced graphene electrodes (LIGs) with fluoros-phase sensing membranes to produce a new generation of highly selective, biocompatible, and resilient neural probes.

9:30 AM **SB11.01.04
Implantable Graphene Electrode for Diagnosis and Treatment of Brain Diseases Jong-Hyun Ahn; Yonsei University, Korea (the Republic of)

Various electrophysiological and imaging techniques have been studied for the diagnosis and treatment of brain diseases such as epilepsy. In particular, electrocorticography (ECoG) provides valuable information that can guide clinical treatment in patients with brain diseases. In this talk, we report a highly flexible graphene electrode that stably wraps onto the cortex surface of the brain, exhibiting a remarkable signal-to-noise ratio and providing enhanced data quality. The graphene multichannel electrode successfully detects brain signals with high-throughput spatiotemporal resolution. Furthermore, the exceptional flexibility of graphene electrodes enables the fabrication of injectable electrodes that can be introduced through tiny skull openings. These injectable electrodes allow precise measurement of ECoG signals without the need for extensive surgical procedures. The results highlight the immense potential of flexible graphene electrode array in improving both diagnostic capabilities and therapeutic interventions for brain diseases. This technology holds promise for revolutionizing current treatment strategies and opening new avenues for effectively managing various medically significant brain diseases.

Conformable Ultrasound Breast Patch for Deep Tissue Scanning and Imaging Canan Dagdeviren; Massachusetts Institute of Technology, United States

Ultrasound is widely used for tissue imaging such as breast cancer diagnosis; however, fundamental challenges limit its integration with wearable technologies, namely imaging over large-area curvilinear organs. We introduced a wearable, conformable ultrasound breast patch (cUSBr-Patch) that enables standardized and reproducible image acquisition over the entire breast with less reliance on operator training and applied transducer compression. A nature-inspired honeycomb-shaped patch combined with a phased array is guided by an easy-to-operate tracker that provides for large-area, deep scanning and multi-angle breast imaging capability. The clinical trials reveal that the array using a piezoelectric crystal (Yb/Bi-PIN-PMN-PT) exhibits a sufficient contrast resolution (~3 dB) and axial/lateral resolutions of 0.25/1.0 mm at 30 mm depth, allowing the observation of small cysts (~ 0.3 cm) in the breast. This research develops a first-of-its-kind ultrasound technology for breast tissue scanning and imaging which offers a non-invasive method for tracking real-time dynamic changes of soft tissue.

10:45 AM SB11.02.03
Heavy-to-Light Electron Transition in Quasi-2D Organic Semiconductor Enabling Real-Time Spectra Detection of Charged Particles Dou Zhao1,2, Tomoyuki Yokota1, Takao Someya1, Wanqi Jie2 and Yadong Xu2; 1The University of Tokyo, Japan; 2Northwestern Polytechnical University, China

Wearable/implantable personal dosimeter achieving real-time and in-vivo radiation safety monitoring are significant for aerospace, medical diagnosis, and radiotherapy, while the current challenge is the lack of suitable detector materials possessing both excellent biocompatibility and high detection performance.

Here, we report a novel biocompatible organic single crystalline semiconductor (OSC-S) with 2D anisotropic crystallographic structure, achieving excellent electron's transport and real-time spectral detection for charged particles. For the first time, the charge-transport mechanism responsible for such superior performance is clarified in this quasi-2D OSCS from the viewpoint of high-energy physics. Radiation-excited electrons occupy the high-energy L1 level with smaller effective mass than LUMO level, leading to a high electron drift velocity of 5×10⁵ cm s⁻¹ under the electric field of 4000 V cm⁻¹ at “radiation-detection mode”. In addition, nanoscale surface layer edges on the OSCS, originating from its 2D crystallographic structure induced molecular self-assembly during the solution growth process, also promote the excitons dissociation along the in-plane direction of this OSCS.

As a result, the OSCS detector exhibit the record spectra detection for α particles among their organic counterparts, with the energy resolution of 36%, the electron's μ product of (4.91±0.07)×10⁶ cm² V⁻¹, and the spectra detection time down to 3 ms. In addition, the OSCS shows good biocompatibility that the cell viability still stays 90% after 24-hour incubation with 2 mg ml⁻¹ OSCS. This work reports a quasi-2D organic semiconductor with superior electron transport property and biocompatibility towards to real-time and in-vivo personal radiation dosimeters.

Transparent Flexible Strain Gauges for Wearable Devices based on Tiled Graphene Films Joseph Neilson1 and Brian Derby2; 1Trinity College Dublin, The University of Dublin, Ireland; 2University of Manchester, United Kingdom

Here we present a novel polyaniline strain gauge, with a large gauge factor (GF) and usable strain range, based on 2D materials confined to the surface of an elastomeric substrate. These have good optical transmittance and demonstrate repeatability, under cyclic straining at frequencies > 1 kHz, Gauges have also been mounted on a thin polymer glove to demonstrate its capability as a transparent e-skin strain sensor. During manufacture, closely packed films of graphene oxide are confined to a 2D plane, through assembly at an immiscible H₂O/hexane interface. These films have predominantly edge-to-edge nanosheet contact and show little overlap after deposition onto a polydimethylsiloxane (PDMS) substrate. The films are treated in a hydroiodic acid (HI) reducing atmosphere to introduce electrical conductivity, with the consequent reduced graphene oxide (rGO) films showing < 900 Ω/sq sheet resistance, and > 88% optical transmittance. Piezoresistivity is generated through a pre-straining process that introduces a population of cracks, normal to the straining direction, into the conducting film. After relaxation the cracked films show a repeatable change in resistance when strained to values smaller than the initial pre-strain. Through careful control of the HI chemical reduction phase, it is possible to generate strain gauging devices with different operating ranges and sensitivity. Films pre-strained after reduction for 30 s form an array of parallel cracks that do not individually span the membrane. Subsequent straining of the cracked membrane does not further extend these cracks and the sheet extends in a kirigami manner as the cracks open. This cracking behaviour results in a strain gauge with a usable strain range > 0.2 and GF of 20 - 100 at low strains, however, this GF increases with increasing pre-strain. In all cases, GF decreases with increasing applied strain and asymptotes to a value of about 3 as it approaches
the pre-strain value. However, if the rGO film is reduced for a longer time of 60 s, the cracks extend during pre-straining to fully span the width of the PDMS membrane, leading to a much more sensitive strain gauge with GF ranging from 1000 - 16000. However, in this case, the usable strain range reduces to < 0.01. We present a simplified, equivalent resistor model, that can be used to interpret the behaviour of both gauge cracking configurations.

**SESSION SB11.03: 2D Bioelectronics II**

**Input/Output (I/O) Bioelectronics using Two-Dimensional Nanocarbons**

**Tzahi Cohen-Karni; Carnegie Mellon University, United States**

My team’s efforts are focused on the development and engineering of nanocarbons-based flexible platforms to interrogate and affect the properties of cells and tissue, with a specific goal to understand signal transduction (chemical or electrical) in tissue or complex three-dimensional (3D) cellular assemblies. Our highly flexible bottom-up nanomaterials synthesis capabilities allow us to form unique hybrid-nanomaterials that can be used in various input/output bioelectrical interfaces, i.e., bioelectrical platforms for chemical and physical sensing and actuation. In this talk I will review our current efforts for monitoring (and affecting) the complex signal transduction in 3D in vitro systems toward disease progression investigations. Utilizing graphene, a two-dimensional (2D) atomically thin carbon allotrope, we can simultaneously record the intracellular electrical activity of multiple excitable cells with ultramicroelectrodes that can be as small as an axon (ca. 2μm). The outstanding electrochemical properties of the synthesized hybrid-nanomaterials allow us to develop highly efficient catalysts, that can be deployed as electrical sensors and (chemical) actuators. We demonstrated sensors capable of exploring brain chemistry and sensors/actuators that are deployed in a large volumetric muscle loss animal model. In summary, the exceptional synthetic control and flexible assembly of nanomaterials provide powerful tools for fundamental studies and applications in life science and potentially seamlessly merge nanomaterials-based platforms with cells, fusing nonliving and living systems together.

**2:00 PM SB11.03.02**

**3D Printed Electronic Skin for Strain, Pressure and Temperature Sensing**

**Akhilesh K. Gaharwar; Texas A&M University, United States**

Electronic skin, or e-skin, is an innovative material designed to emulate human skin's flexibility and stretchability. With its capability to detect environmental changes like pressure, temperature, and humidity, it has the potential to revolutionize fields such as robotics, wearable technology, and healthcare. Nevertheless, developing e-skin poses significant challenges: creating durable materials with skin-like flexibility, integrating biosensing abilities, and using advanced fabrication techniques like 3D printing for wearable or implantable applications. To overcome these hurdles, we have fabricated a 3D-printed electronic skin utilizing a novel class of nanoengineered hydrogels with tunable electronic and thermal biosensing capabilities. Our methodology takes advantage of shear-thinning behavior in hydrogel precursors, allowing us to construct intricate 2D and 3D electronic structures. We simulate the elasticity of skin using triple crosslinking in a robust fungal exopolysaccharide, pullulan, while defect-rich 2D molybdenum disulfide (MoS2) nanocomposites ensure high electrical conductivity. The addition of polydopamine (PDA) nanoparticles enhances adhesion to wet tissue. Our nanoengineered hydrogel exhibits outstanding flexibility, stretchability, adhesion, moldability, and electrical conductivity. A distinctive feature of this technology is the precise detection of dynamic changes in strain, pressure, and temperature enabled by the combination of triple crosslinking and defect-rich MoS2. As a human motion tracker, phono- and tyroid-platform, flexible touchpad, and thermometer, this technology represents a breakthrough in wearable skin and has transformative potential for the future of robotics and human-machine interfaces.

**2:15 PM SB11.03.03**

**Interaction Of Graphene And WS2 With Neural Cells, Neutrophils And Mesenchymal Stem Cells: Implications For Peripheral Nerve Regeneration**

**Domenica Convertino1, Laura Marchetti2,3 and Camilla Coletti4,5; Istituto Italiano di Tecnologia, Italy; 6University of Pisa, Italy**

The employment of graphene and 2D materials in tissue engineering has been recently exploited for the repair and regeneration of nerve tissue. Among the possible applications, these relatively new materials display a great potential as peripheral neural interfaces, especially for their unique combination of electrical, optical and tribological properties1-4.

In this work we present recent results on graphene (G) and tungsten disulfide (WS2) interaction with some of the key players involved in nerve regeneration, namely peripheral neurons, neutrophils and mesenchymal stem cells (MSCs).

Firstly, we will discuss the effect of G on primary peripheral neurons, i.e. neonatal dorsal root ganglia neurons (DRG) neurons. Graphene obtained via chemical vapor deposition (CVD), a promising candidate to realize functional nerve conduits, was used as a culture substrate. There, axons were found to be significantly longer (up to >70%) with respect to controls during the early developmental phase (up to 2 days), confirming the trend previously reported by our group for embryonic DRG neurons on G on silicon carbide (SiC)5. Notably, with the same time-dependent fashion, we found a significative modification of the axonal transport of nerve growth factor (NGF), the neurotrophin involved in the development of peripheral neurons. The amount of retrogradely moving vesicles was strongly reduced in favor of a locally stalled population in the first two days of culture6. In addition, electrophysiological and ultrastructural analysis concurred to show the rearrangements that occur in axons developing on G. Our results provide a broad structural and functional understanding of the impact on G on DRG neurons, key information toward the development of G-based devices for neural regeneration. Similarly, we tested WS2, another 2D material with promising biomedical applications. CVD-grown WS2, known for its optoelectronic properties, was used to culture neuronal-like cells (SH-SY5Y) displaying neurite length and viability comparable to the controls6.

However, the use of these innovative materials has raised questions about their interaction with the other players involved in nerve regeneration, including neutrophils, whose immune response affects the regenerative outcome1, and MSCs, a novel therapeutic avenue for peripheral nerve regeneration8.

Therefore, in the third part of the study we tested WS2 on sapphire and different graphene, namely G on sapphire, G on SiC, both as-grown and H-intercalated, G-CVD transferred on glass, to assess the effect of the production method on neutrophils and MSCs8. We first characterized neutrophil activation and discussed how material properties influenced the NETs production and adhesion to the substrates. Furthermore, G resistance to NETs-induced degradation was carefully investigated and compared with the results reported for graphene oxide8.

Ultimately, 2D materials cytocompatibility for MSCs are tested to estimate cell viability, morphology and mitochondrial health.
Overall, our results aimed at understanding the interface between 2D material and some of the key players involved in nerve injury, with special attention to the molecular mechanisms that govern axon outgrowth in neurons, a critical point for regenerative medicine.

2:30 PM BREAK

3:30 PM *SB11.03.04
Wearable Graphene Biosensors for Microfluidic Sweat Analysis Wei Gao; California Institute of Technology, United States

Wearable sweat biosensors have the potential to provide non-invasive molecular analysis toward predictive analytics and treatment. However, it is highly challenging to accurately detect low-concentration analytes in situ and manufacture high-performance flexible biosensors at large scale and low cost. In this talk, I will introduce our efforts in developing microfluidic wearable sweat biosensors based on laser-engraved graphene. Through materials and sensor design innovations, such wireless wearables can autonomously access human sweat via iontophoresis across activities and seamlessly measure a broad spectrum of analytes including metabolites, nutrients, hormones, proteins, and drugs. The clinical value of our wearable systems is evaluated through various human trials involving healthy and patient populations toward precision nutrition, mental health assessment, gout management, and systemic inflammation monitoring. I will also discuss our research progress on energy harvesting from the human body and the environment to realize battery-free wearable biosensing. These wearable technologies could open the door to a wide range of personalized monitoring and diagnostic applications.

4:00 PM SB11.03.05
Wearable and Implantable Bioelectronics Enabled by 2D Materials-Based Layer Transfer Jiho Shin1, Yeongjin Kim2, Jun Min Suh3, Hyunseok Kim4, Suresh Sundaram5, Young Joon Hong6, Abdallah Ougazzaden7 and Jeehan Kim8; 1Massachusetts Institute of Technology, United States; 2University of Cincinnati, United States; 3Georgia Tech Lorraine, France; 4Sejong University, Korea (the Republic of)

2D materials-based layer transfer (2DLT) is an emerging lift-off technique for producing large-area freestanding single-crystalline epitaxial films, which offer high electronic/optoelectronic performance and ultrathin form factor that are essential for wearable and implantable bioelectronic device applications. Single-crystalline III-V/III-N compound semiconductor membranes can be epitaxially grown on substrates coated with 2D materials such as graphene or boron nitride, which results in weak van der Waals interface that facilitates mechanical exfoliation of the device layer from wafer [1]. In this talk, I will discuss our recent efforts that utilize 2DLT to build: (i) chipless wireless electronic skins based on gallium nitride surface acoustic wave sensors capable of low-power and high-sensitivity detection of a broad range of external stimuli [2], and (ii) 3D-integrated micro-LED heterostructures that achieve extremely high device densities and suggest potential applications in optoelectronic-based neural interfaces [3].

4:15 PM *SB11.03.06
Biointegrated Interfaces with Carbon Nanostructures Maurizio Prato1,2; 1Università Degli Studi di Trieste, Italy; 2CIC biomaGUNE, Spain

Nanostructured interfaces can be shaped for the molecular control of physical/chemical adsorption, with enhanced surface area to promote interfacial chemistry, nano-catalysis, and bio-inspired interfaces. For instance, connecting nanostructured materials to biological compartments is a crucial step in prosthetic applications, where the interfacing surfaces should provide minimal undesired perturbation to the target tissue. Ultimately, the (nano)material of choice has to be bio-compatible and promote cellular growth and adhesion with minimal cytotoxicity or dis-regulation of, for example, cellular activity and proliferation. In this context, carbon nanomaterials, including nanotubes and graphene, are particularly well suited for the design and construction of functional interfaces. This is mainly due to the extraordinary properties of these novel materials, which combine mechanical strength, thermal and electrical conductivity. Our group has been involved in the organic functionalization of various types of nanocarbons, including carbon nanotubes, and graphene. The organic functionalization offers the great advantage of producing soluble and easy-to-handle materials. As a consequence, since biocompatibility is expected to improve upon functionalization, many modified carbon nanomaterials may be useful in the field of nanomedicine. In particular, we have recently shown that carbon nanotubes and graphene can act as active substrates for neuronal growth, a field that has given so far very exciting results. Nanotubes and graphene are compatible with neurons, but, especially, they play a very interesting role in interneuronal communication. Improved synaptic communication is just one example. During this talk, we will discuss the latest and most exciting results obtained in our laboratories in these fast developing fields.

4:45 PM *SB11.03.07
Heterogeneous Integration of 2D Sensors for Wearable and Healthcare Applications Christian Lopez Angeles, Yiyue Luo, David Morales Loro, Jiadi Zhu, Mantian Xue, Wojciech Matusik, Jing Kong and Tomas Palacios; MIT, United States

The next wave of innovation and business opportunities related to electronics will probably be about enabling “edge intelligence”. These are new microsystems with unprecedented levels of autonomy in terms of energy harvesting, sensing and information processing. Heterogeneous integration of new materials will be necessary to provide these microsystems with functionality not possible today in Si chips alone. This talk will discuss a few examples of how edge intelligence enabled by the use of two-dimensional (2D) materials will impact wearable devices for healthcare applications. The first example uses metallic fibers coated with a graphitic material to embed hundreds of pressure sensors on fabrics and garments. These sensors are then coupled to an RF harvesting chip based on a MoS2 rectifier to enable autonomous sensing of people’s movements. A second example uses arrays of hundreds of graphene-based chemical sensors inside a breathalyzer chamber to analyze the volatile organic compounds in patients’ breath. Finally, the low temperature synthesis of MoS2 allows for the integration of high performance devices based on this material on flexible polymer substrates for the development of...
flexible and active electrodes for electrophysiology.

Acknowledgment.- This work has been partially supported by the MIT/Army Institute for Soldier Nanotechnologies, the NSF Center for Integrated Quantum Materials, Ericsson, and the Army Research Office.

SESSION SB11.04: Poster Session
Session Chairs: Nicolette Driscoll, Dmitry Kireev and Duygu Kuzum
Wednesday Afternoon, November 29, 2023
Hynes, Level 1, Hall A

8:00 PM SB11.04.01
Two-Dimensional Cs₂AgBiBr₆-Based Biosensor for the Sensitive Detection of Cardiac Biomarkers
Yin-Cheng Lu¹, Evan Darius¹, Mei-Chin Lien¹, I-Hsui Yeh¹, Hung-Wen Chen¹, Chiang Yuan Su², Ru-Yin Hsu³ and Keng-Ku Liu¹; ¹National Tsing Hua University, Taiwan; ²National Central University, Taiwan; ³National Taiwan University Hospital Hsinchu Branch, Taiwan

Inspired by graphene and transition metal dichalcogenides, 2D layered materials that possess excellent electronic, optical, physical, and chemical properties have been actively investigated and explored to further expand their applications. In particular, 2D lead-free double perovskite with strong quantum confinement and excellent electronic performance are promising for optoelectronic applications. Owing to its nontoxicity, inherent stability, and high optical and electrical sensitivity, 2D lead-free double perovskite has attracted significant research interests. Cardiac troponin I (cTnI), a protein with molecular weight of 23.8 kDa, plays an important role as the regulator that is involved in the process of skeletal and cardiac muscle contraction. Owing to its superior cardiac specificity and selectivity, cTnI has been widely employed as the biomarker for the detection of myocardial damage and risk stratification in acute myocardial infarction (AMI) patients. In this study, we report the synthesis of 2D layered Cs₂AgBiBr₆, and the fabrication of biological sensors based on plasmonic nanomaterials-decorated 2D Cs₂AgBiBr₆ for the sensitive detection of cardiac biomarker, cTnI.

8:00 PM SB11.04.02
Enhancing Mechanical Strength of Wearable Microneedles using Silica Nanoparticle Coatings
Hyewon Cho¹, Sohyun Kim and Hynsik Yoon; Seoul National University of Science and Technology, Korea (the Republic of)

Wearable medical devices are currently being developed for a wide range of healthcare systems, and microneedles (MN) have emerged as promising transdermal delivery systems due to their painless and non-invasive characteristics. Polymers are commonly used as MN materials because of their simple, low-cost fabrication, and biocompatibility. However, their mechanical strength may be insufficient compared to metals and ceramics, resulting in potential penetration failures that can leave fractured MNs under the skin, leading to unsuccessful delivery. Therefore, enhancing the mechanical strength of polymeric MNs is essential. In this study, we employed silica (SiO₂) nanoparticles (NPs) and poly(diallyldimethylammonium chloride) (PDDMAC) through a Layer-by-Layer (LbL) assembly on MNs. Subsequently, we applied hydrothermal (HT) treatment to sinter the coated silica NPs, thereby increasing the mechanical stability of the thin film. Initially, we conducted dye loading and release tests using fluorescent dyes, which demonstrated that MNs coated with the LbL thin film and LbL/HT-treated MNs exhibited significantly higher loading and release efficiency compared to unmodified MNs. This improvement was attributed to the increased surface area facilitated by the silica NPs coating. Additionally, we assessed the mechanical properties of MNs through abrasion and penetration tests, revealing that silica NPs-coated MNs showed higher mechanical stability, which was further enhanced after the HT treatment. The LbL system described in this study holds great potential for application in various three-dimensional structures, including MNs, which will contribute to the advancement of wearable drug delivery systems.

8:00 PM SB11.04.03
Folic Acid-Gold Nanoparticle@MoSe₂ for Targeted Photothermal Cancer Therapy
Chang Hyeon Ha¹, Han Been Lee, Su Hwa Cheon, Su Jeong Lee, Do Hyeon Kim and Gi hun Seong; Hanyang University, Korea (the Republic of)

Transition Metal Dichalcogenides (TMDs) have recently emerged as novel 2D materials, possessing significant electrical, mechanical, and optical properties. These materials consist of a single metal combined with two chalcogens (known as dichalcogenides), and their unique characteristics are determined by the specific elements comprising them. Moreover, TMDs exhibit gifted potential for clinical applications, thanks to their remarkable photothermal capabilities. Photothermal and photodynamic therapies (PTT and PDT) represent notable light-based treatment modalities. PTT involves generating heat through light-to-heat conversion, while PDT involves inducing the production of Reactive Oxygen Species (ROS) using light-sensitive agents. These therapies have gained significant attention in the field of cancer therapy due to their sensitivity and usefulness. Among these approaches, PTT has garnered interest due to the high light-to-heat conversion capability of TMDs. However, relying solely on TMDs may not be sufficient for effective therapy. Therefore, we have incorporated gold nanoparticles (AuNPs) to enhance the PTT potential of TMDs through spontaneous reduction. AuNPs possess biocompatible properties, exhibit photothermal capabilities through Localized Surface Plasmon Resonance, and can be easily modified. As a result, they can be effectively utilized as clinical materials in conjunction with TMDs. To specifically target cancer cells, we have additionally introduced Folic acid (FA). FA is an artificial molecule that closely mimics natural folate, enabling it to bind with folate receptors present in the cellular membrane. This targeted approach allows for precise cancer cell localization, particularly in cases of folate receptor-overexpressed cancer, such as Triple Negative Breast Cancer (TNBC). TNBC, which lacks the widely utilized targeting receptor and carries a high risk of metastasis, exhibits significant potential for successful cancer targeting utilizing FA.

In this study, we synthesized complex materials for PTT by coating MoSe₂ with AuNPs and FA (FA-Au@MoSe₂, FAM). Glycyrhizic acid was utilized to exfoliate bulk MoSe₂ into 2D monolayers. This exfoliation process induced a transition from an indirect to a direct-band gap, enhancing the PTT capabilities of the TMDs. MoSe₂ was selected as the primary TMD due to its well-known high light-to-heat transfer properties in PTT applications. AuNPs were employed as enhanced photothermal agents. To modify the gold surface, cysteine was used and FA was linked to the gold surface through EDC/NHS coupling. Lastly, MDA-MB-231 breast cancer cells, known for their folate receptor overexpression, were used as the target cells since MDA-MB-231 cells are representative of TNBC. The deposition of AuNPs and FA led to an increase in both size and surface charge. This was confirmed by the UV-visible spectra, which exhibited peaks corresponding to AuNPs and FA. SEM and TEM images demonstrated the presence of AuNPs on the surfaces of TMDs. Consequently, the successful synthesis of FAM was achieved. Regarding biocompatibility and PTT, the temperature elevation reached a level sufficient for PTT within biocompatible concentrations. Furthermore, FAM exhibited a significantly greater effect compared to MoSe₂, indicating that AuNPs effectively enhanced the PTT capability of MoSe₂. Specifically, FAM demonstrated non-toxicity to cells at a concentration of 30 μg/mL, similar to MoSe₂, but displayed a higher therapeutic effect when exposed to a NIR laser (808 nm, 0.8 W cm⁻²). These findings, confirmed by WST-1 assay and calcine-AM staining, highlight the biocompatibility and photothermal ability of FAM. As a result, this easily synthesized 2D material, achieved through simple sonication and stirring
In this study, we synthesized monolayer MoSe₂ and investigated its application in a photothermal-based LFIA. The MoSe₂ nanosheets were successfully challenge and achieve increased sensitivity.

Lateral Flow Immunoassay (LFIA) is a powerful method used for the analysis of target molecules. It offers several advantages, including simplicity and between the TMD layers, simultaneously serving as a stabilizer and enhancing the colloidal stability of the resulting TMD monolayer. A natural compound, deionized water can be employed as a solvent. The inclusion of GA in the liquid exfoliation weakens the van der Waals forces approach for producing monolayers. Traditionally, organic solvents have been used in the liquid exfoliation. However, by utilizing glycyrrhizic acid (GA), an amphiphilic natural surfactant from licorice root, as the exfoliating agent. Notably, this study marks the first instance of GA being used as an exfoliating agent for preparing nanosheets. Additionally, we enhanced biocompatibility and intracellular uptake by conjugating polyethylene glycol (PEG), resulting in PEG-modified GA-MoSe₂ (PGM) nanosheets. The successful exfoliation utilizing GA was confirmed by SEM and TEM analysis, revealing the presence of monolayer nanosheets. The PEGylation of the nanosheets was validated through an observed increase in size and zeta potential. Thermogravimetric analysis (TGA) results demonstrated the thermal stability of PGM as a material. Furthermore, UV-visible spectra of PGM exhibited an absorption peak at 808 nm, and when PGM was subjected to NIR laser irradiation (808 nm, 0.8 W cm²), they demonstrated the highest photothermal effect. Based on these findings, PGM was identified as a promising agent for photothermal cancer therapy, offering a minimally invasive treatment option with reduced side effects.

To assess the cytotoxicity and anticancer potential of PGM in MDA-MB-231 human breast cancer cells, we conducted a WST-1 assay and a live-dead cell staining assay. The PGM group without laser irradiation displayed remarkably high cell viability at 98.6%, whereas the group subjected to laser irradiation exhibited viability of 22.7%, indicating a substantial inhibitory effect on cancer cells. Additionally, PGM demonstrated significantly higher intracellular uptake. Subsequently, we directly administered PGM to a breast cancer-bearing mouse model to evaluate its in vivo anticancer effect. Tumors exposed to Near Infrared (NIR) laser exhibited a notable decrease in size or complete disappearance, and no significant weight loss was observed during the treatment period.

The findings obtained from experiments strongly indicate that PGM possesses minimal cytotoxicity and holds great promise as a valuable biomaterial for cancer therapy, particularly in harnessing the photothermal effect of PGM through hyperthermia. Building upon these results, our future objectives include incorporating anti-cancer drugs into PGM to develop drug delivery platforms, as well as directly fabricating PGM scaffolds for transplantation at the target site, thereby enabling effective implementation of photothermal cancer therapy.

Biocompatible Molybdenum Diselenide Nanosheets: A Two-Dimensional Nanomaterial for Near-Infrared Photothermal Cancer Therapy Su Jeong Lee, Se Hwa Cheon, Han Been Lee, Chang Hyeon Ha, Do Hyeon Kim and Gi hun Seong; Hanyang University, Korea (the Republic of)

Transition metal dichalcogenide (TMD) nanosheets are two-dimensional (2D) nanomaterials composed of layered structures. In the 2D TMD structure, denoted as 'X-M-X'; two layers of X chalcogen atoms (such as S or Se) are sandwiched between a layer of M transition metal atoms (such as Mo or W). The interaction between adjacent layers in the nanosheet structure is driven by van der Waals forces. These forces play a crucial role in holding the layers together and are essential for the development of the band structure. 2D TMD possesses outstanding optical, electronic, mechanical, and thermal properties due to its adjustable band gap and interaction with light. Consequently, they have gained significant attention in recent years for applications in electronic devices, energy storage, and photothermal therapy. Among various TMDs, molybdenum diselenide (MoSe₂) has emerged as a prominent focus of research due to its remarkable chemical and physical properties. Notably, when MoSe₂ transitions from multiple layers to a single layer, its electronic bandgap undergoes a significant change from an original indirect bandgap of 1.1 eV to a direct bandgap of 1.55 eV. As a result, single-layer MoSe₂ represents a novel semiconductor material that exhibits strong light absorption in the proximity of the band-gap energy.

In this study, we employed an inexpensive liquid exfoliation method to fabricate MoSe₂ nanosheets. This approach enables high-yield production and renders the nanosheets suitable for application in photothermal cancer therapy. To disperse MoSe₂ in water, we utilized glycyrrhizic acid (GA), an amphiphilic natural surfactant from licorice root, as the exfoliating agent. Notably, this study marks the first instance of GA being used as an exfoliating agent for preparing nanosheets. Additionally, we enhanced biocompatibility and intracellular uptake by conjugating polyethylene glycol (PEG), resulting in PEG-modified GA-MoSe₂ (PGM) nanosheets. The successful exfoliation utilizing GA was confirmed by SEM and TEM analysis, revealing the presence of monolayer nanosheets. The PEGylation of the nanosheets was validated through an observed increase in size and zeta potential. Thermogravimetric analysis (TGA) results demonstrated the thermal stability of PGM as a material. Furthermore, UV-visible spectra of PGM exhibited an absorption peak at 808 nm, and when PGM was subjected to NIR laser irradiation (808 nm, 0.8 W cm²), they demonstrated the highest photothermal effect. Based on these findings, PGM was identified as a promising agent for photothermal cancer therapy, offering a minimally invasive treatment option with reduced side effects. To assess the cytotoxicity and anticancer potential of PGM in MDA-MB-231 human breast cancer cells, we conducted a WST-1 assay and a live-dead cell staining assay. The PGM group without laser irradiation displayed remarkably high cell viability at 98.6%, whereas the group subjected to laser irradiation exhibited viability of 22.7%, indicating a substantial inhibitory effect on cancer cells. Additionally, PGM demonstrated significantly higher intracellular uptake. Subsequently, we directly administered PGM to a breast cancer-bearing mouse model to evaluate its in vivo anticancer effect. Tumors exposed to Near Infrared (NIR) laser exhibited a notable decrease in size or complete disappearance, and no significant weight loss was observed during the treatment period.

The findings obtained from experiments strongly indicate that PGM possesses minimal cytotoxicity and holds great promise as a valuable biomaterial for cancer therapy, particularly in harnessing the photothermal effect of PGM through hyperthermia. Building upon these results, our future objectives include incorporating anti-cancer drugs into PGM to develop drug delivery platforms, as well as directly fabricating PGM scaffolds for transplantation at the target site, thereby enabling effective implementation of photothermal cancer therapy.

Synthesis of Transition Metal Dichalcogenides Nanosheets and its Application to Photothermal Immunoassays Do Hyeon Kim, Chang Hyeon Ha, Han Been Lee, Su Jeong Lee, Se Hwa Cheon and Gi hun Seong; Hanyang University, Korea (the Republic of)

Two-dimensional nanomaterials, including graphene, transition metal oxides, and carbon nitrides, have gained significant attention due to their large surface area, mechanical properties, and unique electro-optical characteristics. Among these materials, transition metal dichalcogenides (TMDs) have emerged as particularly promising in biosensing, electronics, and photothermal therapy, due to their distinctive properties. Most TMDs feature an MX₂-type structure, where M represents transition metals like Mo and W, and X represents chalcogenides such as S, and Se. TMDs exhibit a sandwich-like structure, with hexagonal planes of transition metal atoms separating the chalcogen atoms. TMD, a two-dimensional semiconductor material, exhibits unique electrical, mechanical, and optical properties. One of its most notable characteristics is the photothermal effect. TMD demonstrates the ability to absorb light in the near-infrared region and convert it into heat. Monolayer TMD, in particular, possesses enhanced photothermal capabilities compared to multi-layered TMD, thanks to its altered band gap. The transition from an indirect to a direct band gap occurs when TMD forms monolayers. This transition facilitates more efficient electron transfer and shifts the band gap position from the infrared to the near-infrared region. Consequently, the change in the band gap enables higher photothermal efficiency at near-infrared wavelengths.

To obtain a monolayer of TMD, various methods including mechanical separation and chemical vapor deposition have been employed. However, these methods suffer from drawbacks such as high costs and time consumption. In contrast, the liquid exfoliation method offers a simple and cost-effective approach for producing monolayers. Traditionally, organic solvents have been used in the liquid exfoliation. However, by utilizing glycyrrhizic acid (GA), a natural compound, deionized water can be employed as a solvent. The inclusion of GA in the liquid exfoliation weakens the van der Waals forces between the TMD layers, simultaneously serving as a stabilizer and enhancing the colloidal stability of the resulting TMD monolayer. Lateral Flow Immunoassay (LFIA) is a powerful method used for the analysis of target molecules. It offers several advantages, including simplicity and short assay times. In general, LFIA utilizing gold nanoparticles (AuNPs) as a colorimetric indicator demonstrates high sensitivity in detecting target molecules. However, there remains a challenge in further enhancing the sensitivity of LFIA. Therefore, novel approaches are necessary to overcome this challenge and achieve increased sensitivity. In this study, we synthesized monolayer MoSe₂ and investigated its application in a photothermal-based LFIA. The MoSe₂ nanosheets were successfully obtained through GA-mediated liquid exfoliation, as confirmed by TEM images showing well-dispersed monolayers. UV-visible spectra of GA-MoSe₂ exhibited an absorption peak at 808 nm, within the near-infrared region. Subsequently, we irradiated GA-MoSe₂ with a NIR laser at 808 nm and observed an increase in temperature, validating its role as a photothermal agent. To develop a detection probe for the LFIA, we conjugated GA-MoSe₂ with goat-anti mouse immunoglobulin G (IgG) antibodies, resulting in GA-MoSe₂/mAb. In the immunoassay, as GA-MoSe₂/mAb interacted with IgG and reached the test line, the capture antibody on the test line bound to the conjugate, producing a distinct color line. The intensity of the test line's color increased with the IgG concentration. Additionally, the temperature change associated with laser irradiation also increased with increasing IgG concentration. These results suggest that GA-MoSe₂ holds the potential to serve as a platform for high-sensitivity photothermal LFIA. Looking ahead, the utilization of TMDs as photothermal agents is expected to open up various applications, including biosensors for diagnosing virus infections and wearable sensors.

Structural Deformation using Metal Deposition for Bio-Adhesive Patch Chorong Kim, Jaekyuong Kim and Hyunsik Yoon; Seoul National University of Science and Technology, Korea (the Republic of)

The interaction between adjacent layers in the nanosheet structure is driven by van der Waals forces. These forces play a crucial role in holding the layers together and are essential for the development of the band structure. 2D TMD possesses outstanding optical, electronic, mechanical, and thermal properties due to its adjustable band gap and interaction with light. Consequently, they have gained significant attention in recent years for applications in electronic devices, energy storage, and photothermal therapy. Among various TMDs, molybdenum diselenide (MoSe₂) has emerged as a prominent focus of research due to its remarkable chemical and physical properties. Notably, when MoSe₂ transitions from multiple layers to a single layer, its electronic bandgap undergoes a significant change from an original indirect bandgap of 1.1 eV to a direct bandgap of 1.55 eV. As a result, single-layer MoSe₂ represents a novel semiconductor material that exhibits strong light absorption in the proximity of the band-gap energy.
Recently, adhesive patches have been studied for medical treatment. Depending on their characteristics, these can be applied in various situations such as wound healing, drug delivery, and biosensor attachment. Given that the body is a moist environment, current research focuses on incorporating chemical adhesives or utilizing structural properties for surface attachment such as suction effects. Additionally, liquid-repellency is essential to prevent the risk of detachment caused by wetting. We adopted structural adhesives to avoid allergic reaction due to toxicity of chemical adhesives. This research presents a method of structural deformation through different metal deposition on hyperbola structure to achieve new properties such as wet adhesion (Au) or liquid-repellency (Al). Hyperbola structures were fabricated by wrapping liquid prepolymer around micropillars driven by capillary force. Due to its flexible edges, the metal, deposited on top surface, caused structural deformation depending on its residual stress. In the case of Au, tensile stress of Au thin film made edges shrink inward, created an empty space inside for adhesive behavior. Conversely, in the case of Al, edges expanded outward because of compressive stress of Al thin film caused by oxidation. So, this structure had more liquid-repellency characteristics. These novel structures can be easily replicated and mass-produced using soft lithography, offering the advantage of non-allergic reactions as no additional adhesives are required. Furthermore, deformation can be easily controlled by adjusting the deposition thickness and Young's modulus of the structure's material. This technology is expected to contribute to the medical industry as for skin/organ-attachable patches.

Improving Stability of Nickel Hydroxide/Oxyhydroxide Visible Light-Induced Actuators by Aluminum Doping
Nan He; University of Hong Kong, Hong Kong

Material-based actuation systems have been an emerging field of interest because of their direct and simple mechanism without the need to use bulky and complicated hydraulic, electric or magnetic motors. Material-based actuators utilize external stimuli such as light, temperature or humidity to drive mechanical movements. In recent research studies, transition metal oxides/hydroxides (TMOs) were introduced and studied for light-induced actuation based on their simple and effective photothermal mechanism for water de-intercalation from the turbostratic crystal structures of these materials. Turbostratic phases of nickel hydroxide/oxyhydroxide (NHO) have been found to be high-performing multi-stimuli driven actuating materials. However, these material phases are known to be unstable, and over time they become crystallized and lose their actuating properties. In this work, aluminium doping is used to stabilize the turbostraticity and actuation performance. Visible-light actuation experiments are conducted on NHO samples with and without aluminium doping to characterize their actuation performance over time. Turbostraticity is examined and quantified by techniques including XRD, Raman spectroscopy and high resolution TEM, via information such as d-spacings, intensity ratio and band peak changing. The turbostraticity difference between aluminium-doped and pure NHO actuators is correlated with their actuation performances.

Injectable Neural Sensor Array for Post-Surgery Brain Monitoring
Kyungeol Park, Juyong Hong, Jejung Kim and Jong-Hyun Ahn; Yonsei University, Korea (the republic of)

Brain diseases, such as epilepsy and traumatic brain injury, affect millions of people worldwide, causing severe side effects. Monitoring postoperative seizures and the recovery of brain function after surgery is crucial for diagnosing and treating these conditions, providing vital information. However, conventional neural implants involve a large-area craniotomy and rely on bulky sensors, which restrict the natural movement of patients. In this study, we present an injectable neural sensor array for monitoring the brain after surgery. The device utilizes a thin and flexible mesh-structured substrate that can be injected onto the cortical surface through a small hole, minimizing the invasiveness. This approach allows the 12mm diameter device to spread out from a 2mm diameter syringe and achieve conformal contact with the surface of the cortex. The device performs neural recording and micro-stimulation for seizure alleviation using multichannel electrocorticography (ECoG) electrodes and a stimulation pad. Additionally, it integrates a sensor array for multimodal sensing of intracranial pressure (ICP) and intracranial temperature (ICT). This technology provides a convenient healthcare solution for the comprehensive assessment of the patient's post-surgery brain condition.

The Development of Choline, Calcium and pH Sensors based on Laser-Inscribed Graphene Electrodes
Abdulrahman Al-Shami, Ali Soleimani, Farbod Amirghasemi, Victor Ong, Sina Gharahtekan and Maral Mousavi; University of Southern California, United States

**Introduction:** Graphene, a two-dimensional layer of carbon atoms arranged in a hexagonal lattice, has gained significant attraction in electrochemical biomedical sensors. Graphene exhibits high electrical conductivity, flexibility, and a high surface-to-volume ratio. That makes graphene ideal for developing sensitive, selective, reliable, precise, and accurate sensing platforms for detecting biomarkers and other substances. Another interesting feature of graphene is its high hydrophobicity. This property is important for developing solid contact potentiometric sensors for quantifying biologically important ions. This is because the hydrophilic electrodes allow the formation of a water layer between the electrode surface and the ion-selective membrane, which adversely affects the sensor's sensitivity and selectivity toward the targeted ion. Graphene is conventionally produced by wet chemistry and chemical vapor deposition which are usually complicated, expensive, and labor-intensive. Producing graphene by laser engraving on carbon-rich materials (mostly in the form of repeated aromatic rings) is an attractive approach to overcome the limitations of conventional production methods. The laser-engraving method is simple, precise, cost-effective, fast, scalable, safe, and highly reproducible. In this work, we produced graphene electrochemical electrodes using laser engraving technology. We characterized the produced graphene and employed the electrodes to develop three different sensors for detecting choline and calcium ions and pH levels for human and animal health applications. Choline is a vital infant nutrition factor, supporting brain and nervous system development and functions. Quantifying choline in infant formulas can ensure that infants receive enough choline to grow healthy. The calcium sensor will be used to detect calcium levels in cows' blood, which is important for diagnosing calcium imbalances in dairy cows and preventing milk fever. The pH sensor helps monitor different physiological processes, such as wound healing.

**Methods:** We produced the electrochemical electrodes by ablating a polyimide film (127 µm thickness) using a CO2 laser cutter machine with a 1060 nm laser wavelength. The engraving was conducted with an auto-focused laser beam with power and speed of 3 W and 105 mm/s, respectively. A choline-selective membrane was produced of a mixture of PVC (structural polymer), o-nitrophenyl-octyl-ether (plasticizer), Sodium tetras[3,5 bis(trifluoromethyl)phenyl]borate (ionic site), and Calix 4 arene (ionophore) in THF solvent. The membrane was cast on the electrode surface and dried overnight before measurements. The calcium selective membrane was prepared in the same way as choline but used as an ionophore. The graphene electrode was electrochemically modified for pH sensing by layers of IrO2 NPs. The deposition solution was prepared from IrCl4 using alkaline hydrolysis followed by acidic condensation. The deposition was conducted using cyclic voltammetry in a potential window between 0.6 to 0.65 V for 300 cycles.

**Resilience & discussion**: the laser engraving method successfully produced flexible electrochemical electrodes. The scanning electron microscopy images of the laser-engraved areas demonstrated the formation of three-dimensional highly porous graphene on the PI film. Raman spectroscopy revealed the formation of multiple graphene layers on the PI film with some defects that can be attributed to the presence of oxygen during the engraving in ambient conditions. The graphene-based choline selective electrode demonstrated Nernstian response toward choline ions with a detection limit of 0.07 mM. Also, the sensor could quantitate choline concentration in commercially available infant formulas with a measurement error of less than 5%. The calcium-selective electrode exhibits high sensitivity with a detection limit of 0.01 mM. IrO2-modified graphene electrode demonstrates a linear response in pH values between 4 and 10.
Oxygen, while essential for human function, can be harmful in the context of underwater diving. Divers, to stay safe underwater, need to breathe pure, pressurized oxygen known as hyperbaric oxygen; however, breathing too much of this hyperbaric oxygen at certain depths and pressures risks the development of Central Nervous System Oxygen Toxicity (CNS-OT). CNS-OT can lead to sympathetic overstimulation and cause seizures, which are due to abnormal electrical activity in the brain. Electrodermal Activity (EDA) is a quantitative index of sympathetic nervous system activity measured through changes in skin conductance, which vary according to sweat levels caused by emotional arousal or stress. A significant surge in EDA amplitude is a precursor to epileptic seizures and used as an early indicator for CNS-OT risk. Developing a method to identify the onset of CNS-OT risk underwater means introducing a safety monitoring approach previously unavailable in diving. Currently, commercial EDA devices, while effective, lack the flexibility and wearability of GETs and are not waterproof. We propose a graphene electronic tattoo (GET) capable of EDA data processing while immersed in saltwater conditions through a four-part experimental process. First, we established a control group by measuring bioimpedance with uncovered GETs in air, DI water, and saltwater. Next, we found the best waterproofing sealant by comparing the baseline measurements of bare GETs to GETs covered individually by three sealants. After finding that Nexcare SkinRack Care (NCC) produced the clearest bioimpedance readings in each condition, we used this sealant for electrocardiogram measurements in the same fluid conditions to validate our GETs capacity for underwater measurements. Finally, we took EDA measurements using a NeuLog device by simulating three emotional states: meditative, focused, and stressed through meditation, boring videos, and horror videos. We established an EDA baseline using the commercial electrodes in each emotional state in air then proceeded to measure EDA with our GET sealed by NCC in the conditions of air, DI, and saltwater. The maximum stimulated EDA change obtained by our graphene electrodes in saltwater is 0.217 μS with a response time of 4 seconds, which is comparable to the commercial electrodes in air with a similar response time. As a result, we find that the combination of NCC and a GET enabled successful EDA monitoring in seawater conditions, advancing GETs in underwater medicine.

Here, we report a novel method that leverages the unique combinations of electrical conductivity, functional surfaces, and solution processibility of MXenes, a large family of 2D nanomaterials, to apply a thin layer of MXene coating continuously to commercial nylon filaments (30-300 µm in diameter) at a fast speed (up to 15 mm/s), resulting in a resistance down to 15 Ωcm. The MXene-coated filaments can be batch-fabricated into arrays of fiber electrodes, encapsulated with Parylene C, and exposed only at the tip upon application for localized detection and stimulation. We demonstrated the usability of these multifunctional fiber electrodes for both in-vivo and ex-vivo studies, including neuromodulation and electrical sensing in a rat and H2O2 chemical sensing in bladder cells. These electrodes offer excellent performance, significantly simplified use, and improved flexibility (with no performance changes even when knotted). These versatile MXene filament microelectrodes offer a robust, miniaturized platform for monitoring and stimulating neural activities, facilitating a deeper understanding of health and disease.

These versatile MXene filament microelectrodes offer a robust, miniaturized platform for monitoring and stimulating neural activities, facilitating a deeper understanding of health and disease.

The development of flexible fiber-based microelectrodes opens up opportunities for long-term studying and modulating neural activities and diseases by increasing targeting precision while inducing fewer side effects, thanks to the minimized mechanical mismatch between artificial devices and soft tissues. However, the current manufacturing of such microfabrication faces scalability, reproducibility, and handling challenges, making large-scale deployment of fiber-based microelectrodes difficult. Moreover, few designs allow capturing both electrical and chemical signals, which are necessary for understanding and interacting with complex biological systems.

biosensors are easily worn with minimal nuisance to the user, enabling wearable health sensing anywhere and at any time. Graphene and other two-dimensional materials have emerged as a suitable platform for high performance printed electronics, enabling graphene field-effect transistors (GFETs) on ubiquitous substrates [2,3]. We have recently developed a scalable method for creating high resolution GFETs through spray-coating [4] and demonstrated their use in biosensing.

In this work, a new type of sensor is created by forming the GFETs directly on the tips of polycarbonate microneedles to enable biosensing of interstitial fluid within the skin. The GFETs are formed on the three-dimensional needles through a scalable combination of laser lithographic patterning and spray-coating and uses injection-moulded polycarbonate microneedles. The graphene channels are approximately 2000 µm wide and 80 µm long, with a resistance of 150 Ohms and display characteristic ambipolar modulation under solution gating. We fully characterise the sensors through microscopic and electrochemical methods and demonstrate their biosensing properties through in solution and in-vitro skin measurements. The results demonstrate a new class of sensors that can take advantage of the FET signal amplification directly in situ and enable the development of more sensitive and accurate microneedle biosensors in the future.

Microneedle-Based Potentiometric Sensing System for Continuous Monitoring of Multiple Electrolytes in Skin Interstitial Fluids Hujie Li and Yi Zhang; University of Connecticut, United States

Electrolytes play a pivotal role in regulating cardiovascular functions, hydration, and muscle activation. The current standards for monitoring electrolytes involve periodic sampling of blood and measurements using laboratory techniques, which are often uncomfortable/inconvenient to the subjects and add considerable expense to the management of their underlying disease conditions. The wide range of electrolytes in skin interstitial fluids (ISFs) and their correlations with those in plasma create exciting opportunities for applications such as electrolyte and circadian metabolism monitoring. However, it has been challenging to monitor these electrolytes in the skin ISFs. In this study, we report a minimally invasive microneedle-based potentiometric sensing system for multiplexed and continuous monitoring of Na⁺ and K⁺ in the skin ISFs. The potentiometric sensing system consists of a miniaturized stainless-steel hollow microneedle to prevent sensor delamination and a set of modified microneedle electrodes for multiplex monitoring. We demonstrate the measurement of Na⁺ and K⁺ in artificial ISFs with a fast response time, excellent reversibility and repeatability, adequate selectivity, and negligible potential interferences upon the addition of a physiologically relevant concentration of metabolites, dietary biomarkers, and nutrients. In addition, the sensor maintains the sensitivity after multiple insertions into the chicken skin model. Furthermore, the measurements in artificial ISFs using calibrated sensors confirm the accurate measurements of physiological electrolytes in artificial ISFs. Finally, the skin-mimicking phantom gel and chicken skin model experiments demonstrate the sensor’s potential for minimally invasive monitoring of electrolytes in skin ISFs. The developed sensor platform can be adapted for a wide range of other applications, including real-time monitoring of nutrients, metabolites, and proteins.

Graphene Transistors for Biosensing Applications Amaia Zurutuza; Graphenea, Spain

Over the past years, extensive efforts have been placed in the research and development of graphene-based applications, as a result certain applications have experienced an increased level of maturity and achieved higher technology readiness levels (TRLs) among them is that of sensors.

Graphene’s electronic and mechanical properties make it an ideal candidate to be applied in various types of sensors. The market for sensors is extremely large since it includes many industries such as automotive, electronics and healthcare industries among others. Therefore, it is an excellent starting platform for graphene applications. For example, the COVID-19 pandemic demonstrated the urgent need for fast diagnostics in order to minimise and control its effects, here, biosensors based on graphene field effect transistors (GFETs) have shown great potential as a platform for future diagnostics.

During this talk, I will cover the fabrication of graphene at wafer scale (up to 200mm) and the use of graphene in various types of sensors including ion sensors (ISFETs) [1-3], gas sensors [4] and biosensors [5].

10:00 AM BREAK
Among the existing two-dimensional materials, MXenes stand out for their excellent electrochemical properties. MXene-based inks and films hold great potential for the scalable production of skin-conformable electronics and for constructing electronic sensors and actuators that operate in physiological media. On the other hand, conjugated polymer films, due to their softness and conformability, enable seamless interfacing with the skin and cells. In this talk, I will demonstrate how the combination of soft conducting polymers and printed MXene electrodes brings together the best of both worlds for biointerfacing. The functionalized MXene films serve as multifunctional biosensing units for cation and protein sensing, as well as for capturing physiological signals. Conducting polymers act as both substrates and interconnects. In another platform, the incorporation of MXene as a co-dopant in a conjugated polymer structure results in hybrid films with remarkably high volumetric capacitance and stability. These microfabricated hybrid devices outperform their single-component counterparts in chronic biochemical sensing and stimulation applications. Our findings illustrate how MXene films can streamline the fabrication of next-generation bioelectronic platforms incorporating multimodal sensors.

Deformable and Stretchable EGaIn/Graphene-Based Electrochemical Biosensors Dongwook Lee, Don-Hui Lee, Won-Yong Lee and Jayoung Kim; Yonsei University, Korea (the Republic of)

EGaIn has attractive properties for soft electronics, such as wearable and implantable electronic devices for healthcare applications, due to its high conductivity and deformability near room temperature. However, the formation of an insulating native oxide film of EGaIn impedes its application to soft and stretchable electrochemical biosensors. Herein, we introduce reduced graphene oxide to EGaIn to achieve electrochemical stability and excellent conductivity as well as deformable properties. Graphene oxide easily undergoes galvanic replacement reaction on the surface of EGaIn particles forming reduced graphene oxide capped EGaIn core-shell particles (LM-RGO CSPs), which can be further fabricated to patternable stretchable electrochemical biosensing devices. The resulting deformable electrodes show excellent electrochemical conductivity and stability by preventing the native oxide film growth of EGaIn, even under repetitive stretching with 30% strain without any delamination of RGO. Also, the outer layer of RGO can be further decorated with metals which can effectively catalyze enzymatic reactions for glucose biosensing. In this talk, we will discuss the deformable mechanisms of LM-RGO CSPs-based electrochemical biosensors revealing specific interfacial attractions between RGO and LM, and excellent electrochemical biocatalytic activity for sensitive glucose detection under strains, based on sub-micro sized particle characteristics and their facilitated electron transfer between electrodes and glucose oxidase enzyme. We envision such an electrochemical device system can serve as a platform for multi-modal deformable wearable biosensing devices for healthcare applications, overcoming the inherent limitations of EGaIn as a soft conductor and taking advantage of the excellent conductivity and graphene.

11:15 AM SB11.06.03
The Effect of Partially Reduced Graphene Oxide on The Enzymatic Activity of Yeast Rebecca Isseroff1, Sophia Breaco1, Dominic Rostiello2, Sergio Rosa2, Sam Specht1 and Miriam Rafaelovich1; 1Stony Brook University, The State University of New York, United States; 2South Side High School, United States; 1The Stony Brook School, United States

Enzyme biocatalysts are important for the synthesis of drugs, vitamins, and other products, but research is being done to increase their stability and activity. Previously we have found that partially reduced graphene oxide (pRGO) acts as an enzymatic enhancer for the catalytic activity of microbial transglutaminase in the cross-linking of gelatin. We now set out to determine whether graphene oxide (GO) and/or pRGO would have an effect on the enzymatic activity of yeast to decompose hydrogen peroxide, thereby testing whether these 2D materials are biocompatible with a living organism that produces an enzymatic reaction rather than just testing the effect on the enzyme itself.

A solution of pRGO reduced in a concentration of 18 mM sodium borohydride, as well as an unreacted GO solution, were compared with water as a control. While initial qualitative results suggested that GO had no effect on yeast’s catalytic activity, H2O2 decomposition seemed to be enhanced by 18 nm pRGO. However, further quantitative measurements were conducted by collecting O2 by water displacement. Twenty milligrams of yeast were suspended in two milliliters of water containing 0.2% sucrose by weight and incubated at 41 degrees Celsius for 4 minutes. (As a third variable, twenty milligrams of yeast were suspended in two milliliters of water containing 0.2% sucrose by weight but with 0.5 ml pRGO added to the yeast + water before incubation.) Then, 5 ml of 3% H2O2 + 0.5 ml DI water for the control, and 5 ml of 3% H2O2 + 0.5 ml pRGO for the test solution, were added and the time it took to displace 25 ml of water was measured. After 3 minutes, an additional 4 ml of 3% H2O2 were added, and the time it took to displace 25 ml water was again measured, to determine whether the yeast maintained its activity. Results showed that yeast activated in water had the same rate of decomposition of H2O2 containing pRGO as the control containing no pRGO, but yeast incubated in water containing pRGO actually had a slower rate of H2O2 decomposition, both initially as well as retesting five minutes later by adding additional H2O2. Macroscopic changes observed in the pRGO-yeast include darkening of the yeast, suggesting incorporation of pRGO by the cells. Microscopic examination of pRGO-incubated yeast at various time points provides further insight on the biocompatibility of partially reduced graphene oxide with living cells.

Advances in Pressure and Chemical Sensing with 2D Materials Paolo Samori; University of Strasbourg, France

Physical and chemical sensor bear a direct societal impact on well-being, which includes, among others, the monitoring of human’s health, the quality and composition of the air we breathe, the water we drink, and the food we eat. Physical sensors are essential components for the fabrication of devices for medical diagnosis and health monitoring, upon use of active materials with sensitivities in the low-pressure or medium-pressure range, respectively. In this framework, flexible piezoresistive pressure sensors are compatible with wearable technologies for digital healthcare, human-machine interfaces and robotics. Among active materials for pressure sensing, graphene-based materials are extremely promising because of their outstanding physical characteristics. Currently, a key challenge in pressure sensing is the sensitivity enhancement through the fine tuning of the active material’s electro-mechanical properties. We have achieved this by combining chemically reduced graphene oxide (rGO) with (macro)molecular materials with controlled mechanical properties. Among these, the use of a polybenzoxazine thermoresist matrix in combination with rGO made it possible to tailor electrically conductive nanocomposites where the thermally triggered resist polymerisation modulates the active material rigidity and consequently the piezoresistive response to pressure. [1] In chemical sensing higher sensitivity, faster response time and fast recovery time can be achieved by using 2D materials as active components. Instead, selectivity can be achieved either through the optimization of the energy levels of the analyte with respect of those of the active material, as demonstrated via the fabrication of sensors of heavy metals[2] or polyaromatic molecules[3], or through the functionalization of the latter with supramolecular receptors ensuring a high discrimination of ions and small molecules in the sensing event.[4] Strategies for simple integration of working devices with electrical read-outs will be presented.

Wireless, Graphene-Based Multifunctional EEG and ECG Sensor for Clinical Monitoring with thionine-tagged detector antibody-conjugated gold nanoparticles for signal transduction and amplification, autonomous sweat gland-driven analysis across human activities was realized through seamless integration of a mesoporous graphene-gold nanoparticle modified immunosensor (coupled speller system augmented by deep neural networks to exhibit the diagnostic capabilities of the monitoring system. These personalized, wearable, and highly simultaneous monitoring of both EEG and ECG enables accurate and holistic analysis of the patient's status. We also demonstrate a clinical BCI

real-time monitoring of EEG and ECG for up to 11 hours on a single charge with accuracy and precision on par with that of conventional clinical systems.

epilepsy patients.

animals and humans, longitudinal monitoring of post-traumatic epilepsy evolution with subcutaneous EEG in murine models, and clinical scalp EEG in epilepsy patients.

In this talk I will present multiscale arrays for intracranial, subcutaneous, and scalp EEG based on high-throughput liquid-phase processing of 2D Ti3C2T1 MXene. Leveraging the colloidal stability of MXenes in aqueous dispersions, we have developed a rapid fabrication process to produce EEG arrays with fully customizable geometry, scale, and density. For scalp EEG, the devices feature 3D pillars of varying diameter and height fabricated from PVA aerogel templates infiltrated with Ti3C2T1. Due to the high electrical conductivity (155 ± 4 Ω, n=5), porosity, and surface area, these 3D electrodes can establish a low impedance interface with the scalp without the need for any gel or conductive adhesive (10 Hz impedance of 8 mm pillar electrodes: 2.1 ± 1.8 kΩ, n=5 participants).

To illustrate examples of applications of these multiscale MXene EEG arrays, I will present our most recent studies on intraoperative recordings in large participants).

With the advent of advanced digital healthcare technologies, the need for imperceptible user-friendly portable devices for clinical monitoring of physiological anomalies has greatly increased. The brain and the heart are two major organs that would benefit greatly from such real-time monitoring apparatus, as the symptoms of various diseases readily manifest themselves in their operation. Brain diseases, such as stroke, epilepsy, and Parkinson’s disease, and cardiovascular diseases, including arrhythmia, heart attacks, and atrial fibrillations, known for their high fatality, are among the many conditions where quick diagnosis and preventative measures may be taken via the continuous monitoring of the brain and the heart. As such, electroencephalogram (EEG) and electrocardiogram (ECG) have become an essential tool in the monitoring and diagnosis of patients. However, conventional monitoring devices are hard-pressed to facilitate prolonged real-time monitoring of patients. These devices typically fail to support the simultaneous monitoring of vitals on a single wearable device and causes discomfort owing to the bulky, wired electrodes and recording devices, thus limiting their daily use and leaving patients vulnerable to unpredictable medical emergencies. As such, in this research, a wireless, graphene-based EEG and ECG sensor for clinical monitoring is proposed. We demonstrate a simultaneous monitoring and analysis of EEG and ECG with improved accuracy for both clinical monitoring and brain-to-computer interface (BCI) applications. The ultrathin and imperceptible graphene-based electrodes exhibit lower contact impedance, high signal-to-noise ratio (SNR), and stable properties owing to the excellent mechanical and electrical properties of the constituent materials and structural design. Paired with a high-throughput portable wireless recording device for clinical monitoring, the system enables user-friendly, real-time monitoring of EEG and ECG for up to 11 hours on a single charge with accuracy and precision on par with that of conventional clinical systems. The simultaneous monitoring of both EEG and ECG enables accurate and holistic analysis of the patient’s status. We also demonstrate a clinical BCI speller system augmented by deep neural networks to exhibit the diagnostic capabilities of the monitoring system. These personalized, wearable, and highly imperceptible devices are expected to aid in the advancement of daily healthcare for patients.

A Wearable Nanobiosensor for Automatic, Non-Invasive and Wireless Monitoring of Systemic Inflammation Jiaobing Tu and Wei Gao; California Institute of Technology, United States

Real-time monitoring of inflammatory proteins allows remote disease progression tracking and early intervention, thus improving patient outcomes and lowering economic burdens in chronic diseases. However, most current commercial protein sensing technologies rely on invasive blood draws, and require lengthy target incubation and labor-intensive washing steps to reach nanogram-level sensitivity. Although sweat is a non-invasive source for disease monitoring, wearable immunoassaying is complex and sweat protein secretion is extremely underexplored, presenting a major challenge for personalized inflammation monitoring. Here, we present a wearable nanoengineered electrochemical biosensing technology that allows real-time and non-invasive analysis of a crucial inflammatory biomarker, C-reactive protein (CRP). Highly sensitive, selective, and fully automatic in situ inflammatory protein analysis across human activities was realized through seamless integration of a mesoporous graphene-gold nanoparticle modified immunosensor (coupled with thionine-tagged detector antibody-conjugated gold nanoparticles for signal transduction and amplification), autonomous sweat gland-driven microfluidics, and multimodal graphene sensor calibration. Through in vitro and in vivo clinical studies, we discovered the presence of CRP in chemically-induced human sweat and identified substantially elevated sweat CRP levels from patients with heart failure, chronic obstructive pulmonary disease, and active and past infections (e.g., COVID-19). We obtained a high correlation between sweat and blood CRP levels, demonstrating the potential of this technology toward non-invasive chronic disease management.

Thermal Drawing of Graphene-Integrated PVDF Fiber for Improved Performance in Wearable Triboelectric Nanogenerator Md Sazid Bin
Triboelectric nanogenerators (TENG) exploit the phenomenon of triboelectrification enabling energy harvesting from low-frequency mechanical and biomechanical energy. Flexible ferroelectric polymers such as polyvinylidene difluoride (PVDF) are excellent candidates for fabricating a TENG device due to its high triboelectric charge density. Embedding 2D materials that have a high specific surface area into the PVDF matrix has proven to be an efficient strategy to affect surface morphology and friction property to improve the performance of TENG. Graphene and its derivatives have become a desired multi-functional material for fabricating high-performance TENGs. In this study, we demonstrate the successful fabrication of continuous PVDF graphene nanocomposite fiber via scalable thermal drawing process. Fibers were fabricated with varying concentration of graphene in the PVDF matrix (1 wt%, 3 wt% and 5 wt%) by optimizing the fiber drawing parameters. The 5 wt% graphene integrated PVDF TENG fiber generates peak power up to 12.08 μW, which is more than two times higher compared to pristine PVDF TENG (5.80 μW). This research will further expand our understanding on the dynamics of 2D nanomaterials into the polymer matrix of a thermally drawn fiber, leading to the performance optimization of wearable triboelectric devices and sensors.

Highly Piezoelectric, Biodegradable and Flexible Amino Acid Nanofibers for Medical Applications Thanh D. Nguyen; University of Connecticut, United States

Amino acid crystals are an attractive piezoelectric material as they have an ultra-high piezoelectric coefficient and possess an appealing safety profile for medical implant applications. Unfortunately, solvent-cast films made from glycine crystals are brittle, quickly dissolve in body fluid, and lack of crystal orientation control, reducing the overall piezoelectric effect. Here, we present a material processing strategy to create biodegradable, flexible, and piezoelectric nanofibers of glycine crystals embedded inside polycaprolactone (PCL). The glycine-PCL nanofibers film exhibits stable piezoelectric performance with a high ultrasound output of 334 kPa (under 0.15Vrms), which outperforms the state-of-the-art biodegradable transducers (Nguyen et al., highly piezoelectric, biodegradable and flexible amino acid nanofibers for medical applications, Science Advance, 2023). We employ this material to fabricate a biodegradable ultrasound transducer for facilitating the delivery of chemo-drug to the brain. The device significantly enhances the animal survival time (2-fold) in mice-bearing orthotopic glioblastoma models. The piezoelectric glycine-PCL presented herein could offer an excellent platform not only for glioblastoma therapy but also for developing medical implantation fields.

Electronic Skins with Air-Stable Ultraflexible Organic Photonic Devices Tomoyuki Yokota1, Kenjiro Fukuda2, Sanghoon Lee2,1 and Takao Someya1,2; 1The University of Tokyo, Japan; 2RIKEN, Japan

Inspired by the human skin, which is a large-area, multi-point, multi-modal, stretchable sensor, electronic skins that simultaneously detect pressure and thermal distribution have been developed. By improving its conformability, electronic skin can be directly attached on the human skins as next-generation wearables. In particular, ultraflexible organic photonic devices have been utilized as electronic skins that continuously monitor biological information in humans non-invasively. In this paper, we report recent progress of ultraflexible organic photonic devices that consist of organic light-emitting diodes and photodiodes. The environmental stability has been improved significantly using an inverted structure that does not employ atmospherically unstable cathode materials. We will also address issues and the future prospect of electronic skin using organic photonic devices.

Biosensors and Wearable Tattoo Sensors Based on 2D Atomic Materials Dmitry Kireev1 and Deji Akinwande2; 1University of Massachusetts Amherst, United States; 2The University of Texas at Austin, United States

This talk will report on the development of 2D atomic materials such as graphene for wearable sensors, biosensors, and physiological monitoring of vital signs such as blood pressure. 2D materials offer many advantages in terms of mechanical, electrical, and optical performance compared to conventional materials. In addition, progress towards in-vivo uses of graphene for cardiac monitoring will be presented.

8:00 AM *SB11.08.02
2D Materials-Based Acoustic Sensors and Actuators He Tian; Tsinghua University, China

There is a great demand of developing 2D materials-based wearable electronics. In this talk, I will introduce several wearable electronics: 1. Graphene-based thermoacoustic device can enable sound emission with transparent properties. 2. We have developed graphene artificial throat, which can help mute people to speak again. 3. We also have created Mxene-based eardrum with high sensitivity. Our work can great promote the wearable electronics toward practical applications.

8:30 AM *SB11.08.03
Skin-Integrated Wearable Sensors and Systems Shideh Kabiri Ameri; Queen’s University, Canada

Skin-integrated wearable sensors and systems are a group of different types of sensors and their integrated electrical circuits that are laminated on skin and enable real time monitoring of the body and the surrounding environments for the applications in mobile health care, Internet of Things (IoT) and Human Machine Interfaces (HMI). The grand challenge in making reliable sensors and systems of such is the interface between conventional sensors and rigid electronics and soft, stretchable, and dynamic skin. Novel materials, designs and approaches are required to overcome this challenge. In this talk a group of nano materials based non-intrusive wearables with superior performance and visual imperceptibility and their applications for electroencephalography (EEG), electrocardiography (ECG), electromyography (EMG), Electrooculography (EOG), sensing skin temperature and hydration, human machine interface and IoT will be presented.

Final Program 1/25/24
Revolutionary advancements in healthcare and well-being rely on the integration of cutting-edge self-powered sensing technologies within textiles. A pivotal breakthrough in this field involves the emergence of nanoscale self-powered sensors specifically triboelectric nanogenerators (TENG). The underlying principle of TENGs lies in the combination of the triboelectric effect, based on the interaction between materials with different electronegativity and electrostatic induction. TENG devices have the capacity to effectively harness untapped energy resources, for example they can convert biomechanical energy from human movements such as walking, running, and breathing into electricity. TENG based biosensors are emerging as a viable alternative to battery-powered devices due to their self-powered and environmentally friendly properties. As a result, they are well-suited for wearable health monitoring applications, where they can behave as self-powered sensors. To pave the way for these transformative advancements, it is crucial to develop flexible, mechanically robust, lightweight, and resilient TENG biosensors.

In this invited talk, I will present our recent work on the solutions we explored to the design and fabrication of such generators, which possess the vital characteristics to meet the demands of practical applications. I will present several approaches for the development of textile-based triboelectric nanogenerators using 2D materials both as active sensing layers and as electrode materials. In our earlier work we demonstrated various methods to integrate graphene with textile substrates and create electrodes displaying displayed a good range of conductivity, and resilience to bending, compression and tension. These textile electrodes are used in the fabrication of TENGs along with a triboelectric layer of polydimethylsiloxane (PDMS) polymer and nylon fabric as a counter triboelectric layer. Different parameters affecting the TENG output such as chemical modification of the PDMS layer, frequency, contact force, contact area and separation distance between the two triboelectric layers are studied to provide insights into the working mechanisms of the device and to enhance the TENG output. The flexible textile TENG presents a stable output performance under strong deformation and its sensitivity to movement was explored as wearable sensor to monitor biomechanical movements. Due to the conformation ability of the triboelectric sensors, they were able to be implemented on key moving parts of the human body and used to monitor biomechanical motion through electrical signals. The self-powered sensors demonstrate their potential for wearable bioelectronics, intelligent robotics, prostheses, and rehabilitation purposes. Furthermore, we have demonstrated the use of 2D Transition Metal Dichalcogenides materials for wearable sweat sensors of uric acid for applications in personalised healthcare. Among the emerging technologies for continuous monitoring wearable technologies, triboelectric nanogenerators have emerged as a particularly promising and innovative approach for self-powered sensors in the detection of sweat biomarkers. These results show that the distinctive combination of electrical, morphological, and mechano-elastic properties positions these 2D materials attractive candidate for the development of self-powered sensing textile technologies.
3D ink extrusion printing (i.e., direct ink writing) enables powder deposition in a layer-by-layer fashion, in air at ambient temperature, to create 3D complex geometries. For thermoelectric materials (TEs), this versatile manufacturing technique can unlock the potential of fully printed TE modules consisting of p-type and n-type TE legs. Recently, pre-alloyed particles (e.g., Nb_{1-x}CoSb) were suspended in inks, printed and then densified via sintering; also, bismuth and tellurium oxide particles deposited from inks resulted in Bi_{2}Te_{3} after hydrogen reduction. Here, we demonstrate inks, containing blended elemental powders, which are printed into TE legs and reacted during sintering to synthesize the high-temperature TE phases Yb_{4}MnSb_{11} and La_{3}Te_{4}. To build mechanically robust TE module with high density and phase purity, several approaches are explored during post treatments of printed green bodies.

Infiltration of lower-melting elements in pre-sintered structures followed by annealing can close open porosity and help achieve targeted compositions. By blending low-melting elements like Sb into precursor powders, liquid phases are formed which facilitate interdiffusion and densification during sintering. For blended elemental powders, sublimation of elements with high vapor pressure (such as Yb and Te) during sintering introduces deviations from phase stoichiometry and formation of secondary phases. We demonstrate strategies - via addition of excess elements and/or binary compounds in precursors - to mitigate elemental losses and increase phase purities in sintered TE legs. We discuss the effects of microstructure and phase purity on the thermoelectric figure of merit (\(zT\)), which is controlled by the Seebeck coefficients and the electrical and thermal conductivities.

**11:00 AM ~SF01.01.02 Direct Ink Printing of Thermoelectric Materials** David C. Dunand, Ming Chen, Alexander Proschel and Yunjia Zhang; Northwestern University, United States

An estimated one million bone grafting procedures are performed annually in the U.S. and a few million worldwide to repair fractures, cysts, bone defects, tumors, and hip and knee replacements. An increase in the number of procedures is strongly tied to increased musculoskeletal disorders, the aging population segment, and sports-related injuries. Sometimes, patient-matched devices are necessary for patients with special anatomical needs or concerns related to specific defect size complexity.

3D printing (3DP) or additive manufacturing (AM) is becoming essential in patient-matched implants due to lower cost and shorter manufacturing lead time. Additively manufactured components must be controlled and optimized carefully for their reproducibility, machine-to-machine part quality variations, and process-specific material properties. Establishing process property relationships for different AM techniques is vital to successfully implementing these manufacturing practices in biomedical devices. Complex biomaterials, e.g., calcium phosphate (CaP) ceramics compositionally similar to the inorganic part of the bone, show significant promise toward implant applications in both 3DP tissue engineering scaffolds and surface-modified hip and knee implants. It is worth noting that even with all the excitement on 3DP in recent years, reliable and reproducible 3DP ceramic scaffold manufacturing is rare compared to porous polymeric or metallic structures due to their ease of processability.

We have used extrusion-based and commercial binder jetting 3DP printing machines (ExOne, PA) with various ceramic powders for the past 25 years to critically identify and understand the effects of process-property variations on 3DP CaP scaffolds. Our CaP scaffolds using 3DP have an average designed pore size of 300-400 microns, with 40 volume % porosity and compressive mechanical strength of >15 MPa, followed by NMC loading on those CaP scaffolds. We have designed and built a 3DP machine capable of printing high-viscosity slurries to directly print doped CaP–polymer scaffolds with similar inorganic composition as bone. 3D interconnected channels in CaP scaffolds provide pathways for micronutrients, improved cell-material interactions, and increased surface area, allowing improved mechanical interlocking between scaffolds and surrounding bone.

In vivo studies show improved osteogenesis, angiogenesis, and controlled drug delivery using natural medicinal compounds (NMCs) in these 3D-printed scaffolds and coatings. The use of NMCs in CaP or CaP-polymer composites can eliminate the need for autografts and related second-site surgery for harvesting. NMCs can also replace growth factors (GFs) and proteins for faster healing. NMCs work with CaPs and other materials, such as titanium metals, to enhance early-stage bone tissue ingrowth for applications in load-bearing or non-load-bearing implants. These systems show promise for use in orthopedic and dental devices while eliminating the need for autografts and the second site surgery for harvesting and improving current hip/knee implant lifetime. The presentation will address the design of next-generation bone tissue engineering scaffolds and hip/knee devices based on clinical needs in the fixation of bone disorders and scientific challenges.

**11:30 AM ~SF01.01.03 Additive Manufacturing and Natural Medicine in Bone Regeneration: Opportunities and Challenges** Susmita Bose; Washington State University, United States

In this presentation, we will cover some of the latest work in advanced and custom additive manufacturing processes for the fabrication of architected materials and functional structures. The concept of architected materials evolves around the notion that material properties are traditionally governed by the chemical composition and spatial arrangement of constituent elements at multiple length-scales. This usually limits material properties with respect to each other creating trade-offs when selecting materials for specific applications. For example, strength and density are inherently linked so that, in general, the more dense the material, the stronger it is in bulk form. We will review advanced additive micro- and nanomanufacturing techniques to create new material systems with previously unachievable property combinations. These processes include, but may not be limited to, projection microstereolithography (PuSL), direct ink writing (DIW), and electrophoretic deposition (EPD) as well as more advanced concepts such as volumetric additive manufacturing (VAM), computed axial lithography (CAL), parallel two-photon polymerization, liquid metal jetting, and diode-based additive manufacturing of metals (DiAM). The performance of the resulting material constructs is fundamentally controlled by geometry at multiple length-scales,
Additive Manufacturing as a Unique Platform for Fabrication of (Meta-)Materials with Complex Topologies and Designer Microstructures

Lorenzo Valdevit; University of California, Irvine, United States

Additive manufacturing (AM) technologies have enabled the fabrication of geometries of significant complexity. Nevertheless, the design optimization of AM cellular materials for high strain rate loading scenarios remains relatively underdeveloped. Furthermore, even if those material structures dissipate energy efficiently during dynamic crushing, they do not recover their shape after impact. It is, therefore, necessary to understand the relationship between the AM process parameters, cellular material structures and dynamic performance, but also to develop the recovery of those structures after suffering an impact.

Firstly, quasi-static and dynamic mechanical testing on stainless steel 316L cellular geometries is combined with a wide range of material characterization treatments to significantly push the strength and toughness of metallic meta-crystal for load-bearing and safety-critical applications. The talk also discusses new ways of tuning mechanical behaviour to specific locations to enhance the spatial programming of local deformation.

Additive Manufacturing Smart Cellular Materials: Self-Healing Protection for Space Applications

Marlini Simoes1,2; 1California Institute of Technology, United States; 2University of Cambridge, United Kingdom

Metallic cellular materials, such as lattices and honeycombs, are of interest in the design of lightweight and impact-resistant structures (high energy absorption capacity). However, the use of cellular materials in engineering applications has been hindered due to the challenges associated with the fabrication of such complex geometries. Additive manufacturing (AM) technologies have enabled the fabrication of geometries of significant complexity.

Nevertheless, the design optimization of AM cellular materials for high strain rate loading scenarios remains relatively underdeveloped. Furthermore, even if those material structures dissipate energy efficiently during dynamic crushing, they do not recover their shape after impact. It is, therefore, necessary to understand the relationship between the AM process parameters, cellular material structures and dynamic performance

In this work, the opportunities created by additive manufacturing processes have been explored by: (1) studying the process-geometry-property interactions of metallic cellular materials, and (2) manufacturing cellular structures which can exhibit a "self-healing" functionality through shape memory effect.

Firstly, quasi-static and dynamic mechanical testing on stainless steel 316L cellular geometries is combined with a wide range of material characterization techniques to understand the interplay between AM process parameters, geometry and high strain rate performance. Five cellular structures were investigated, finding that the geometry played a dominant role, relative to the Laser Powder Bed Fusion (LPBF) AM process. Secondly, bulk and complex cellular structures that exhibit shape memory effect have been successfully manufactured. A diamond lattice structure and a new auxetic structure obtained through topology optimization recovered up to 70% of their shape after impact. The main motivation and focus are on space applications to mitigate against impacts but this research is of relevance to a wide range of sectors: e.g., automotive crashworthiness, structural defence, and civil blast protection.

**Tuning Local and Global Disorder in Architected Materials via Frequency-Based Noise**

Lorenzo Valdevit; University of California, Irvine, United States

The rapid development of additive manufacturing technologies has enabled the fabrication of truss metamaterials, i.e., a novel class of lightweight-yet-strong materials with engineered complex hierarchical structures. Manipulating the architecture over chemical composition dramatically expands the achievable materials design space, allowing to largely control the mechanical response of metamaterials. While methods such as topology optimization and machine learning have demonstrated to be powerful tools to discover structures with desired material properties, designing three-dimensional (3D) complex truss metamaterials with programmable mechanical behaviors is still a challenge. Here we propose a paradigm, based on graph neural networks (GNNs) and deep reinforcement learning, to design 3D truss metamaterials with programmable nonlinear quasi-static and dynamic responses. By combining the ability of our GNN-based model to accurately predict the mechanical response across multiple orders of magnitude and the explorative power of deep reinforcement learning, together with numerical simulations and mechanical testing, we inverse design truss metamaterials for compressive loading up to 30 % of strain and dynamic transmissibility with desired band gaps. Our method not only demonstrates a pathway to design mechanical metamaterials with desired mechanical behaviors but also provides a flexible framework that can be applied to tailor the response of 3D photonic or robotic metamaterials.
fabricate architectures that incorporate this randomness. However, current efforts to introduce disorder in metamaterials are often restricted to periodicity-disruptions on a global scale. Here, we propose a new design approach that allows us to study the influence of both local and global disorder on the material performance of periodic and random metamaterials. Shell-based topologies are used throughout as model architectures, due to their mechanical advantages (e.g., higher specific strength and energy absorption) over more common truss-based lattices [7]. The mathematically described shell topology is superimposed with frequency-based signals to disturb the “short-range” order, with different frequencies and amplitudes used to tune this local disorder parameter. Characteristic power spectral densities [8] of three frequency-based noise signals – white, pink, brown – are then used to tune the local disorder across the structure, thus introducing a global disorder gradient. To test the influence on both periodic and random metamaterials, triply periodic minimal surfaces (TPMS) and spinodal shell architectures are printed using two-photon lithography, which provides the necessary resolution to incorporate local features in the printing process. The impact of the various levels of disorder on the elasto-plastic behavior of the metamaterial is characterized by means of in situ micro-compression tests performed at different strain rates. Our approach allows us to study the effect of local disorder on globally periodic and random structures by overlaying local features with frequency-based signals. In addition, the characteristic rates of power loss from three different colors of noise introduce a global and tunable disorder gradient opening up new opportunities to design highly multifunctional (meta-)materials.

Embedded 3D Printing of Soft Materials and Ultrafine Hair Structures
Won-sik Eom¹, Mohammad A. Hossain¹, Vidush Parasramka¹, Ryan W. Siu¹, Jeongmim Kim², Katherine Sanders², Dakota Piorkowski², Andrew Low³, Michael D. Volder³, Douglas S. Fudge³, Randy H. Ewoldt³ and Sameh Tawfick²; ¹University of Illinois at Urbana-Champaign, United States; ²University of Cambridge, United Kingdom; ³Chapman University, United States

Embedded 3D printing enables the direct ink writing of ultrasoft materials which, due to gravity, cannot support their own weight in air. For this reason, embedded 3D printing is a platform to replicate nature's complex, branching, and tortuous fibrous structures. However, this recent technology has been limited by a complex interplay of factors such as interfacial tension ratios between the printing materials and the support gel, the viscosity of the ink, and the yield stress of the gel. Because of these complexities, the minimum feature diameter is limited to around 50 µm. Recently, a feature diameter of 8 µm was achieved by tailoring the interfacial tension. This limitation prevents the accurate replication of natural structures, many of which feature dimensions at the micrometer scale, such as long aspect ratio mechanosensing stereocilia and the hairs on the feet of beetles and geckos. Here, we introduce solvent exchange between the ink and the support gel as a key mechanism to expand the capabilities of embedded 3D printing and allow the fabrication of ultrafine and tortuous structures from a variety of soft materials. This method facilitates the immediate solidification of the extruded polymer solution upon its interaction with the gel's solvent, enabling the printing of ultrafine features as small as 2.1 µm in diameter. Our work exploits the rheological underpinnings that make such precision possible. We elucidate the critical roles played by the gel's yield stress and solvent concentration in achieving this high resolution, thereby offering a comprehensive understanding of the mechanics behind this proposed approach. Solvent-exchange extends to the versatility of materials available for embedded 3D printing. We demonstrate printing of soft thermoplastic elastomers like styrene-ethylene-butylene-styrene (SEBS) copolymers as well as rigid polymers such as polyvinyl chloride (PVC), and electrically conductive carbon nanotube composites. We applied this method to produce intricate hair arrays, thereby meeting the requirements for bio-mimicking applications. These arrays feature fibers with diameters less than 2 µm and lengths exceeding 1500 µm.

In summary, the solvent exchange method presents a notable advancement in polymer 3D printing. The solvent exchange of direct ink writing embedded in support gels enables the fabrication of biomimetic high ultrafine tortuous structures, overcomes previous resolution limitations, and expands the palette of polymeric materials available for printing. This capability opens new avenues for replicating nature's intricate fibrous morphologies towards the design of new architectured composite materials. This work was sponsored by the Defense Advanced Research Project Agency (DARPA), under contract no. N660012124036.

Mechanical Characterization of Additively Manufactured Ceramic Nanocomposites Reinforced by Boron Nitride Nanotubes
Dimeli Wane, Nasim Anjum and Changhong Ke; State University of New York at Binghamton, United States

Ceramic materials face significant challenges in industrial applications due to their inherent fragility and limited manufacturability. These limitations can potentially be overcome through the use of reinforcements and additive manufacturing (AM) techniques. Boron nitride nanotubes (BNNTs) exhibit many exceptional structural and physical properties, making them promising candidates for reinforcing ceramics and creating lightweight, strong, and durable ceramic materials. These characteristics are attractive to a number of industries, such as aerospace, automotive, and biomedical sectors. The reinforcement potential of BNNTs for ceramic composites is supported by our recent findings of efficient interfacial load transfer in BNNT-ceramic nanocomposites, which is attributed to the partially ionic B-N bonding and the resulting rugged anisotropic energy landscape. Here, we investigate the bulk mechanical properties of AM-produced BNNT-reinforced silica (SiO₂) nanocomposites. Our study aims to elucidate how the superior interfacial load transfer characteristics observed at the nanoscale translate into enhancements in the bulk mechanical properties of these nanocomposites. The BNNT-silica nanocomposites employed in our study are additively manufactured using digital light processing (DLP) techniques. Our study shows that the addition of a small quantity of BNNTs can substantially enhance the AM-produced ceramic nanocomposite's bulk mechanical properties (flexural modulus and strength, and fracture toughness). We further analyze the local interfacial load transfer within the AM nanocomposite through in situ Raman micromechanical measurements. The findings provide valuable insights into the role of the nanotube-ceramic interfacial strength in enhancing the mechanical properties of the nanocomposite. Our research contributes to a better understanding of the relationship between process, structure, and properties in AM-produced ceramic nanocomposites and the development of durable and reliable ceramics technology.

8:00 PM SF01.03.27
Urethane-Water-Cellulose Composite: Improving Mechanical Properties of Urethane-Based Photocurable Resin for Stereolithography 3D-Printing
Akira Kudo1, Atsuya Fujita2, Kazuya Eguchi2, Kota Matsuhashi1, Kota Toyama1, Takeharu Yoshi1, Dmitri Louguine1, Hiroomo Nishihara1, Mingwei Chen1 and Satoko Kusano2; 1Tohoku University, Japan; 2Tohoku Gakuin University, Japan; 1Johns Hopkins University, United States

Here, we introduce solvent exchange between the ink and the support gel as a key mechanism to expand the capabilities of embedded 3D printing and allow the fabrication of ultrafine and tortuous structures from a variety of soft materials. This method facilitates the immediate solidification of the extruded polymer solution upon its interaction with the gel's solvent, enabling the printing of ultrafine features as small as 2.1 µm in diameter. Our work exploits the rheological underpinnings that make such precision possible. We elucidate the critical roles played by the gel's yield stress and solvent concentration in achieving this high resolution, thereby offering a comprehensive understanding of the mechanics behind this proposed approach. Solvent-exchange extends to the versatility of materials available for embedded 3D printing. We demonstrate printing of soft thermoplastic elastomers like styrene-ethylene-butylene-styrene (SEBS) copolymers as well as rigid polymers such as polyvinyl chloride (PVC), and electrically conductive carbon nanotube composites. We applied this method to produce intricate hair arrays, thereby meeting the requirements for bio-mimicking applications. These arrays feature fibers with diameters less than 2 µm and lengths exceeding 1500 µm.

In summary, the solvent exchange method presents a notable advancement in polymer 3D printing. The solvent exchange of direct ink writing embedded in support gels enables the fabrication of biomimetic high ultrafine tortuous structures, overcomes previous resolution limitations, and expands the palette of polymeric materials available for printing. This capability opens new avenues for replicating nature's intricate fibrous morphologies towards the design of new architectured composite materials. This work was sponsored by the Defense Advanced Research Project Agency (DARPA), under contract no. N660012124036.
Impact of Nanoparticle Size and Loading on Printability of Polymer-Nanoparticle Composite Inks for Direct Ink Writing

3D printing has become one of the most attractive fabrication techniques in materials science and engineering, offering its immense degree of freedom in designing complicated architectures with feature sizes smaller than millimeters or even micrometers. Since the earliest stage of 3D printing, polymeric materials, especially thermoplastic polymers for fused deposition modeling (FDM) and photopolymerizable resins for stereolithography (SLA), have been playing a major role in this field. As the utility of 3D printing expands, eco-friendly development of these polymeric materials will garner increasing attention.

In this presentation, we introduce a composite photopolymerizable resin compatible with SLA 3D printing based on urethane, water and cellulose. A commercially available urethane-based photopolymerizable resin was homogeneously mixed with water and printed into microchannels architectures at a mass ratio of resin:water=3:1. We demonstrated that, despite a considerable portion (20-25% by mass) replaced by water, adding water increased compressive strength and stiffness of fabricated microchannels architectures by 50% or more. Miscibility of urethane-based resin with water also enabled homogeneous dispersion of cellulose nanofibers (CNFs), which would not disperse in pure urethane-based resin. Microchannels made of the urethane-water-cellulose composite showed even more improved properties than the ones without CNFs, achieving strength of 7.5MPa and stiffness of 80MPa at 0.25 g·cm⁻³. Structural characterization by Raman spectroscopy, Fourier transform infrared (FTIR) absorption spectroscopy and optical microscopy was performed to investigate the origin of this unintuitive enhancement in mechanical properties and the impact on microstructures brought by water.

Using water and cellulose, both of which are natural materials, our results can inspire a simple, sustainable and high-performance polymeric material compatible with SLA 3D printing.

8:00 PM SF01.03.06
Machine Learning-Based Predictive Model for Jet Flow Rate in Electrohydrodynamic Direct-Writing

Electrohydrodynamic direct-writing (EDW), also known as near-field electrospinning, is an extrusion-based additive manufacturing (AM) approach. One of the prominent advantages of EDW over other extrusion-based printing techniques is its utilization of electric forces to deposit fibers with orders of magnitude smaller diameters compared to nozzle diameters, enabling much faster printing speeds. As a result, the fiber diameters achievable through EDW can range from the micro to nanometer scale. Furthermore, EDW employs polymer solutions in a liquid state as printing inks, which broadens the range of available polymers and solvents. Consequently, EDW has been employed to print various functional polymers, finding applications in diverse fields including fiber lithography platforms, energy harvesting, gas sensors, and scaffolds for tissue engineering.

Having precise control over the fiber diameter and shape is of great importance in order to tailor the desired properties of the printed fibers, such as electrical resistance, birefringence intensity, sensor sensitivity, and porosity. However, the Electrohydrodynamic direct-writing (EDW) technique has encountered challenges due to the lack of prediction parameters for the printing outputs, including fiber diameters or deposition patterns. As a result, the EDW process has heavily relied on a time-consuming trial-and-error approach to achieve the desired fiber properties. Therefore, the development of practical and purposeful predictive models is crucial for driving innovation and potentially commercializing the EDW method, similar to other state-of-the-art extrusion-based additive manufacturing (AM) techniques. Nevertheless, due to the complex multiphysics mechanism of EDW and the wide range of process parameters involved, developing a predictive model to identify the optimal print parameters presents a highly challenging task.

Machine learning (ML) is a branch of artificial intelligence (AI) that involves an ML model learning the relationship between input and output features to uncover hidden patterns. The application of ML has gained significant popularity in additive manufacturing (AM) processes, particularly due to the complex physics involved in AM processes such as rapid evaporation, solidification, and ingestion, which surpasses traditional manufacturing methods.

Unlike traditional physics-based equations that require explicit programming, ML models can learn these relationships, making them rapid, practical, and analytical prediction tools for AM processes. Consequently, ML-based models have been developed for tasks like geometrical design, process optimization, and anomaly detection in various AM techniques, including fused deposition modeling, power bed fusion, direct energy deposition, direct ink write, and aerosol jet printing. Moreover, ML-based models hold promise as potential candidates for optimizing the Electrohydrodynamic direct-writing (EDW) process, surpassing the capabilities of physics-based models in practical applications.

In this poster presentation, we will introduce a framework for developing an ML-based predictive model of jet flow rate in Electrohydrodynamic direct-writing (EDW). To accomplish this, a monitoring system was established to capture actual images of the jet profiles during the EDW process. Subsequently, image analysis techniques were employed to extract jet profile data, which was then utilized to train a multi-output regression model using artificial neural networks (ANNs). A comparison between the predicted and observed jet profiles demonstrated the model's high prediction accuracy. The proposed approach presented here represents a futuristic method for optimizing the EDW process and holds tremendous potential for realizing smart manufacturing of functional micro/nanofibers through EDW.

8:00 PM SF01.03.11
Impact of Nanoparticle Size and Loading on Printability of Polymer-Nanoparticle Composite Inks for Direct Ink Writing

Direct ink writing (DIW) is a most inclusive 3D printing technology in which polymer can be mixed with different nanoparticles and create 3D structures with a wide range of mechanical properties and functionalities. The key challenge of DIW process is the creation of printable inks. Although a significant process has been made to develop printable recipes with different combinations nanoparticles, polymers, and solvents, two fundamental questions have not been elucidated: 1) how to evaluate the printability of the ink and 2) how nanoparticle size and loading affect ink printability. To bridge this gap, this work utilizes the SiO₂ nanoparticle-Polydimethylsiloxane (PDMS) system and evaluates three commonly used printability analysis methods—single-layer printing analysis, ink rheology, and printing line width analysis. The influence of particle size (diameter = 26 nm-847 nm) and loading (0-66.67 wt.%) were systematically studied. Through the comparison, single-layer printing analysis (DLPA), in which the merging behavior of two vertically stacked printing layers was analyzed, is found to be the most direct and reliable method to evaluate printability. The printability factor (Pr) in DLPA approaches 1 means less merging between layers and good printability and empirically Pr = 0.9 is set as a critical value for printable ink. To achieve this critical value, for 26 nm nanoparticles, a small loading of 2.91 wt% is required, while for 847 nm nanoparticles, 28.57 wt % is required. Increase the particle size will improve Pr but there is an upper limit under the fixed printing pressure and nozzle size. The highest printable particle loading is 66.7 wt% for 847 nm nanoparticles under 120 psi with a nozzle diameter of 300 μm. Our results conclude that nanoparticles can be utilized to tailor the DIW materials from soft bio gels to hard ceramics. Moreover, the comparison of different analysis methods highlights the need for developing generic standards to evaluate printability.

8:00 PM SF01.03.48
Synthesis of Scaffolded Carbon Electrodes via Catalytic Graphitization

Graphitic electrodes are widely used in lithium-ion batteries due to their electrical performance and resistance to chemical degradation. However, the inherent geometry of slurry-based graphite electrodes limits the ability to tune key parameters, such as the diffusion length within the electrode, the path of ions in the electrolyte/electrode region, the extent of active material loading, and the overall mechanical strength. By contrast, electrodes with scaffolded three-dimensional (3D) structures offer freedom over such tunable parameters. While the tunability of scaffolded electrodes may appear attractive, there...
exists a tradeoff: current 3D printing techniques used to fabricate such scaffolded electrodes offer limited control over the intrinsic material properties, namely the crystal phase and microstructure. In turn, improvements in diffusion length and the intercalation of lithium ions within the electrode are still limited. Achieving the desired microstructure and phase control requires significant thermal activation, with temperatures greater than 3000°C in the case of carbon, that is infeasible in most tube furnaces and especially challenging for larger samples.

Here, we offer a repeatable method for microstructural and crystal phase tuning of scaffolded carbon electrodes via catalytic graphitization. Electrodes are 3D printed using a hygroscopic resin capable of swelling in an aqueous solution, offering significant compositional control in post-printing. In this study, samples are submerged in a solution of nickel salts, where the 3D printed polymer swells with nickel cations and water to produce a hydrogel. These samples are then pyrolyzed in a vacuum furnace between 800-1000°C to form a carbon electrode, in which the presence of nickel catalytically produces graphite.

In this study, we first investigate the impact of the aqueous nickel concentration on the resultant nickel incorporated in the pyrolyzed electrodes. We also examine how the nickel concentration leads to the presence of a crystalline graphite phase, as opposed to the glassy carbon phase typically observed during pyrolysis. X-Ray Diffraction (XRD) patterns display pure glassy carbon at zero nickel concentration, while both glassy and graphitic carbon signatures appear as nickel incorporation increases. The ratio of graphite (G) to disorder (D) Raman peaks improves from less than 1:1 to greater than 10:1 in catalytically produced samples. Future studies using Transmission Electron Microscopy (TEM), in-situ high temperature TEM, electrochemical cycling, and capacity measurements are discussed. We also compare the electrochemical performance of slurry and scaffolded electrodes with varying degrees of graphitic microstructure and architectural features.

Finite Element Analysis of Weathering Resistant Spherical Robot Shell Wei-Lin Wu, Yen Shuo Chen and Fu-Hsiang Ko; National Yang Ming Chiao Tung University, Taiwan

With the fast pace of human civilization development, various types of robots, particularly autonomous amphibious robots, have seen significant advancements in recent research(1). As robots increasingly work in challenging environments to perform specialized tasks, it is critical to have a robot shell that can adapt to various conditions to ensure proper functioning of internal sensing components(2). Therefore, it's crucial to find a material with strong mechanical reliability and good optical properties.

This paper presents a proposed 3D printing resin for spherical robot shells with high transparency in the visible region. The use of 3D printing technology in creating various robots has gained widespread acceptance(3), and the stereolithography (SLA) method has many advantages over other methods, such as relative precision and higher mechanical strength(4). We also conducted a two-month accelerated corrosion test on our print samples. The weather resistance of the printable resin was then evaluated by measuring changes in surface tension, tensile strength, UV-visible and FTIR spectrums. For the purpose of enhancing the impact resistance, we also performed a mechanical study of 3D printed shells with different layer structures through finite element analysis. The finite element technology has many advantages such as less time, manpower, energy and material resources(5). Our simulation results showed that a protective layer with larger holes offers better protection for the inner cooling ball compared to one with smaller holes, leading to a reduction of 80% in residual deformation energy compared to a single-layer ball.

Besides mechanical test, Passive cooling is an important consideration for the robot shell given the proper functioning of the internal electronic sensors. Recently, radiative daytime radiative cooling (PDRC) has become a high-profile topic due to the intensification of Earth’s climate problems (6, 7). Because of the heat dissipation to outer space (3 K) through the 1st atmospheric transparency window (8–13 μm) and in the 2nd atmospheric transparency window (16–25 μm)(8). This approach requires the cooling material to have high emissivity around those atmospheric windows.

In this work, a multiple functional shell fabricated by stereolithography (SLA) technology was developed. We demonstrate the mechanical and weatherability of a spherical robot shell made of SLA 3D printed resin.

Keywords: 3D-printing; mechanical simulation; weathering resistance; sphere robotics; thermal radiation

Stress Management by Design in Two-Photon Polymerization Printed Structures Sarah M. Fess1, David R. Harding1,2, Mark Bonino1 and Yongfeng Lu1; 1University of Rochester's Laboratory for Laser Energetics, United States; 2University of Rochester, United States; 3University of Nebraska–Lincoln, United States

Two-photon polymerization (TPP)-printing millimeter size components with sub-micron features and resolution is an attractive alternative to traditional chemical and machining processes, as it holds potential for increased yields and high controllability. However, maintaining design fidelity can be a challenge in the face of stress-induced deformations which occur during and after the printing process, caused by localized volumetric shrinkage as polymer networks form. This is especially true when many print blocks must be stitched together to form a contiguous larger structure. The extent and manner of deformation can vary greatly depending on print conditions and structural design, even for a single resin, and can lead to misalignment and discontinuity at the stitching boundaries.

Within the limitations of a commercially available TPP system and resin (Nanoscribe PPGT+Zeiss 63x NA1.4/IP-Dip2) we seek to fabricate millimeter-scale thin-wall spherical shells with stochastic foam liners for laser-driven fusion experiments. For this application, it is important to maintain wall uniformity and structural integrity across stitching boundaries, and to minimize bulk out-of-roundness. Observed bulk structural shrinkage for IP-Dip2 is typically 5-10%, which can be compensated for by oversizing the design. However, individual high aspect ratio or cantilevered print blocks such thin-wall curved surfaces can deform by >10-μm over a 200-μm arc length. Here we present a method for preemptive stress management via design by using nTop software to section and pre-deform print blocks to correct for anticipated in situ polymerization shrinkage, to within 1.5-μm of the intended location, or on
par with the stage repeatability. Characterization of the stitching boundaries via scanning electron microscopy (SEM) and atomic force microscopy (AFM) provides critical feedback for the design and print approach. The intended result is a printed structure with minimal stitching defects and high fidelity compared to the original design.

8:00 PM SF01.03.04 Laser Powder Bed Fusion Fabricated Near Grain-Oriented and Near Non-Oriented Silicon Steel: A Study on Texture Components and Magnetic Properties Fanbo Meng, Sheng Huang, Xiaojun Shen and Christopher H. T. Lee; Nanyang Technological University, Singapore

The rapid development of additive manufacturing techniques has opened up new possibilities for the production of complex metallic components with tailored properties. Silicon steel, as the most widely used soft magnetic material, necessitates different texture components to meet diverse requirements of various applications (i.e., static machine and rotating machine), and thus is typically categorized as grain-oriented and non-oriented. However, how to fabricate such types of silicon steel via laser powder bed fusion (LPBF) has not been comprehensively investigated until now. In this study, LPBFed near grain-oriented and near non-oriented Fe-3.5 wt.%Si silicon steel is obtained by designing processing parameters. The morphology of the molten pool is characterized through optical microscopy (OM) and scanning electron microscopy (SEM), and various texture features are explored using electron backscatter diffraction (EBSD). Besides, dynamic magnetic properties are assessed by conducting the alternating current (AC) method. The results indicate that the reduction of linear energy density (LED) and laser power induces the side morphology of the molten pool to change from large, flat, and well-overlapped to small, protuberant, and less-overlapped, where this change leads to the formation of an exceptionally pronounced <001>/⟨110⟩ building direction (BD) (i.e., ⟨001⟩ texture) or random distribution of grain orientations, respectively. Meanwhile, by simultaneously decreasing the laser power and scanning speed, the top morphology of the molten pool transforms from a teardrop shape to an elliptical shape at the trailing edge, which ultimately causes a shift in the angle between the <001> crystallographic orientation of grains in the ⟨001⟩ texture and the scanning direction from 45° to 30°. Moreover, samples with fewer defects (i.e., larger grain size and fewer pores) and a larger area fraction of <001> parallel to applied magnetic field perform better in dynamic magnetic properties (specifically, higher permeability and flux density), although the extent of this superiority is limited by residual stress and high dislocation density in the as-built samples. This study provides insight into the correlation of processing parameters, texture evolution, and dynamic magnetic properties in LPBFed silicon steel. The results could provide a design reference for LPBFed soft magnetic materials, which further provides the possibility of utilizing additive manufacturing in assisting in fabricating electromagnetic machines.

8:00 PM SF01.03.05 Rigid and Tough Composite Additive Manufacturing using Co-Axial Material Extrusion of Hard Thermoplastic and Soft Elastomer Taemin Kim and Sanha Kim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Multi-material additive manufacturing (MMAM) can realize three-dimensional products with extreme complexity not only in their shape but also in their mechanical behavior. Direct writing, vat photopolymerization and material jet type AM techniques have shown their versatile capability to print multiple polymeric materials, yet materials are limited to UV-curable resins and thermoset polymers. Material extrusion 3D printers had also been attempted to print multiple thermoplastics, but the weak interfacial bond due to the cold-hot welding between one layer and the next causes poor overall mechanical properties. Herein, we invented a new multi-material extrusion 3D printer which can extrude thermoplastic polymers in a core/shell configuration. We design and fabricate the nozzle to independently feed three filaments from right, left, and center, which are heated up to melt and unite each other right before the extrusion. In particular, when we insert the right and left filament as the same material, we can print dual-material layer in a co-axial mode. Such strategy allows strong interfacial bond between the different materials even when the two materials have large contrast in mechanical properties. As a result, we observe unprecedented properties with certain combinations. By extrusion printing the polyolactic acid (PLA) and the thermoplastic polyurethane (TPU) in co-axial configuration, for example, we can realize a 3D specimen which exhibits stiff as the hard PLA yet elongates as the soft TPU before failure, therefore possess an extreme rigidity and toughness. In detail, the core/shell extrusion printing enables the brittle PLA core to elongate about 30 ~ 50 times more than their original fracture strain, and such super-ductility is driven by the chemical bond between the two extruded materials. We further investigate diverse thermoplastic polymer combinations and verify that such exceptional outcome is only possible when a strong interfacial adhesion develops via the existence of hydrogen bonds. We discuss the fracture mechanism of our extruded co-axial polymer fibers and the chemical aspects at the interface. We also show a more variety of functionality that can be realized by extruding three different filaments in the co-axial nozzle. Applications that are now possible via bi-material and tri-material extrusions show that co-axial multi-material extrusion 3D printing opens a new avenue toward versatile material design, for additive manufacturing of fully customizable protective wearable devices and artificial muscles.

8:00 PM SF01.03.07 Challenges and Opportunities for Machine Learning Accelerated Materials Qualification for Brittle Particle Cold Spray Cheng Zeng, Andrew Neils, Nathan Post and Jack Lesko; The Roux Institute at Northeastern University, United States

Brittle particle cold spray is a low-pressure and low-temperature manufacturing technique developed by TTEC, a company based in Virginia. It can produce dense brittle particle coatings at a high deposition rate and low-energy cost with unlimited thickness. Applications include high temperature thermal barrier coatings, all-solid-state batteries and corrosion resistant coatings. However, the application of this technique to new material systems currently requires extensive trial and error to get the correct size and morphology distributions and spray parameters. In order to accelerate qualification of new materials for this process improved understanding of the mechanics of particle impact and consolidation is required. The mechanism of impact consolidation can span in different length scales, ranging from atomic chemical bonding to mechanical interlocking. Moreover, the complex cold spray technique involves multiple physical phenomena, such as fluid dynamics, aerodynamics, heat transfer and deformation. A combined multiscale and multiphysics approach is needed to develop a thorough fundamental understanding of brittle particle cold spray. Recent advances in machine learning approaches have great potentials in improving our understanding for linkages between process-structure-property. Here, we review current multiscale and multiphysics methods, and machine learning algorithms for cold spray technology, and we discuss remaining challenges and present an outlook for future research opportunities in this area.

8:00 PM SF01.03.08
Reliable printing of materials onto any surface, regardless of its shape, is a key enabling technology for many processes. Traditionally, most additive manufacturing techniques require a 3-axis gantry system which only moves planarly in the XYZ directions, limiting the type of print surface and the orientation achieved relative to the surface. Print direction and orientation is widely known to largely affect the material properties of additively manufactured components especially in prints using anisotropic materials. Recently, there has been increased interest in additive manufacturing using 6-axis robotic arms, however, research is limited on how the additional degrees of freedom of motion affect the material properties compared to a gantry system. This work investigates the effects on the anisotropic material properties by utilizing the additional degrees of freedom the robotic arm enables to maintain the direct ink write (DIW) nozzle constantly normal to a contouring surface. We compared the printed components produced by a 6-axis robotic system to a traditional 3-axis gantry system to investigate how remaining normal to the print surface affects the mechanical properties, fiber alignment, and geometrical accuracy. The research will compare the similarities and differences of the robotic system to the traditional gantry system using anisotropic carbon nanotube carbon fiber Epon 826 resin along a contoured surface, which has relevance on structural materials, electronics, and flexible devices.

8:00 PM SF01.03.10
Optimizing Process Parameters in Selective Laser Melting for Enhanced Mechanical Properties of 17-4PH Stainless Steel
KyuHyun Kim and In-Suk Choi; Seoul National University, Korea (the Republic of)

Selective Laser Melting (SLM) is a key technique in metal 3D printing, involving the repeated melting of metal powder using a laser, followed by its layer-by-layer solidification. This technique enables the fabrication of products with intricate designs and complex geometries, making it indispensable in high-precision industries such as aerospace, automotive, and healthcare. However, the rapid heating and cooling during the layering process could induce porosity and changes in the microstructure, which may significantly reduce the durability and strength of the components.

In this study, we examined the influence of porosity and microstructure on the mechanical properties of components produced using 17-4PH stainless steel powder, a material predominantly employed in the aerospace sector. Initially, we modulated the energy density by varying laser power and scan speed, and monitored the evolution of porosity via Optical Microscopy (OM). Following this, we analyzed the microstructure and phase fraction with Scanning Electron Microscopy (SEM) and Electron Backscatter Diffraction (EBSD), and investigated the correlation with mechanical properties derived from hardness and tensile tests. Ultimately, we aimed to identify optimal process parameters that minimize porosity and maximize mechanical performance through control of phase fraction changes.

The findings of this research underline the importance of porosity and microstructural control in SLM processes, as they significantly impact the quality of materials and performance of parts. This insight is anticipated to draw considerable attention, particularly in the aerospace industry, where high-strength components are of critical importance.

8:00 PM SF01.03.13
Ultrahigh-Strain-Rate Tribological Nonlinearity and Adhesion Mechanism of Diblock Copolymers for Polymer-Based Cold Spray
Ara Kim1, Sinan Mufidi2, Edwin Thomas3 and Jae-Hwang Lee1,1; University of Massachusetts Amherst, United States; 2Northeastern University, United States; 3Texas A&M University, United States

The adhesion strength between feedstock microparticles and pre-deposited layers and the collision-induced material behaviors determine the quality of cold-sprayed products. Unlike ductile metals, polymers having weak intermolecular interactions present severe nonlinear dynamic response due to their rate-dependent and temperature-dependent material characteristics resulting from the relatively slow macromolecular dynamics with low phase transition temperature. The distinctive complexity requires a comprehensive understanding of the collision-induced rheological changes near the collision interface, affecting interfacial friction and determining adhesion during impact. However, the interfacial response during ultrahigh-strain rate (UHSR) collision has not been thoroughly studied. As an experimental approach to gain deeper insight into the collision-induced rheological characteristics of polymeric microparticles at the collision interface, the angled laser-induced projectile impact test (θ-LIPIT) with an off-normal incidence angle was introduced in this work. A colliding microparticle with 45 degrees of the incidence angle undergoes moderately distributed compression and shear motions without arresting at the target substrate during the UHSR collisions.

Controlling or predicting the dynamic nonlinearity of polymers resulting from the rate- and temperature-dependent material properties is crucial for the applications of polymers in cold spray additive manufacturing. Therefore, diblock copolymers consisting of mechanically distinctive multi-domains are intriguing materials as their material properties are tailorable by adjusting the volume fraction of the respective chain blocks. Polystyrene-block-polydimethylsiloxane copolymers having glassy- and rubbery-domains are used for microparticle production. Using a lab-built ultrasonic atomization system, block copolymer solutions are solidified into spherical microspheres with 10–30 μm diameters via spraying and hot-air solvent drying. These microspheres are then impacted onto rigid substrates such as silicon wafers during the θ-LIPIT.

Due to the relatively large incidence angle and diameters, adhesion of microspheres does not occur in the θ-LIPIT but minor polymeric residues are occasionally found on the surface of the substrate. Impact and rebound velocities are decomposed along the horizontal and vertical directions to the collision surface, and the resultant coefficients of restitution are used to quantify the effective coefficient of friction representing the UHSR rheological changes of a microparticle at the collision interface. The effective coefficients of friction obtained from the θ-LIPIT reveal that the collision-induced rheological changes resulting from thermal softening near the collision interface determine the tribological nonlinearity during the UHSR event. Furthermore, it is further thought that this rheological response could alter the adhesion strength of the polymer microparticles by increasing chain mobility. The rheological changes of polymeric microparticles are thus thought to determine their adhesion behavior as the compression-induced shear stress flow along the tangential direction to the collision surface is expected to generate thermal softening in the material near the interface.

Systematically conducted research with θ-LIPIT demonstrates the collision-induced rheological changes near the interface and the resultant tribological conditions for adhesion during UHSR collisions. The demonstrated methodology in this study is expected to be utilized to examine the cold spray applicability of polymers and to predict spraying conditions for cold spray using solid-state consolidations of feedstock powders.

Metrology of Shrinkage-Induced Deformation in Structures Made using Two-Photon Polymerization
Mark Bonino, David R. Harding, Sarah M. Fess, Madelyn J. Jeske and Mitchell J. Anthamatten; University of Rochester, United States

Two-photon-polymerization (TPP) printing provides a deterministic method compared to traditional processes for fabricating millimeter-size spherical and hemispherical polymer parts with nanometer precision. The small print field (<0.2 × 0.2 mm²) needed to achieve the highest resolution, however, requires...
individual blocks be printed and “stitched” together to achieve the final component. A consequence of this methodology is that shrinkage from polymerization and the residual stresses in the printed polymer create a misalignment of up to 10 μm with the adjacent print block; these offsets need to be reduced to less than 1 μm. Fortunately, the TPP process is sufficiently precise that the misalignments can be compensated in the design, provided the magnitudes and locations are accurately known.

This presentation describes the metrology used to characterize highly curved surfaces (radius of curvature <1 mm) of spherical and hemispherical structures. The change in curvature of individual print blocks along their lengths and widths is quantified for different laser doses (combination of laser power and scan speed) and print-block sizes, and is used to optimize the printing conditions for improved surface roughness and sphericity. Atomic force microscopy and variable-pressure electron microscopy are used to acquire the data. The quality control and metrology techniques applied to TPP shells are presented.

This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003565, the University of Rochester, and the New York State Energy Research and Development Authority.

8:00 PM SF01.03.15
Reducing the Anisotropy in Fused Filament Fabrication Additive Manufacturing by Blending a Diels-Alder Covalent Adaptable Network with Polycaprolactone Derek J. Bischoff and Michael E. Mackay; University of Delaware, United States

Additive manufacturing (AM) is an emerging polymer processing technique that allows users to create complex geometries and customized forms with ease in addition to rapidly prototype designs, making it a valuable tool for product development. The most popular AM technique is based on material extrusion where spools of thermoplastic filament are the raw material that is fed into a hot end where it is melted and extruded through a nozzle on the order of 0.4mm in diameter. The deposited tracks of material are stacked on top of each other in a layer-by-layer sequential manner to build the object. A variety of thermoplastics are commercially available such as polyactic acid (PLA), acrylonitrile butadiene styrene (ABS), and polyethylene terephthalate glycol (PETG) to use on consumer grade desktop machines such as a Prusa i3 MK3S. A limiting factor of these materials is the high degree of anisotropy when 3D printed, as determined by printing tensile testing specimens where the interface between tracks is either parallel (stronger) or perpendicular (weaker) to the tensile stress. The mechanical strength of printed objects is limited by the healing that occurs at the interface. Since interfaces are required to build in the Z-direction off the bed, the term Z-strength is typically used. Due to the highly non-isothermal nature of the printing process, the thermoplastic material only remains above Tg, enabling the reptation and entanglement of polymer chains across the interface, for a brief period of time, on the order of a second. To eliminate the anisotropy in printed objects, new materials specifically designed for AM are necessary that shift the strengthening mechanism from polymer chain diffusion to something else.

Thermosets are the other major class of polymers that contain crosslinked chains to form a network architecture. The static crosslinks that offer improved mechanical properties and dimensional stability prevent thermosets from flowing, making them incompatible with the AM process. By using reversible covalent bonds in place of static crosslinks, thermosets are transformed into covalent adaptable networks (CANs). CANs behave as thermosets when the reversible covalent bonds are in their adduct state, but can flow when the bond exchange reaction is activated upon exposure to an appropriate level of stimulus (heat, light, pH, etc.). One such reversibly dynamic covalent bond is made from the Diels-Alder (DA) reaction between furan and maleimide functionalities. When exposed to a thermal stimulus, the covalent bonds begin to dissociate and exchange, enabling the CAN to flow as a viscoelastic fluid at elevated temperatures. Upon cooling, the material recovers crosslinking density and the rate of bond exchange slows. CANs have been used successfully in the AM literature to reduce the anisotropy in printed objects since covalent bonds form between tracks, however, they typically require specialized machines using cold air on the build plate to cool the object or use a syringe loaded with the material, necessitating a custom feed system different from the usual thermoplastic spools. In this work, a highly crosslinked DA CAN is blended with polycaprolactone (PCL) to create a semi-interpenetrating polymer network (IPN) that has enough flexibility to be extruded into a spool to be used in commercially available 3D printers without modification. Without the PCL, the DA CAN is too stiff preventing it from being spoiled. The CAN/PCL semi-IPN is shown to reduce the degree of anisotropy from >60% in PLA for example to only 11%. Microscopy of the cross sections reveal that the void space typically found in between tracks of material has vanished and is attributed to the viscosity of the material at the printing temperature. The fracture surfaces reveal that a ductile failure mechanism takes place in the tensile testing specimen, improving the toughness of the material compared to pure DA CAN.

Development of Filament Manufacturing Technology and Selection of 3D Printing Process Parameters for Biodegradable Material Blends to Optimize Print Quality Piotr Makula, Anna Dmitruk, Pawel Kaczynski, Joanna M. Ludwiczak and Mateusz Skwarski; Wrocław University of Science and Technology, Poland

Biodegradable materials are increasingly being used, with their utilization being legislated in some cases and a conscious choice of users in others. Polyactic acid (PLA) is a commonly used biodegradable material for 3D printing in Fused Filament Fabrication (FFF) technology. Besides its print hardness, the low purchase cost also contributes to its popularity. The study has shown that effective utilization of mixtures of Poly(lactic acid) (PLA) with poly(butyleneadipate-co-terephthalate) (PBAT) or thermoplastic starch (TPS) for 3D printing is possible. The aim of their production is to modify the mechanical properties of PLA by increasing its flexibility while maintaining the biodegradability of the material. After analyzing the literature, a successful attempt was made to produce a filament with a diameter of 2.85 mm, which was later used to manufacture samples. The material, after the extrusion process, underwent three consecutive drawing operations through a die on a specially adapted drawing machine. These operations were carried out to reduce and stabilize the filament diameter. The mixtures were prepared in the following mass ratios:

PLA50%-PBAT50%(PBAT50)
PLA30%-PBAT70(PBAT70)
PLA50%-TPS50%(TPS50)
PLA30%-TPS70(TPS70)

The printer parameters were calibrated before starting the sample printing, which ensured the correct structure of the prints. The tensile tests were initially conducted on the elements printed perpendicularly to the tensile axis. During the printing process, temperatures ranging from 190-270 degree Celsius [C] were set, with a step of 1°C. The aim of that test was to determine the optimal temperature that provides the best layer bonding. At the most optimal temperatures (PBAT50 - 230°C , PBAT70 - 220°C, TPS50 - 210°C, TPS70 - 210°C), the samples were destroyed by brittle fractures rather than layer delamination.

The next research step was to test the strength of longitudinally printed samples. The experiment showed that when the layers were arranged in this orientation, the material strength was comparable to the homogeneous material obtained through injection molding. The PBAT50 material exhibited layer delamination during stretching, but it did not fracture in a brittle manner. In the case of the second material, PBAT70, the samples behaved like a typical ductile material during stretching. They stretched evenly along their entire length, and no local necking occurred. Mixtures of TPS with PLA, when printed like the previous samples, exhibited more brittle fractures. However, the mechanical values were comparable to those of homogeneous samples.

In the summary of the study, a comparison was made between the obtained results and the results obtained from tests on homogeneous samples produced
by injection molding. The results show that the material printed perpendicular to the stretching axis can withstand a 70% of the strength of the homogenous material. The same result was obtained for all mixtures. Longitudinal printed samples achieved similar results in terms of strength and the shape of the stress-strain curve. However, they present a faster decrease in strength immediately after exceeding the yield point.

The conducted research can be effectively utilized in further studies and to model the behavior of the material for finite element analysis methods.

**Study on the Multifunctional Sandwich Structure Fabricated by 3D Printing**

Hui-Jin Ung1, Na-Hyun Jeon1 and Hak-Sung Kim2, 3; 1Hanyang University, Korea (the Republic of); 3Hanyang Research Center for Advanced Semiconductor Packaging, Korea (the Republic of)

Reducing fuel and energy consumption, greenhouse gas emissions, and other air pollutants is a major goal for the global transportation sector, including aerospace, automobiles, and railways. As an approach to achieving this goal, there has recently been a growing movement to change internal combustion engines to hybrid or electric engines. Secondary batteries, such as lithium batteries, are mainly used as energy sources for electric vehicles (EVs), so studies are being conducted to increase mileage. One way to increase mileage is to have a high-capacity battery, which requires more space for batteries and increases the weight of the vehicle. For this reason, reducing the weight of the structure is essential to achieve longer mileage. There is a growing interest in structural design using fiber-reinforced plastic composites instead of steel and aluminum. Especially, carbon fiber-reinforced plastic composites (CFRP) with high specific strength and non-rigidity are in the spotlight.

To achieve higher mechanical load-bearing properties using lightweight materials such as CFRP, a sandwich structure consisting of skins and cores can be applied to the structural design. The core of the sandwich structure mainly uses low-density plastic foam or consists of a lattice structure to increase bending properties while lowering the overall weight of the structure. These sandwich structures can be applied to multifunctional structures that can increase energy storage capacity and save space for electric vehicles. The sandwich structure of the neutral axis is hardly affected by the load, so the battery can be integrated into that position to provide reliable energy storage. Thomas et al. integrated a LiPo battery into a foam-core sandwich structure and analyzed mechanical properties through the bending test. However, the flexural failure strength of the multifunctional sandwich structure was reduced by 57%, and the bending load partially increased the battery’s internal resistance. In other words, the load-bearing properties and energy storage capabilities of multifunctional structures are in conflict with each other.

In this study, the multifunctional sandwich structure using lattice structure cores was designed and manufactured to overcome these limitations. 3D printing technology using continuous carbon fiber filament was applied to implement a lattice structure of complex shapes. The multi-functional composite sandwich structure was manufactured by embedding a LiPo battery using an empty space in the 3D-printed corrugated lattice core. Static and cyclic 3-point bending tests were conducted for analysis of the mechanical characteristics. The battery capacity change was analyzed through battery charge/discharge test before and after the mechanical tests. For the 3D-printed corrugated sandwich structure, the mechanical characteristics were maintained regardless of whether the battery was embedded or not, and the battery was not damaged by external loads. In other words, the battery damage caused by external loads was minimized by utilizing the empty space of the core of the lattice structure, and the degradation of mechanical characteristics was minimized.

**On-Demand Rapid Fabrication of Components using Forward Operating Base Aluminum Waste**

Danyang Zheng, Yutao Wang, Mishra Brajendra and Jianyu Liang; Worcester Polytechnic Institute, United States

According to the study conducted by the US Army Research Laboratory (ARL), and the US Natick Soldier Research Development, and Engineering Center (NSRDEC), aluminum waste makes up the Second largest category of metals in solid waste generated on forward operating bases (FOB). Therefore, an agile manufacturing process that can reclaim and recycle aluminum waste on battlefields is highly desirable. In this project, a 3D printing-enabled rapid-casting manufacturing process was developed to reuse Al waste and a mobile foundry system based on this process has been designed. This remanufacturing process includes three main stages: the preparation stage, the casting stage, and the post-treatment stage. It starts from the 3D design of the casting mold, using advanced software to conduct a simulation to minimize the defects in the cast parts. Then 3D printing is used to fabricate the polymer pattern according to the design. These polymer patterns are covered with coating. After drying, the patterns are removed by a burn-out process to obtain the needed cast molds. On the other hand, the waste metal alloys from FOBs are collected and sorted. The harmful impurities are removed. The Al wastes are then blended according to the desired composition of the target product. This composition can be further adjusted during the melting process. After the molten metal with the desired composition is obtained, it is poured into the cast molds. Finally, after the solidification of the metal, the mold is removed, and necessary post-treatments are conducted to ensure the quality of the parts. The information obtained from quality control can be used as feedback to further improve the mold design and the composition adjustment for re-alloying.

A mobile foundry design that places this rapid casting process in standard-sized shipping containers as developed to efficiently convert battlefield waste into valuable products. The mobile system consists of three containers: the first for investment preparation, the second for casting and heat treatment, and the third for product characterization. A simulation has been conducted to ensure the safety of the casting container.

In this presentation, the results and outcomes of this project will be discussed. The lessons learned and future work will be introduced.

**3D Printing and Biocementation of Hierarchical Porous Ceramics**

Alessandro Dutto, Elena Tervoort and André R. Studart; ETH Zürich, Switzerland

Novel low-cost and low-energy strategies for the consolidation of ceramic materials are demanded to reduce the environmental impact of the building sector. Living building materials containing soil microorganisms have shown to be a promising strategy to bind together aggregates or sand-based materials into bricks at room temperature taking advantage of the microbiobly induced precipitation of calcite (MICP).

The effectiveness of the precipitated calcite network in providing the required structural integrity relies on the uniform distribution and activity of the microbes, as well as the availability and diffusion of nutrients and precursors for the MICP throughout the bulk of the material. Current technologies overcome the limits of diffusion by actively pumping a calcifying solution and by optimizing the calcification setup. Despite the commercial use of this approach, partial clogging or the formation of an outer calcite shell hinder the access of further precursors and thus remain unsolved challenges of this technology.

Here, we take advantage of additive manufacturing to develop and study a bio-cementation process to create strong, porous ceramics at room temperature. Hierarchical porous structures were produced via direct ink writing of cellular grids using bacteria-laden suspensions of ceramic hollow spheres. The effect of geometry, bacterial concentration, and calcification time on the bio-cementation process and the resulting mechanical properties were investigated. The presence of a millimeter-sized open porosity was found to be essential to maintain a high permeability to the precursors during the entire process, ensuring
an optimal MICP throughout the material. The presence of porosities at multiple length scales has a beneficial effect on both the bio cementation process itself and on the mechanical efficiency of the produced structures. Combining 3D printed hierarchical porous structures with the low-energy consolidation process of MICP, allows us to produce strong, porous ceramics with reduced environmental impact.

High Pressure Heat Treatment for Porosity Reduction of Binder Jet 17-4 PH Stainless Steel
Ellen Troynowski, Chuhao Li, Richard Sisson and Jianyu Liang; Worcester Polytechnic Institute, United States

The age hardenable 17-4 PH stainless steel has been additively manufactured (AM) using the binder jet (BJ) method. To achieve comparable mechanical properties to wrought steel, the porosity must be reduced in the AM steel. Two sets of BJ, one starting with high porosity and the other low porosity, are treated to the traditional 900H age hardening treatment or a combined hot isostatic pressing (HIP) and 900H treatment, referred to as High Pressure Heat Treatment (HPHT). The effects of change in porosity and pore morphology on the microstructure, mechanical properties, and distortion are examined. These experimental results indicate that the HPHT process is more effective than the 900H treatment at reducing porosity and improving performance.

Dual Material Fused Filament Fabrication via Core−Shell Die Design
Ahmad Naqi1,2 and Michael E. Mackay1, 1University of Delaware, United States; 2Kuwait University, Kuwait

In this work a fused filament fabrication (FFF) die design, capable of extruding two thermoplastics simultaneously in a core−shell configuration, is demonstrated as a means to produce composite structures in a single step. Despite the enormous advancements in 3D printing, fabrication of FFF objects with a composite structure remains a challenge due to the difficulty in finding dies to extrude such structures. We used polyethylene terephthalate glycol (PETG) and high-density polyethylene (HDPE) filaments to perform core−shell 3D printing. HDPE is one of the most commonly produced plastics but rarely used in FFF due to the severe warpage caused by volume changes upon its crystallization. Rheological and thermal analyses suggest the use of HDPE as a shell material due to its extremely short reptation time and sharp melting peak that facilitate superior surface contact and interlayer weld strength at the interface between neighboring FFF tracks. PETG is a commonly used 3D printing filament with excellent printability and sufficient zero shear viscosity to help maintain the extruded filament shape against shrinkage induced by the HDPE shell.

Impact and tensile properties of core−shell objects revealed tremendous improvements in the impact resistance and toughness especially at 30 vol % HDPE shell with 120% and 150% enhancement in impact resistance when compared to individual components: PETG and HDPE, respectively. Scanning electron microscopy was used to analyze the fracture morphology of the tested specimens to obtain an understanding of the fracture mechanism leading to the increased impact resistance. Using this die design can help open avenues of fabricating high impact resistance materials suitable for high performance applications and using HDPE in 3D printed objects with its superior solvent resistance.

Laser Powder Bed Fusion of TiB2-Reinforced 316L Stainless Steel Composites with Excellent Mechanical Properties
Wuxian Yang1, Jian Liu1, Wen Chen1 and Tianjia Li2; 1University of Massachusetts at Amherst, United States; 2Argonne National Laboratory, United States

Laser powder bed fusion (LPBF) additive manufacturing is an emerging technology that enables melting and consolidating powders layer by layer, which has high potential in developing novel alloys with highly refined microstructures. This study discusses the unique microstructure and superior mechanical properties of additively manufactured 316L steel composites reinforced by various amounts of TiB2 ceramic phase. Scanning electron microscopy (SEM), transmission electron microscopy (TEM), and in situ synchrotron X-ray diffraction are used to analyze the microstructure and deformation behavior of the 316L/TiB2 composites. The TiB2 particles are homogeneously distributed in the 316L matrix. The 3 vol% TiB2 reinforced sample exhibits a high ultimate tensile strength over 1.3 GPa with a large uniform elongation of 18%. Such mechanical properties well surpass those of other additively manufactured 316L steel composites. Hence, the LPBF process shows high potential for fabricating advanced ceramic-reinforced metal matrix composites with outstanding mechanical properties.

Effects of Printing Direction and Layer Thickness on the Mechanical Properties of 3D Printed Polymer Laminates
Ammar Batwa and Yaning Li; Northeastern University, United States

For polymeric additive manufacturing (AM), printing direction and layer thickness are critical processing parameters that directly impacts the effective mechanical properties of the final polymeric laminates fabricated via polymer jetting AM technology. To fully exploit AM potential for fabricating polymeric composites, it's crucial to have a deep understanding of the effects of these factors during the printing processes. This research aims at evaluating the effects of printing direction and layer thickness on the effective mechanical properties of 3D printed polymer laminates.

The printing direction is defined via the angle of the specimens relative to the movement of the print head. Specimens of stratified composites fabricated via combining glassy and rubbery polymer layers with various layer thickness are designed and fabricated via a multi-material 3D printer (Stratasys Connex3). Mechanical experiments are conducted to evaluate both the layer thickness and printing directions collectively influence the overall mechanical properties of the designs. Digital Image Correlation (DIC) is used to track the local and overall strain of the specimens during deformation. The microstructures of the specimens are explored via Scanning Electron Microscope (SEM) imaging. Nanoindentation experiments are performed to quantify the transition in stiffness across dissimilar material interface. The results show a significant correlation between the mechanical properties of the final printed laminates, the properties of the dissimilar interface/interphase, and the printing direction and layer thickness.

Controlling Microstructures and Modulus in Direct Ink Writing of Stainless Steel for Biomedical Applications
Havva E. Ayad1, Brian K. Paul2, Chih-hung Chang2 and Konstantinos Sierros1; 1West Virginia University, United States; 2Oregon State University, United States

As metals are employed in additive manufacturing at an accelerated pace, environmentally friendly, and less-cost 3D printing processes are required. Direct ink writing (DIW) is a highly versatile technique that utilizes solution-based formulations, known as inks, which exhibit shear-thinning behavior and can accommodate a wide variety of unique precursors. In this study, we present environmentally safe binders for aqueous bio-based metal inks, specifically exploring cellulose-based binders engineered for rheological compatibility with DIW.

Furthermore, we investigate the use of novel inks to control the microstructures of the printed product. The effects of ink formulation, processing parameters, and post-processing techniques on the microstructure and mechanical properties of the printed objects are being explored. Specifically, the
Effect of Solidification Rate on Microstructure and Mechanical Properties of Additively Manufactured AlCrFe2Ni2 High-Entropy Alloys

8:00 PM SF01.03.31

Effect of Solidification Rate on Microstructure and Mechanical Properties of Additively Manufactured AlCrFe2Ni2 High-Entropy Alloys

Shengqian Zhang1, Chenyang Li2, Wei Chen’ and Wen Chen1; 1University of Massachusetts Amherst, United States; 2Illinois Institute of Technology, United States

The development of high-entropy alloys (HEAs) has attracted significant attention due to their potential for enhanced mechanical properties. However, the formation of undesired intermetallics in HEAs limits their practical applications. Additive manufacturing (AM) offers a promising approach to overcome this limitation by providing unique thermomechanical processing conditions that result in far-from-equilibrium solidification microstructures, leading to exceptional material properties. To fully harness the benefits of AM and HEAs, understanding the processing-structure-property relationship is crucial but challenging due to the complex phase selection and non-equilibrium microstructures formed during AM. In this study, we investigated the effect of solidification rate on the microstructure and mechanical properties of a laser additively manufactured AlCrFe2Ni2 HEA. By varying the laser scan speed, we observed distinct solidification features, including partitionless single-phase, anomalous eutectic, and coupled lamellar eutectic microstructures. These microstructures offer a wide range of strength-ductility combinations. Thermodynamic modeling and molecular dynamics simulations are performed to gain insights into the solidification mode transition from partitionless through anomalous eutectic to coupled eutectic as the solidification rate continuously decreases. Our findings demonstrate that AM enables access of a rich variety of phase and microstructure space for HEAs, expanding the material design possibilities for technologically relevant alloys.

Flexible pressure sensors enable to measurement various biological signals for long-term monitoring. Obtaining plantar pressure distributions and body weight measurements through wearable devices is significant for healthcare applications and monitoring various diseases such as diabetes, obesity, and heart failure. To detect the planter pressure of such disease patients, wearable, flexible pressure sensors with a high-pressure sensitivity range (1 MPa) can provide precise critical biomedical information. Among the various flexible pressure sensors, capacitive pressure sensors are among the most promising candidates owing to their simple fabrication process, rapid response, small hysteresis, and low power consumption. Despite these advantages, typical silicone rubber has a relatively low dielectric constant (2-3), contributing to low sensitivity. Therefore, porous structures at the dielectric layer and dielectric/conductor interface are essential for higher sensitivity because they reduce the initial dielectric constant and compression modulus. On the other hand, essential characteristics of stable operation, such as linearity over a wide range, have yet to be dealt with enough. Balancing the linear response and high sensitivity in porous structures remains challenging owing to the sensitivity saturation of porous materials. To the author's knowledge, no capacitive pressure sensor with porous structures that maintains linearity up to 1 MPa with a high sensitivity (> 10^-3 kPa^-1) exists.

This study proposes a capacitive flexible pressure sensor containing thermoplastic microspheres (TPM) with linearity and high sensitivity over a wide pressure range. The TPM expanded at relatively low temperatures (95–125 °C) and increased 50 times in volume. The TPM containing Polydimethylsiloxane (PDMS) was spin-coated to fabricate an elastomeric membrane with a homogeneous porous structure. Notably, the TPM has a large size distribution with the temperature increasing. This size distribution variety of porous TPM may contribute to the high sensitivity and enhance the linear response owing to the deformation of different sizes of pores under the different pressure. Owing to this characteristic of TPM, we achieved a pressure sensor with a high sensitivity (3.1 × 10^-3 kPa^-1) while maintaining linearity (R^2 = 0.996) under a high compression pressure (1 MPa).

Furthermore, the sensor responded within 100 ms under 140 kPa and indicated the durability by 10000 cyclic loadings. As a pressure distribution application, we implemented 3 x 3 multichannel pressure sensors with a large area (3.4 cm x 3.4 cm) to demonstrate the uniformity of the materials. In addition, we fabricated gait wearables that can detect body weight. As a result, a 4.9 kPa load fluctuation can be detected equally well in a high and low weight range without sensitivity compensation systems, such as non-linear fitting, which implies the significant potential to achieve reliable and simple wearable applications.

Flexible pressure sensors enable to measurement various biological signals for long-term monitoring.

Flexible pressure sensors enable to measurement various biological signals for long-term monitoring.
personalization of medicines, but difficult to achieve through traditional solid dosing and formulation approaches.

While tight control of feed location is easily accomplished using traditional 3D printer hardware, achieving a stable vapor flux is difficult, yet crucial. The source can be operated near vapor-solid or vapor-liquid equilibrium, allowing use of carrier gas flow as a linear control of flux. Faster flow rates drive the system away from equilibrium, presenting boundaries on the process window. In this talk we describe an apparatus configuration that can enable high, yet stable, deposition rates, linear control of rate, and greatly facilitated material handling.

8:00 PM SF01.03.37
Electrically-Driven Textile using Hierarchical Aramid Fiber Abdullah Islam and Shenuqiang Ren; University of Maryland, United States

High strength and flexible electronic textiles promise in aerospace, robotics, and extreme environment applications, while it is indispensable to develop functionally integrated fiber building blocks with the durable materials performance. Here we report multifunctional sensory e-textiles driven by using copper-grafted polyaramid (Kevlar\textsuperscript{®}) fiber networks for the integrated electromagnetic interference shielding, thermal and pressure response sensing. The hierarchical structural design and synthesis of flexible conductive networks is accomplished via the synergistic coordination between molecular copper complex and Kevlar\textsuperscript{®} fibers, which facilitate long-term cyclability, stability, and washability. Superior Joule heating capabilities with a rapid thermal response under a low driving voltage (a heating-up rate of 6 degrees C/s and a cooling-down rate of 5.8 degrees C/s), together with a high level of EMI shielding (80 dB from 8 GHz to 13 GHz), are resulted from its multilayer vertically-aligned structure with continuous percolation of conductive coating. This work presents a new and feasible grafting approach for the large-scale fabrication of multifunctional wearable e-textiles for use in extreme environments.

8:00 PM SF01.03.38
Fully Printed 2D Material-Based Memristors Alessandro Grillo\textsuperscript{1}, Zixing Peng\textsuperscript{1}, Aniello Pelella\textsuperscript{2}, Matthew Boyes\textsuperscript{1}, Xiaoyu Xiao\textsuperscript{1}, Minghao Zhao\textsuperscript{1}, Jingjing Wang\textsuperscript{1}, Zhirun Hu\textsuperscript{1}, Antonio Di Bartolomeo\textsuperscript{1} and Cinzia Casiraghi\textsuperscript{1}; 1University of Manchester, United Kingdom; 2University of Salerno, Italy

The von Neumann architecture relies on separate entities for the processing and memory functions, so these units engage in extensive and continuous data exchange. However, in the last few years the production and use of information is growing dramatically, leading to a new brain-inspired computing paradigm, where data storage and process are done by the same unit. In this framework, the memristor, which is a circuit element that can store information due to the phenomenon of resistive switching between two resistance states upon application of an external electric field, is gaining significant attention as non-volatile memory. 2D materials (2DMs) are very attractive for the next-generation memristors\textsuperscript{1,2} due to their flexibility, transparency, and compatibility with solution-based processing, enabling to use techniques such as inkjet printing for the cost-effective, and scalable integration of devices onto flexible substrates, like paper and plastic. In this study, we printed silver as the bottom electrode, graphene (Gr) as the top electrode and MoS\textsubscript{2} as dielectric, creating an Ag/MoS\textsubscript{2}/Gr heterostructure.\textsuperscript{3} After optimization of the fabrication process, the fully printed Ag/MoS\textsubscript{2}/Gr memristors on silicon exhibit performance comparable with those achieved in printed devices using silver electrodes or other nanomaterials like TiO\textsubscript{2} and ZrO\textsubscript{2} on rigid substrates.\textsuperscript{4} Furthermore, the same device, when printed on Kapton, displays stable memristive behaviour up to 3% of strain. The memristor resistance switching is attributed to the formation of Ag conductive filaments, which can be suppressed by integrating graphene grown by chemical vapour deposition (CVD) onto the silver electrode. Temperature-dependent electrical measurements starting from 200 K show that the memristive behaviour appears at temperature of ~300K, confirming that an energy threshold is needed to form the conductive filament. Interestingly, the CVD Gr integration also significantly reduces hysteresis, suggesting that CVD Gr not only serves as a barrier against ion migration but also improves the interface between the electrode and the dielectric layer, enhancing the reliability and reproducibility of the devices.

Printed Electrochemical Cu\textsuperscript{2+} and Cd\textsuperscript{2+} Ion-Selective Electrodes for Combinatoric Multi-Heavy Metal Ion Sensing Applications Maninder Kaur, Priya Vinayak, Henam Sylvia S. Devi, Bhaskar Mitra and Madhusudan Singh; Indian Institute of Technology Delhi, India

Requirements for onsite monitoring of heavy metals in utility water supply and in effluents include low sensor drift, and high sensitivity. While it is standard practice to detect ions in lower ppb ranges using laboratory analytical techniques including atomic absorption/emission spectroscopy and inductively coupled plasma-mass spectrometry, these techniques require careful sample preparation, a skilled operator and potentially long turnaround times for measurements from the site to the lab. Recognizing the health hazards posed by heavy metals, regulatory agencies like the Environmental Protection Agency (EPA) have specified permissible exposure limits for copper (1.3 ppm\textsuperscript{1}) and cadmium (5 ppm\textsuperscript{2}). Previous work\textsuperscript{3} has demonstrated the efficacy of low-cost potentiometric ion-selective electrodes for ppb-level detection of such species. Given several such ions of concern, and well-known and significant cross-sensitivities\textsuperscript{3} exist amongst them, and with other ions deemed to be safe for human health at naturally occurring levels, it is essential to develop multi-sensor chips for combinatoric sensing of heavy metal ions, possibly aided by machine learning (ML) methods. While individual ion-selective electrodes with custom sensing films can in principle be fabricated, traditional lithographic techniques are a) inapplicable (owing to foundry process contamination), and b) complex (owing to demands for a potentially large number of sensing layers). Thus, multi-ion sensors production at scale needed for real-time regulatory monitoring requires an alternative fabrication technology. In this work, we have used an inkjet printed Cds film to detect copper and cadmium ions in water. Cadmium acetate precursor (98%, Sigma Aldrich) was added (70°C, 15min) to ethylene glycol (98%, Qualigens), followed by addition of thiourea (99%, Sigma-Aldrich) under constant stirring (70°C, 3 hr), resulting in a bright yellow product (CdS). Elemental composition of the ink was validated by energy dispersive X-ray analysis (EDX, Hitachi), and powder X-ray diffraction (PXRD, Rigaku Ultima, Cu-K\textalpha, 1.54Å) indicating the formation of a pure hexagonal phase (ICDD: 96-900-8863) of CdS. Hydrodynamic nanoparticle size measurements (dynamic light scattering, Malvern Zetasizer) yield a value of 40.63±4 nm, indicating suitability for inkjet printing (Fujifilm Dimatix DMP2850, DMC11610 cartridge). After optimization of the fabrication process, the fully printed Ag/MoS\textsubscript{2}/Gr memristors on silicon exhibit performance comparable with those achieved in printed devices using silver electrodes or other nanomaterials like TiO\textsubscript{2} and ZrO\textsubscript{2} on rigid substrates.\textsuperscript{4} Furthermore, the same device, when printed on Kapton, displays stable memristive behaviour up to 3% of strain. The memristor resistance switching is attributed to the formation of Ag conductive filaments, which can be suppressed by integrating graphene grown by chemical vapour deposition (CVD) onto the silver electrode. Temperature-dependent electrical measurements starting from 200 K show that the memristive behaviour appears at temperature of ~300K, confirming that an energy threshold is needed to form the conductive filament. Interestingly, the CVD Gr integration also significantly reduces hysteresis, suggesting that CVD Gr not only serves as a barrier against ion migration but also improves the interface between the electrode and the dielectric layer, enhancing the reliability and reproducibility of the devices.

Soft Pressure Sensor Fabricated by Implementation of Ultrathin Silicon Strain Sensors on 3D-Printed Cantilever Structures for Cyber Physical System Car Seats Seiichi Takamatsu, Junya Nakagawa and Toshihiro Itoh; The University of Tokyo, Japan

To monitor the posture and driving behaviors of autonomous vehicles, we developed a car seat embedded with a soft pressure sensor array beneath its urethane foam layer. The soft pressure sensors feature a cantilever structure formed using a 3D printer, at the root of which thin MEMS piezoresistive sensors are wired. Monitoring the health and cognitive state of drivers is crucial, especially in the context of semi-autonomous vehicles up to Level 3. Traditional techniques often employ cameras and vital sensors to detect behavior, fatigue, and drowsiness. However, these methods can be limited due to factors such as lighting conditions and the driver's attire. Given that car seats are in direct contact with drivers, there is growing interest in embedding pressure sensor arrays within them to measure body pressure distribution. These sensors can complement cameras for a more robust driver-monitoring system. Previous research has shown that analyzing body pressure distribution can estimate a driver's attention and fatigue levels effectively. Driver posture, which is intricately linked to comfort, influences alertness; deteriorating comfort could lead to distractions. Also, there is a known correlation between a driver's alertness level, fatigue, and their driving posture. Despite its potential, current pressure sensor technology has limitations. Most research relies on expensive and uncomfortable electrostatic capacitive sensors, costing around $2000 per seat. This has led to a demand for low-cost, comfortable pressure sensors that can be integrated under the seat's urethane foam layer. However, placing sensors under the urethane foam is challenging. The foam's nonlinear deformation under load leads to reduced sensor sensitivity and inconsistent output. The foam material disperses the applied force between the sensor and its surrounding substrate, affecting the sensor's performance. To be effective, a pressure sensor array needs to maintain high sensitivity levels (0-10 kPa) and produce near-linear outputs in response to the applied force. This study developed a car seat equipped with a pressure sensor array beneath the urethane foam to monitor the driver's posture and driving behavior. Urethane foam exhibits nonlinear behavior, such as maintaining constant stress in response to varying displacement in the plateau region. Sensors placed under the urethane foam face challenges like producing nonlinear output signals and low sensitivity. In this research, we combined a low-cost pressure sensor, made of a 3D printer and MEMS sensors, with a unique embedding structure beneath the foam and a stress-concentrating design. This new driver-monitoring device aims to overcome the issues associated with sensitivity and linearity. The developed soft cover is attached to the pressure sensors to concentrate stress from the urethane foam.

Additionally, the area surrounding each sensor includes a base of the same height to prevent geometrically nonlinear responses. The sensors are integrated into the car seat's urethane foam in an array. The proposed pressure sensor exhibits a sensitivity range of 0-20 kPa. Through experiments, we demonstrated that the prototype sensor array could detect changes in the driver's posture as well as braking actions. The sensors in this structure hold promise for future applications in intelligent car seats for autonomous vehicles.

Computer Vision enabled Eye-In-Hand Robotic In-Situ Bioprinting of Multimaterials for Fast Wound Repair Seo-Hea Jeong and Su Ryon Shin; Harvard Medical School, United States

Current in-situ printing techniques depend on pre-determined printing paths in order to directly build complex functional architectures at injured areas, limiting adaptability in clinical scenarios. We present INSIGHT (INtelligence in-Situ printing Guided by Eye-in-Hand robot Technology), an innovative computer vision enabled system that combines a depth camera with a 6-degree of freedom robot arm, empowering it to identify arbitrary areas at various angles without pre-designed code and calibration procedures. Layer-by-layer volumetric printing approach is performed by dynamic image recognition based on color and contour differences, which achieves highly accurate printing through real-time adjustments and is capable of continuous targeting of multiple wounds. Dual printing modes, extrusion and spray printing, are designed for rapid printing with seamless switching between different bioinks. Through in vivo tests, INSIGHT demonstrates its practicality for targeting and treating diabetic wounds, highlighting its adaptability to enable customized care for rapid emergency treatment of trauma patients. In this research, as targeting to treat a diabetic wound healing, a microgel based bioink is introduced, which is mixed with a plant protein-based oxygenating microparticles and mesenchymal stem cells in order to boost angiogenesis and immune response at initial wound healing stage. We not only demonstrate the pressure sensor array could detect changes in the driver's posture as well as braking actions. The sensors in this structure hold promise for future applications in intelligent car seats for autonomous vehicles.

8:00 PM SF01.03.42
Printable Silicone Elastomers to Provide Magnetic Resonance Imaging Contrast for Medical Phantoms Michael Avery, Yasmine Osmani, Ben Dickie, Stephen Edmondson and Brian Derby; University of Manchester, United Kingdom

Phantoms are manufactured structures which mimic the properties of objects that are characterised by a range of different medical imaging technologies. They have a number of applications, including: standards for instrument calibration, reference samples to ensure common performance from multiple site experimentation, replacement for animal studies or human volunteers during training or technique development. Phantom development for magnetic resonance imaging (MRI) is particularly challenging because the imaging modality is the relaxation of the nuclear magnetic resonance excitation of protons that are ubiquitous in biological systems and these relaxation times (T1 and T2) are much longer than in conventional polymeric materials because of the presence of water and the soft matter nature of biological tissue. Thus, conventional MRI phantoms are based on aqueous solutions or weak gelling biological materials, e.g. alginites, agarose or carageen gels, doped with paramagnetic ions to further control the relaxation times. The phantoms themselves are thus limited to simple shapes, e.g. spherical or cylindrical cavities, and have poor long term stability. The use of MRI to guide radiological or surgical procedures requires more advanced shape control for the next generation of medical phantoms. This is particularly the case for surgical training but also for the generation of large datasets for machine learning where precise robotic control of beam placement and motion from intense X-Ray sources is desired for use in clinical radiology such as the MRI-Linac. The ability to replicate the unavoidable motion of internal organs (e.g. heart and lungs), while also mimicking complex tissue geometries, MR imaging properties and radiation response of tissues, is critical for advancing MR-Linac treatment. These medical challenges can be achieved by developing and engineering 3D-printed silicone soft-robotic “4D” phantoms, enabling a transformational step-change in the manufacture and function of medical phantoms. A successful soft robotic phantom must display the appropriate balance of mechanical properties, MRI contrast and manufacturability. Here we present materials development for 3D printable silicone
material that work towards overcoming this challenge. Robotic phantoms must present MRI relaxation times that simulate biological tissues, typically assessed using the time constants and for longitudinal and transverse relaxation respectively. Human tissue relaxation times can range from 600 – 3000 ms for and 35–240 ms for , although the precise range depends on the magnetic field used during a particular MRI scan. Therefore phantom materials should allow for significant and tunability. For soft robot fabrication, the challenge is to develop compositions that achieve the desired relaxation values while also maintaining mechanical properties comparable to those human tissues and pre-cure viscoelasticity suitable for printing.

Two strategies to achieve these desired material properties have been investigated, both following the principles of formulation of material blends using readily available commercial materials. The first uses commercial silicones that have been successfully used to print soft robotic structures but modified by blending with short chain, relatively mobile silicone oils. This gives good control of and but has limited long term stability of property variation due to the mobility of the short-chain oils within the polymer network. The second approach uses a multiphase composite concept rather than a blended composition. Both methods have been used with Direct Write Extrusion printing to fabricate 3D structures with defined variation of materials and these have been used in pre-clinical MRI scanners to demonstrate good imaging quality.

8:00 PM SF01.03.45
Microstructural Evolution Simulations in Additive Manufacturing and Post Heat-Treatment of Aluminum Alloys Jiwoon Park, Joo-Hee Kang and Chang-Seok Oh; Korea Institute of Materials Science, Korea (the Republic of)

The extreme solidification condition in metal additive manufacturing causes out-of-equilibrium phase transformation and unique microstructures: i) vertically connected grains across several layers along the building direction, ii) severe segregation of alloying elements on the inter-dendritic region and the absence of secondary phases, which expect to be formed under equilibrium condition. These microstructural features are of great importance in tailoring the desired properties. This work simulated the microstructural evolution of as-built and post heat-treated Al-Si-Mg alloy in a phase-field approach. Local grain orientation selection and growth morphology under rapid solidification and extreme thermal gradient conditions are studied and compared to electron back-scatter diffraction analysis. Then, the precipitation behavior of Si from super-saturated solidification microstructure is investigated. The formation of Si precipitate demonstrated above the solution-treatment temperature, which experimentally occurs. It reveals that the precise digital twin of mesoscale microstructure can be fabricated by phase-field modeling with specified thermal conditions.

8:00 PM SF01.03.47
On The Development of Bio-Compatible, Chemically Recyclable, 3D-Printable Silicones Sensea J. Velling1, Hongyi Zhang2,1, Sammy Shaker1 and Julia R. Greer1,2,3; 1California Institute of Technology, United States; 2Tsinghua University, China

Silicone is a versatile polymer material with many desirable characteristics, such as corrosion resistance, thermal stability, low toxicity, and its electrically insulating nature. It has widespread application in commercial, medical, and research scenarios. However, its irreversibly 3D crosslinked structure has impeded its recycling and manufacturing through thermoplastic extrusion-based 3D printing techniques. Similarly, its high gas permeability and crosslinking has prevented its application in UV-curing-based additive manufacturing techniques. Previously, it was reported that the photoinitiated thiol-ene click chemistry, where a thiol and an alkene connect to form a thioether, allowed the UV-crosslinking of mercapta-functionalized polysiloxane and vinyl-terminated polysiloxane thereby enabling the use of stereolithography 3D printing of silicone elastomers. Separately, introduction of disulfide moieties in polymer chains was shown to facilitate the chemical degradation of the cured material through base-catalyzed thiol-disulfide exchange reactions. This work targets the development of a chemically recyclable, 3D-printable silicone materials by integrating the thiol-disulfide exchange mechanisms within a photoinitiated thiol-ene silicone system. We show that disulfide moieties can be introduced into mercapta-functionalized polysiloxanes through a clean and facile iodide-catalyzed oxidative coupling reaction, and the resulting partially oxidized mercapta-functionalized polysiloxanes, when mixed with vinyl-functionalized polysiloxane and photoinitiators, can be UV-cured to form disulfide-containing silicone networks. Ongoing work focuses on performing chemical degradation on the cured disulfide-containing silicone, examining the viability of self-healing in such silicone elastomers via photodecataylzed disulfide metathesis, and characterizing the thermomechanical properties of silicones prepared from the recrosslinking of recycled polysiloxane oligomers. Together, these efforts will make possible the additive manufacturing of complex functional structures (e.g. microfluidic devices, cell scaffolds, O-rings and gaskets) from highly oxygen-permeable, hydrophobic, thermally and chemically resistant Silicones capable of self-healing and chemical recycling.

SESSION SF01.04: Session III
Session Chairs: Allison Beeze and Ting Zhu
Tuesday Morning, November 28, 2023
Sheraton, Second Floor, Republic B

8:00 AM SF01.04.01
Laser Powder Bed Fusion of Mixed Powders Christopher Hutchinson, Huikai Li, Erin Brodie and Sebastian Thomas; Monash University, Australia

Laser powder bed fusion (LPBF) of metals is a popular mode of additive manufacturing (AM) that has the advantage of producing complex shapes with little or no additional processing. However, an important limitation is that the metallic microstructures obtained are usually relatively simple solidification structures and there are few means available to enrich this without subjecting the components to subsequent thermal processing routines, which has its own difficulties due to dimensional control. This limits the microstructural complexity that can be achieved in components fabricated by LPBF and hence the properties obtainable.

In this work, we present and validate a physically-based model to predict the chemical distribution resulting from LPBF of physically mixed powders of different compositions. We demonstrate that mixing of powders with different compositions can be used to generate a deliberately controlled, mesoscale chemical heterogeneity in LPBF that allows the formation of multiphase microstructures and delivers new microstructural complexity to LPBF. A duplex stainless steel, consisting of equal fractions of ferrite and austenite in the as-built state is used as a demonstration of the approach. The model describing the chemical distribution in the consolidated build can be extended to describe remelting effects and exploited for the design of spatially varying microstructures. This provides a path towards generating architectured materials from random mixes of initial powders. Examples of using spatially controlled remelting to generate architecture materials for random powder mixtures will be shown.

This opens up an interesting path for delivering microstructural complexity to LPBF of metals.

8:30 AM SF01.04.02
Multiscale Process Control in Metal Additive Manufacturing Manvalilo Matthews; Lawrence Livermore National Laboratory, United States
Tremendous gains have been made over the past several years to improve understanding of defect formation in laser powder bed fusion (LPBF) processes and develop predictive material models that can guide process optimization. However, while control of defects may be achievable at a given length scale for a given material, there remain significant challenges in efficiently predicting and mitigating defects wholistically across length scales, e.g., grain-, melt pool-, feature-, part-scale. In this talk I will present efforts to improve the efficiency and accuracy of predictive models that describe defect formation across the multiple relevant length scales found in LPBF. Beyond predictions, effective means to implement defect mitigation solutions are also required. Efforts to manipulate the optothermal coupling in both custom and commercial LPBF systems will be discussed that begin to address such requirements. Prepared by LLNL under Contract DE-AC52-07NA27344.

9:00 AM SF01.04.03
The Use of Mechanically Derived Powders for Additive Manufacturing: Flow and Function David F. Bahr1 and John E. Barnes2; 1Purdue University, United States; 2Metal Powder Works, United States

Metal additive manufacturing (AM) provides the opportunity of “on demand” customizable fabrication to minimize supply chain constraints. However, powder availability could become a similar constraint, and creating affordable regional sources for low-embodied energy powders will be a crucial step in distributed manufacturing. Current gas or water atomization processes methods for form metal powders (which are then often remelted in powder bed fusion) adds significant energy budget to the process. First, atomized powders are regularly sorted so that only a portion of the powder produced reaches the AM user. Secondly, if the alloy already exists in solid form, the energy needed to melt to form the powder form is an energetically “hungry” step. A powder creation method using cold mechanically derived (CMD) of particulates can create a wide range of alloy compositions with approximately 90% less embodied energy than gas atomization (GA). CMD powder is often less spherical than GA powders, and thus the powder flow characteristics in common powder bed systems must be demonstrated. Our study has shown that the flowability of Al 7075 and Copper 14500 powders made via GA and MF are similar at rates appropriate for powder bed additive methods. Particle morphology descriptions (size and shape) do not strongly correlate to tap density in this case, which suggests under common AM bed filling processes the bed density will be similar in both cases. Morphology comparisons and particle size/shape distributions were made by comparing large particle statistics, rather than solely comparing mean particle size. Laser powder bed fusion tensile specimens were formed from AL 7075 and heat treated to T6; the GA and CMD powders showed equivalent tensile test performance to both each other and conventionally wrought 7075.

9:15 AM SF01.04.04
High Absorptivity Nanotextured Powders for Metal 3D Printing Ottman Tertuliano1, Philip DePond2,3, Andrew Lee2, Jiho Hong2, David Doan2, Mark L. Brongersma2, Wendy Gu2, Manyalibo Matthews1, Wei Cai2 and Adrian Lew2; 1University of Pennsylvania, United States; 2Stanford University, United States; 3Lawrence Livermore National Laboratory, United States

The widespread application of metal additive manufacturing (AM) is limited by the ability to control the complex interactions between the energy source and the feedstock material. Here we develop a scalable process to introduce nanoscale grooves to the surface of copper powders which increases the powder absorptivity by up to 70% during laser powder bed fusion. The absorptivity increase enables printing of pure copper structures with densities up to 92% using laser energy densities as low as 82 J/mm^3. We demonstrate similar effects in silver and tungsten. Simulations show the enhanced powder absorptivity results from plasmon-enabled light concentration in nanoscale grooves combined with multiple scattering events. The approach taken here demonstrates a general method to enhance the absorptivity and printability of reflective metal powders at low energy densities by changing the surface morphology of the feedstock without altering its composition.

9:30 AM SF01.04.05
Additive Manufacturing: Technology Maturation and Synchrotron X-Ray Microscopy Insights Anthony D. Rollett; Carnegie Mellon University, United States

Additive manufacturing (AM), aka 3D printing is a relatively new technology that has given rise to the “maker culture” and an intense interest in design. That has carried over into metals AM, which has jumped almost immediately into manufacturing of actual parts in a variety of alloys. In doing so it has liberated thinking about part design albeit within certain constraints and complex components have been deployed that were previously inaccessible, e.g., high temperature heat exchangers (HX). An example is described of the co-design of HX against printing constraints, alongside evolution in alloy choice. Nothing is ever as simple as it seems, however, and the reliability of parts that must carry load depends on the internal micro-structure, especially with respect to fatigue loading. This motivates detailed study of all aspects of materials microstructure ranging from defect structures to strain, all of which is ideally suited to the use of intense sources of high energy x-rays as only third generation light sources can deliver. Computed tomography (CT) has revealed the presence of porosity in all additively manufactured metals examined to date and confirmed that appropriate process control can limit it. CT has also provided data on surface condition that we are trying to link to fatigue performance. High speed radiography reveals even more crucial details of how laser light generates vapor cavities that can deposit voids past a critical instability point. “Hot” cracking has been imaged as it happens during the solidification process, which offers the possibility finding printing recipes for alloys previously considered off-limits to 3D printing. High speed, high resolution diffraction in stainless steel, alloy 718 and Ti-6Al-4V reveals unexpected solidification and precipitation sequences. Diffraction microscopy reveals the highly strained nature of printed metals and how microstructure and internal strain state evolves during subsequent annealing. Permeating all these activities is machine learning as an invaluable tool and aid to the researcher.

Support from multiple agencies is gratefully acknowledged, including NASA, DOE/BES, DOE/NNSA, ONR, NSF, OEA, Commonwealth of Pennsylvania, and Ametek.

10:30 AM SF01.04.07
Designing Against Failure in Additive Manufacturing: From Fracture in Monolithic Samples to Designing Functionally Graded Materials Allison M. Beese; The Pennsylvania State University, United States

To adopt metallic materials made by additive manufacturing (AM), it is critical to understand, and design against fracture, particularly under complex stress states accessed in service, and with the possible presence of internal pores. Additionally, when designing functionally graded materials (FGMs) in which composition is deliberately varied with position within a component to result in spatially tailored properties, it is critical to avoid deleterious phase formation and solidification cracking during fabrication. This talk will describe our approach for studying the combined effects of stress state and internal pores on the fracture behavior of stainless steel 316 and Ti-6Al-4V manufactured using laser powder bed fusion AM, providing a pathway for designing against failure under realistic conditions. Additionally, it will describe our framework for considering deleterious phase formation and crack susceptibility when designing compositional pathways for FGMs, and more broadly, compositions amenable to AM in general.
SESSION SF01.05: Session IV
Tuesday Afternoon, November 28, 2023
Sheraton, Second Floor, Republic B

1:30 PM SF01.05.01
Mechanics of Extremely Heterogeneous Materials by Additive Manufacturing Ting Zhu; Georgia Institute of Technology, United States

Our recent studies of additively manufactured alloys (Nature, 608, 62–68, 2022; Nature Materials, 17, 63-71, 2018) have raised fundamental questions on the role of extremely complex microstructural heterogeneities in the mechanical behavior of these novel material systems. We combine mechanics modeling and experimental characterization to elucidate the strengthening effects of microstructural gradients and resultant strain gradients in additively materials alloys. We quantitatively compare the results from crystal plasticity modeling and in situ synchrotron X-ray experiment, highlighting the less recognized concept of back-stress hardening and various stages of extra back-stress hardening in materials with extremely complex microstructural heterogeneities. Mechanistic insights are gained for further enhancing the strength-ductility synergy in the design of materials with extremely heterogeneous microstructures.

2:00 PM SF01.05.02
Improving Measurement and Classification of SLM Feedstock Powders by X-Ray Microscopy and Machine Learning Daniel Sinclair, Eshan Ganju and Nikhilesh Chawla; Purdue University, United States

Additive manufacturing (AM) has introduced revolutionary changes in design, production, and innovation sectors over the past decade. This transformative technology, including Laser Powder Bed Fusion (LPBF), Direct Energy Deposition (DED), Binder Jetting (BJ), Metal Extrusion (ME), and Sheet Lamination (SL), has enabled significant advances in aerospace, automotive, medical, energy, and tooling industries. Out of the five, LPBF is favored for its near-net-shape printing, high dimensional accuracy, superior mechanical characteristics, and swift prototype assembly. Within LPBF, Selective Laser Melting (SLM) has gained significant traction in commercial, industrial, and defense applications, specifically for Al alloys. The reliability of SLM parts is often compromised due to defects originating from irregular feedstock powders originating from re-use of powder feedstock or differences in feedstock sources. To accommodate the variation in feedstock required to meet the increasing demands of manufacturing, advanced granulometric methods which are sensitive to varying powder morphologies (as seen in recycled or composite powders) are needed. Lab-scale 3D X-ray Computed Tomography ( XCT) presents a viable solution for feedstock powder characterization, enabling non-destructive quantification of changes within recycled particles. Our research delved into a gas-atomized AA7050 feedstock powder with unusual powder morphologies and titanium additives (AA7050-RAM2). Through the synergy of lab-scale x-ray microscopy and automated watershed segmentation, we were able to quantify the shapes and sizes of particles in an aluminum alloy (AA7050-RAM2) feedstock. Additionally, to describe nonstandard particles more accurately, we introduced novel 3D shape metrics to effect low-temperature consolidation. New alloys based on Mg- and Ni- will be highlighted, and processing advantages in terms of energy and shape retention elaborated. Finally, the properties of these alloys will be evaluated and opportunities for alloy substitution discussed.

2:15 PM SF01.05.03
Development of a Low Thermal-Budget, Distortion-Free Process for Binder-Jet 3D Print-and-Sinter Alloys Christopher A. Schuh1,2, Christian Oliver1, Yannick Naunheim1 and Jasper Lienhard2; 1Massachusetts Institute of Technology, United States; 2Foundation Alloy, Inc., United States

Binder-jet printing and sintering is a pathway to scalable, high-volume, low-cost manufacturing of complex metal parts. It also presents an opportunity to design new alloys produced entirely in the solid state, thus using less energy and involving less residual stress and distortion than other modes of metal 3D printing. This talk will overview research aimed at such alloy and process development, with an emphasis on understanding and tailoring sintering mechanisms to effect low-temperature consolidation. New alloys based on Mg- and Ni- will be highlighted, and processing advantages in terms of energy and shape retention elaborated. Finally, the properties of these alloys will be evaluated and opportunities for alloy substitution discussed.

2:45 PM SF01.05.04
Additive Manufacturing of Novel Aluminum Alloys: Structure and Properties Jin Liu, Jingyu Xu and Cheng Zhang; Huazhong University of Science and Technology, China

Additive manufacturing (AM) offers significant advantages over conventional manufacturing techniques in processing Al alloys, however, high-strength Al alloys produced by AM commonly encounter a few challenges including poor processibility and undesirable microstructures with coarse columnar grains and micro-cracks, leading to poor mechanical properties. Here, we demonstrate that these issues can be largely resolved by micro-allying of Zr element in the Al-based alloys. In this study, a series of novel Al-Fe-0.5Cu-xZr alloys with different content of Zr (x=0.3, 0.6, 0.9, 1.5at%) are designed and fabricated by laser powder bed fusion (LPBF). It is observed that the LPBF Al alloys all exhibit notably heterogeneous structures with alternate distribution of coarse grain zones (CGZs) and fine grain zones (FGZs). With increasing Zr content, the grain size in both CGZs and FGZs gradually decreases and the columnar-to-equiaxed transition (CET) occurs in the CGZs, which make the processibility be improved for the Al alloys with higher Zr content. To understand the formation of the heterogeneous structures and the correlation between microstructure and mechanical properties, the LPBF Al-Fe-Cu-1.3Zr alloy was selected, as an example, for detailed investigations. It is revealed that the formation of FGZs, locating at the low boundaries of the molten pools, is attributed to the pre-formed Al3Zr nanocrystals, which sever as nuclei and results in the refinement of grain size, while the CGZs are formed at the interior of molten pools, where no Al3Zr precipitates are formed, leading to the formation of relatively coarse grain size. In addition, Fe/Cu co-segregation appears at the GBs in both FGZs and CGZs although Cu and Fe are thermodynamically immiscible. As a result, these unique microstructures allow the LPBF-processed Al-Fe-Cu-1.5Zr alloy to have high strength at both room temperature and elevated temperatures. For example, the yield strength reaches 500 MPa at room temperature and 163 MPa at 573 K, respectively, both are higher than those of additive manufactured Al-based alloys reported thus far. The findings in this work provide a guide for design of novel Al alloys with good processibility and advanced mechanical properties for additive manufacturing.

Additive Manufacturing: Transforming Engineering Design Through Functionally Integrated Materials, In-Situ Imaging, and Alternative Feedstock Materials  
Julie M. Schoenung1 and Xin Wang2; 1University of California, Irvine, United States; 2The University of Alabama, United States

This presentation will provide an overview of various aspects of additive manufacturing that can lead to transformative materials and engineering design. Directed energy deposition (DED) additive manufacturing enables the precise control of composition for the development of functionally integrated materials (FIMs) with site-specific functionality. This compositional control is enabled by the powder injection delivery system that allows for the sequential and/or co-deposition of multiple feedstock powders through individual powder feeders. This strategy provides a path to the rapid development of novel alloys and components with location-dependent chemical composition and properties. The FIMs concept is demonstrated using two material systems: stainless steel 316L with Haynes 282 nickel superalloy, and nickel with nickel-aluminum. Extensive characterization of microstructure, interfaces, diffusion zones, grain boundary morphology and texture, chemical composition and phase transformations provides insight into the fundamental material science governing the solidification process and consequential component performance in FIMs. DED also entails complex particle-laser-melt pool interactions due to the powder injection mechanism. In-situ imaging using both thermal imaging and high-speed video provides insight into these complex interactions, as highlighted here for various examples including nickel superalloy powder and TiC reinforcement particles. Lastly, the benefits of using recycled and repurposed alternative feedstock materials are considered.

4:00 PM SF01.05.06
Additive Manufacturing of Co-Based Superalloys via Direct Ink Writing  
Jian Liu1, Zhiyu Zhang2, Shuai Guan1, Jonathan Poplawsky1, Tianyi Li1, Yang Yang2 and Wen Chen1; 1University of Massachusetts Amherst, United States; 2The Pennsylvania State University, United States; 3Oak Ridge National Laboratory, United States; 4Argonne National Laboratory, United States

Additive manufacturing of superalloys enables innovative, geometrically complex designs combined with excellent mechanical properties. Here, we developed an additive manufacturing method based on direct ink writing (DIW), to fabricate a high-performance Co-based superalloy. The ink consists of metal powders, polymer binders, and volatile solvents. The deposited architectures are thermally sintered to near-full density, followed by ageing. The sintered Co-based superalloy exhibits a homogeneous microstructure of equiaxed grains with MC carbides uniformly distributed in the FCC matrix, which leads to a high ultimate tensile stress in excess of 1.2 GPa and a large tensile ductility over 20% at room temperature. The outstanding combination of strength and ductility originates from the coherent γ′ nanoprecipitates and deformation-induced stacking faults, as revealed by in situ synchrotron X-ray diffraction and high-resolution transmission electron microscopy. The introduced additive manufacturing approach provides new opportunities to print a wide range of superalloys for high-temperature applications.

4:15 PM *SF01.05.07
Understanding Ultrahigh-Rate Behavior of Macromolecules for Advances in Polymer-Based Cold Spray Additive Manufacturing  
Jaehwang Lee1,2, Ara Kim1 and Anurag Gangineri Padmanaban1; 1University of Massachusetts, United States; 2University of Massachusetts Amherst, United States

The solid-state coating and additive manufacturing of polymers are feasible by the cold spray (CS) technique, in which solid feedstock powders or microparticles (μPs) conveyed by a high-speed gas stream are subjected to a head-on collision against a stationary surface at transonic or supersonic velocities. Due to the ultrahigh-strain-rate (UHSR) viscoplastic deformation upon collision, polymer μPs can be consolidated without volumetric melting or phase transition. In CS, μPs adhesion is accomplished by the highly localized thermal softening (or melting), and other inelastic mechanisms, especially brittle fracture, may also become significant. As local temperature fields, the consequence of impact-induced plastic strains, are coupled with temperature-dependent mechanical properties, the UHR adhesive plasticity of polymers is inherently nonlinear and is very difficult to predict via the time-temperature superposition. In this talk, we will introduce our recent efforts to understand the UHSR behavior of polymer μPs through single-particle experiments realized by laser-induced projectile impact testing (LIPIT). For glassy polymers modeled by polystyrene of various molecular weights (MWs), the MW-dependent interplay of the primary inelastic mechanisms is systematically and comprehensively investigated through ultrafast optical images from LIPIT. Due to the ambivalent effect of MW on fracture toughness and interfacial rheology, our study demonstrates that the proper selection of MW is crucial for the feasibility of the solvent-free and solid-state deposition of glassy polymers. Meanwhile, LIPIT experiments with an incidence angle of 45° are conducted to investigate the tribological response at the contact interface. We elucidate the strain-dependent tribological properties of deblock copolymers under extremely dynamic collisions and the correlation between friction and adhesion properties at the nanosecond time scale. Furthermore, we demonstrate that phase-separated deblock copolymers can be ordered via collision-induced shear flows. The extended knowledge from our study about the UHSR behavior of polymers will be crucial for advances in polymer-based CS additive manufacturing that can also open opportunities for creating novel materials properties.

4:45 PM SF01.05.08
Correlations Between Porosity, Sputter and Process Metrics for Powder Bed Fusion Laser Beam Metallic Additive Manufacturing  
J.-A. S. Hockett1, Joseph N. Zalamenda1, Brodan Richter1, Andrew R. Kitahara2, Sang-Hyon Chu1 and Edward H. Glaeser1; 1NASA Langley Research Ctr, United States; 2Analytical Mechanics Associates, United States

The large scale and deposition sequence of powder bed fusion laser-based metallic (PBF-LB/M) additive manufacturing (AM) create tremendous computational challenges for establishing precise ‘process-structure’ correlations throughout the process. A recent approach, AM model-based process metrics (AM-PM), has addressed the challenge by applying analytical reduced-order models to the heat source position. AM-PMs can reveal quantifiable trends in space and time throughout the PBF-LB/M process. The AM-PMs furnished by the reduced-order models were evaluated against high-speed imaging (coaxial with the laser beam) of weld melt pools, and metrics from ex-situ metallurgy of the welds. The presentation will discuss how AM-PMs, such as melt pool width, correlate with measurements from in-situ imaging and ex-situ metallurgy
Transfer printing is one of the attractive routes toward additive manufacturing of flexible/stretchable electronics, micro/nanophotonic devices, micro-LED displays, and healthcare sensors via assembling micro/nano components. However, a major challenge in micro/nano transfer printing is achieving both high throughput and yield. An important factor in minimizing the transfer failure is the adhesion contrast between the picking and placing stages, particularly when manipulating microscopic substances that cannot be placed using gravitational force alone. Accordingly, realizing the large contrast in surface adhesion and its rapid transition is essential for the assembly of miniaturized parts.

Herein, we propose a novel nano-fluidic device enabling manipulation of micro components via capillary grasping and releasing mechanism. We fabricate the surface via vertical self-assembly of carbon nanotubes which allows liquids to infiltrate into the nanoscale channels when a strong gripping force is necessary and rapidly evaporate the fluid when a weak releasing force is needed. We quantitatively characterize the adhesive strength and find that the structure can exhibit high adhesion as liquid infiltrates the channel (~17.4 kPa) while it can switch into low adhesion as the surface is fully dried (< 0.1 kPa). The adhesive behavior is evaluated using atomic force microscopy and capacitive force sensing, resulting in an adhesion contrast of greater than 100-fold. Due to the nature of the liquid-solid interface, a minimal preload of 0.8 kPa is sufficient to enable the picking and placing which is particularly ideal for physical-contact-based manipulation of delicate electronic components. Our study demonstrates the successful transfer of μLED chiplets, ultrathin films, and CNT supraparticles, as well as the application of strain sensors by transferring CNT particles onto a flexible PDMS substrate. To further elucidate insights into the underlying mechanism, we develop a mechanics model to analyze the adhesive force with respect to the types of liquid and films, and CNT supraparticles, as well as the application of strain sensors by transferring CNT particles onto a flexible PDMS substrate.

To combat these challenges a novel method of additive manufacturing is explored, which can employ microbial cell factories suspended in hydrogel and optogenetics to selectively deposit the desired biological or synthetic material in a three-dimensional (3D) volume. Genetically engineered Escherichia coli that produces a synthetic light response system, CcaSR v3.0, was used in order to allow for spatially selective gene expression. A custom designed system was built to house the hydrogel suspended E. coli and to provide and shape green and red light, which were used to interact with the cells. Green light was used to induce gene expression and red light was used to suppress gene expression. Localized gene expression was achieved within the hydrogel build volume with proper overlap of the green and red light and with the help of a predictive model describing the behaviour of the CcaSR system in response to light.

This approach of 3D printing is unique in that it shifts the burden of material from the bioink to the cells, which changes material engineering to bioengineering. This approach effectively exploits the cells for in-situ material production. As the cells are suspended in a hydrogel medium, any mechanical stress during the printing process is eliminated. Provided that the cells’ engineered metabolism is not toxic, chemical stress is also eliminated. As opposed to conventional polymerisation, which generates cytotoxic free radicals.

3D Printing of Photoconductive Zinc Oxide-Based Photoresins

The interest in 3D-printed functional microstructures has significantly increased over the past decade due to their potential utilization in microelectronics, photonics, optoelectronics, and biological applications. Compared to commonly used additive manufacturing techniques such as fused deposition modeling and selective laser sintering, light-based 3D Printed methods (Stereo lithography) offer faster processing and higher spatial resolution. However, for light-based 3D printing, mainly 3D structures based on organic polymers have been assembled due to the limited availability of multifunctional (e.g. conducting, semiconducting, etc.) photoresins. One of the main challenges that have been encountered when designing functional photoresins is the undesired light absorption of the ink, which leads to relatively low spatial resolution or crosslinking efficiency.

Here we use an approach for designing a multifunctional photoresin to fabricate 3D-printed ZnO microstructures by mixing a commercial photoresin with a Zinc-based metal-organic complex. This material doesn’t have any optical absorption that interferes with the photoresin photopolymerization process and can be transformed to ZnO at low annealing temperatures (~ 200 °C). The utilized functional resin is comprised of a commercial photoresin and a Zinc-O precursor, a stabilizer, and an organic solvent are added. Additionally, high zinc loading is possible by using a stabilizer in the precursor solution which can lead to high ZnO conversion hence better optoelectronic properties. Depending on the material ratio and optimized composition which favors both printing resolution and optoelectronic properties can be prepared. After printing of the photoresin by Digital Light Processing (DLP) (27 μm)
structures which will be potentially used in applications such as miniaturized optoelectronic and bioelectronic devices.

In future work, we plan to extend the obtained results towards its use in the Direct Laser Writing (DLW) process to obtain micro-architected 3D ZnO photodetectors exhibiting a photocurrent of 5 nA and an on/off ratio of 600 when excited at the same wavelength.

Three-Dimensionally Printed, Vertical Full-Color Display Pixels for Multiplexed Anticounterfeiting

Permanent magnet materials play a vital role in numerous electronic devices, from electric vehicles and wind turbines to smartphones and smartwatches. Their ability to efficiently convert electrical energy into mechanical energy makes them essential components in modern technology. With the increasing demand for high-performance magnets with diverse shapes, driven by the trend towards miniaturization and lightweight design, there is a need to explore innovative manufacturing techniques which can meet these requirements and improve overall efficiency.

Currently, the production of permanent magnets primarily uses two main methods: sintering and polymer-bonded techniques. Sintered magnets exhibit superior magnetic properties compared to bonded magnets because of their higher density and crystalline structure. However, they possess inherent limitations, including poor corrosion resistance, limited shape complexity, and higher energy consumption during the manufacturing process. On the other hand, bonded magnets are created by combining magnetic powders and polymer binders through compression molding, extrusion, or injection molding. Compression molding allows for magnets with high filler ratios, but it is restricted to producing magnets with simple shapes. Injection molding, although capable of fabricating magnets with complex geometries, results in material waste and requires additional tooling processes.

To overcome these challenges and advance the production of bonded magnets, our research utilizes the additive manufacturing technique known as Fused Deposition Modeling (FDM). Unlike conventional methods that use filament, we employ powders or pellets consisting of binder polymers and anisotropic magnet fillers in our process. This approach reduces process time by skipping the filament manufacturing step and allows for control of the filler ratio. It also enables the creation of complex-shape bonded magnets and addresses the limitations of conventional manufacturing techniques. Moreover, during the layer-by-layer printing process, we incorporate an in-situ electromagnetic alignment method to orient the anisotropic magnetic fillers along the desired magnetization axis. This alignment technique determines the orientation of the magnetic filler during processing, resulting in bonded magnets with superior magnetic properties, including improved remanence, coercivity, and energy products.

In our presentation, we will provide a comprehensive overview of the FDM-based bonded magnet fabrication process and discuss the crucial parameters involved. One significant parameter is the printing temperature, which determines the viscosity and flow characteristics of the binder polymer and affects the overall quality and integrity of the printed magnet. Additionally, the application of in-situ magnetic fields during the printing process plays a crucial role in aligning the anisotropic magnetic fillers with the magnetization axis and influences the final magnetic properties of the fabricated magnet.

Understanding and controlling these variables is essential for achieving magnets with optimal performance.

Continuing our research and development efforts, we aim to further optimize the FDM-based bonded magnet fabrication method. Our goal is to improve the magnetic properties of the magnets produced while increasing the complexity of their small, lightweight, and shaped forms. To achieve these goals, we will explore various aspects, including the formulation of magnet fillers, binder polymers, and their interactions, as well as the optimization of printing parameters and post-processing techniques. By continuously improving this additive manufacturing approach, we aim to provide an efficient and sustainable method for producing high-performance bonded magnets tailored to the specific requirements of modern electronic devices.
Thermal Conductivity Measurement for Aligned Particle Monolayers

Herein, we propose vertically stacked multicolor micropixels for high-resolution, multiplexed anticounterfeiting. The micropixel is produced by sequentially stacking luminescent dye-doped red-green-blue (RGB) subpixels, realized with high-resolution 3D printing. Our 3D printing approach is based on the use of a femtoliter ink meniscus enables vertical stacking of micron-sized subpixels without the existence of a subpixel pitch, drastically increasing the pixel density up to 13,400 pixels per inch (PPI), which is not easily attainable by the traditional lateral subpixel layout. Furthermore, a full-scale color synthesis for each micropixel is achieved by modulating the height ratio of red, green, and blue subpixels, which is reflected in the CIE 1931 diagram. These features create high-resolution, multiplexed anticounterfeiting labels, inaccessible by conventional optical imaging, and 3D printing offers the simplest, most versatile route to manufacture. This work demonstrates the exceptional ability of 3D printing to construct vertically stacked structures and highlights the possibility to devise 3D printing for photonic device manufacturing.

3D-Printed Single-Material Carbon Nanotube Thermocouple Microdevices Zhuoran Wang and Ji Tae Kim; The University of Hong Kong, Hong Kong

Miniaturized thermocouples have emerged as an essential component for the power generation or thermal management of microelectronic devices due to their capability to convert heat to electricity. Recently, extensive research has focused on the structural design of micro-thermocouples to improve the thermoelectric performance, and one resulting insight is that a three-dimensional (3D) geometry can be beneficial in terms of integration density and thermal contact efficiency [1]. However, the construction of a 3D micro-thermocouple typically comprising two dissimilar materials suffers not only from the process complexity with high cost but also from the low mechanical strength of the junction.

Here, we have developed a micro 3D printing method for fabricating a single-material carbon nanotube (CNT) thermocouple device. The device is configured with an electrical junction of two freestanding CNT microwires with different widths, by exploiting the size-dependent Seebeck coefficient at the electron mean free path scale [2, 3] instead of using two different materials. The developed micro 3D printing method that uses a femtoliter ink meniscus enables a single-step, continuous, high-resolution (< 1 μm) manufacturing of CNT micro-thermocouples in three dimensions. This greatly ensures structural robustness, cost-effectiveness, and design flexibility, which have not been attained by other traditional manufacturing approaches, reinforcing practicality. In this talk, we will present the experimental results including the fabrication and characterization of 3D CNT micro-thermocouples, and discuss the prospects of our work for potential applications.

References

comprising a polymeric matrix and inorganic magnetic fillers, have traditionally found use in large scale applications (such as dampers and isolators) that sacrifice accuracy for performance and fabrication simplicity.

With additive manufacturing (AM) technologies, however, complex structures could be fabricated through different techniques, such as direct ink writing (DIW), that allow to achieve higher pattern resolutions and allow new and exciting applications in the field of healthcare, automotive and printed electronics. The issue with traditionally designed MREs is that they are typically based on carbonyl iron microparticles that, albeit their high saturation magnetization and low coercivity, are not suitable for AM due to their size and hinder high resolution patterns.

Thus, a transition should be made into using nanoparticles (NPs) for high-resolution applications. To this end, we have studied the impact that magnetic properties, concentration, shape, and orientation have on the performance of nanoparticle based MREs, in order to achieve the optimize performing material compatible with AM.

Nanoparticles with different values of saturation magnetization, coercivity, and remanence have been selected to fabricate the MREs. Six different fillers were tested: CoFe$_2$O$_4$, Fe$_3$O$_4$, Co, Ni and Ni$_2$Fe$_2$Mo$_3$ (Permalloy). The magnetorheological (MR) effect achieved for the Fe$_3$O$_4$ composite was the highest one at 18%, and comparable to other composites reported in the literature, but with a lower content of magnetic material (only 6 vol% versus 20 vol%), which is expected to improve the processing and integration of the MRE. Moreover, by using different concentrations (20 wt%, 40 wt% and 60 wt%) of the Permalloy filler, we obtained a linear relationship between MR effect and filler concentration, increasing from 8% at 20 wt% to almost 30% at 60 wt%.

This increase in performance should be carefully balanced with the variation of the mechanical properties.

Further, Fe$_3$O$_4$ nanorods (NRs) have been synthesized with an aspect ratio of 10 to compare with the 70 nm sized cubic Fe$_3$O$_4$ NPs. Anisotropic MREs (A-MREs) were then fabricated by curing the composite inside a magnetic field to achieve a preferential orientation and compared them with isotropic MREs (I-MREs) cured without the presence of the magnetic field. The results of the relative magnetorheological effect confirmed that the A-MREs exhibit higher values of the MR effect, as it increased from 12% to 27% in the case of the NPs and from 8.3% to 17% in the case of the NRs. Interestingly, these results imply that lower aspect ratios are more suitable to enhance the MR effect in anisotropic composites, since the relative increase between oriented and non-oriented samples was 125% for the NPs and 104% for the NRs.

The suitability of these materials for DIW additive manufactured devices has been further evaluated in Fe$_3$O$_4$-based MREs. We fabricated a fully printed patterned device combining magnetoelastic and magnetorheological properties, where the conversion from applied magnetic field to output voltage could be manipulated by taking advantage of the change in mechanical properties and magnetostriiction of the magnetorheological layer.

Additive Manufacturing of Flexible Photonic Waveguides with Active Components Maxine Ong, Yu Shu, Max Jenkins, Harish Bhaskaran and Peter Bruce; University of Oxford, United Kingdom

An emerging research direction in flexible devices is in photonics. Having the ability to manipulate and deform photonic devices gives the additional benefit of controlling light-matter interaction. Flexible photonic devices are seen in applications such as interconnects, detectors and bio-photonic sensors, where the mechanical flexibility of the devices is exploited. However, there are still many challenges associated with the fabrication due to the poor compatibility of available flexible substrates to conventional methodologies.

In this work, we demonstrate the fabrication of polymeric waveguides on flexible substrates and the integration of active components (e.g. 2D materials, phase-change materials) through additive manufacturing, such as direct laser writing and pick-and-place. These have potential optoelectronic applications in photodetection, and memory devices that can be seamlessly affixed to conformal surfaces.

Expanding the Toolbox of PhotoROMP Additive Manufacturing Alex Comissiono, Annika Jansen and Samuel Leguizamon; Sandia National Labs, United States

Stereolithographic additive manufacturing (SLA) processes provide agility and complex design development of components necessary for a wide range of critical applications. Yet this technique is limited to a small subset of monomers that traditionally produce polymer materials with poor thermal and mechanical properties. Conversely, ring-opening metathesis polymerization (ROMP) can produce relatively tough, high Tg thermosets using latent ruthenium catalysts. Furthermore, spatiotemporal control of the polymerization using photosensitizers affords high resolution patterning of high Tg thermosets using photorOMP. Dicyclopentadiene (DCPD), an inexpensive but robust photorOMP monomer, has been featured in SLA resins to generate highly complex three-dimensional geometries at print speeds approaching industry-leading standards using continuous SLA techniques. However, the minimal exploration into the monomer space in photorOMP and ROMP SLA hinders the utility of ROMP polymers as the DCPD-based resins are generally non-processable, non-degradable, and lack other useful functionalities that have previously been imbued in polymeric materials. By examining the strained olefin monomer space for their photopolymerization kinetics, material properties, and print fidelity, we have identified potential routes to rapid SLA of functional polymers using photorOMP.

Additively Manufactured Ceramic Combustor for Power-Plant Scale Electricity Generation Shomik Verma, Mehdi Pishahang, Kyle Buznetsky, Alina LaPatin, Santosh Shanbhogue and Asegun Henry; Massachusetts Institute of Technology, United States

Existing power plants have many downsides, as they have low efficiency, emit CO$_2$, and include high-temperature rotating machinery requiring frequency maintenance. However, they are dispatchable, which provides a direct benefit over variable renewable energy resources such as solar. The ideal technology would be both dispatchable and solid-state. A recent alternative is fuel cells, which can directly extract the chemical energy in fuels into electricity with electrochemistry, but they require expensive catalysts and have low power density.

Combustion-powered thermophotovoltaics is a promising alternative for power generation. In this system, a combustor is designed that preheats air above the auto-ignition point of a fuel, such that the mixture combusts upon contact. The heat from combustion is used to heat up an emitter to ultra-hot temperatures, and the emitter radiates heat to the TPV cell. The TPV cell converts the emitted light to electricity. If hydrogen is used as the fuel source, the electricity produced is clean, creating a solid-state, catalyst-free method of generating electricity. When combined with high-efficiency, high-power density TPV cells, this combustion-TPV system has the potential to be high-performing. However, there are many challenges in the system design, for example that high temperatures (2000°C) are required, hefty insulation is needed to prevent heat loss, and cost may be high.

Thus, this study addresses three key challenges in the combustor design: materials identification, scalable design, and fabrication with additive
For materials identification, the objective of the material is to limit thermal stresses when a thermal gradient is applied, meaning the product of Young’s modulus and coefficient of thermal expansion must be low. The material’s yield strength must also be high, so that it does not fracture when a thermal stress is present. Due to the extreme environments present, the material should also be oxidation resistant and have high service temperature. Thus, oxides are the best option, and yttria-stabilized zirconia (YSZ) is identified as the candidate material due to its reduction resistance in the presence of high-temperature hydrogen.

Next, we design a high-efficiency combustor with 93% combustion efficiency using YSZ, enabled by milli-scale channels and a large surface area to volume ratio. The combustor also features a near-isothermal emitter wall at approximately 2000°C. It is also modular, enabling vertical and horizontal stacking to reach the large length scales required for cheap insulation and grid-scale power generation.

However, the intricate internal geometries enabling the effective heat transfer within the device necessitate additive manufacturing. Because this technique can be expensive, two techniques are used to ensure cost-competitiveness. One is maximizing the power output per volume of the device, which is enabled by a large emitter surface area surrounded by high-power density TPV cells. Another is design for manufacturing, in which the device is 3D printed in 3 sections which are joined together in post-processing. This enables parallel processing and easier access to the internal channels, which would otherwise be difficult to clear. One challenge of this stacking method is how to properly join the slices, and a leak-proof joining methodology is developed to solve this.

Based on these improvements, we achieve a predicted cost per power of $0.30/W, which is significantly less than the cost of a natural gas turbine at $1/W, and leaves room for balance-of-plant costs such as pollution control, TPV cooling, and electronics.

Overall, in this work we push the boundaries of ceramic additive manufacturing to develop a next-generation power plant based on hydrogen combustion coupled with thermophotovoltaics.

Maximizing Photosynthetic Current Density of 3D Printable Thylakoid-PEDOT:PSS Composite Inks Through Bayesian Optimization JongHyun Kim, JaeHyung Yun and WonHyung Ryu; Yonsei University, Korea (the Republic of)

Thylakoid membranes (TM) isolated from living plants can produce high energy electrons through photosynthesis under sunlight. If placed near an electrode, the high energy electrons can be harvested and put to practical use, creating an eco-friendly power cell. Recently our group has demonstrated TM-embedded 3D printable ink based on a conductive polymer, poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) [1]. Compared to the conventional post-electrode-deposition methods, the pre-embedding method allowed drastic increase in TM-electrode contact. While this previous study has focused on optimizing electrode geometry, in this work, we seek to optimize the electrode material itself to reach maximum current density. However, in achieving high current density, the two key parameters: the electron production rate and electrode conductivity, are always in tradeoff. Denser TM embedment surely increases photosynthesis but decreases electrode conductivity as it interrupts the conductive networks of PEDOT, responsible for charge flow. Addition of secondary dopants, such as dimethyl sulfoxide (DMSO), boosts conductivity by facilitating phase separation between PEDOT and PSS chains, but such organic solvents are prone to damage TMs. Post treatments of dry-annealing in PEDOT:PSS electrodes are considered essential in formulating and crystallizing PEDOT-rich domains [2], but heat treatments can damage the protein structures in TM. As multiple correlated factors in the material and manufacturing process account for the overall current density of the power cell, it is not only laborious but also very difficult to optimize each parameter. Therefore, we implemented Bayesian optimization, a technique used widely in Machine Learning, to simultaneously fine tune the concentrations of TM, PEDOT:PSS, and DMSO, along with dry-annealing time and temperature. To stay within 3D printable boundaries, we conducted rheological studies of the ink composites and set their lower boundaries to where their storage modulus is just above the loss modulus. Their upper boundaries were set at a nozzle clogging point referenced from the previous work on 3D printing PEDOT:PSS [3]. Additionally, we conducted a parametric study of gradual heating of drop casted TM on ITO glass. The upper boundary of the temperature parameter was set as 150°C, where no current was longer measured from TM. In each iteration step of the Bayesian optimization, the ink was mixed thoroughly, screen printed with fixed volume on an ITO glass substrate, and dry-annealed in oven. The current density value, measured through cyclic amperometry, was fed into the Bayesian optimizer and the experimenter received back the next sampling point. As the experiment prolonged, the Bayesian optimizer attempted to find the global maxima of the surrogate model built from these current density values.

Digital Light Processing 3D Printed Thermochromic and Thermoresistive Sensors Based on Soybean Oil and Ionic Liquids Cristian Mendes-Felipe1,2, Daniela Correia1, Mohammad Tariq1, José Esperança3, Marco Sangermano3 and Senentxu Lanceros-Mendez1; 1BCMaterials - Basque Center for Materials, Applications and Nanostructures, Spain; 2Politecnico di Torino, Italy; 3University of Minho, Portugal; 4Universidade Nova de Lisboa, Portugal

Additive Manufacturing (AM) has revolutionized the field of manufacturing by enabling the fabrication of complex three-dimensional structures with unprecedented design freedom. This work focuses on Digital Light Processing (DLP), for the processing of soybean oil-based materials. The use of reactive solvents and the study of suitable inks for printing purposes are explored, allowing or enhance the performance, sustainability and versatility of AM processes.

Soybean oil-based materials have gained significant attention due to their renewable nature, biodegradability, and potential for sustainable manufacturing. By formulating soybean oil-based resins and optimizing the processing parameters, digital light processing techniques can effectively harness the advantages of these materials. The incorporation of reactive solvents in the formulation allows for controlled material properties, including viscosity, curing kinetics, and mechanical strength, facilitating precise material design for specific applications.

To achieve successful printing of soybean oil-based resins, it is essential to develop compatible and stable inks. The study delves into the investigation of suitable ink formulations for DLP-based AM, considering factors such as ink rheology, surface tension, and photocuring behaviour. By understanding the ink characteristics, printing parameters can be optimized, ensuring high-quality prints, and expanding the range of printable materials. Thus, different reactive diluents including isobornyl acrylate or lauril acrylate are added decreasing that the viscosity of soybean oil and reaching proper values for DLP
printing, together with enhance the photopolymerization process. Furthermore, the thermal and mechanical properties of printed materials are tested showing a wide range of both properties depending on the reactive diluent content. Also, high-quality 3D printed parts are observed in all cases. Additionally, this work explores the integration of thermochromic materials, specifically ionic liquids, into the AM process to obtain functional 3D structures for sensor applications. Thermochromic materials exhibit reversible colour changes in response to temperature variations, enabling the development of smart and responsive sensors. The incorporation of ionic liquids with thermochromic properties provides an avenue to achieve enhanced sensitivity and precise control of the thermochromic response in printed sensor structures without the ascribed problems of using thermochromic nano- or microparticles. Bis(1-butyl-3-methylimidazolium) tetrachloronickelate ([Bmim][NiCl4]) ionic liquid is easily dispersed in quantities up to a 40 wt.% filler content. All prepared materials present humidity dependent thermochromism from colourless to blue and this colour variation is thermally activated and humidity governed, being 55% the minimum value of the relative humidity for colour change to occur. Further, the electrical conductivity increases with increasing IL content and decreases with increasing temperature, demonstrating also the applicability of the materials as thermoresistive sensors. The proposed research contributes thus to the advancement of AM techniques by expanding the materials palette to include soybean oil-based resins, optimizing ink formulations for DLP printing, and exploring the functional integration of thermochromic ionic liquids in sensor applications. The findings from this study hold great potential for the development of sustainable, customizable, and intelligent 3D-printed structures with broad applications in fields such as sensing, robotics, and biomedical engineering.

3D-Printed Fused Silica Glass Hollow Microneedle Arrays – From Fabrication to Transdermal Applications
Yanwen Jia and Ziyong Li; City University of Hong Kong, Hong Kong

Microneedle arrays (MNAs), a micron-scale device that recently emerged, are being recognized for their significant potential in enhancing transdermal delivery and extracting interstitial tissue fluid (ISF). Advanced 3D printing techniques have been utilized to fabricate MNAs with enhanced functionality, improved performance, and increased structural flexibility; however, the current 3D-printed MNAs are primarily composed of polymers that suffer from high costs, low durability, and poor robustness. To overcome the constraint, we integrate fused silica glass with projection micro-stereolithography (P(SSL)) 3D printing technology for the fabrication of transparent and high-quality fused silica glass MNAs with micron resolution, high stiffness, and excellent optical properties for the first time. The in vitro penetration test suggests that the 3D-printed fused silica glass MNAs are capable of piercing skin safely and smoothly. ISF extraction test demonstrates its ability to extract sufficient model biomarkers-contained fluid in a short time under capillary force. We confirmed its potential in further transdermal applications. In the future, 3D-printed fused silica glass MNAs, coupled with technology like microfluid, could be applied in precise drug delivery, intelligent transdermal biosensing, real-time monitoring, etc.

Ink Optimization and Pattern Design for Fast Charge Electrode Through 2R Printing
Hongli Zhu and Ying Wang; Northeastern University, United States

Reducing the tortuosity of electrodes through vertical channels establishing is a recognized method to improve the ion transfer kinetics and enhance the fast chargeability of electrodes. Concurrently, investigating the relationship between channel structure on the electrochemical performance of electrodes is meaningful for optimizing the structure of fast-charging electrodes. In order to realize these demands, screen printing is a promising technology to fabricate low-tortuosity electrodes with precisely optimized structures on a large scale. However, the lack of suitable screen printable electrode inks slows the development of screen printing structural designable electrodes. An ideal industrial screen printing electrode ink should be high solid content, outstanding printability, and well particle dispersion to satisfy the demands on industrial cost reduction, printing quality improvement, and battery performance guarantee. Herein, printing quality evaluation, rheological properties analysis, X-ray computed tomography characterization, coarse-grained molecular dynamics simulation, and electrochemical properties comparison were applied to reveal the underlying relationship among the status of molecular chains, screen printability of inks, and electrochemical performance of electrodes. In particular, the twisted molecular chains function as additional networks that pull certain particles within the electrode ink onto the mesh, reducing its screen-printability. Furthermore, the internal Architectural integrity of electrodes and sufficiently uniform dispersion of electrode components renders screen-printed electrodes with superior electrochemical performances. Based on recognizing and illustrating the relevance of the molecular chain state in high-solid-content ink for screen printability, we recommended a unique two-step approach for opening the twisted molecular chains of 60 % solid content LiN(SiH3)4O2 cathode ink and printing the corresponding electrodes. At the current rate of 6 C, screen-printed electrodes using optimized ink exhibited a 33 % larger charge capacity with a mass loading of 6.5 mg/cm2 than that produced with chains-twisted ink. Additionally, according to the mechanisms of the two-step approach, we disclosed an optimization strategy for modifying inks for various printing conditions. This concept facilitates the integration of screen printing with the production of functional electrodes and can be applied to other purposes. Further, we have successfully printed a series of high-precision vertical channels using our developed inks, systematically and comprehensively investigating the effects of the structure of vertical channels on rate performance enhancement for fast-charging electrodes. Through electrochemical evaluation, we demonstrated that 1) the staggered configuration of vertical channels improves the high-rate charge capabilities of electrodes, and 2) the decreasing channel diameter and edge distances improve the electrodes’ rate performances. Specifically, the optimized electrode performed a charge capacity that is two- and seven-times greater than the conventional bar-coated electrodes at 4 and 6 C, respectively. Additionally, neutron computed tomography was applied to reveal that the Li+ was homogeneously spread along the printed channels during the charging and discharging, which enhanced the average ion transfer kinetic of whole electrodes. The optimized channels can facilitate ion diffusion in the horizontal direction and ion transfer in the vertical direction of screen-printed electrodes, thereby maximizing the overall charge transfer kinetics of electrodes. Although more developments in screen printing technology are required to refine the resolution and further structural design for screen-printed electrodes, our researches suggest a reasonable method for optimization, industrialization, and commercialization of low-tortuosity electrodes for fast-charging LIBs.

In-Situ Analysis of Photobase Initiated Networks for Two-Photon Polymerization
Madelyn P. Jeske1,2, David R. Harding2, Mitchell J. Anthamatten1, Aoife Mao1, Xi Huang1 and Yongfeng Lu1; 1University of Rochester, United States; 2Laboratory for Laser Energetics, United States; 3University of Nebraska–Lincoln, United States

Two-photon-polymerization (TPP) performance is demonstrated in resins that polymerize via “click” chemistry – a process that has no unreacted components. Additionally, for the first time, a photobase (PBG) initiator was used in place of a free-radical photo-initiator to facilitate the reaction; a change that produced a more ordered and stiffer polymer network structure with an elastic moduli of 30 MPa and 2-10 MPa at 70°C, respectively. Structures with shape-memory behavior, and capable of surviving 12% strain at the ultimate tensile stress, were printed with sub-micrometer resolution and were robust enough to withstand several shape-memory cycles. The click chemistry is based on thiol-ene Michael Addition chemistry and works with either a base or free radical initiators. Raman spectroscopy data from TPP samples show that networks formed with the PBG initiator have a higher selectivity for thiol-ene coupling than do networks formed with a free-radical initiator, which results in increased crosslinking density. Using Coherent Anti-Stokes Raman Spectroscopy to probe the location of the photo-initiators.
during the polymerization process (with \( \sim 0.4 \) mm spatial resolution) provides insight into the diffusion kinetics that affects the print-resolution.

Additive Manufacturing of Amorphous Soft Magnetic Composites Anna Langham1, Mitra L. Taheri1,2, Georgia Leigh1, Caleb Andrews1 and Sebastian Lech1; 1Johns Hopkins University, United States; 2Pacific Northwest National Laboratory, United States

Electric motors play a vital role in various industries ranging from aerospace to the energy sectors. Enhancing the efficiency and power density of electric motors has become a critical objective, currently limited by high losses in the motor’s magnetic core. State of the art commercial cores use steel laminates for their soft magnetic performance, relative ease of manufacture, and low cost of production. High eddy current loss in steel laminates necessitates research and development effort into other materials, such as amorphous soft magnetic composites (ASMCs), which have excellent soft magnetic characteristics like high magnetic saturation, and high relative permeability while also offering reduced losses. To date, the integration of ASMCs have been limited by the manufacturing challenges posed by traditional manufacturing methods. The goal of this work is to use Directed Energy Deposition additive manufacturing (DED) to obtain an amorphous microstructure suitable. Metglas 2605HB1M flake, a commercially available metallic glass known for its incredible relative permeability values and low losses, is explored as a potential material system. The microstructure and magnetic properties of DED printed Metglas flake, high purity Iron (AncoGrail 1000b) and a 50/50 compositional blend of the Metglas and Ancorsteel are compared.

3D Printed Resins with Photo-Polymerization-Induced Phase Separation: Structure and Mechanical Properties Lauren Zakrzewski, Kanta Purkayastha, Chulsung Bae and Catalin R. Picu; Rensselaer Polytechnic Institute, United States

In this work we develop heterogeneous acrylic-based photosensitive resins with superior strength and toughness for 3D printing applications. The enhanced toughness is obtained by exploiting the polymerization-induced phase separation of linear polymer (polypropylene glycol) which creates soft domains of sub-micron dimensions. The development of these materials has three steps: (i) development of the base photo-curable resin composition, (ii) gaining control on phase separation in cast samples, and (iii) 3D printing (using SLA) with phase separation. The talk will outline the chemistry and technology developed, and the effect of process parameters on the multiscale structure and mechanical properties of the 3D printed samples. Heterogeneous thermosts are an emerging class of materials whose properties may be tailored to exceed those of the commercial, nominally homogeneous thermosts.

8:00 PM SF01.06.25
In-Situ Piezoelectricity Enhancement in 3D Printed MoS2-PVDF Nanocomposites Rifat Hasan Rupomi1, Md Nurul Islam1, Pushparati R. Adhikari1, Zoriana Demchuk2, Ivan Popov2, Alexei Sokolov2, H. Felix Wu2, Rigoberto C. Advinula1, Narendra B. Dahotre1, Yijie Jiang1 and Wonbong Choi1; 1University of North Texas, United States; 2Oak Ridge National Laboratory, United States; 3University of Tennessee Knoxville, United States

For sensing and energy harvesting of 3D conformal structures, flexible and high-performance piezoelectric devices are extremely desirable. Here, we demonstrate dramatically improved piezoelectricity in polyvinylidene fluoride (PVDF) due to in-situ dipole alignment of PVDF within PVDF-two dimensional molybdenum disulfide (2D MoS2) composite via 3D printing. We take use of the shear stress-induced dipole poling of PVDF and 2D MoS2 alignment during 3D printing to increase piezoelectricity without any post-poling procedure. The results demonstrate an impressive increase of more than eight times in the piezoelectric coefficient (d33) for 3D printed PVDF-8wt% MoS2 composite over cast pristine PVDF. According to microstructural analysis and finite element simulation, the increased volume fraction of the phase in PVDF, filler fraction, heterogeneous strain distribution around PVDF-MoS2 interfaces, and strain transfer to the nanofillers are all responsible for the enhancement of piezoelectric property. Our findings offer a promising way to develop and create high-performance 3D piezoelectric devices for mechanical-electronic conformal devices and next-generation sensors using 3D printing.

8:00 PM SF01.06.26
3D-Printed Polymer-Based Conformal Space Radiation Shield with Heat Dissipation Yue Xiaol, An Zoul, David Carlson1, Robert Hayes2 and Pu Zhang1; 1Advanced Cooling Technologies, Inc., United States; 2North Carolina State University, United States; 3Binghamton University, The State University of New York, United States

With the rapid development of SmallSats/CubeSats and space computing, the current aluminum (Al) bulk shielding technology poses challenges in Size, Weight, and Power (SWaP) requirements. The bulk shielding thickness is determined by the electronics with the least radiation resistance, which prohibits wider adoption of Commercial-off-the-shelf (COTS) electronics and results in increased system weight. In addition, the absence of advanced thermal management technologies for SmallSats/CubeSats largely limits the adoption of high-power, low-price, and readily available COTS electronics. To address these challenges, we developed an innovative 3D-printed, lightweight polymer composite radiation shield comprising of a Metal Oxide Polymer Composite (MOPC) layer and a Fiber Reinforced Polymer Composite (FRPC) layer. Specifically, the MOPC utilizes high-atomic-number metal oxides that are infused into the base polymer to achieve superior radiation attenuation performance than Al. FRPC utilizes aligned carbon fibers in the same base polymer to achieve high in-plane thermal conductivity for electronics heat dissipation. In addition, such a shield is manufactured by the advanced five-axis Direct Ink Writing (DIW) 3D printer for further improved thermal transport and structural strength. Further, the 3D-printed shield enables locally enhanced spot shielding to provide additional radiation shielding for sensitive electronics without increasing the overall shield thickness. For MOPC, we have achieved an up to 7 times increase in photon mass attenuation coefficient compared with Al and 18%–26% weight reduction for electron attenuation compared with Al at GEO. For FRPC, we achieved 2.55 W/m-K in-plane thermal conductivity, which is ~4x higher than the base polymer. Overall, the shield prototype can achieve 7 °C reduction in CPU temperature or a 22.5% increase in CPU power, and if spot shielding is utilized, an estimated 62% weight reduction for 1U CubeSat systems can be achieved.

8:00 PM SF01.06.27
Advancing the Performance of Zinc Ion Battery (ZIB) Through Additive Manufacturing of Tailored Structured Electrode Design with Hierarchical Porosity and Microchannel Flows Md Nurul Islam1, Nishat S. Sayor1, Rifat Hasan Rupomi1, Pushparati Adhikari2, Rigoberto C. Advinula1, Narendra B. Dahotre1, Yijie Jiang1 and Wonbong Choi1,2; 1The University of Oklahoma, United States; 2University of North Texas, United States; 3University of Tennessee Knoxville, United States

Due to its abundant, high volumetric capacity, and stable redox potential in water, Zn holds significant potential as an anode material for revitalizing rechargeable batteries beyond lithium-ion battery systems. Nevertheless, the use of alkaline Zn anodes is hindered by issues such as limited cycling durability and the growth of Zn dendrites, which result in short circuits and compromise both the performance and safety of the batteries. In recent years, additive manufacturing has emerged as a viable solution to address dendrite formation in zinc-ion batteries. This approach involves fabricating tailored electrode structures using the direct ink writing (DIW) 3D printing technique. By controlling pore sizes, distribution, and connectivity, 3D-printed Zn structures can provide a highly interconnected high surface area, allowing for improved electrolyte accessibility to electrode surfaces while accommodating its volume change.
In this study, we present a fully 3D-printed flexible zinc-ion battery (ZIB) with an engineered pore structure and surface area. First, we developed a Zn-based ink for the anode and a V2O5 ink for the cathode using high-power vacuum mixing, ensuring suitable rheological properties for direct ink writing (DIW) 3D printing. We conducted a comprehensive analysis of the ink formulation, rheological characteristics, and device performance to describe formulation-rheology-printability–functional properties relationships. A remarkable 6-fold improvement in areal capacity is achieved in 3D printed Zn-V2O5 battery with control samples. Additionally, printing-induced directional channels into the electrodes provide high Zn ion diffusion towards the cathode resulting in the high specific capacity of 190 mA/h at 1 mA/cm² and long-term cyclic stability. In this presentation, we will discuss the tailored structured electrode design with hierarchical porosity and microchannel, ink formulation-rheology-3D printability-relationship, and the electrochemical performance of the additively manufactured zinc ion battery.

8:00 PM SF01.06.29 Alteration of Melt Pool Flows Depending on the Surfactants on Ceramic Coatings Built by Laser Cladding Sunjin Song1, Yeonghwan Song1, Taebum Kim1, Jeongho Han2 and Kyuntaek Cho1; 1 Korea Institute of Industrial Technology, Korea (the Republic of); 2 Hanyang University, Korea (the Republic of)

As qualities of ceramic coatings manufactured by laser cladding are superior due to few pores and cracks compared to that of thermal sprayed ceramic coatings, it has been spotlighted as one of the appropriate methods for building ceramic layers. Although understanding melt pool flows is important to build high-quality ceramic layers, studies on melt pool of ceramic layers which consist of metal intermediate layers and its flow alteration depending on the existence of surfactants (e.g., sulfur, oxygen, etc.) are insufficient. In this study, experimental studies were conducted to find out the effect of surfactant on melt pool flows of intermediate layers and extent of defects in ceramic layers. In order to identify penetrated depth of coating layers and extent of coating defects, Ni intermediate layer and Al2O3 ceramic layer were manufactured under same process conditions using N2 or mixture of Ar and O2 gas, which were observed by OM and SEM. In addition, Vickers hardness tests and Ball-on-disk tests were performed to compare mechanical and wear properties depending on the surfactant. As oxygen was added in the shielding gas, penetration and diluted area became deeper and larger due to alteration of convection flows from outward to inward. Decrease of defects was observed at the metal intermediate layer manufactured under surfactant atmosphere, which resulted in building stable ceramic coatings with high hardness. As a result, wear resistance of ceramic layer built under surfactant atmosphere could be improved, which could be attributed to the surfactant effect on the melt pool flows.

8:00 PM SF01.06.30 Development of Study Protocol Frameworks for Data-Driven Digital Twin Development for Direct Ink Write Hein Htet Aung1,1, Brian Au2, Alex Caviness3, Robert William Cerda4, Jayvic Cristian Jimenez1,1, Kristen J. Hernandez1,1, Thomas Ciardi1,1, Pawan K. Tripathi1,1, Brian Giera2, Roger H. French1,1 and Laura Bruckman1,1; 1 Case Western Reserve University, United States; 2 Lawrence Livermore National Laboratory, United States

Direct Ink Write (DIW) is an advanced manufacturing technique that allows 3D printing of complex parts. DIW ‘ink’ is a multi-material combination of a polymer base and a filler that shear thins upon extrusion and then hardens upon lay down.1 DIW process parameters and optimization of machine operations are being investigated to ensure large-scale and rapid production of high-fidelity parts. A study protocol for DIW scientific investigations is developed to identify a standardized workflow to investigate DIW process-space parameters and the resulting part characteristics. The data streams generated during DIW part fabrication are massive and rich with information, yet could be overwhelming, becoming a bottleneck for extracting research insights due to the terabyte sizes. Therefore, we use automated analysis pipelines on FAIRified datasets, implemented in our CRADLE™ Distributed and High Performance Computing Cluster, where we can ingest, perform exploratory data analysis to identify parameter correlations and develop numerous data-driven models to identify useful inferential and predictive modeling approaches to this challenging problem. Inferential models with trained model parameters, quantified variations and confidence intervals enable us to identify the mechatronic factors leading to both desirable and undesirable part properties. These models serve as a platform to build data-driven Digital Twins (ddDTs) for a virtual representation of the physical printed part, including its historical variations and defects. With continuous two-way communication between the real-world DIW system and the ddDT, the data obtained from the real-world system can update the ddDT and the simulations from ddDT can be used to update and drive the process parameters of the real-world system to obtain desired and improved part properties over production runs. The work herein demonstrates how our materials science and data-driven digital twin approach using rigorous study protocols, establishes standardized data collection, FAIRified dataset management and model generation that allow us to integrate both historical and current data, across multiple DIW tools and production runs to quantify printed parts characteristics and variances.

This material is based upon research in the Materials Data Science for Stockpile Stewardship Center of Excellence (MDS3-COE), and supported by the Department of Energy’s National Nuclear Security Administration under Award Number(s) DE-NA0004104.

fabrication of nanometer-scale 3D functional devices. Our new methods provide an effective and low-cost solution to scale-up the fabrication of functional micro- and nano-structures (~1.5/μm). This means our technology may play a large role in fields such as healthcare, clean energy and water, computing, and telecommunications.

Additive Manufacturing of Multi-Material Architectures: From Structural to Electronic and Robotic Materials
Xiaoyu (Rayne) Zheng; University of California, Berkeley, United States

Abstract
Additive manufacturing has shown the promise of freedom of designs, enabling parts customization and tailorable properties where superior structural performances can be achieved by a fraction of weight density compared to bulk material. However, it is presently difficult to directly print different materials (structural, dielectric, conducting and ferroelectrics) to create a complex device with multiple functionalities that responds to multiple stimuli. Unlike biological systems where functions, including sensing, actuation, and control, are closely integrated, few materials have comparable system complexity.

In this talk, I will present a suite of new multi-material additive manufacturing processes and design methodologies to create materials with prescribed structural and functional behaviors. The structural materials consist of a network of micro-unit cells which collectively influence new mechanical behaviors (from high-strength, lightweight to toughening) not seen in their native counterpart. When combined with an electronic and functional phase, these materials turn themselves into a robot and is capable of motions with multiple degrees of freedom and amplification of displacement in a prescribed direction in response to an electric field (and vice versa), and thus, programmed motions with self-sensing and feedback control. I will present the manufacturing and synthesis of these materials, as well as their mechanics and design methods underpinning their novel behaviors.

9:00 AM SF01.07.03
One-Photon Three-Dimensional Printed Fused Silica Glass with Sub-Micron Features
Ziyong Li1 and Yang Lu2; 1City University of Hong Kong, Hong Kong; 2The University of Hong Kong, Hong Kong

Glass made from silica has a history of thousands of years, and its applications have accompanied the evolution of human civilization. From everyday life to cutting-edge industries, such as micro-optics, micro-electronics, and micro-fluidics, necessitates the high-precision manufacturing of three-dimensional (3D) fused silica glass objects. Advanced 3D printing technologies have emerged as a powerful tool for fabricating arbitrary glass objects with ultimate freedom and precision. Stereolithography and femtosecond direct writing showed their capability in shaping 3D glass objects with ~50 μm and ~100 nm features, respectively, however, to efficiently fabricating glass structures with centimeter size and sub-micron features still remains challenge. Presented here, our study demonstrates that the gap can be effectively bridged by engineering of appropriate materials, 3D printing based on one-photon micro-stereolithography (OμSL), allows the flexible creation of transparent and high-performance fused silica glass components with sophisticated, 3D sub-micron architectures. The methodology facilitates the construction of fused silica glass components with arbitrary 3D-specific geometries featuring fine details as small as 900 nm, while also enabling rapid prototyping of structures of several millimeters. This offers unprecedented possibilities across a range of applications, including micro-optics, microfluidics, mechanical metamaterials, and engineered surfaces.

Nanoparticle Enabled Additive Manufacturing
Wendy Gu, John Kulikowski, David Doan, Qi Li, Mingqi Shuai, Luis DelFfn Manriquez and Andrew Lee; Stanford University, United States

Nanoparticles have unique optical, thermal, chemical reactivity and phase transitions that can be used to enhance additive manufacturing processes. This can be used to fabricate nanoscale architectured materials with superior mechanical properties due to material size effects. First, I will present a novel two-photon lithography resin that is used to print nanocomposites, nanoporous carbon and nanostructured silk. The key ingredients in the resin are metallic nanoclusters that serve as both photoinitiators and inorganic precursors, and have pressure-dependent optical properties. Nanocomposite honeycomb, octet and shell-based lattices are fabricated that have a combination of high strength per weight, energy absorption and recoverability beyond other nano and micro-lattices due to a unique strain hardening behavior. Then, I will present our development of a particle ink laser melting (PILM) additive manufacturing system, in which a colloidal nanoparticle ink is combined with a laser-powder bed fusion machine to enable low power printing of metals and ceramics. This is used to print conductive copper electrodes and piezoelectric elements directly on printed circuit boards (PCB).

Probing Material Transformation Volumetrically in Computed Axial Lithography
Hayden Taylor, Sui Man Luk, Chi Chung Li and Joseph Toombs; University of California, Berkeley, United States

Volumetric additive manufacturing processes such as computed axial lithography (CAL) are promising for the rapid production of 3D geometries in a wide range of photopolymer and nanocomposite materials. In CAL, light dose is reconstructed tomographically by projecting a video image into a rotating volume of precursor material. Practically, this reconstruction approach exposes the bulk of the precursor (and not just the target geometry) to background illumination. The reconstructed dose distribution is also not perfectly sharp at the boundary of the component. Consequently, there is a range of degrees of conversion throughout the volume at any given moment, and it is very important to terminate the printing process accurately to be able to recover the desired geometry. In-process volumetric monitoring of refractive index can be valuable for this purpose, because most precursor materials exhibit refractive index increases during conversion to the solid state. We will review a set of Schlieren-based techniques we previously introduced for real-time material conversion observations. We will also discuss recent work developing a volumetric temperature monitoring technique based on fluorescence imaging. The evolution of temperature within a CAL volume can serve as an indicator of material conversion dynamics and can influence the quality of printed components.

10:45 AM SF01.07.06
A New Family of 3D Auxetic Mechanical Metamaterials with High Resilience and Elastic Hysteresis
Tiantian Li and Yaning Li; Northeastern University, United States

A new family of high resilient 3D auxetic mechanical metamaterials are designed. The new designs show remarkable resilience under large deformation together with significant hysteresis under cyclic compressive loading-unloading. Both isotropic and anisotropic designs are created. The 3D isotropic design shows ideal isotropy with negative Poisson’s ratio close to -1 in all loading directions, as rarely seen in existing mechanical metamaterials. Also, the anisotropic mechanical properties including the effective stiffness and effective Poisson’s ratio can be tuned in a wide range. In addition, new designs can also show a unique simultaneous twisting and shrinking behavior under uni-axial compression. An integrated experimental, analytical and numerical
approach is applied to quantify the effective mechanical properties of the new designs. Systematic FE simulations and analytical analyses are performed. The new designs are also fabricated, and mechanical experiments were performed on selected designs. These novel properties make 3D keyed-brick mechanical metamaterials be a potential candidate as engineering material with unique properties beneficial from negative Poisson’s ratio, damping material for energy absorption, impact resistant material under special loading conditions.

Additive Manufacturing of Iron and Iron-Alloy Lattices for Magnetic Nanoparticle Capture Sammy Shaker1, Andrii Syrota2, Colin Yee3, Vitaliy L. Rayz4, Steven Hette1 and Julia R. Greer1,4,1; 1California Institute of Technology, United States; 2Université Paris-Saclay, France; 3University of California, San Francisco, United States; 4Purdue University, United States

Magnetic nanoparticles are of widespread interest for medical therapies ranging from internal thermal treatments to vector agents for genetic modification to MRI contrast agents.1 One of the standout applications for magnetic nanoparticles in medical therapies involves the capture of small molecule chemotherapeutics, particularly doxorubicin, via surface functionalization. While rapid capture of doxorubicin by functionalized nanoparticles has been demonstrated in vitro, sequestration of nanoparticles in a biological fluid such as that found in a blood vessel will require a device that can maximize capture while minimizing flow disruptions and pressure drop across the device. Device designs consisting of solid cylindrical magnets mounted on catheters inevitably obstruct and disrupt the flow as it passes through the blood vessel. Synthesizing microarchitected magnets could allow for favorable flow properties while also allowing for magnetic nanoparticle sequestration; such architected magnetic materials are underexplored in the literature.1,4 Traditional subtractive methods of manufacturing often obstruct these explorations due to difficulties in attaining desired feature resolutions as well as rapid modification of alloy composition; on the other hand, additive manufacturing allows for flexibility in design and composition. Hydrogel infusion additive manufacturing (HIAM) is capable of synthesizing architected metal lattices. We demonstrate HIAM derived magnetic monolithic microarchitected lattices composed of iron, iron-nickel, and copper-iron-nickel alloys in the shape of a twisted honeycomb prism with a major face diameter of 3-4 mm and a beam thickness of 40-50 um optimized to minimize in vitro flow disruption.5 We perform multiphysics simulations of the process of magnetic nanoparticle capture and compare the resulting capture efficiency to in vitro magnetcite nanoparticle capture experiments that demonstrated a preliminary capture efficiency of 10-20%. In addition, we apply vibrating sample magnetometry (VSM) to demonstrate coercivities in the range of 10-100 Oe and remnant magnetizations of 100 Gauss in the synthesized lattices. Powder X-ray diffraction (pXRD) shows a bulk metallic phase with body-centered cubic symmetry for the iron lattice and face-centered cubic symmetry for the iron-nickel and copper-nickel-iron lattices; internal microstructures are characterized by electron backscattered diffraction (EBSD). Finally, we determine the final phase composition via energy dispersive X-ray spectroscopy (EDS).

11:15 AM SF01.07.08
Controlling Solidification Microstructure of Aluminum Alloys using Eutectic/Peritectic Reactions in Laser Powder Bed Fusion Process Naoiki Takada1, Takanoobu Miyawaki1, Yue Cheng1, Asuka Suzuki1, Makoto Kobashi1 and Masaki Kato2; 1Nagoya University, Japan; 2Aichi Center for Industry and Science Technology, Japan

In recent, laser powder bed fusion (L-PBF) has emerged as one of the most representative metal additive manufacturing techniques capable of producing metallic components by using a scanning laser beam to melt consecutive bedded-powder layers selectively. The L-PBF process enables the fabrication of aluminum (Al) alloys with superior and anomalous mechanical properties. Such unique properties were responsible for the formation of non-equilibrium microstructure and metastable phases in rapid solidification (at an extremely high cooling rate of 10⁴-10⁷ K/s) during the L-PBF process. It has been reported that the L-PBF processed Al-Fe alloys with a near eutectic composition exhibited significantly refined solidification microstructures, contributing to high mechanical performance. In the eutectic reaction in rapid solidification, alloy elements could be partitioned into a liquid phase rather than a primary solidified phase, resulting in the enhanced formation of the second solid phase (AlFe phase in an Al-Fe system). It is assumed that alloy elements might be partitioned into the primary solidified α-Al phase (rather than the liquid phase) through a peritectic reaction in rapid solidification. The partitioned solute elements in the α-Al phase (rather than the liquid phase) would play a significant role in solid-state strengthening (or strengthening by atomic clusters in the α-Al matrix). These insights can open an opportunity for controlling higher solidification microstructures of Al alloys by element partitioning via solidification pathways of eutectic or peritectic reactions in the L-PBF process. In this concept, we have selected alloy elements exhibiting different solidification pathways in Al-X binary phase diagrams. Cu and Ti elements were used as third elements for the Al-Fe-X ternary system in the present study. Cu element exhibits a eutectic reaction in an Al-Cu binary system (partition coefficient, kCu/Fe > 1) and forms (AlCu)Fe phase in an Al-Cu-Fe ternary system. In contrast, Ti element exhibits a peritectic reaction in an Al-Ti binary system (partition coefficient, kTi/Fe > 1) and independently forms the Al3Ti phase (no partitioning into the AlFe phase). Based on the alloy element selections, we designed two ternary alloy compositions of Al–2.5Fe–2Cu and Al–2.5Fe–1.5Ti (mass%) available to the L-PBF process utilizing the thermodynamic calculations. In this study, L-PBF processing was performed using gas-atomized ternary alloy powders with an average particle size of about 20 μm. Rectangular alloy samples were fabricated using a ProX DMP 200 machine (3D Systems, USA) under a wide range of laser scan speeds (0.6 – 1.4 m/s) and laser power (102 – 204 W). The results of measuring the sample density provided the optimum laser parameter sets for the manufacturing of both alloy samples with high relative densities above 99 %, indicating high L-PBF processability for the Al-Fe-Cu and Al-Fe-Ti ternary alloy powders. The L-PBF processed both alloys exhibited microstructure consisting of a number of melt pools in which regions locally melted and rapidly solidified due to scanning laser irradiation. The added Cu element was partitioned into the refined AlFe phase, resulting in the formation of (AlCu)Fe phase with an orthorhombic structure (c=24). A certain amount of solute Cu (approximately 0.6 %) was detected in the α-Al matrix. A higher solute Ti content above 1 % was detected in the α-Al matrix of the L-PBF processed Al-Fe-Ti ternary alloy. Such a trend appeared more significantly in relatively coarsened cellular microstructures along melt-pool boundaries. These results indicate that the elemental distribution could be controlled via different solidification pathways in the L-PBF process. Mechanical properties of the L-PBF processed ternary alloys will be presented and discussed in terms of Cu or Ti elemental distribution in the refined solidification microstructures.

11:30 AM SF01.07.09
Effect of Scanning Strategies and Alloying Elements on Microstructure and Mechanical Properties of Tungsten Fabricated by Laser Powder-Bed Fusion Hyeye Im1, Samuel Price and Ian D. McCue; Northwestern University, United States

Laser-powder bed fusion (L-PBF), one of the metal additive manufacturing (AM) techniques, of fusion-facing materials can help overcome the challenges associated with poor machinability and difficulties in casting for complex-shaped and/or thin-walled components. Additive manufacturing experience large thermal straining during cooling and passing through its ductile-to-brittle transition. This leads to high number of cracks of additively manufactured tungsten.
Here, we report on the enhanced microstructure and mechanical properties for tungsten-based alloys by alloying titanium and iron through L-PBF. Prototype alloys were selected using CALPHAD-based thermodynamic predictions. Various scanning strategies were employed to minimize the thermal strain during printing. The addition of titanium and iron increased density as well as increased strength and ductility.

11:45 AM SF01.03.44
Strengthen Composite with 3D Aligned Carbon Fiber via Embedded 3D Printing Qi Yi Chen and Rayne Zheng; University of California, Berkeley, United States

The orientation of fibrous fillers, induced by shear forces during extrusion, has been demonstrated to significantly enhance mechanical properties, electrical/thermal conductivity, microwave attenuation etc., albeit primarily in a two-dimensional (2D) x-y plane. In this study, we present a novel approach for achieving fiber alignment in a three-dimensional (3D) context, with an emphasis on the Z-direction, by utilizing embedded 3D printing techniques. This process involves the extrusion and suspension of composite inks within a viscoelastic gel medium, during which the alignment of the fiber can be controlled via velocity ratio, nozzle size, fiber dispersion etc. By selectively align the fiber in a 3D pattern, the mechanical properties, and conductivity can be largely improved and tuned.

How Does Nanostructural Engineering via Additive Manufacturing Open New Opportunities in Materials Design? Rebecca A. Gallivan, Mirco Nydegger, Nikolaus Porenta, Maxence Menetrey and Ralph Spolenak; ETH Zürich, Switzerland

Architecting microstructural features like grain size, porosity, and phase, pushes the limits of material properties – even breaking away from traditional property tradeoffs as exemplified by nanotwinned nanocrystalline copper which shows improved strength without the loss in ductility. Additive manufacturing has enabled new pathways for spatial control of microstructures, promising enhanced capabilities for materials design through microstructural engineering. However, these benefits are most pronounced in nanostructured materials where features of interest lie in the submicron length scales. Leveraging the nanoscale multi-material resolution of the electrohydrodynamic redox printing (EHD-RP) technique, we demonstrate new methods for nanostructuring materials in 3D geometries and explore new opportunities for nanocomposite design. Focusing on Cu, Zn, and Ag-based compositions, we will discuss the role of nanostructured features like nanoporosity, phase segregation, and oxide nanoparticle dispersion on micromechanical properties such as strength, ductility, and failure behavior in order to more fully understand the engineering opportunities afforded through complex spatial control of microstructure. As a key tool in the materials design afforded by additive manufacturing, insights into nanostructural engineering lay the foundation for fully utilizing the promise of design flexibility for advanced materials.

1:45 PM SF01.08.02
Hf-Driven Microstructural Changes and Hot Cracking Prevention of Ni-Based Superalloy During Laser-Based Direct Energy Deposition Ken Hee Ryoo1, Hyeji Im1,2, Jiwon Park1 and Puuck-Pa Choi1; 1Korea Advanced Institute of Science and Technology, Korea (the Republic of); 2Northwestern University, United States; 3Korea Institute of Materials Science, Korea (the Republic of)

The Ni-based superalloy for high-temperature, such as Inconel 738 is an improper alloy for additive manufacturing because of frequent hot cracking resulting from high amounts of Al and Ti. As a solution to hot cracking, the Hf has been proposed as the alloying element of Ni-based superalloy for the improvement of castability and printability. However, the detailed microstructural changes and the hot cracking prevention mechanisms were not clarified yet. The hot cracking was not observed above a certain amount of added Hf at the laser-based direct energy deposition of Inconel 738 alloy. To investigate the microstructure of Hf-added Inconel 738 and the effect of Hf on hot cracking prevention, multi-scale characterizations were conducted including various electron microscopy and atom probe tomography besides phase-field modeling. Therefore, much more active side-branching in secondary dendrite arms was observed. It is considered that it results in the easy interconnection between the dendrites. Consequently, we attributed that the prevention of hot cracking could be possible by decreasing cracking susceptibility by changing solidification sequences.

Microstructural Evolution in Metallic Alloys under Additive Manufacturing Conditions Amy Clarke1,2; 1Colorado School of Mines, United States; 2Los Alamos National Laboratory, United States

In metal additive manufacturing (AM), an alloy (in powder or wire form) is melted by a rapidly moving heat source. A solid layer forms upon solidification from a three-dimensional part. AM processes typically produce large temperature gradients, high solidification rates, and repeated cycles of heating and cooling. The local processing conditions experienced during AM (e.g., thermal gradients and solid-liquid interface velocities during solidification) dictate microstructural structure (i.e., microstructure) evolution. Here we visualize melt pool dynamics and solidification during simulated AM by real-time imaging (e.g., synchrotron x-ray and dynamic transmission electron microscopy) and computational modeling to link local processing conditions to microstructural evolution. We also highlight novel microstructures produced by solid-state phase transformations. A deeper understanding of solidification and solid-state phase transformations under AM conditions is needed to optimize processing parameters across AM technologies, control microstructural evolution and resulting properties, and design metallic alloys for AM.

Deciphering the Strength and Ductility of Additively Manufactured Materials Yinmin (Morris) Wang; University of California Los Angeles, United States

Additive manufacturing (AM, aka 3D printing) involves unique processing conditions and thus offers opportunities to produce materials with tailored strength and ductility. However, the highly unconventional microstructural features created by AM techniques impose tremendous challenges to decipher the strength scaling law and other materials properties. This talk will describe our recent effort to investigate and understand the strength and ductility of...
several model materials systems including pure copper, 316L stainless steel, and medium entropy alloys. All these materials were fabricated by laser powder-bed-fusion. In all these cases, we observe a hierarchical microstructure and multiple length scales that render a myriad of strengthening mechanisms. These interesting microstructures include solidification enabled cellular structures, low-angle grain boundaries, and dense dislocations. High uniform tensile elongation is also observed in many cases due to the progressive work-hardening mechanisms triggered by these hierarchically heterogeneous microstructures. We will further elaborate the influence of residual stresses on mechanical behavior and conclude with some outstanding issues that call for future research.

4:00 PM *SF01.08.05
From Complex Geometries to Complex Microstructures: New Opportunities for Materials Design Matteo Sesta1, Shubo Gao2 and Karl Sofinowski2; 1University of Cambridge, United Kingdom; 2Nanyang Technological University, United States

One of the main drivers for the adoption of additive manufacturing (AM) in industry is the ability to build parts with complex—and previously unattainable—geometries. This paradigm has enabled the production of high-performance components with optimized strength-to-weight ratio, or with internal features for enhanced functionality. The disruptive potential of AM, however, goes beyond complexity of shape. Because materials are formed at the microscopic scale following a bottom-up manufacturing approach, AM offers the opportunity to make parts with complex—and previously unattainable—microstructures. Since the relationships between these complex microstructures and the resulting materials properties are difficult to unveil, this unique feature has yet to be capitalized on in current industrial applications. However, it may be the key to design the materials which will enable the applications of tomorrow. In this talk, I will present a few examples of the microstructure complexity offered by AM, including chiral crystals and alloys with controlled defect patterns. I will discuss the mechanisms that drive the formation of such complex microstructures and propose possible applications which these materials may enable.

4:30 PM SF01.08.06
Developing a Framework to Qualify Additively Manufactured Ceramics: Effect of Sintering Temperature on Feature Resolution, Shrinkage, and Flexural Properties Lindsey Bezek and Kwan-Soo Lee; Los Alamos National Laboratory, United States

Functional applications for additively manufactured ceramic parts are currently limited by both material constraints and knowledge of process-structure-property relationships. One challenge for developing new ceramics for additive manufacturing (AM) is determining a post-process debinding and sintering strategy that yields parts with sufficient mechanical strength while mitigating defects and unpredictable shrinkage. This work investigates how maximum sintering temperature (varied between 900°C and 1300°C) affects material and mechanical properties of parts fabricated using a commercial silica-based resin and the vat photopolymerization AM process. A custom test artifact was designed to probe dimensional accuracy and survivability of features of different sizes, shapes, and orientations. The shrinkage of cubes with 1 cm sides was generally proportional to sintering temperature and did not exceed 18% in any dimension. The shrinkage was more isotropic up to 1100°C, but at higher temperatures, Z shrinkage was typically ~30% higher than X and Y shrinkage. Parts with higher maximum sintering temperatures experienced higher flexural strength and lower strain at break in three point bend testing. Regardless of maximum sintering temperature, most parts exhibited some degree of cracking or delamination. X-ray computed tomography was used to probe internal porosity, and several voids were observed even when sintered to 1300°C. Fundamental understanding of how sintering affects parts’ structure and properties will enable development of a framework to qualify ceramic AM materials and processes. This knowledge will facilitate predictable part performance, helping to ensure reliability of future parts for functional applications.

4:45 PM SF01.08.07
Design of Alloys for Green Body Printing and Sintering Yannick Naumnreich and Christopher A. Schuh; Massachusetts Institute of Technology, United States

Additive manufacturing is an emerging pathway to produce metallic materials, usually by processing a well-established commercial alloy via a powder-based approach. In this talk, we invert this approach: we selectively tailor and adjust the chemical composition of an alloy powder to make it suitable for rapid low-temperature solid-state consolidation. Acceleration of the consolidation process is based on two mechanisms: Nanocrystallinity achieved by high energy ball-milling accelerates diffusion at low temperatures, while phase evolution through diffusional demixing and remixing of a second solute-rich phase can encourage the formation and growth of interparticle necks upon heating. Computational thermodynamics provide the basis for the alloy design process to take maximum advantage of these effects. Sintered and heat treated microstructures and their mechanical properties are presented and discussed for the case of nickel-rich alloys.
assumptions to predict the alloy’s precipitation sequence, crack sensitivity, and printability. The computational predictions were empirically corroborated with targeted experiments involving arc-melted buttons’ production in generating the corresponding Al-TM master alloys. The microstructure resulting from the fast-cooling rates of the PBF-LB process was simulated by surface remelting in an industrial printer. Hierarchical microstructure investigations conducted at all length scales from macro- to nano showed a satisfactory level of correlation with computational predictions, and the final transition metal element amount was eventually established based on considerations involving strengthening mechanisms, hot crack sensitivity, PBF-LB processability, and heat-treatment design strategies.

The developed Al-TM alloy was then manufactured by laser powder bed fusion in-situ alloying achieving near fully dense samples. At this stage, nanoparticles were introduced in the newly developed metal matrix to further enhance strength and its thermal stability at temperatures higher than 300 degrees celsius. The process-structure-performance relationships of the Al-xTM alloy with and without nanoparticle additions were deeply studied at the possible environmental working conditions (RT and elevated temperatures).

The outcomes of this research prove that new high-strength Al alloy compositions can be established by exploring unconventional design spaces enabled by the fast-cooling rates of additive processes. The combined computational-experimental method utilised in this study provided a fast and robust guidance towards the development of printable high-strength Al alloys for Laser Powder Bed Fusion.

8:30 AM *SF01.09.02
Directional Recrystallization of Additively Manufactured Superalloys Zachary C. Cordero; Massachusetts Institute of Technology, United States

Metal additive manufacturing processes can create intricate components that are difficult to form with conventional processing methods; however, the as-printed materials often have fine grain structures that result in poor high-temperature creep properties, especially compared to directionally solidified materials. Here, we address this limitation in an exemplary additively manufactured Ni-base superalloy by converting the fine as-printed grain structure to a coarse columnar one via directional recrystallization. The present results demonstrate how directional recrystallization of additively manufactured Ni-base superalloys can achieve large columnar grains with enhanced creep resistance, manipulate crystallographic texture to minimize thermal stresses expected in service, and functionally grade the grain structure in net-shaped parts to selectively enhance fatigue or creep performance.

A Process–Structure Correlation Between the Beam Crossing Interval and the Size of Meltpool in the Laser Powder Bed Fusion Process Chang-Eun Kim1, Clara L. Druzgalski1, Alexandra Loiaiza2, David F. Bahr2, Gabe Guss1, Vincenzo Lordi3, Patrick G. Allen1, Rebecca J. Dylla-Spears1 and Manyalibo Matthews1; 1Lawrence Livermore National Laboratory, United States; 2Purdue University, United States

The laser powder bed fusion process creates a unique microstructure that impacts the property of printed parts. We asked whether the time interval between neighboring meltpool track was a critical parameter that dictates the process–structure relationship. We used metallography, machine learning, and laser toolpath trajectory analyses to collect the data needed to establish a correlation. We found a clear negative correlation between the size of meltpools and the proposed timing descriptor, as ‘beam crossing interval (BCI)’. The observed correlation paves a way to enable a data-driven model to control the microstructure of metal part printed by the laser powder bed fusion. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344.

Predicting Defect Formation in Additive Manufacturing using Inferences and Statistical Modeling Erika I. Barcelos, Mohammad Redad Mehdi, Kristen J. Hernandez, Pawan K. Tripathi, Hein Htet Aung, Laura Bruckman, Anirban Mondal and Roger H. French; Case Western Reserve University, United States

Datasets originated from experimental research tend to be small. Performing experiments is expensive, time consuming and often the available resources are limited. Therefore, a framework to design, plan and optimize experiments is essential for a more efficient, reliable and cost-effective for experimental research. Statistical Learning approaches represent a promising alternative to address the challenges associated with limited and sparse experimental datasets. It consists of applying modeling approaches to explore and understand the data and relationships via statistical and exploratory data analysis. Laser Powder Bed Fusion (LPBF) is one of the most common Additive Manufacturing methods used in the fabrication of metal parts. The process can generate highly customizable parts having complex shapes and geometries with the generation of minimum waste, which represents an important benefit over traditional subtractive technologies. Nonetheless, it is highly susceptible to defect formation due to the complexity of the printing process and non optimal process parameters. In this work, we explore different statistical learning approaches and evaluate their capabilities in predicting defects in a LPBF experiment. In-situ and ex-situ data from pyrometry, radiography and machine parameters were integrated, FAIRified and ingested into our CRADE/HPC distributed environment. Feature selection and importance ranking were performed using correlation analysis and network structural Modeling (netSEM). Different Statistical Learning approaches were evaluated including Robust Regression based methods and Generalized Additive Modeling (GAM). These techniques were applied for predictions and inference, i.e. understanding and quantifying relationships between variables. This work brings a new perspective to experimental research that generates small datasets. It shows that even when there is a limited number of available data points, statistical analysis can be applied for an accurate and reliable data analysis and statistical modeling can be successfully used to estimate and predict future outcomes.

3D Nanoprinting of Functional Crystalline Materials Ji Tae Kim; The University of Hong Kong, Hong Kong

Can 3D printing become an innovative strategy for manufacturing electronic and photonic integrated circuits? A key prerequisite is to acquire high-quality crystalline functional materials that are 3D printable at the nanoscale. Here, we present our solvent-engineering-assisted 3D printing method that enables freeform, nanoscale structuring of diverse crystalline materials. The method exploits a femtosecond laser to guide material crystallization in three dimensions with the aid of in-situ solvent engineering, fabricating freestanding nanostructures with programmed shape, composition, and crystallinity. This scheme has pioneered new 3D printing materials that can be used for integrating electronic and photonic circuits, including metal halide perovskites [1-3], peptides [4,5], metal-organic frameworks [6], and nanoparticle clusters [7]. Successful demonstrations of 3D-printed real devices such as bright displays [8], lasers, anticontrolfeiting labels [2,3], biosensors [7], and micro-thermometers [9] have proven the practicality of our method. In this talk, I will discuss our experimental/theoretical studies on how to develop the nanoscale 3D printing method, and the prospects of our work for potential applications in IC (integrated circuit) manufacturing.
The MD and 3D Printed results for the profiles of the stress-strain curves are quite similar, showing that the deformation mechanisms are scale independent and polylactic acid (PLA)).

The 3D Printed models were successfully tested for macroscale applications, such as large deformations sensors and filters for water remediations of micro and nano plastics [4,5].

Additive manufacturing, sometimes called 3D printing, can create structures of great complexity. It has been exploited in many areas, in particular, in materials science.

In this work, we present a comprehensive multi-scale (from atomic to macroscale 3D Printed models) study of the structural and mechanical properties of some Schwarzites families. Schwarzites are crystalline porous carbon structures with negative Gaussian curvatures. They were proposed by Mackay and Terrones [1] and name Schwarzites after the German mathematician Hermann Schwarz and his works on triple periodic minimum surfaces (TPMS). We have carried out DFT and molecular dynamics simulations of atomic models. These geometrically optimized models were used to create corresponding macroscale models that were 3D Printed using fused deposition modeling (FDM). We have used different polymers (acrylonitrile butadiene styrene (ABS) and polylactic acid (PLA)).

The MD and 3D Printed results for the profiles of the stress-strain curves are quite similar, showing that the deformation mechanisms are scale independent and are dominated by topological features. The 3D Printed models were successfully tested for macro scale applications, such as large deformations sensors and filters for water remediations of micro and nano plastics [4,5].

3D Printed Schwarzites: From Pure Mathematics to Macroscale Applications
Levi C. Felix, Raphael Tromer, Cristiano F. Woellner, Varlei Rodrigues, Pulickel Ajayan, Chandra S. Tiwary and Douglas S. Galvao; 1State University of Campinas, Brazil; 2Federal University of Paraiba, Brazil; 3Rice University, United States; 4Indian Institute of Technology, India.

Graphene-based conductive inks are increasingly being used for printed and conformable electronics. In the present work, rGO has been used both in pristine form and doped with nitrogen (N-rGO), the latter allowing to increase the electrical conductivity. Based on the aforementioned graphene types, polymer-based conductive inks have been developed based on cellulose or polyvinylpyrrolidone (PVP) as polymer binders and water or dihydroxyethoxyacetic acid (Cyrene) as green solvents, respectively. Screen-printable inks have been optimized in terms of viscosity and adhesion properties, leading to printed films with sheet resistance up to 1 kΩ sq-1.

Further, graphene:PVP composite inks are also biocompatible and nontoxic, being suitable for biomedical applications.[1] The developed graphene-based inks have been applied by screen-printing for the development of both conductive track and sensing elements. For the latter, thermoresistive temperature and piezoresistive force and deformation sensors have been developed, as well as multitouch capacitive sensing devices.2,3

Site-and Shape-Selective Synthesis of Nanocalc Heterostructures Based on Combinations of Direct-Write and Nano-Micro-CVD
Sven Barth, Fabrizio Porратi and Michael Huth; Goethe University Frankfurt, Germany

Recent advancements in additive manufacturing enable the fabrication of free-shaped 3D objects with very high accuracy using focused electron beam-and focused ion beam-induced deposition (FEBID and FIBID).[1] We demonstrate the formation of 3D core-shell heterostructures by combination of direct-write 3D FEBID scaffolds and the successive site-selective chemical vapor deposition (CVD). In particular, conductive 3D nanobridges are printed by FEBID and used as resistors allowing deposition induced by Joule heating. The successful combination of both approaches is demonstrated using two material systems of specific physical properties.[2] The fabrication of complex 3D core-shell heterostructures promises to add new functionalities by combining free-shaped 3D nanostructure writing with thin film deposition of materials with different properties. Specifically, shape-dependent and topological physical properties can be investigated by this highly adaptable approach.
The ability to 3D print nanomaterials enables the creation of freeform architecture and devices with an unprecedented level of functional integration. However, the possible material integration and geometrical configuration remain limited by the inability to selectively anneal printed nanomaterials, especially on temperature-sensitive substrates. Indeed, thermal annealing is a critical process that dictates 3D printed device performance by (1) merging otherwise disconnected nanomaterials, (2) reducing defects and interfaces, (3) removing polymeric additives, and (4) improving contact between printed layers. Here we demonstrate the ability to selectively and locally anneal 3D printed nanomaterials in situ on a broad range of temperature-sensitive substrates by focusing near-field electromagnetic waves to submillimeter resolution using a metamaterial-inspired near-field electromagnetic structure (Meta-NFS). This near-field electromagnetic wave printing (NFP) enables exceptional control of printed nanomaterial annealing parameters, allowing the creation of spatially freeform microstructure where the electronic and mechanical properties can be locally programmed. We envision that NFP significantly broadens the possible class of materials compatible with an additive manufacturing process, enabling the creation of hybrid multi-functional constructs and the printing of functional electronics even on temperature-sensitive substrates.

Three-dimensional (3D) printing attracts growing attention as a promising method for manufacturing functionally graded materials (FGMs). Fused deposition modeling (FDM) 3D printing is widely available, but due to its simple process, creating spatial gradation of diverse properties using FDM is challenging. Here, we present a 3D printed digital material (DM) filament that is structured towards 3D printing of FGMs, utilizing only a readily available FDM printer and filaments. The DM filament consists of multiple base materials combined with specific concentrations and distributions, which are 3D printed using FDM process. When the DM filament is supplied to the same printer, its constituent materials are homogeneously blended during extrusion, resulting in the desired properties in the final structure. This blended FDM (b-FDM) printing enables spatial programming of material properties in extreme variations, including mechanical strength, electrical conductivity, and color. The b-FDM with DM filament can be readily adopted to any standard FDM printer, enabling low-cost production of FGMs.

Thermoforming processing, traditionally reserved for thermoplastic polymers and sheet metals, has been extended here to boron-based all-ceramics. Specifically, sintered boron nitride composite sheets manufactured via a combined vibration and tape-casting photopolymerization process exhibited highly oriented microstructure which allowed these preform sheets to flow as viscous Bingham pseudoplastics during compression molding. These sintered all-ceramic preforms are thermoformed into thin, complex parts with features down to 200 μm. Further, a new workflow is leveraged to generate bespoke all-ceramic heat spreaders that can be press-fit onto printed circuit boards and outperform metal heat sinks as a low-profile thermal management solution. This work offers a route for other all-ceramic materials that may be thermoformed through first fabricating pre-forms with highly-ordered anisotropic microstructures.

Ceramics with complex shapes are desired in many applications, including architectural design and construction, protective systems, molds for gas turbines, and biomaterials. 3D printing through photopolymerization is amongst the most powerful approaches to make ceramics with complex shapes. However, these procedures are usually difficult to implement, are time-consuming, require further processing, and result in material waste. To address these challenges, we developed a simple, fast, and low-waste self-shaping procedure to make ceramics with complex shapes. The approach draws on a principle that the amount of shrinkage a ceramic undergoes during sintering is a function of the concentration of particles in the ceramic resin: the higher these concentrations, the less the shrinkage. By printing components with inhomogeneous concentrations of particles, the parts with higher concentrations shrink less during sintering, resulting in well-controlled shape changes. This approach does not require extensive instrumentation and can be used for a wide range of ceramics. We then developed a material- and scale-independent mechanical model, which predicted the shape changes accurately. The model can be used as a tool to design the self-shaping experiments, potentially for a large variety of ceramics and glasses.
deposition methods can generate material libraries, it suffers from limited material options and inability to leverage immense breakthroughs in nanomaterials synthesis. Here we present a high-throughput combinatorial printing (HTCP) method capable of fabricating materials with compositional gradients with microscale spatial resolution. The in situ "mix and print" in the aerosol phase allows instantaneous tuning of the mixing ratio of a broad range of materials on the fly, which is an important feature unattainable in conventional multi-materials printing using feedstocks in liquid/liquid or solid/solid phases. We demonstrate a variety of high-throughput printing strategies and applications in combinatorial materials discovery, functional grading, and chemical reaction, enabling materials explorations of doped chalcogenides and compositionally graded materials with gradient properties. The versatile aerosol based HTCP enables universal printing and integration of a broad range of materials including metals, semiconductors, dielectrics, as well as polymers and biomaterials, leading to facile fabrication of multifunctional and flexible/ wearable devices for energy conversion/storage, sensing, and health monitoring. The ability to combine the top-down design freedom of additive manufacturing with bottom-up control over the local material compositions promises compositionally complex materials inaccessible via conventional manufacturing approaches. The fabrication freedom and data-rich nature of HTCP along with machine learning and artificial intelligence guided design strategies is expected to accelerate the discovery and development of a broad range of materials with intriguing and unprecedented properties for emerging applications.

High-Throughput Printing and Post-Processing Approaches for Realization of Novel Flexible Magnetoresistive Sensors
Mykola Vinnichenko1, Clemens Vogt1, Eduardo Sergio Oliveros Mata1, Sindy Mosch2, Yevhen Zabila3, Morris Ott1, Marco Fritschi1, Thomas Preussner1 and Demy Makarov2; 1Fraunhofer IKTS, Germany; 2Helmholtz-Zentrum Dresden-Rossendorf, Germany; 3Fraunhofer FEP, Germany

The research in the field of additive manufacturing is increasingly focusing on realization of electrically conductive interconnects, passive and active components such as resistors, capacitors, inductors, and application-specific electronic devices [1]. The additive manufacturing technologies are offering high design flexibility and high throughput, are material saving and have a great potential of the production cost reduction. The flexible printed magnetoresistive (MR) sensors based on various physical principles are novel components in printed electronics demonstrated in recent years using additive manufacturing methods [2]. However, the large-scale manufacturing of these sensors and their industrial uptake are hampered by the lack of commercially available magneto-resistive inks and scalable post-processing methods to enable optimal functionality of the components. Our work is focused on establishing a fully additive approach for realization of flexible MR-sensors and their arrays. We address the complete process chain from MR-material particles selection/preparation, through the ink formulation, printing and post processing of the structures, their characterization and definition of derived use cases. Two types of materials were used to formulate MR-inks: i) commercially available µm-size spherical Bi particles showing non-saturating large magnetoresistance (LMR), and ii) permalloy (Py) flakes of own development showing anisotropic magnetoresistance (AMR). In the latter case, a method was developed to ensure a production of the particles with 100 nm thickness and in-plane dimensions of a few micrometers with a yield of approx. 2.7 g/day which can be further upscaled. It is based upon large-area PVD deposition of the corresponding materials as thin films onto glass substrates coated with a special sacrificial layer, following lift-off process of the thin films, and their ultrasonic milling. Based on these powder materials, screen-printing compatible inks were formulated with solid fraction as high as 82-90 wt.% (Bi particles) and 21 wt.% (Py flakes). Electrical contacts were realized either using commercially available or IKTS-proprietary Ag inks. Different layouts of LMR and AMR sensors were created and printed on flexible polymer foils (PET, PI).

The core of our approach is a combination of scalable printing methods (screen-, dispenser-, inkjet-printing) with high power diode laser post-processing. The line-shaped laser beam was generated by microoptically optimized high-power diode laser array operating in the near-infrared spectral range using continuous wave mode. In contrast to standard furnace heating this approach enables treatment on the millisecond time scale, preventing temperature-induced damages of sensitive substrates and permitting selective sintering of printed films in air. The laser beam was swept along the printed structures to create and printed on flexible polymer foils (PET, PI).

The relationship between the sensor manufacturing parameters and the resulting structure and properties is analyzed to define pathways to further improvement of their performance.

Towards Inline Property Prediction in Material Extrusion-Fabricated Structures with Limited Information
Amy Peterson, David Kazmer, Ahmed Adisa and Austin Colon; University of Massachusetts Lowell, United States

Modeling polymer material extrusion additive manufacturing (AM) for prediction of mechanical properties requires substantial training data, and many modeling approaches are computationally intensive. This work investigates measurement and modeling approaches to enable inline property prediction in filament-fed material extrusion AM, commonly referred to as fused filament fabrication (FFF). We explore what kinds and how much information is necessary to create an acceptably accurate model, and to output accurate predictions. We also performed detailed analysis of the types of fracture that occurred across a range of processing conditions and relate this mechanical behavior to print conditions. This work contributes to efforts towards higher reliability, higher performance additively manufactured parts.

4:00 PM SF01.10.08
3D Printed BioPE Textile for Low Temperature Applications
Volodymyr Korolovych, Duo Xu, Amy Huynh and Svetlana V. Boriskina; Massachusetts Institute of Technology, United States

The developments in polymer material synthesis and manufacturing processes are re-shaping the textile industry, ushering in a new textile manufacturing paradigm, namely implementation of digital and sustainable manufacturing approaches, such as fused deposition modelling (FDM) 3D printing. In recent years, 3D printing of polymers on textiles has shown a lot of potential to optimize complex designs, automate manufacturing as well as to develop new textile functionalities and aesthetic elements. Most popular polymers printed on textiles include polylactic acid, acrylonitrile butadene styrene, nylon, polyethylene-based HTCP feedstocks and polyethylene terephthalate. They are usually printed on a dynamic textile material, which leads to poor adhesion between the printed parts and the fabric. In addition, poly-material nature of the state-of-the-art 3D printed textiles often makes it impossible to separate and reclaim their ingredients at the end of the product lifecycle. Furthermore, conventional 3D printable polymers are typically stiff and have poor thermal management properties, which may cause thermo-physiological wear discomfort of 3D printed textiles. Overcoming these challenges will significantly improve wear comfort, sustainability of 3D printed textile and drastically expand their functionality.

This work aims to develop bioderived, low-carbon-footprint monomaterial 3D printed textile platform for low temperature applications in defense and
aerospace industries. We explore the role of the nanostructure of bioderived polyethylene (bioPE) 3D printed structures in engineering their tensile and elastic performance at extremely low temperatures (down to -70 °C). A range of bioPE yarns and textile with various 3D printed patterns and different nano-scale structure has been fabricated via a combination of a scalable fiber melt-extrusion method and fused deposition modelling. These yarns and textiles have been characterized by their tensile and viscoelastic performance, as well as classified according to their meso- and nanoscale structure. Wide angle (WAXS) and small angle (SAXS) X-ray scattering techniques confirmed that by precise engineering of bioPE material nanostructure, we can tune the material crystallinity degree from ~60% to ~80% and to achieve high degree of crystalline domain orientation along the fiber axis. This tunability of the fiber nanostructure translates into tunable elongation at break (up to ~100%) and tensile strength (up to ~180 MPa) values of the bioPE yarns at -70 °C. We further show that mono-material bioPE 3D printed textiles exhibit great adhesion between the printed parts and the fabric, together with high flexibility and durability. In addition, bioPE 3D printed textiles are fully recyclable into a high-value and utility material stock. Overall, our work provides novel route towards development of lightweight, multifunctional bioPE 3D printed textiles with potential applications from uniforms and wearables to aerospace suits, while offering lower environmental footprint in production and full mechanical recyclability.

This work was supported by the Advanced Functional Fabrics of America (AFFOA) and the US Army Research Office. We thank Brandon Henry, Michael Lampkin, Tony DeLaHoz and Jeff Haggard from Hills Inc. for help with the PE yarns fabrication and Braskem for providing bio-derived PE resins. A.H. was supported by NSF GRFP. Useful discussions with Leslie Yan, Michael Rein, and Michelle Farrington are gratefully acknowledged. We also thank Steven Kooi for his help with equipment installation.

Infrared Scanning Near-Field Spectroscopic Studies of Self-Assembled Nanostructures Based on Photo-Crosslinkable Block Copolymers

Nadine von Coelln, Britta Weidinger, Christian Huck, Irene U. Wacker, Rasmus Schroeder, Eva Blasco and Petra Tegeder; Heidelberg University, Germany

Block copolymers, i.e., chemically distinct polymer blocks which are covalently bond, are known for their ability to self-assemble into a variety of morphologies on the nanometer scale.[4] The self-assembly of block copolymers has been extensively investigated for 2D films,[2,3] however, less attention has been paid to 3D bulk morphologies as well as light-based 3D printed microstructures. To achieve long-range ordered samples in thermodynamic equilibrium, in this work, 3D bulk morphologies were prepared via solvent annealing and 3D printed microstructures were fabricated from pre-self-assembled block copolymer inks.

Infrared scanning near-field optical microscopy (IR-SNOM) offers the unique possibility of infrared chemical imaging and spectroscopy with a spatial resolution down to ~20 nm.[4] When irradiating a well-defined diblock copolymer consisting of polystyrene and a methacrylate-based copolymer decorated with photo-crosslinkable units at an independently addressable absorption band of a polymer block, chemical imaging of the blocks’ nano-ordered spatial arrangement is possible.

Here, the internal nanostructure of self-assembled 3D bulk morphologies with lamellar nanostructures is studied by means of IR-SNOM. When selectively exciting each polymer block, a switch of the relative optical phase, related to the local absorption, is observed, revealing a strong phase segregation via spectroscopic contrast. A successful correlation with scanning electron microscopy (SEM) measurements, performed after post-staining with ruthenium tetroxide, furthermore demonstrates, that ruthenium tetroxide creates a specific metal stain for polystyrene. These studies are extended to cylindrical nanostructures as well as two-photon laser printed microstructures exhibiting complex geometry and hierarchically nano-ordered structures.

Influence of Diffusion on Print Fidelity in Vat Polymerization 3D Printing—Acrylate-Chain vs Thiolene-Step Growth Chemistry

Bhavana Deore1, Chantal Paquet1, Hendrick deHaan2, Thomas Lacelle2, Laura Dickson1, Katie Sampson1 and Yujie Zhang1; 1National Research Council Canada, Canada; 2Ontario Tech University, Canada

3D printing is an emerging additive manufacturing technology poised to transform both design and manufacturing due to its ability to customize design and generate structural complexity not possible using traditional manufacturing processes. Light-based 3D printing techniques, such as SLA, DLP or tomographic printing, use patterned light to trigger polymerizations within a volume of a photoresin and thus producing 3D objects. The process of printing in a vat of resin using light that varies temporally and spatially creates dynamics within the resin that ultimately influences properties of the printed part. In this work, we present how concentration gradients and changes in miscibilities during printing causes phase separation and diffusion of species that effect the printing process. The dynamics created by 3D printing are complex with factors governing the extent of the diffusion of inhibiting and reactive species include the geometry and dimensions of the printed features, the viscosity of the resin, rates of polymerization and gelation point. These factors are in turn governed by the formulation and on the type of polymerization i.e., step growth vs. chain growth. By tuning the formulations, changes in diffusivity, viscosity and gelation rates can be control and therefore allow control over phase separation or deviations from nominal print dimensions. The results are supported by modeling allowing us to identify the underlying mechanism behind each.

8:30 AM SF01.11.02
On-Demand Printing of Metallic Polymer Composite Microstructures via Hybrid 3D Printing

Yeewon Yoon, Youngwoo Lee, Yang Xu and Yong Chen; University of Southern California, United States

On-demand printing of microstructures using polymer composites can enhance the materials’ functionality with tailored properties. Especially metallic polymer composites have been used in a wide range of applications, including electronics, energy solutions, soft robotics, and four-dimensional printing.
due to their mechanical strength, high electrical/thermal conductivity, and ferromagnetic behavior. However, current manufacturing challenges limit the concentration of the filler materials in these metallic polymer composites to be low so low viscous slurry can be used in printing. In this study, a novel hybrid additive manufacturing (AM) process is developed to print a highly concentrated metallic polymer composite with over 80% metal particles within the polymer matrix. In this hybrid AM process, highly viscous slurry (~400,000 mPa·s) is printed using DDW, and metal (Iron)-polymer composites are fabricated at designed locations in both discrete and continuous manner so functional material portions can be well defined. In addition, DLP-based VPP is used to print bulk matrix portions using photopolymers to build intricate matrix structures at a fast building speed. An extensive range of composite inks including various photopolymers can be employed in this hybrid 3D printing process to fabricate functional structures with adjustable mechanical properties and multifunctional characteristics. The printing parameters of this hybrid process have been studied, including nozzle height, dispensing speed, and different surface conditions. Using ferromagnetic particles (44 µm) with soft and elastic photopolymer resins, magnetic-actuated grippers were fabricated to demonstrate design functions. The developed 3D printing approach offers a promising route to manufacture metallic polymer composites with tunable magnetic and mechanical properties, which could have potential applications in soft-form sensors, actuators, and biomedical devices.

8:45 AM SF01.11.03
Strategies for Integrating Metal Nanoparticles with Two Photon Polymerization Process
Jiun Im1,2, Liu Yaan3, Qin Hu1, Gustavo Trindade2,3, Zeynab Tavasolyzadeh1,2, Richard Hague1, Lyudmila Turyanska1 and Christopher Tuck2; 1University of Warwick, United Kingdom; 2University of Nottingham, United Kingdom; 3University of Exeter, United Kingdom; "Technical University of Berlin, Germany

A femtosecond laser-induced two photon polymerization (2PP) is a high-resolution additive manufacturing technology that allows for the creation of highly precise and complex microstructures with submicron resolution. This technology has revolutionised the creation of micro- and nano-scale structures, leading to the emergence of new products and technologies. However, the limited availability of functional materials, especially metal nanoparticles that are suitable for use in this process, hinders the technology’s full exploitation. Here we propose three complementary strategies for the integration of metal nanoparticles (MeNPs) with 2PP processes to fabricate nanoparticle-polymer composites and metal nanoparticle-decorated surface patterns in microscale: 1) in-situ formation of MeNPs through a single-step photoreduction process, 2) integration of pre-formed MeNPs into 2PP resin, and 3) site-selective MeNPs decoration of 3D 2PP structures. We demonstrate successful fabrication of high-fidelity structures with incorporated MeNPs and provide detailed morphological and compositional analysis including advanced time-of-flight secondary ion mass spectrometry (ToF-SIMS) mapping results. These complementary strategies open up a broad range of prospective applications from metamaterials and nano/micro-photonics to optoelectronics and biomedicine.

9:00 AM SF01.11.05
Interpenetrating Networks with Tuned Thermal and Mechanical Properties by Multiphoton Lithography
Paulina Szymoniak1, Dorothee Silbernagl1, Zeynab Tavasolyzadeh1, Heinz Sturm1,2 and Ievgeniia Topolnik1; 1Federal Institute for Materials Research and Testing (BAM), Germany; 2Technical University of Berlin, Germany

Multiphoton lithography (MPL) has recently attracted significant research interest as a versatile tool capable of fabricating 2D and 3D micro- and nanoscopic features with high spatial resolution. The integrity of MPL microstructures, or their ability to respond to external stimuli, is of critical importance. Often, the mechanically flexible micro-objects are expected to be capable of shape morphing, bending, or other motion to ensure their functionality. However, achieving the desired properties of MPL-manufactured micro components for a specific application still remains challenging. In this work, we present new MPL materials based on epoxy-acrylate interpenetrating networks (IPNs). We aim at fabrication 3D microstructures, whose properties can be easily tuned by varying the ratio of the IPN components and fabrication parameters. The studied mixtures consist of polyethylene glycol diacrylate (PEGDA) and cycloaliphatic epoxide functional groups. Consequently, tryarylsulfoxonium salt and cyclopentanone photoinitiator tailored for MPL were used to ensure cationic and radical polymerization, respectively. The resulting library of 3D microstructures was investigated for their thermal and mechanical properties using highly sensitive space-resolution methods. For the first time, we were able to evaluate the glass transition behavior of 3D MPL microstructures using fast scanning calorimetry. The influence of both IPN composition and fabrication parameters on glass transition temperature and material fragility was demonstrated. AFM force-distance curve and intermodulation methods were used to characterize the micromechanical properties with lateral resolution of the techniques in the range of 1 micron and 4 nm, respectively. The elastic-plastic behavior of the microarchitectures was evaluated and explained in terms of IPN morphology and thermal properties. The fabricated 3D IPN microstructures exhibit higher structural strength and integrity compared to PEGDA. In addition, IPNs exhibit high to full elastic recovery (up to 100%) with bulk modulus in the range of 4 to 6 MPa. This makes IPNs a good base material for modeling microarchitectures with intricate 3D designs for biomimetics and scaffold engineering.

4D Printing of Free-Standing Carbon Fiber-Reinforced Shape Memory Polymer Composites via Frontal Polymerization
Hyon-Ju Jang and Woong-Ryol Yu; Seoul National University, Korea (the Republic of)

Continuous carbon fiber-reinforced polymer composites have been used in various industries, such as automobiles and aerospace, due to their high strength performance and lightweight. With the emergence of 3D printing technology, there has been a growing interest in utilizing this technique to fabricate continuous carbon fiber-reinforced plastics, particularly thermoplastic composites. In this study, we developed a 3D printing process for fabricating free-standing continuous carbon fiber-reinforced shape memory polymer composites without supports using frontal polymerization. Frontal polymerization is a self-catalytic exothermic reaction that converts monomers into polymers without external energy supply. One of the key challenges in printing continuous carbon fiber-reinforced shape memory polymer is to achieve a high degree of resin impregnation of carbon fibers to ensure optimal physical properties. We enhanced the degree of impregnation by developing an in situ pin-assisted printing head. Subsequently, we investigated the printability of frontal polymer with continuous carbon fibers with a focus on the degree of impregnation. Finally, the newly developed 3D printing system was evaluated characterizing the mechanical properties of the printed composites including their shape memory performance.

Embedded 3D Printing of Mechanically Robust Ionogel Composites
Alexander Q. Kane, EvanBi Oh and Ryan L. Truby; Northwestern University, United States

Multifunctional materials with programmable mechanical properties and electronic/ionic conductivities are required for many emerging applications, including soft electronics, robotics, structural batteries, and more. Additive manufacturing has revolutionized our ability to fabricate these materials, which often require complex 3D forms. Poly(ionic liquid) composites are an emerging structural electrolyte that provide a wide electrochemical window and high ionic conductivity. However, poor intrinsic mechanical properties (e.g. Young’s modulus) limit the printability of precise functional poly(ionic liquid) architectures, hindering their potential utility as materials for the aforementioned applications. Moreover, existing light-based 3D printing methods are
often incompatible with filler particles that can enhance the mechanical properties of poly(ionic liquids) or provide additional functionalities. In this work, we present a method for overcoming the challenges of 3D printing poly(ionic liquids) with embedded 3D (EMB3D) printing. Our integrated material design and manufacturing process produces free-form, lightweight, and flexible poly(ionic liquid) composites that are mechanically robust under cyclic compression. We demonstrate the modularity of our methods by showcasing multimaterial printing with various particle fillers (e.g., carbon black, hexagonal boron nitride, and fumed silica) and poly(ionic liquids). We anticipate our contributions will open new avenues for fabricating complex, architected solid electrolytes for soft robotics and wearable devices, solid-state batteries, and more.

9:45 AM SF01.11.08
Discovery of New Strengthening Law in Ceramic Nanoarchitected Materials Gwanmun Bang1, Dong Gyu Kang2, Changui Ahn1, Daeho Kim1, Hyeon Gyun Nam2, Gayea Hyun3, Dongchan Jang4, Seung Min Han2 and Seokwoo Jeon1; 1Korea University, Korea (the Republic of); 2Korea Advanced Institute of Science and Technology, Korea (the Republic of); 3Korea Institute of Ceramic Engineering and Technology, Korea (the Republic of)

Engineers have long sought to utilize the exceptional mechanical properties achieved by size effect at the macroscopic level, as the strengthening effect derived from size is exclusive to the nanoscale realm. In this work, we present a novel approach to harness the size-induced strengthening effect and apply it on a macroscopic scale in a three-dimensional (3D) metal/ceramic/metal (MCM) nanocomposite. 3D Ni matrix nanocomposites embedding nanoscale Al2O3 nanoarchitectures were produced in a large area (~1 inch) using Proximity-field nanopatterning (PnP) and material conversion techniques. Ceramic thin-shell nanoarchitected materials (t < 100 nm), utilized by a reinforcement of metal nanocomposite, perfectly separate 1st and 2nd metal layers. 1st and 2nd metals are densely infiltrated in and out of the ceramic nanoarchitected materials without defects. The 3D Ni/Al2O3 Ni nanocomposite exhibits a significantly higher compressive strength, surpassing the upper bounds predicted by conventional rule of mixture by approximately 30%. This remarkable strength is attributed to the extrinsic size effect of the ceramic nanoarchitected materials. By integrating the size-induced strengthening of ceramics into the traditional strengthening models of composites, a new strengthening model is derived and experimentally validated using the 3D Ni/Al2O3/Ni nanocomposite system. The utilization of size-induced strengthening in nanomaterials allows the 3D MCM nanocomposite system to offer a novel approach for enhancing the mechanical properties of bulk materials.

3D-Printed Microarray Biosensor for Real-Time Monitoring in Interstitial Fluid Jean Won Kwak, Tuan Trinh, Alexander D. White, Yue Xu, H. Tom Soh and Joseph M. DeSimone; Stanford University, United States

Real-time tracking of biochemical biomarkers in the body can provide personalized healthcare information. Microneedles, as a promising platform, enable continuous access to interstitial fluid in the dermal region through a minimally invasive and painless approach. However, wearable microneedle-based sensors face limitations, including the lack of reagent loading capacity due to conventional fabrication processes (e.g., microfabrication, molding) and deficiencies in continuous sensing capabilities caused by restricted biorecognition elements. Here we present a microarray biosensor (MAB) that integrates 3D-printing technology with biochemical sensing techniques for continuous and real-time monitoring of small molecules, such as cortisol and lactate. The MAB leverages the Continuous Liquid Interface Production (CLIP) to achieve tunable geometries, enabling utilization of the void volume of each microarray projection. These voids facilitate loading of hydrogel membranes, where optical molecular switches are immobilized within the network, enhancing signal detection and providing biochemical protection. Additionally, the MAB allows omnidirectional diffusion of targeted analytes while offering mechanical support during insertion. Ex vivo and in vivo evaluations are underway to validate the performance of the MAB in an effort to demonstrate its potential to provide comprehensive information about our bodies for precise prognosis and diagnosis of our health.

10:45 AM SF01.11.10
Towards a 3D Solid–State Na–Ion Battery using a Direct Ink Writing–Infiltration Approach Shreyas Pathrebreker1, Shahrtyoor Moori2, Selina Liu1, William R. Fullerton1, Hyoengjun Koh1, Wen Chen2, Russell J. Composto1, Eric A. Stach1, Christopher Y. Li1 and Eric Detsi1; 1University of Pennsylvania, United States; 2University of Massachusetts Amherst, United States; 3Drexel University, United States

3D solid–state batteries based on porous materials offer significant advantages over conventional 2D batteries, namely, high areal energy and high power density due to their increased surface area and intimate contact between cell components. They can also exhibit enhanced safety due to the high modulus of the solid electrolyte, which is known to suppress dendrite growth. The fabrication of 3D batteries calls for innovative, sustainable, non–roll–to–roll manufacturing approaches. We describe a three–step fabrication approach comprising direct ink writing, Capillary Rise Infiltration (CaRI), and vacuum–assisted infiltration for the development of a 3D solid–state battery. Pre–alloyed NiMn2 powder mixed with a porogen is 3D printed into lattices, and sintering time and temperature are optimized to create a porous NiMn2 3D lattice comprising two different pore sizes in the range of 5 µm–10 µm and 150 µm–200 µm, respectively. Partial oxidation of the porous lattice generates a Na2/3[Ni1/3Mn2/3]O2 (NNMO) layer, which serves as the cathode. Following this step, capillary–rise infiltration (CaRI) of an optimized poly(glycidyl methacrylate)–poly(ethylene glycol) (PGMA–PEG6k) electrolyte solution is used to deposit the polymer electrolyte within the small pores of the lattice. Thermal crosslinking between the epoxy groups on the PGMA backbone and amine end groups of the PEG within the pores yields a dense composite of solid polymer electrolyte in conformal contact with the pore surfaces. To deposit the anode in the nores of the 3D lattice, vacuum–assisted infiltration of Na80K20 metal is carried out, thereby completing the battery. Notably, this sequential fabrication approach uses zero solvent and polymer binder during either cathode (NNMO) or anode (Na80K20) deposition, which is in remarkable contrast to conventional slurry–casting methods that require the use of both N–methyl–pyrrolidone (NMP) and a polymer binder such as polyvinylidene fluoride (PVDF). Focused ion beam (FIB) milling, scanning electron microscopy (SEM), and energy dispersive x–ray spectroscopy (EDS) on the 3D matrix reveal excellent scaffold–polymer–anode contact, confirming the formation of robust interfaces that are necessary for battery application, which is currently being investigated. This work underscores the importance of cross–cutting collaborative research in materials science for emerging energy applications.

11:00 AM SF01.11.11
End-To-End Performance Analysis of 3D Printed Luminescence Devices for Energy Conversion Applications Shomik Verma1 and Rachel Evans2; 1Massachusetts Institute of Technology, United States; 2University of Cambridge, United Kingdom

In recent years, there has been increasing urgency to develop cheap, efficient solar devices. However, most solar modules are large, bulky, and rectangular, making integration into the built environment non-trivial. A promising technological solution that may help solve this problem is the luminescent solar concentrator (LSC). A typical LSC is a plastic slab that absorbs sunlight and re-emits light of a tailored wavelength towards its edges, where solar cells can
be installed. Because LSCs are colorful, semi-transparent, and modular, they hold great potential in reducing the cost and barrier to entry of solar technologies. However, they suffer from significant optical losses limiting their efficiency. Many novel device shapes have been proposed to improve light transport pathways in LSCs, but these often rely on expensive or wasteful fabrication techniques.

A potential solution to this is 3D printing, which has gained immense traction as an alternative manufacturing technology. 3D printing has many benefits including accessibility, rapid prototyping, and fabrication of completely new designs. This study presents an end-to-end performance analysis methodology to evaluate new LSC designs that can take advantage of this novel manufacturing technology. This methodology is applied to some preliminary 3D printed parts as a proof of concept that can be applied to a wider variety of designs.

This study consists of 3 distinct steps: simulating the optical efficiency of the printed part, 3D printing the part with luminescent filament, and characterizing its optical efficiency experimentally.

The simulated results of this study indicate 3D printed devices have the potential to offer a twofold increase in efficiency over conventionally manufactured bulk devices. Actual 3D printed devices were measured to have similar efficiency to bulk devices (within 1%), but extrapolating the results to parts made with higher quality material also suggests some parts would have twice the efficiency of their bulk counterparts. 3D printed parts may have additional benefits in improving directionality of edge-emitted light, but this will have to be confirmed in future work.

Overall, 3D printing provides major benefits over conventional manufacturing techniques, as it introduces rapid prototyping by allowing experimental iteration and model validation, allows custom-built designs for easier integration into the built environment, and increases the optical efficiency of devices by improving light transport pathways. With further development, this technology can help make widespread solar adoption a reality.

11:15 AM SF01.11.12
Unique Mechanical Behaviors of Mechanical Metamaterials with Engineered Imperfections
Siya Liu and Yaning Li; Northeastern University, United States

Traditionally, imperfections are undesired in the materials and structures, because they often reduce the load-bearing capacity and cause premature failure. However, if imperfections are designed and engineered, they could generate unique new mechanical properties. In this investigation, we introduce patterned and hierarchical imperfections to lattice structures and find that the new designs show dramatically different mechanical properties under loads at different locations. Also, by utilizing the concept of tensegrity, the mechanical properties can be further controlled and tuned. In this investigation, new hybrid lattices are designed, which are composed of hard cells connected via engineering soft connections. Upon external mechanical or thermal loads, the hard cells will either keep the orientation or rotate due to the chiral arrangement or the soft components. Both deformation mechanisms will contribute to the overall volume change of the material and are related to the loading type and location. Therefore, the pattern transformation will lead to a change in both mechanical properties and functionality related to the material structure. To further prove the concept, prototypes of selected designs are fabricated in both macro- and micro-scales. Quasi-static uniaxial compression experiments were conducted in both room temperature and elevated temperatures. Finite element simulations are performed to further quantify the mechanical behaviors.

11:30 AM SF01.03.32
Investigation of Structure-Processing Relationships in Metal Additive Manufacturing Through Featureization of Microstructural Images
Dipayan Saha1, Anirban Chandra2, Sukriti Manna1,2, Partha Sarathi Dutta3,4, Maria K. Chum1, Henry Chum1,2 and Subramanian Sankaranarayanan1,2,3, US Argonne National Laboratory, United States; 2University of Illinois at Chicago, United States

The understanding and prediction of accurate property-structure-processing relationships is essential in designing robust, reliable parts and assemblies, both forward and inverse. The direct mapping of process parameters to property values can be plausible in some cases, but it is often hampered by poor microstructural control. Therefore exploring a straightforward relationship between processing conditions and microstructural features can offer important physical insights and assist the overall design procedure. In this work, we present an automated high-throughput approach towards simulating an AM process that is uncertainty-aware, can characterize microstructural images, and extract appropriate features and descriptors. We used a kinetic Monte Carlo (KMC) based model of the AM process to simulate microstructural evolution for a variety of processing conditions, having utmost relevance with the experimental conditions. We perform a parametric study by selecting four input processing parameters in KMC simulations (velocity, hatch spacing, melt-pool width, and tail length) to explore the relationship between microstructural features and processing conditions. As a first step towards the exploration of microstructural features and processing conditions, we performed a parametric study by selecting the four input processing parameters in KMC simulations (velocity, hatch spacing, melt-pool width, and tail length). With systematic variations of the process parameters, a large number of simulations were performed for obtaining a diverse set of microstructural images. Subsequently we performed thorough analysis of the simulated images and extracted meaningful descriptors using conventional algorithms and an off-the-rack image processing tool, the Watershed algorithm. Finally, we present an approach towards discussion of the ability of various quantitative microstructural features to differentiate between the obtained microstructures. For accurate featureization of microstructural images, we focus on a set of six most relevant microstructural descriptors: Orientation, Aspect ratio, Perimeter-Area ratio, Equivalent diameter, Two-point statistics and chord length distribution (CLD) in two dimensions. As byproducts of our featureization algorithm, we realize many-to-one mapping is a necessity for representation of microstructural images unambiguously, multiple descriptors are therefore required to unambiguously map processing conditions to typical descriptors. Depending on the differentiability of the distributions of the microstructural features, a unique score can be allotted to a particular grain profile. This unique value of the metric or score can be further utilized to propel the inverse design problems. Defining a unique score is impossible if the four dominant microstructural features do not differ across the chosen processing conditions. Hence our research work provides very important information, in both qualitative and quantitative aspects, that would help in the proper understanding of microstructural representations. Appropriately characterized microstructural representations can then be utilized for development of data-driven models for predictive control of grain profiles, resulting in tailored mechanical or thermal properties of additively manufactured parts.
Additive manufacturing (AM) is emerging as a powerful tool for fabricating antennas particularly in the capability of creating arbitrary complex geometries without incorporating excessive materials owing to its unique materials build-up mechanism. Taking such benefits, 3D printed antennas, including horns, waveguides, and dielectric antennas, have been reported with enhanced performances in different aspects. These examples, however, are constructed mainly by single materials (either all-dielectric or all-metal). While multi-process AM can potentially perform conductive coating on 3D printed dielectric structure, the lack of selectivity and limited access to complex 3D geometries exclude a considerable amount of antennas from current AM approaches. The charge-programmed multi-material 3D printing technique integrates multiple materials and functionalities into 3D devices, which is achieved by programmed volumetric deposition of one (or multiple) materials into arbitrary 3D micro-architectures. The printed structures had programmed surface charge regions, enabling the selective deposition of functional materials into complex 3D architectures based on localized electrostatic interactions. For antenna applications, charge-programmed AM can achieve sophisticated 3D architected lattice materials with interpenetrating dielectrics and metals, allowing free space for designing antennas being ultra-light and yet mechanically robust. In this paper, we present the materials design principles enabling charge-programmed multi-material printing of lightweight antennas with unique mechanical properties and competitive antenna performances.

**CHARGE-PROGRAMMED SELECTIVE DEPOSITION**

Charge-programmed selective deposition for the fabrication of antennas is based on a multi-material printing system. Resins with positive, negative, or neutral charge polarity were alternately solidified and bound to the previously built layer of the printed parts. The process was repeated layer by layer, pin-pointing multiple materials with different polarities into their designated coordination in 3D space. The charged surfaces immobilize the oppositely charged catalyst species, which in-situ catalyze the subsequent deposition of functional materials. In such a way, the printed objects obtained patterned structures that selectively integrated different functionalities in designated locations with a resolution as high as the 3D printer could achieve.

**MATERIALS DESIGN FOR ANTENNA APPLICATION**

Charge-programmed selective deposition allows a wide range of space for materials design. Particularly for antenna applications, a variety of combinations of conductivity and dielectric constant, the most crucial parameters, can be achieved, suggesting the versatility of the charge-programmed selective deposition for custom tailored antenna applications.

The composition of the negative resin directly influences the antenna performances which relies on the quality of the plated Cu layer as well as antenna’s mechanical robustness. Based on the molecular configurations of the polymerized photo-monomers, the negative resins were formulated to deliver either stiffness or flexibility for the printed antennas. By tuning the composition of the resins, we achieved a balance across the cross-link density and charge density. This enabled a uniform catalyst distribution on the stiff and tough negative resins and consequently grew a crack-free conformal Cu coating on the surface, serving excellent electrical properties for a K-band horn antenna. By introducing flexible monomers, we fabricated transmitarray with considerable flexibility, which promises potential for deployable antennas.

**Additive Manufacturing of Micro-Architected Metals via Hydrogel Infusion**

Metal additive manufacturing (AM) has emerged as a uniquely powerful tool to produce complex and high-performance parts with applications from the aerospace to biomedical fields. Most existing metal AM techniques use heat to define part shape via thermally initiated melting or sintering. In contrast, we report a polymer-based AM technique, coined hydrogel infusion additive manufacturing (HIAM), that produces metals and alloys with microscopic resolution via vat photopolymerization (VP). To fabricate micro-architected metal structures, we infuse 3D-architected hydrogels with aqueous metal precursors, then calcine and reduce the infused hydrogel scaffolds to create miniaturized metal replicas. Unlike previous VP strategies, which incorporate target materials or precursors into the photosensitive matrix, HIAM does not require re-optimization of resins and curing parameters for different materials, enabling quick iteration, compositional tuning, and the ability to fabricate multimaterials. We demonstrate HIAM of micro-architected metals including copper, nickel, silver, cobalt, cupronickel alloys, high entropy alloys, and tungsten with critical dimensions of ~50 µm. This work shows how single architected gel scaffold can respond to a variety of chemical and thermal stimuli to transform into a vast array of metals, providing a pathway to create advanced micro-architected metals.
Piezoelectric hydrophones are crucial for underwater applications such as communication and seafloor mapping. Limited by the brittleness of piezoelectric ceramics, conventional manufacturing methods restrict hydrophones’ shapes to simple geometries such as disks, cylinders, or spheres, which limits the sensitivity, directivity pattern, and working frequency bandwidth of the device.

Here, we present a new class of high-performance 3D printed piezoelectric hydrophones consisting of rationally designed micro-architectures. Using a high-resolution light-based printing process, and thanks to a liquid sealing sintering process, the piezoelectric coefficients and electromagnetic coupling factor can reach respectively 92% and 85% of the pristine material’s values, the highest values among all existing 3D printing work.

We have developed a framework to artificially develop the piezoelectric coefficients of an architectured material by modifying the spatial arrangement of unit cell struts. This can be harnessed to develop a new class of metamaterial hydrophones whose sensitivity can be locally manipulated. We take advantage of this framework to generate hydrophones with sensitivities ~10 dB higher than the commercial ones, and whose directivity patterns can be inversely designed.

This work holds great promises for high frequency sound localization without the need of hydrophone arrays, and for low frequency sound monitoring thanks to a hydrostatic figure of merit five times higher than the one of commercial transversely isotropic piezoelectric hydrophones.

2:30 PM SF01.12.05
The Role of Particle Microstructure and Polymer Configuration in 3D Printed Thermal Composites Daniel Brackenier1, Eric Wetzel1, Ryan Dunn1 and Randall M. Erb1; 1Northeastern University, United States; 2U.S. Army Research Laboratory, United States

While everyday device sizes continue to shrink, the power being packed into them increases drastically, driving internal heat generation to the point of overwhelming current thermal management solutions and limiting system-level performance. New thermal management materials and solutions are required to support higher energy density electronics; incumbent materials including metals like copper and aluminum satisfy many applications, however they are heavy and cannot be placed adjacent to electronics or in the proximity of radio frequency components. Additive manufacturing and fine-tuned composite creation can enable lightweight and geometrically complex thermal management solutions that provide a distinct advantage over current solutions. Here we present a collection of new understandings around process-structure-property relationships that will help enable higher performing thermal parts via additive manufacturing. This work focuses on the interplay between the filament composition, the processing conditions of fused filament fabrication (FFF), and the post-processing of printed parts (annealing). The goal of this research is to enable emergent properties in FFF printed composites through material interface and interphase engineering, flow-induced self-assembly of mesostructure, and temperature-induced self-assembly of polymeric nanostructure. The ability to locally control the thermal conductivity of FFF parts would enable a new class of advanced thermal management materials.

2:45 PM SF01.12.06
Radiation Shielding of Microelectronics via Additive Manufacturing Avery Ross1, Austin Coon1, Devon Beck1, Rich D’Onofrio1, Ethan Cascio1, Ksenofono Konomi1, Andrea Barney1, Robert Longton1, Pascale Gouker1, Melissa Smith1 and Bradley Duncan1; 1Massachusetts Institute of Technology Lincoln Laboratory, United States; 2Massachusetts General Hospital, United States; 3University of Massachusetts Lowell, United States

The miniaturization of satellite systems has compounded the need to protect microelectronic components from damaging radiation. Current approaches to mitigate this damage, such as indiscriminate mass shielding, built-in redundancies, and radiation hardened electronics, introduce high SWaP-C (Size, Weight, and Power-Cost) penalties that reduce the overall performance of the satellite. Additive manufacturing provides an appealing strategy to print radiation shielding only on susceptible components within an electronic assembly. Utilizing direct ink writing, we are able to conformally print customized inks at room temperatures directly and selectively onto COTS (commercial-of-the-shelf) electronics. The suite of inks uses a flexible styrene-isoprene-styrene block copolymer binder that can be filled with particles of varying atomic densities for varying radiation shielding capabilities. Additionally, blended composites of both high and low Z fillers were created to investigate the performance in radiation attenuation depending on composition. We anticipate this low SWaP-C alternative to traditional shielding methods will enable the development of novel complex and compact satellite designs.

3:00 PM BREAK

3:30 PM SF01.12.07
High-Speed Fabrication of Intrinsically Flexible Perovskite Optoelectronic Devices on Diverse Substrates (Elastomer, Paper, Textiles, etc.) Using Printing and Direct Writing Junyi Zhao and Chuan Wang; Washington University in St. Louis, United States

Flexible optoelectronic devices built on thin elastomer substrates may find a wide range of applications in wearable electronics, soft robots, deformable displays, and more. While considerable efforts have been made to explore the potential of halide perovskites in high-performance light-emitting diodes (LEDs), existing fabrication techniques using rigid substrates cannot meet the growing demand for large-area flexible devices. In this work, we report a high-speed fabrication approach for intrinsically flexible perovskite LEDs (PeLEDs) directly printed on elastomer thin films. Using a highly scalable inkjet printing approach, each layer in the device, from the bottom anode to the top cathode, is patterned. In addition to elastomer, paper, and textiles commonly used in our daily lives also hold great potential as platforms for next-generation flexible and wearable electronics. Therefore, we have developed a versatile, scalable, and eco-friendly direct writing approach that enables multicolor PeLEDs (covering the entire visible spectrum) and perovskite photodetectors (PePDs) (both vertical-photodiode configuration and planar-photocurrent configuration) to be directly drawn onto various unconventional substrates (paper, textiles, plastic, rubber, metal, and common three-dimensional objects) in an ultrafast and mask-free manner. This is achieved by daily used ballpoint pens filled with our uniquely formulated inks of conductive polymers, metal nanowires, and perovskite/polymer composite for photosensitive layers. The addition of an ionic polymer in the inks helps address the challenge of rough surface morphology on yarn and fiber networks, ensuring uniform printed film thickness and minimizing leakage current. Just like drawing with multicolor pens, by writing the above functional inks layer-by-layer, high-performance perovskite optoelectronic devices can be customized on almost any target substrate within minutes even by untrained individuals. Notably, the entire manufacturing was conducted in ambient conditions without the need for specific moisture and temperature control. The simplified device architecture and fabrication strategy significantly reduce the fabrication time compared to the hours or days required by conventional microfabrication processes. The written PeLEDs exhibit a brightness as high as 15,225 cd/m², a current efficiency of 6.65 cd/A, and a turn-on voltage of 2.4 V. The PePDs exhibit an on/off ratio over 10⁴, and a response time of less than 15 ms. Owing to the extraordinary flexibility of each functional layer, the written LEDs on the paper substrate could be bent to a 1 mm extreme curvature radius for over 5000 cycles without decay in performance. Overall, this work paves the way for the practical application of perovskite optoelectronics in cost-effective and large-area scenarios, such as E-textile, E-paper, smart packaging, disposable electronics, and wearables.

3:45 PM DISCUSSION TIME

4:00 PM SF01.12.09
Direct Photopatterning of Metals on Polymer Surfaces at Ambient Conditions Ivan B. Dimov1, Antonio Dominguez Alfaro2, Tobias Naegle3 and George G. Malliaras1; 1University of Cambridge, Department of Engineering, Electrical Division, United Kingdom; 2University of Basque Country, Spain
Metal interconnects on polymer substrates are an integral part of many stretchable and flexible electronic devices. However, metal deposition typically involves harsh conditions, such as high vacuum and temperature. These requirements limit compatibility with many substrates and impede rapid prototyping and increases and energy requirements. Solution-phase depositing such metal features is an attractive alternative to conventional processes, especially when combined with a rapid additive manufacturing technique.

Here we present an aqueous gold ink, comprised of [AuCl₄]⁻ as a metal source, a reducing agent and a benign, non-toxic dye as an initiator, that allowed us to deposit gold onto silicone surfaces upon UV illumination at ambient conditions. Altering the reaction time and ink composition, we could tune the morphology of the deposited metal, between isolated nanoparticles and a continuous film. Using this ink, we deposit stretchable gold interconnects on pre-stretched silicone, using solely UV illumination, achieving conductivity of 40% of bulk gold. We additionally used a commercial stereolithographic printer without any modifications as a maskless lithography system, allowing us to pattern conductive features of 300 μm. Investigating different substrates suggests a preference for polymers with reducible species on the surface. Lastly, we have successfully performed the reaction with AgNO₃ as a metal source, depositing silver on silicone. We are working towards 2-photon illumination, in order to increase resolution and expand to 3D metal structures.

4:15 PM SF01.12.11
Chemically Coalescing Liquid Metal Emulsions as 3D Printed Soft Conductors  Stephanie F. Zopf, Chloe Kekedjian, Ramon E. Sanchez, Lu Ping and John W. Boley; Boston University, United States

Patterning room temperature liquid metals as soft conductors requires nontrivial solutions due to its complex rheology. To facilitate material handling, liquid metals are often transformed into an emulsion by dispersing it as droplets within a continuous liquid. Oxides present on liquid metal droplets, however, render liquid metal emulsions nonconductive, which must be ‘activated’ through droplet coalescence for the ink to be conductive. Although liquid metal droplet coalescence in emulsion inks has been shown by using mechanical ([1], [2]), laser [3], and extreme thermal ([4], [5]) means, these modes of activation make it challenging to integrate with other materials and device components. This work presents a liquid metal emulsion ink that is 3D printable through direct ink writing (DIW), and can be activated chemically through the use of an active ingredient. It requires a low thermal stimulus (~80°C), which is compatible with commercial off the shelf electronic components. The ink developed in this work is able to retain its printed structure after being thermally activated. Coalescence through chemical etching of the oxides on the liquid metal droplets is evident through electrical conductivity measurements, scanning electron microscopy, nuclear magnetic resonance, and x-ray photoelectron spectroscopy characterization. Conductivities of formulated emulsions are precisely calculated using measured resistances combined with micron-level 3D scans with the maximum conductivity obtained of attempted formulations being 3.54 x 10² S/cm. Printability outcomes of emulsion inks with respect to formulated chemistries will be presented. Rheology for the most printable formulation with the highest conductivity shows that the ink is shear thinning and shear yielding and exhibits a high plateau modulus and high yield stress, giving it the ability to print features that span long distances. Lastly, an automated 3D print and electronic device assembly process will be shown to demonstrate the utility of this ink as a soft conductor for manufacturing integrated electronic systems.

4:30 PM SF01.12.12
Computational Discovery of Microstructured Composites with Optimal Strength-Toughness Trade-Offs  Bolei Deng¹², Beichen Li¹, Wan Shou¹ and Wojciech Matusik¹;¹Massachusetts Institute of Technology, United States;²Georgia Institute of Technology, United States;³University of Arkansas, Fayetteville, United States

The conflict between strength and toughness is a fundamental problem in engineering materials design. However, systematic discovery of microstructured composites with optimal strength-toughness trade-offs has never been demonstrated due to the discrepancies between simulation and reality and the lack of data-efficient exploration of the entire Pareto front. Here, we report a widely applicable pipeline harnessing physical experiments, numerical simulations and artificial neural networks to efficiently discover microstructured designs that are simultaneously tough and strong. Using a physics-based simulator with moderate complexity, our strategy runs a data-driven proposal-validation workflow in a nested-loop fashion to bridge the gap between simulation and reality in high sample efficiency. Without any prescribed expert knowledge of materials design, our approach automatically identifies existing toughness enhancement mechanisms that were traditionally discovered through trial-and-error or biomimicry. We provide a blueprint for the computational discovery of optimal designs, which inverts traditional scientific approaches, and is applicable to a wide range of research problems beyond composites, including polymer chemistry, fluid dynamics, meteorology, and robotics.

8:00 AM SF01.13.01
Additive Manufacturing of Carbon Nanotubes Reinforced Metal Matrix Composites  Li Cao; University of Dayton, United States

High-performance components are always highly demanded for modern aerospace applications due to their critical role in ensuring safety and efficiency. Developing metal matrix composites (MMCs) reinforced with nanomaterials is an effective strategy to enhance the properties of such functional components. Among the various reinforcements, 1D nanomaterials such as carbon nanotubes (CNTs) have attracted much attention due to their exceptional mechanical, thermal, and electrical properties. Meanwhile, Additive manufacturing (AM) offers innovative manufacturing techniques that can be used to construct complex and intricate structural components. Integrating advanced material development and AM techniques has drawn significant attention as it overcomes the limitations and challenges of conventional fabrication approaches. This research focuses on the development of CNTs reinforced nickel-based alloys using laser powder bed fusion, a popular AM technique. The result showed significant improvements in the yield strength, ultimate tensile strength, and elastic modulus of the 3D printed specimens when 2.5vol.% CNTs were incorporated, demonstrating the remarkable impact of CNTs on enhancing the performance of the metal-based alloys.
Miniature flapping drones equipped with lightweight membranous wings have shown great potential for operating effectively in small spaces. Achieving optimal flight performance in these drones heavily relies on the appropriate design of their flexible wings. In this study, we explore the utilization of 3D-printing technology to fabricate high-fidelity, bioinspired wings and expedite the design process for miniature flapping drones. Drawing inspiration from the wings of the rose chafer beetle, we employ a bioinspired approach to develop 3D-printed wings. By modulating the wing structure, we create twelve distinct wing models that feature variations in vein cross-section shape, tapering geometry, and membrane thickness. Through a comprehensive comparison of their mechanical and aerodynamic properties, we establish guidelines to correlate wing form and function. Our findings reveal the following key insights: first, manipulating the cross-section shape of the veins provides a powerful tool for engineering in-plane and out-of-plane deformations. Second, tapering veins enhance the wings' mechanical stability, improving their overall performance. Empirical results demonstrate that the optimized wings exhibit a 16% increase in lift and a 27% improvement in lift production efficiency (N/Watts) when tested in a revolving wing setup. The successful design of lightweight, flexible, robust, and aerodynamically efficient wings poses a formidable engineering challenge that we aim to address through our bioinspired methodology. By reverse engineering these intricate structures, we contribute empirical knowledge to the field of wing design for miniature flapping drones. Our work highlights the potential of bioinspiration and 3D-printing techniques to advance the development of miniature flapping drones with enhanced flight performance. The insights gained from this study provide valuable guidance for future advancements in the field of bioinspired wing design and optimization.
Printing metals and polymers together to form complex electronic devices is difficult due to the large difference in fusion temperature between those materials. In a previous article, we have introduced a hybrid printing technique based on the fused filament deposition of a copper-polylactic acid composite followed by a step of laser sintering, to produce a conductive, porous copper material. This technology integrates together a conventional fused filament deposition printer and a 10-watt laser diode. The printer is used to deposit layer by layer a composite material containing a polymer matrix, copper, and copper oxide particles. After printing each layer, the laser diode is used to selectively sinter the composite. Under the effect of the laser, the polymer matrix is evaporated, and the copper oxide is reduced, forming a highly conductive, porous copper material.

However, in our precedent experiments, the out-of-plane resistivity of this printed porous copper was high, and the applications were restricted to low dimensionality, 2.5D applications. More recently, we have investigated more composite materials and sintering conditions and developed a new TPU based composite. After sintering, this composite presents a resistivity as low as 10−5 Ω x cm in the in-plane direction and 10−4 Ω x cm in the transverse direction.

As a result, we can now design and print completely embedded 3D electronic circuits and complex electronic components. We demonstrate these capabilities by making an embedded 3D circuit controlled by capacitive sensors.
particular the surface energy and kinetic attachment anisotropies) and the processing parameters such as thermal gradient $G$, growth velocity $v$, and composition of the sample. The microstructure plays a critical role in determining the final properties of the material. One can distinguish two different macroscopic types of interface: rough where the kinetic attachment of atoms is fast and heat and solute diffusion in the liquid is dominant; and faceted where the kinetic attachment of atoms is anisotropic and slow and considered as the dominant effect. In this last, the crystals grow with smooth surfaces at the atomic scale, and facets at macroscopic scale. Despite numerous researches, particularly for semi-conductors such as silicon, the understanding of the faceted growth is still a significant challenge.

In this work, directional solidification experiments of organic transparent materials are used to evidence and analyze mechanisms involved during the growth of faceted solid-liquid interfaces. Such transparent model materials are chosen to have similar solid-liquid interface properties as technological materials studied, and thus to form similar microstructures, with the advantages of being transparent to visible light, so that common optical techniques can be used to follow their growth. We use salol, which is orthorhombic in structure and grows from its melt with a distinct macroscopic faceted interface because of its very high degree of anisotropy. Directional solidifications are performed in the ECODIS device a Bridgman furnace designed for thin samples geometries, equipped with an optical microscope to observe solid-liquid interface dynamics in situ and real time.

A highly faceted solid-liquid interface appears and keeps evolving till the end of the experiment. The faceting angle is characterized and it shows that they correspond mostly to $\{111\}$ and $\{100\}$ crystallographic planes. Velocities of the different facets are measured and they vary with facet orientation relatively to the thermal gradient. These measurements allow to establish kinetic growth laws which depend on the crystallographic nature of the facet. Facets are also studied in terms of size evolution and distribution, which are affected by facet competition and interaction with defects.

Growth Dynamics of Three-Dimensional Grain Boundaries in Polycrystalline Solidification using DECLIC-DSI Experimental Device Fatima L. Mota1, Younggil Song2, Khaiah J1, Damien Tourret2, Alain Karma3 and Nathalie Bergeon1; 1Aix-Marseille Université, IM2NP UMR CNRS, France; 2Lawrence Livermore National Laboratory, United States; 3Northeastern University, United States; 4IMDEA Materials Institute, Spain

The microstructures formed by directional solidification are often polycrystalline, made up of a several large grains of different crystallographic orientations. Grain boundaries (GBs) have a crucial influence on the mechanical behavior of materials, by their peculiar interactions with dislocations, or by providing solute segregated regions prone to the formation of secondary phases. In technological alloys, GBs typically evolve in the solid state through a series of complex thermomechanical post-processes. However, their initial shape and existence goes back to the initial stage of solidification from the liquid phase. The importance of GBs is well-acknowledged at the macroscopic scale, and grain growth competition is already used in the design of technological components (e.g., grain selectors in single-crystal turbine blades). However, our understanding of GB selection during polycrystalline solidification remains qualitative at best, and a number of unsolved questions remain.

Until now, grains have been assumed to occupy distinct compact regions of 3D space separated by smooth borders on a scale larger than the cellular/dendritic array spacing. In this presentation, we report experimental observations revealing for the first time that cells from one grain can invade a nearby grain during polycrystalline growth. This unexpected invasion process causes grains to interpenetrate each other on the fine scale of the array spacing, and hence grain borders to become highly irregular. By computational modeling, we further reveal the ubiquitous nature of this invasion process by showing that it occurs for a wide range of grain misorientations beyond those studied experimentally. Those results fundamentally alter the traditional view that cellular/dendritic grains are distinct regions embedded in three-dimensional space.

These observations are made possible by in situ visualization of the spatiotemporal evolution of the solid-liquid interface during directional solidification of a transparent organic alloy (Succinonitrile-0.24wt%Camphor) using the DECLIC-DSI experimental device installed onboard the International Space Station. Transparent alloys have similar solid-liquid interface properties as metallic alloys and thus form similar microstructures. The microgravity environment of the space station eliminates buoyancy-driven fluid convection and the associated large scale inhomogeneities of alloy composition, thereby facilitating quantitative comparisons with computational modeling in a purely diffusive regime.

Disorder to Order in Interface Patterns: Thermal Noise to Limit Cycle Transition in Dendrite Sidebranch Formation Trevor D. Lyons1, Louise S. Littles2 and Rohit Trivedi2; 1Northeastern University, United States; 2NASA, United States; 3Iowa State University of Science and Technology, United States

Thin sample directional solidification experiments have been carried out in the model succinonitrile-camphor system to examine the origin of secondary branches in dendritic morphologies. Thermal noise at the dendrite tip creates interface instabilities which amplify to form sidebranches. This is accepted as the primary mode of sidebranching in dendritic growth from an undercooled melt and occurs in directional solidification of dendrites. The proposed limit cycle couples the growth of the tip with the initiation of the sidebranch. Directional solidification of curved interfaces is a driven dissipative system with the potential to form a limit cycle. Two sets of experiments were performed, the first holding velocity constant and evolving the gradient and the second imposing oscillating velocities around the natural period of sidebranching. Both experimental methods were found to characterize a transition from disordered sidebranching induced by thermal noise to ordered sidebranching produced by the limit cycle mechanisms. This is the first quantitative measurement of previously hypothesized limit cycle growth.

These experiment sets have been quantitatively analyzed for dynamic behavior seen in limit cycles. High-quality data sets of the tip and instability enable the measurement of the FFT and analysis through a power spectrum. At low gradients, the sidebranches are found to be excited by thermal noise far away from the tip. As the gradient increases and velocity is held constant, the distance between the instability and tip decreases until limit cycle growth is found between the tip of the primary dendrite and the first forming sidebranch. An alternative to the deterministic limit cycles seen in experiments of gradient evolution is a limit cycle actively driven through the square wave oscillation of velocity. Crucial observations of the solidified microstructure conclude that this produced periodic interconnected bridges between the primary dendrites. This is a finding with potentially significant implications for commercial applications.

Direct Observation of Growth and Interfacial Dynamics of Ice Nanocrystals with Cryo-Electron Microscopy Minyoung Lee and Jungwon Park; Seoul National University, Korea (the Republic of)

Ice at low temperatures exhibit structural polymorphs including hexagonal ice, cubic ice, or a hetero-crystalline mixture of the two phases. These polymorphs can coexist at a broad range of temperatures, but exhibit distinct growth kinetics. While numerous studies, mainly based on spatially-averaged techniques, have investigated the structural properties of ice formed at low temperatures, mechanisms behind the growths of coexisting polymorphs and their interfacial properties have been difficult to probe individually. Here, we use in-situ cryo-electron microscopy and computational ice-dynamics simulations to directly observe ice formation and growth amidst amorphous ice. We reveal that nanoscale ice crystals exhibit polymorph-dependent growth kinetics, with hetero-crystalline ice exhibiting anisotropic growth based on accelerated growth of the prismatic planes. Fast-growing facets are associated with low-density interfaces that possess high surface energy, driving tetrahedral ordering of interfacial water molecules and accelerating growth. Our approach of observing ice crystallization, based on nanoscale techniques, improve our understanding on early stages of ice formation and the mechanistic
roles of ice interfaces, providing important insight into various fields such as ice physics, cloud physics, or designing cryoprotective molecules.

11:30 AM SF02.01.05
Phase-Field Modeling of Ice-Templated Hierarchical Structures Kaihua Ji1, Mingwang Zhong1, Kaiyang Yin2, Louise S. Littles3, Rohit Trivedi4, Ulrike G. K. Wegst1 and Alain Karma1; 1Northeastern University, United States; 2University of Freiburg, Germany; 3NASA Marshall Space Flight Center, United States; 4Iowa State University, United States

Directional solidification of aqueous solutions and slurries in a temperature gradient has emerged as a promising method to produce cellular materials through a phase separation of solutes or suspended particles between growing ice lamellae. Those ice-templated cellular materials are hierarchically organized into a honeycomb-like porous structure on the largest scale, lamellar cell walls at an intermediate scale, and different unilateral surface features including ridges and other more complex shapes reminiscent of living forms that decorate the cell walls on a yet smaller scale. While the strong anisotropy of ice-crystal growth has been hypothesized to play a role in shaping those structures, the mechanism by which they form has remained elusive. We report the results of a detailed phase-field simulation study of ice templating of binary mixtures that reproduces the salient features of those cellular materials and that sheds light on the mechanism by which anisotropic ice crystal growth shapes their hierarchical structure. The simulation results reveal that the flat side of lamellae forms because of slow faceted ice-crystal growth along the c-axis, while weakly anisotropic fast growth in other directions, including the basal plane, is responsible for the unilateral features. Diffusion-controlled morphological primary instabilities on the solid-liquid interface form a cellular structure on the atomically rough side of the lamellae, which template regularly spaced ridges while secondary instabilities of this structure are responsible for the more complex features. The simulation results are compared with experimentally obtained results by directional freezing of binary water mixtures containing small solutes. Good quantitative agreement is found for the lamellar spacing that is shown to obey the scaling law $\lambda \sim (V G)^{-1/2}$, where $V$ and $G$ are the local growth rate and temperature gradient, respectively. Preliminary simulation results are presented that address the basic question of how other solvents such as DMSO, which exhibit different anisotropic crystal growth properties than ice, can produce a rich variety of hierarchical structures.

11:45 AM SF02.01.06
Ice Crystal Growth and the Dynamics of Ice Templating by X-Ray Tomoscopy Paul H. Kamm1,2, Kaiyang Yin1, Tillmann R. Neu1,2, Christian M. Schlepütz4, Francisco Garcia-Moreno2,3 and Ulrike G. K. Wegst1,2; 1Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; 2Technische Universität Berlin, Germany; 3University of Freiburg, Germany; 4Swiss Light Source, Switzerland; 5Northeastern University, United States

The physics of ice-crystal growth from the liquid phase and the complex dynamics of microstructure formation by ice-templating during the directional solidification of aqueous solutions and slurries, also termed freeze casting, has to date received comparatively little research attention. Recent advances in synchrotron-based X-ray tomoscopy, which is time-resolved X-ray tomography, enable us now to investigate in situ under well-defined experimental conditions the formation of the hierarchical architecture of freeze-cast materials. We can quantify in 3D ice crystal growth at high spatial and temporal resolution and observe the ice-templating mechanisms, which determine the morphology of the freeze-cast material. The performance-defining morphology is defined by a honeycomb-like material structure with lamellar cell walls that frequently are decorated with a range of unilateral surface features. Analyzing the tomoscopy data we can determine, which features of the freeze-cast materials are templated by the slow faceted growth along the c-axis of the hexagonal ice-crystal, and which are templated by the slightly anisotropic fast crystal growth along the preferred a- and t-axes, both of which are characterized by atomically rough ice-water interfaces. Additionally, we can observe, which role secondary instabilities play in the formation of cell wall surface features. Important advantages, which in situ X-ray tomoscopy offers over post-mortem imaging and state-of-the-art simulation techniques, are that the dynamics of the structural evolution can be monitored over several minutes in a sample volume of several cubic millimeters so that also transient phenomena are captured.
Supported metal catalysts are used in many applications such as combustion gas purification catalysts, gas reforming systems, and chemical product synthesis processes. Supported metal catalysts generally have a structure with high specific surface area and high dispersion of precious metal to improve catalytic activity and economic efficiency. One of the big challenges in these catalysts is to prevent deterioration of catalytic activity caused by thermal aggregation of precious metal nanoparticles in high-temperature environments. To achieve both high thermal stability and high catalytic activity, it is necessary to properly control the oxide and metal particle sizes and metal/oxide interface structure. However, in the case of wet processes such as the impregnation method, precise structural control requires complex multi-step processes, which can be disadvantageous for practical application. The aim of this study is to synthesize supported metal catalysts with high catalytic activity and thermal stability in a simple process. For this purpose, we synthesized Pt/CeO2 nanoparticles by flame-assisted spray pyrolysis using a burner diffusion flame, and the effects of material precursor concentration and flame conditions on the structure of the synthesized nanoparticles were investigated. In addition, the CO oxidation properties and thermal stability of the particles synthesized by flame-assisted spray pyrolysis were evaluated and compared with those of particles prepared by the impregnation method.

A coaxial flow diffusion flame burner with a double-tube structure was used for the particle synthesis experiments. A mixture of oxygen and nitrogen is supplied to the outer tube, and a mixture of nitrogen and methane containing a precursor solution atomized by an ultrasonic transducer (2.4 MHz) is supplied to the inner tube. The synthesized Pt/CeO2 particles consisted of submicron-scale CeO2 with 10 nm-scale Pt and aggregation of fine CeO2 less than 10 nm with highly dispersed Pt (1 nm or less). When the flame temperature was varied by changing the ratio of oxygen and nitrogen supplied to the burner outer tube, more fine particles were produced at higher flame temperatures. Submicron-level particles may have formed by the droplet-to-particle route, in which the precursor droplets do not evaporate completely and nucleation occurs within the droplet. On the other hand, fine nanoparticles may have formed by the gas-to-particle route, in which the droplets completely evaporate and nucleation occurs in the gas phase. The evaporation of precursor droplets is enhanced at higher flame temperature, resulting in the solidification of particle formation route from droplet-to-particle to gas-to-particle. The fine Pt/CeO2 nanoparticles synthesized by the high-temperature flame showed CO catalytic activity comparable to that of particles prepared by the impregnation method. Moreover, the thermal stability of the Pt particles on CeO2 by flame synthesis was better than that of the impregnation method.

Colloidal Metal-Halide Epitaxial Heterostructures: From Serendipity to Rational Design
Stefano Toso1, Muhammad Imran1,2, Derek Dardzinsky3, Noa Marom1 and Liberato Manna1, 2, 3
1Istituto Italiano di Tecnologia, Italy; 2University of Toronto, Canada; 3Carnegie Mellon University, United States

Colloidal epitaxial heterostructures are nanoparticles made of two crystalline materials connected at an interface. These architectures profitably combine the properties of their components, and can express unique ones stemming from their interactions. Historically, heterostructures have produced major breakthroughs in the field of colloidal nanomaterials, with core/shell quantum dots being the most renowned examples. Indeed, heterostructures are often grown from isostructural materials like CdSe/CdS, where the only requirements are similar lattice parameters. However, the increasing number of heterostructures reported between non-isostuctural materials points to the limits of this design strategy. In this talk, we will take the serendipitous discovery of heterostructures between lead halide perovskites (CsPbX3) and lead sulfohalides (Pb4S3X2) as a case study.[1] We will first identify empirical criteria behind the formation of these heterostructures by comparing them with other interfaces formed by lead halides.[1] Then, we will exploit in-situ spectroscopies performed directly in the liquid reaction medium to gain insight into the growth mechanism of these composite nanomaterials. As a next step, we will take advantage of such knowledge to master the synthesis of two competing nanomaterials (PbS2Cl2 vs Pb3S2Cl2) by exploiting heterostructures as phase-selective reaction intermediates.[4] This approach is inspired by the retrosynthetic strategies typical of organic chemistry, and provides advanced control over the product of colloidal synthesis. Finally, we will rationalize these results with the help of a novel computational tool, which is capable of predicting the formation of stable colloidal epitaxial heterostructures. By providing fundamental insights into the growth mechanism and stability of colloidal nanocrystal heterostructures, we hope to lower the barrier that separates the widely appealing properties of these fascinating composite nanomaterials from real-world applications.

resolution exploration of nanoparticle surface processes with time resolutions ultimately limited by detector readout speeds (0.0001 – 0.001 s is now common). We are investigating the surface dynamics of Pt nanoparticles with temporal resolutions of ~0.01 s under different ambient conditions. Typical kinetic pathways are observed to follow elementary surface transformation steps including atom column activity (e.g., adatom migration, adatom fluxionality, surface layer growth, surface layer fluxionality, surface layer removal), shearing (e.g., surface shear, subsurface shear creating or annihilating stacking faults). Since there is a tight connection between the surface and subsurface structure in small particles, instabilities in the surface structure can trigger instabilities in the entire nanoparticle crystal. The relationship between these different metastable states and kinetic pathway will be discussed in the presentation.

Observing Crystal Nucleation on Graphene via High-Speed Atomic-Resolution TEM Won Chul Lee1, Jungwon Park2 and Peter Ercius3; 1Hanyang University, Korea (the Republic of); 2Seoul National University, Korea (the Republic of); 3Lawrence Berkeley National Laboratory, United States

Nucleation in atomic crystallization remains poorly understood despite advances in classical nucleation theory. The nucleation process has been described to involve a non-classical mechanism including a spontaneous transition from disordered to crystalline states, but a detailed understanding of dynamics requires further investigation. Here, using in-situ transmission electron microscopy of heterogeneous nucleation of individual gold nanocrystals with millisecond temporal resolution, we show that the early stage of atomic crystallization proceeds through dynamic structural fluctuations between disordered and crystalline state, rather than through a single irreversible transition. Our experimental and theoretical analyses support that structural fluctuations originate from size-dependent thermodynamic stability of the two states in atomic clusters. These findings, based on dynamics in a real atomic system, reshape and improve our understanding of nucleation mechanisms in atomic crystallization.

4:00 PM SF02.02.06
The Onset of Crystallization of Aerosol Au Nanoparticles Yi Wang1, Southis E. Pratsinis3 and Eirini Goudeli2; 1ETH Zürich, Switzerland; 2The University of Melbourne, Australia

Gold nanoparticles have versatile applications in catalysis, chemical and biological sensing, medicine (drug carrier, therapeutic agents and gene delivery), nanolithography and microelectronics [1]. The performance of these nanoparticles is heavily influenced by their crystalline characteristics. Even though Au nanoparticles are routinely made in the liquid phase, their gas-phase (aerosol) synthesis is most attractive for its proven scalability (25 t/h) and high-purity products (i.e. optical fibers) [2]. During aerosol synthesis, the formation of particles occurs at high temperatures, steep cooling rates and short residence times that affect considerably nanoparticle characteristics, including their crystallinity, size, and morphology [3]. Here, the gas-phase crystallization of Au nanoparticles is investigated by molecular dynamics (MD) using the embedded atom method (EAM) that is most relevant to their synthesis by aerosol processes (flame, plasma, laser, etc.). We elucidate the onset of crystallization and growth dynamics of 2.5 – 11 nm Au nanoparticles under isothermal conditions.

The relationship between Au melting point and particle size is used to validate the method. A metastable region of 200 - 300 K wide between the melting point and super-cooled solidifying temperature of Au is revealed as a function of particle size. The crystalline disorder parameters and potential energy are used to elucidate the isothermal crystallization dynamics of Au nanoparticles in three distinct stages at 500 – 800 K (subcritical cluster dynamics, onset of crystallization and crystal growth). The degree of crystallization (predominantly face-centered cubic (FCC) with some hexagonal close-packing (HCP)), is quantified from the local crystalline disorder. In the first stage, before the onset of crystallization, subcritical Au cluster form and deform continuously similar to the subcritical nucleation dynamics of liquid (i.e. water) droplets in the atmosphere. The onset of crystallization is detected by the steep rise of the retained atoms fraction (RAF) of the largest subcritical cluster. This increase is accompanied by a sharp drop of the amorphous fraction of the Au nanoparticle.

In the second stage, crystallization usually starts from the nanoparticle surface as a result of lower kinetic energy barriers there. 3D-snapshots of the Au particle reveal two crystallization nucleation pathways: (A) Catastrophic nucleation when crystallization takes place well below the Au supercooled solidifying temperature resulting in many small crystal domains within the nanoparticle; and (B) Accretion nucleation when crystallization takes place at temperatures near the super-cooled solidifying temperature where fewer nanocrystals are formed that gradually coalesce into larger crystal domains.

In the third stage, after the onset of crystallization, crystals grow via both accretion and cluster merging, with crystal domain reorganization after the crystalline transformation is completed. X-ray diffraction (XRD) patterns are generated, from which the dynamics of crystal growth are elucidated and compared to direct tracing of crystal sizes. The product crystal size is influenced largely by crystallization temperature, with the largest crystal size obtained when crystallization takes place near the supercooled solidifying temperature consistent with the literature [4].

The results of this study can facilitate the process design for aerosol synthesis of Au as well as other metal nanoparticles for optical, electronic, catalytic and biomedical applications.

Nickel (Ni) is an interesting material for several applications, due to qualities including resistance to high temperature, oxidation, and corrosion, which are also present at the nanoscale. In particular, Ni nanowires show many applications in biology, optical devices, solar cells, and sensors, among others. Ni nanostructures have been created so far using a variety of methods, including hydrothermal, laser ablation, and chemical vapor deposition techniques. In this study, we investigate the fabrication of Ni nanostructures via local corrosion of thin Ni films deposited by physical vapor deposition. Slow Ni corrosion is achieved using water, glycine, and calcium chloride static solutions with various pH levels. After a considerable amount of time (24-48 hours) of contact between the Ni film and the solution, micron-sized, roughly circular isotropic corrosion patterns are observed. Scanning Electron Microscopy (SEM) images show that nanostructures form inside the corrosion patterns. Typically, a nanowire-like structure extends vertically from the center of most patterns; for those with larger diameters, very thin planar nanowires extend from this central structure. SEM-based Energy Dispersive Spectroscopy measurements reveal that the central nanostructure is made of Ni, while the composition of the thinner, planar nanowires cannot be resolved using this technique. Our findings via simulations suggest a process of corrosion starting at specific locations such as film defects, with subsequent Ni redeposition due to a radial Ni concentration gradient at the metal film-solution interface. Further studies should determine if this process can be made controllable as a new synthesis process of Ni nanostructures.

The development of structural hierarchy on various length scales during crystallization process is ubiquitous in biological systems and is common in synthetic nanomaterials. The driving forces for the formations of complex architectures range from local interfacial interactions, that modify interfacial speciation, local supersaturation, and nucleation barriers, to macroscopic interparticle forces. Although it is enticing to interpret the formation of hierarchical architectures as the assembly of independently nucleated building blocks, often crystallization pathways follow monomer-by-monomer addition with structural complexity arising from interfacial chemical coupling and strongly correlated fluctuation dynamics in the electric double layers. Here, we show that the development of structural hierarchy through heterogeneous nucleation is driven by dipolar and solvation forces. Specifically, coupled simulations and experimental studies revealed that dipole build up along the slow growth direction can trigger twinning and the development of branched architectures. Enthalpic solvation interactions were shown to either enhance or reduce the dipole moment of the nanoparticles and, thereby, control crystal morphology and architecture. The systematic studies of chemical coupling between different solvents and undercoordinated surface atoms of the growing nanocrystals revealed the mechanism of dimensionality control and the development of structural hierarchy in the absence of ligands or other controlling agents.
Colloidal nanocrystals containing a few tens to hundreds of atoms have applications in a range of areas, from electronics to catalysis and biological sensors. This versatility stems from the high sensitivity of nanocrystal properties to size, chemical composition, and shape, which are largely determined by the synthesis route by which they are produced. However, structure characterization based on bulk-originating methods is usually not enough because of the unique structural characteristics emerging at the nanoscale. Exposed surfaces, defects, dislocations, and quantum effects are dominant in nanocrystals of finite size. In addition, the ensemble of nanocrystals produced from conventional colloidal synthesis displays a large degree of heterogeneity in the atomic structures and has the effects of organic ligands and solvent molecules. Thus, understanding the structures of nanocrystals at a level where fundamental structure-property relationships can be linked requires new analysis methods that allow precise and reproducible determination of the positions of the constituent atoms of single nanocrystals directly from the solution phase. We developed a “one-particle Brownian 3D reconstruction method” for the analysis of the three-dimensional (3D) structures of colloidal nanocrystals based on graphene liquid cell electron microscopy. “One-particle Brownian 3D reconstruction” can be applied to not only uni-component metallic nanoparticles but also multi-component nanoparticles such as CdSe, PbSe, and FePt. We further extend 3D structure characterization approach to time-resolved domain such that colloidal nanoparticles undergoing structural transition in solution can be captured in time-resolved 3D resolution. To enable 3D and 4D reconstruction of colloidal nanoparticles directly from liquid phase TEM imaging, a series of large image data processing, a part of which is potentially enhanced by machine-learning based data analysis, is developed.

4D Structures of Colloidal Nanoparticles using Graphene Liquid Cell TEM and Self-Supervised Machine Learning Analysis Jungwon Park; Seoul National University, Korea (the Republic of)

Colloidal nanocrystals exhibit a versatile range of applications in electronic devices, catalysis, and biomedical applications. The precise control of their size, composition, and shape is crucial for tailoring their properties. Understanding the structure-property relationships at the atomic scale is essential for the design of new materials.

Observation of Amorphous-To-Crystalline Transition at the Single-Atom Level Jianwei (John) Miao; University of California Los Angeles, United States

The amorphous-to-crystalline transition is fundamental to many physical, chemical and biological phenomena, but is a challenging process to study at the atomic scale. An approach to overcome this challenge is atomic electron tomography (AET) (1). AET combines high-resolution tomographic tilt series with advanced computational algorithms to resolve the three-dimensional (3D) atomic structure of materials without assuming crystallinity (2). We have recently advanced AET to determine the 3D atomic structure of amorphous materials and characterize the short- and medium-range order of the 3D atomic arrangement (3,4). In this talk, I will present our most recent results on the application of AET to observe the amorphous-to-crystalline transition in 3D at the atomic resolution. By using a carbothermal shock method (5), we trapped high entropy alloy nanoparticles at different stages of crystallization. We then used AET to determine the 3D atomic structure of the high entropy alloy nanoparticles as a function of crystallization. By quantitatively characterize the 3D atomic arrangement inside a large number of nuclei, we observed crystal nucleation pathways at the single-atom level. We expect that these experimental results not only open the door to study the amorphous-to-crystalline transition at the atomic scale, but also could transform our fundamental understanding of nucleation and crystal growth.

In a rechargeable battery, the transport of ions between the electrode and the electrolyte plays a crucial role in governing electrochemical kinetics and can strongly influence the battery performance. Studying the diffusion of metal ions during battery operation is therefore important in developing new battery designs aimed at mitigating existing technical challenges associated with mass transport, such as dendrite growth. To date, a wide range of techniques, including X-ray/neuron imaging, NMR spectroscopy, and electrochemical impedance spectroscopy, have been developed to study the diffusion phenomena of metal ions under operando conditions. Nevertheless, the experimental determination of the nanoscale spatial distribution of ionic concentration gradients remains a challenge.

Rechargeable alkaline iron-air batteries have recently emerged as the leading candidate for long-duration energy storage due to their environmental friendliness, low cost, safety, and scalability. Although the reverse rusting of iron in alkaline electrolytes has been extensively investigated over the last five decades, the transformation pathways of iron species during this process are still under debate. Specifically, the role of diffusion gradients of the initially formed soluble HFeO₂⁻ species in governing the precipitation of amorphous Fe(OH)₃ passivation layers during anodic reactions remains poorly understood.

Here we present the use of operando electrochemical transmission electron microscopy (EC-TEM) as a probing technique to investigate the diffusion gradient during battery operation. Using the iron-air battery as a case study, we focus on studying the concentration gradient of the soluble iron ions, i.e., HFeO₂⁻, formed during the anodic dissolution of body-centered cubic (BCC) iron at pH 14. We first discuss the importance of electrolyte volume in mitigating the ion diffusion limitations within the confined cell to achieve reproducible cyclic voltammograms. Subsequently, by manipulating the positioning of one or multiple counter electrodes (CE) relative to the iron anode along the electrolyte flow channel, we observe that dendrites can grow on these CE electrodes during battery discharge. The concentration gradient of HFeO₂⁻ can therefore be estimated by quantifying the size/mass of these dendrites as a function of the distance from the anode. Our findings suggest that EC-TEM could serve as a useful tool for comprehending the effects of local ion concentration on the morphological evolution of the electrodes in the various battery systems during charge and discharge processes.
Cinematographic Recording and Analysis of the Whole Process of Crystal Nucleation/Growth at Millisecond Sub-Angstrom Resolution. Finchi Nakamura, The University of Tokyo, Japan

Chemical phenomena are complex events where a variety of molecules stochastically appear on time scales ranging from nanoseconds to hours. Studying the stochastic behavior of individual molecules requires unconventional methods that differ from the traditional ensemble- and time-averaged experimental techniques. Crystal nucleation/growth is no exception. Since 2004, we have spent considerable effort on developing the SMART-EM technique (Single Molecule Atomic Resolution Time-resolved Electron Microscopy, ref 1, 2). In this talk, I will discuss the cinematographic recording of the whole process of the nucleation and growth of NaCl crystal (ref 3, 4) and of the PAN carbon fiber formation by pyrolysis of polycrylonitrile (ref 5). We are transforming chemistry from the macroscopic paradigm of thermodynamics to the microscopic statistical mechanical paradigm.

8:00 PM SF02.05.01 Dynamic DNA Nanodevices with Switchable Optical Properties Soojung Lee1, Jason Kahn2, Daniel McKeen1 and Oleg Gang1,2; 1Columbia University, United States; 2Brookhaven National Laboratory, United States

Advancements in DNA nanotechnology have opened up the ability to fabricate nanomaterials with dynamic properties for applications in optics, medicine, and electronics. Such properties are defined by precisely controlled arrangements of functional nanocomponents. However, there remains a continual challenge in gaining dynamic control of nanoscale materials. DNA-based self-assembly offers a promising approach to form switchable three-dimensional (3D) clusters and large-scale ordered nanostructures that can encapsulate, organize and manipulate various types of nanoscale objects through programmable interactions.

Here we study the assembly, reconfiguration and optical performance of a nanoscale device with stimuli-responsive and switchable properties. We utilized a 3D polyhedral DNA frame to establish a system that can switch between different conformations that allow for the manipulation of nanoparticles. Our previous studies have demonstrated that the optical output of a binary self-assembled system composed of gold nanoparticles (AuNP) and quantum dots depends on the interparticle separation distance. With this as a reference, we designed a structurally switchable 3D DNA frame for nanoparticle repositioning. By utilizing a DNA motif that acts as a manipulator, we show an ability to pass molecular information over a distance of tens of nanometers on a frame. We used this principle to investigate how this DNA device is able to direct nanoparticle reconfigurations and induce different optical responses.

Interactions between the plasmonic and fluorescent particles were explored by testing various system designs. The structural reconfiguration of the system was examined by electron microscopy and small-angle X-ray scattering (SAXS), while spectroscopic measurements were applied to correlated optical responses with structural switching.

8:00 PM SF02.05.02 Enhancing Biosensor Performance by Optimizing Surface Coverage of the Self-Assembled Monolayer Jaehyun Kim, Honglin Piao, Dael Park and Heon-Jin Choi; Yonsei University, Korea (the Republic of)

Self-assembled monolayers (SAMs) are widely used in various fields such as nanotechnology, electronics, and biomedical applications. SAMs are a crucial component in the fabrication of biosensors, as they provide functional surfaces for the immobilization of biological recognition elements. However, non-uniform SAM coverage on biosensor substrates can lead to variability in detection and quantification, which can severely hamper the biosensor’s performance. The method proposed in this research includes experimental SAM analysis and prediction of SAM formation results through fitted function. After fixing several deposition parameters such as concentration, temperature, we applied logistic functions to create a function for the deposition rate of SAMs. Using this function, deposition has clearly improved the uniformity of SAMs. This outcome, confirmed through various characterization techniques including atomic force microscopy (AFM), and X-ray photoelectron spectroscopy (XPS), leads to an enhanced biosensor performance in terms of sensitivity and selectivity. To validate the accuracy of our developed function, we employed a comparative approach using machine learning techniques. These techniques, known for their ability to predict complex patterns and interactions, served as a benchmark for our optimization function. Preliminary results indicate that the proposed function holds significant promise in optimizing SAM surface coverage, with performance comparable to or exceeding that of the machine learning models. The proposed methodology not only provides a more stable and predictable biosensor response but also contributes to the advancement in the broader field of biosensing technology. This new approach offers significant implications for the development of high-performance biosensors, enabling more precise and consistent biomedical diagnostics, environmental monitoring, and other related applications. We will show experimental evidences on our proposed approach from glucose monitoring system (GMS).

8:00 PM SF02.05.03 Temperature Measurements During Laser-Induced Graphitization of Polydimethylsiloxane Masato Kai, Shuichiro Hayashi, Ken Kashikawa and Mitsuhiro Terakawa, Keio University, Japan

Laser-induced graphitization of polymers has attracted attention as a technique to simultaneously form and pattern graphitic carbon on and/or inside polymers. Depending on the laser parameters, the morphology and the crystallinity of the formed graphitic carbon vary with photochemical and photothermal effects. However, the mechanism of laser-induced graphitization of polymers has not been revealed in detail. In this study, we measure the
temperature of a polymer’s surface during laser-induced graphitization to investigate the relationship between the laser parameter and the characteristics of the developed carbon with regard to photothermal effects of organosilicon polymer/polydimethylsiloxane (PDMs), was irradiated with high-repetition rate femtosecond laser pulses at different laser scanning speeds. The temperature of the PDMs surface was measured using a thermography camera. Plano-convex lenses were located between the irradiated surface and the thermography camera for micro-thermographic measurements with a spatial resolution of ~40 μm. The morphology of the formed structure was observed using scanning electron microscopy (SEM), and the crystallinity of the structure was analyzed using Raman spectroscopy, respectively. SEM observations showed that the cross-sectional area of the formed structure increased with the decrease in scanning speed, suggesting that the amount of energy absorbed by PDMS was positively correlated with the number of irradiated pulses per spot. Furthermore, for significantly low scanning speeds, the formation of cracks was observed in the formed structures, which may be attributable to the laser ablation induced by the excessive amount of energy absorbed by PDMS. Raman spectra showed peaks at ~1350, ~1600, and ~2700 cm⁻¹ that correspond to the D, G, and 2D bands, respectively, indicating the formation of graphitic carbon. Also, a peak at ~520 cm⁻¹ was observed in the obtained Raman spectra in the case of significantly low scanning speeds, indicating the formation of crystalline silicon. Taking the results of SEM observations into account, it can be assumed that crystalline silicon was formed owing to the high temperature induced by the excessive amount of energy absorbed by PDMS. The formed structures performed in temperature measurements that the increase in the amount of energy absorbed by PDMS with the increase in the number of irradiated pulses per spot. However, in the case of significantly low scanning speeds, the measured temperatures kept constant regardless of the scanning speed, indicating the saturation of the temperature of the laser-irradiated area. The saturation of the temperature at significantly low scanning speeds cannot be explained solely by the change in the amount of the energy absorbed by PDMS. One possible explanation for the saturation is the change in the energy diffusion property of the laser-irradiated area with the change in the morphology and the material composition. It can be suggested from the obtained SEM images that the bulk density of the laser-irradiated area may be changed with the formation of cracks, changing the energy diffusion property of the laser-irradiated area. Moreover, considering the obtained Raman spectra, the formation of crystalline silicon in addition to the graphitic carbon may change the energy diffusion property of the laser-irradiated area.

Assembly of Short-Sequence Amphiphilic Peptoids into Helical Nanostructures with Controllable Supramolecular Chirality 
Renyu Zheng1,2, Mingfei Zhao3, Jingshan Du2, Yicheng Zhou1, Shuai Zhang1, Wenhao Zhou1, Andrew Ferguson1 and Chun-Long Chen2; 1University of Washington, United States; 2Pacific Northwest National Laboratory, United States; 3Los Alamos National Laboratory, United States; 4The University of Chicago, United States

A long-standing challenge in biomimetic research is to create sophisticated hierarchical nanostructures that mimic the biomaterials found in living organisms. Self-assembly is a crucial process for creating these nanostructures, but the forces and dynamics governing the self-assembly of biomacromolecules, such as proteins and peptides, are complex. Developing sequence-defined synthetic polymers with simplified molecular interactions is a promising approach to synthesizing information-rich nanostructures and understanding their self-assembly mechanisms. Peptoid is a peptidomimetic molecule that moves the side group from nitrogen to carbon to keep the sequence programmability while simplifying the structure without backbone hydrogen donors and no backbone chirality. Previous studies have shown that amphiphilic peptoids can crystallize into highly ordered nanostructures, including nanoribbons, nanosheets, nanotubes, and nanohelices, by controlling peptoid-peptoid and peptoid-substrate interactions. However, achieving the predictable self-assembly of peptoids into designed nanostructures remains a significant challenge. In this study, we report a system of short tetramer peptoids to form crystalline peptide helices. Due to the reduced hydrophobic interactions compared to those with six hydrophobic side chains, we showed that the self-assembly of these peptoids into nanohelices and other nanostructures are highly sensitive to the solution ionic strength and solvent condition, resulting in the formation of various nanostructures including nanohelices, nanohelix bundles, as well as nanotubes. We also demonstrate the control of supramolecular chirality of self-assembled peptoid nanohelices by using chiral polar groups with D- or L-configuration. By combining the synchrotron XRD results with molecular dynamic simulation studies, we showed the twisted form of bi-layer structures of these amphiphilic peptoids are the most stable form for those polar side chains to hide hydrophobic domains in the aqueous environment. We further demonstrated that the organic cosolvent in the self-assembly could also affect the self-assembly morphology from nanohelices to nanotubes, which provides additional information on peptoid-solvent interactions as well as the self-assembly kinetics and thermodynamics. Our findings provide a facile system for controlling the twisting and stacking of peptoid amphiphiles into helical and tubular structures and suggest an approach for the precisely controlled synthesis of biomaterials.

8:00 PM SF02.05.05
Molecular Dynamics Characterization of Gas Diffusivity of CO2-CH4 in sI Clathrate Hydrates 
Ali Beydoun, Alejandro D. Rey and Phillip Servio; McGill University, Canada

Clathrate hydrates are cage-like water structures entrapping a gaseous guest molecule in their cavities. The need for alternative fuel sources has spurred an interest in methane hydrates as estimates predict that two thirds of the fossil fuel global reserves. However, their exploitation is not without fault as methane hydrates occupy a crucial role in stabilizing the soil as well as being a potential major source of greenhouse gases. Fortunately, methane found in clathrate hydrates can be swapped with carbon dioxide (CO2), thus allowing for carbon sequestration, and rendering the production of methane effectively carbon neutral. The process has been shown to be feasible and resulting in the formation of stable CO2 hydrates, but the mechanism surrounding the exchange remains to be elucidated. This presentation focuses on a system where pure methane sI hydrates are exposed to a front of CO2 dissolved in water. The system conditions are set to be favorable to the melting of methane hydrates and to the formation of CO2 hydrates. As the system evolves with time, methane escapes the lattice and CO2 diffuses into the latter, replacing methane in partially melted cages as well as forming new cages at the interface in a phenomenon known as co-growth. An analysis of the impact of temperature, pressure, and CO2 concentration on the diffusivity of CO2 and methane is conducted. It is followed by an analysis on how co-growth at the interface hinders diffusion and prohibits CO2 from diffusing deeper in the lattice. Previous work found in the literature has quantitatively described the impact of such impediment on the ultimate replacement ratio, but the presented research is the first quantify the effect on mass diffusivity. This work will also discuss the impact of water vacancies and of gas occupancy on mass diffusivity. To understand the effects of vacancies and gas occupancy on the thermodynamics of the system, the Gibbs free energy, the enthalpy, and the entropy are calculated. Our previous work quantified diffusivity in a CO2 filled hydrate system and the impact of such vacancies and serves as a basis for comparison. The investigation also looks into how diffusion evolves from a non-Fickian process to a Fickian one. Finally, this work also tackles how the swapping mechanism between methane and CO2 differs near the interface from deeper strata with the hole-in-cage model dominating the latter. The methodology is based on molecular dynamics. The Large-scale Atomic/Molecular Massively Parallel Simulator (LAMMPS) is used to perform simulations on a 3×3×3 methane hydrate lattice juxtaposing a CO2 front dissolved in water. The force fields used for methane, carbon dioxide, and water are OPLS-UA, EPM2, and TIP4P/ICE respectively. The LAMMPS software allows to quantify the mean squared displacement (MSD) which can be correlated to the mass diffusivity. Furthermore, LAMMPS computes primordial thermodynamics parameters such as the Free Gibbs energy, the entropy, and the enthalpy.

8:00 PM SF02.05.06
Investigation of the Amorphization Threshold by Ion Implantation as a Function of Energy and Implant Temperature in Silicon Substrates 
Amy Maén1, Noel Kennedy2, Christopher Hatem3 and Kevin S. Jones1; 1University of Florida, United States; 2Applied Materials, Inc., United States
As semiconductor devices continue to scale, ion implantation processes must follow suit to confine fabrication to nanosized structures. One such process is ion-beam induced amorphization, namely in silicon devices. Pre-amorphizing implants are known to increase dopant solid solubility once post-annealed, increasing the active carrier concentration within the recrystallized layer. Because of this, they are often incorporated during the processing of top-off implants, used to decrease contact resistance. The mechanism of silicon-substrate amorphization mechanism varies with ion mass but for heavier ions, it is associated with the overlap of damage cascades induced by nuclear stopping. As such, it should show little dependence on the surface. However, if the point defect accumulation mechanism associated with light ions is active, then the surface may play a role. To better understand the amorphization mechanism at ultra-low energies, the critical threshold for amorphization is investigated for different implant temperatures and energies. Silicon substrates were implanted with Si+ ions at low energies between 1 keV to 10 keV and implant temperature was varied ranging between 25°C to 150°C. The dose is kept constant at 3×10¹⁴ ions/cm² at a dose rate of 0.95 mA. The amorphous layer was studied by high resolution cross-sectional TEM and to SRIM simulations to determine the threshold damage density for amorphization. By studying the amorphization extent at varying energies and implant temperatures, it was possible to observe how the amorphization layer thickness produced by the implant differs as the damage becomes closer to the surface. It was found that as the implant energy decreased, the threshold damage density for amorphization increased, suggesting a shift in the amorphization mechanism possibly induced by an increasing role of the surface. The role of implant temperature will also be presented.

Enhancing the Self-Assembly of Binary Colloidal Crystals with Confinement Nathan Huang, Rachael S. Skye and Julia Dshemuchadse; Cornell University, United States

Photonic crystals with a bandgap in the visible-light range have been theorized to self-assemble from a binary colloidal dispersion but difficulties remain in robustly assembling high-quality crystals in quantities sufficient for large-scale applications. Computational methods give insight into the conditions under which photonic crystals can self-assemble. In this study, we performed hard-particle Monte Carlo simulations of tetrahedral and octahedral nanoparticles in spherical and flat-wall geometries to determine the influence of confinement on the process and products of crystallization compared to the bulk. Confinement was found to improve crystallization at non-ideal stoichiometries but did not lower the minimal packing fraction at which crystallization occurred throughout the system. Crystals formed under confinement exhibited higher crystallinity and lower quantities of secondary phase defects. These findings demonstrate the potential for enhanced control over the synthesis of novel materials with tailored structures and properties for photonic applications.

Bimetallic ZnCo Metal-Organic Framework at NiCo-Layered Double Hydroxides for Multiple Storage and Capability Synergy All-Solid-State Supercapacitors Nagel K. Allam; American University in Cairo, Egypt

Rational design and structural regulation of hybrid nanomaterials with superior electrochemical performance are crucial for developing sustainable energy storage platforms. Among these materials, NiCo-layered double hydroxides (NiCo-LDHs) demonstrate an exceptional charge storage capabilities owing to their tunable 2D lamellar structure, large interlayer spacing, and rich redox electrochemically active sites. However, NiCo-LDHs still suffer from severe agglomeration of their particles with limited charge transfer rates, resulting in an inadequate rate capability. In this study, bimetallic ZnCo-metal organic framework (MOF) tripods were grown on the surface of NiCo-LDH nanowires, which significantly reduced the self-agglomeration and stacking of the NiCo-LDH nanowire arrays, offering more accessible active sites for charge transfer and shortening the path for ion diffusion. The fabricated hybrid ZnCo-MOF@NiCo-LDH and its individual counterparts were tested as supercapacitor electrodes. The ZnCo-MOF@NiCo-LDH electrode demonstrated a remarkable specific capacitance of 1611 F g⁻¹ at 2 A g⁻¹ with an enhanced rate capability of 66% from 2 to 20 A g⁻¹. Moreover, an asymmetric all-solid-state supercapacitor device was constructed using ZnCo-MOF@NiCo-LDH and palm tree-derived activated carbon (P-AC) as positive and negative poles, respectively. The constructed device can store a high specific energy of 44.5 Wh Kg⁻¹ and deliver a specific power of 876.7 W Kg⁻¹ with outstanding Columbic efficiency over 10,000 charging/discharging cycles at 15 A g⁻¹.

Effect of Sulfate Regiposition on Ca²⁺-Heparin Binding Thermodynamics and Implications for Nucleation of Sparingly Soluble Salts Brenna M. Knight, Connor M. Gallagher, Michael D. Schulz, Kevin J. Edgar, Louis A. Madsen and Patricia M. Dove; Virginia Tech, United States

Heparin is a sulfated glycomaterial of long-standing importance as an anticoagulant in biomedicine due to its antithrombin binding sequence. Many more protein binding sequences are identified in heparin and other glycosaminoglycans (GAGs) but are understudied relative to antithrombin. Heparin and sulfate-rich macromolecules are also widely associated with biological crystallization in diverse animals. However, the lack of systematic and quantitative studies is impeding the potential of furthering heparin applications as well as a mechanistic understanding of how functional groups modulate biominalization. Using heparin as a model for understanding the role of sulfate groups associated with macromolecules in biological and synthetic settings, we test the hypothesis that the position of these groups influences Ca²⁺ binding to regulate calcite nucleation. This experimental study employs isothermal titration calorimetry (ITC) to quantify the binding thermodynamics of Ca²⁺-heparin interactions for a group of characterized heparin materials that differ by sulfate regiposition. Previous studies indicate Ca²⁺-heparin interactions involve water molecule(s) and are independent of electrostatic interactions. Our preliminary ITC findings show the binding is entropically driven, supporting this model. We further observe sulfate position moderates Ca²⁺-heparin binding to regulate calcite nucleation. In parallel experiments that measure the rate of nucleation of the sparingly soluble salt, CaCO₃, onto the corresponding heparin materials, we are determining the relationship between sulfate position and the interfacial energy barrier to calcite crystallization (γ₉₀). Initial results suggest materials that more efficiently bind Ca²⁺ (i.e., require fewer repeat units per ion) present a higher barrier to nucleation. To better understand this interaction, we are also determining the dependence of NMR relaxation time and chemical shifts on Ca²⁺ concentration. This study highlights the potential for using sulfate position to tune and optimize the design of heparin-based materials for advanced material design and biomedical applications.

DNA-Programmable Assembly in Bulk and at Liquid-Air and Liquid-Solid Interfaces Oleg Gna1,2; 1Columbia University, United States;
Organizing diverse types of functional nanocomponents into the designed 3D architectures promises to enable new functions with a broad range of applications, from engineered biomaterials to photonic devices and energy materials. However, current methods are limited in their ability to create such 3D nanomaterials with prescribed structures and integration of different types of nanocomponents. Using sequence-specific interactions and structural plasticity of DNA we established a self-assembly platform for assembly of designed large-scale and finite-size nano-architectures from diverse inorganic and biomolecular nanocomponents. We applied in-situ and ex-situ methods to reveal the lattice formation processes in bulk and at the interfaces for DNA-programmable systems. By combining designed nanoscale anisotropic bonds and their DNA encoding, we developed assembly approaches that allow for the creation of periodic and hierarchical organizations from inorganic nanoparticles and proteins. The formed nanostructures were further transformed into inorganic 3D replicas via several nano-templating methods. The novel DNA-assembled nanomaterials were investigated for nano-optical, mechanical, electrical and biochemical functions. Furthermore, approaches for integration with surface-based devices were established.

9:00 AM SF02.06.02
Programmable Colloidal Kagome Superlattices for Anisotropic Light Emission Zhiwei Li and Chad A. Mirkin; Northwestern University, United States

DNA-mediated programmable assembly of nanomaterials has given rise to a diverse library of colloidal superlattices and crystals with precise phase and symmetry control. Design rules for colloidal crystallization have been extensively studied but most of them, regardless of structural complexity and phase diversity, are driven by thermodynamically favored processes that lead to maximum DNA hybridization and complete particle surface overlap. Here, we show that the assembly of non-space-filling bipyramids results in partial DNA surface matching and yields colloidal Kagome superlattices. In short, Au pentagonal bipyramids of different sizes are used as building blocks and modified with single-stranded DNA as programmable atom equivalents (PAEs).

Driven by DNA hybridization, the bipyramids assemble into distorted Kagome lattices through partial surface matching, featuring shield-like lattices, lattice distortion, bipyramid twisting, and rhombohedral super unit cells.

Characterization of these low-symmetry Kagome lattices reveals diverse lattice plasmon resonance modes, which are dependent on the light incident direction and polarization. We take advantage of the Kagome lattice plasmon resonance and report facet-dependent anisotropic light emission enabled by doping dyes into the Kagome lattices. Taken together, this work opens up new avenues towards designing and accessing exotic colloidal superlattices and thus new materials for anisotropic light emission, which has implications for emerging optical platforms such as coupled optics and sensing.

9:15 AM SF02.06.03
Mapping The Spatial Dependence of Surface Ligand Binding in Individual Nanoparticles Zhi Yang1, Duua Ansari1,2, Manuel Pichardo1 and Matthew Jones1;1 Rice University, United States; 2the University of Texas at Austin, United States

While it is well-appreciated that surface ligands bind preferentially to certain locations on an inorganic nanoparticle (e.g. tips vs. flat facets), a quantitative understanding of this phenomenon is lacking. In this work, ligands are “tagged” with small gold nanoparticles so that their spatially-resolved binding positions can be measured in Cryogenic Transmission Electron Microscopy (CryoEM) images. Labeled thiol ligands were then exposed to hexadecyltrimethylammonium bromide (CTAB) modified gold triangular nanoprism particles, which present energetically distinct face, edge, and tip regions that we hypothesized would reveal different binding properties. By recording the relative positions of ~700 ligand binding events, a 3D energetic map of thiol chemisorption to gold nanoparticles could be generated, revealing a strong preference for edge and tip sites compared to {111} triangular faces.

Interpreting these data as a thermodynamic measure of binding probability allows for the use of the Boltzmann distribution to calculate the Gibbs free energy differences between tips or edges relative to faces of -8.01 and -6.81 kJ/mol, respectively, from which relative binding constants can be calculated. This work establishes an experimental platform for quantifying the spatial preferences of ligand binding that, because of the superior resolution of modern TEM instruments, is limited in accuracy only by the effective size of the tag-ligand conjugate.

9:30 AM SF02.06.04
Interfacial Assembly of Ligand-Functionalized Nanoparticles into Low-Dimensional Architectures Yilong Zhou1, Brian H. Lee1, Tsung-Yeh Tang2 and Gaurav Arya1;1 Duke University, United States; 2University of California, San Diego, United States

Self-assembly of nanoparticles (NPs) is a powerful approach for fabricating materials with unique architectures and properties. This is especially important for plasmonic, optical, and electronic applications where nanostructures need to be arranged in non-close packed clusters or periodic arrays to take advantage of the unique electromagnetic couplings that emerge from such arrangements. However, achieving unique and complex assemblies remains a challenging task. In this talk, I will demonstrate how fluid-fluid interfaces can be used to self-assemble ligand-functionalized NPs into exotic 1D and 2D architectures by harnessing the three-way competition between particle-particle interactions, particle-fluid surface energy, and fluid-fluid surface tension. I will begin by demonstrating via molecular dynamics simulations the interfacial assembly of binary systems of spherical NPs [2]. I will also show how this approach can be extended to shaped NPs, where a range of periodic porous superlattices may be assembled from polymer-grafted nanospheres by controlling their orientation at the interface [3]. Lastly, I will discuss the development of multibody potential via a machine learning approach to elucidate the role of multibody effects in the self-assembly of polymer-grafted NPs [4]. Overall, our results suggest that the interfacial assembly approach could be a versatile platform for fabricating 1D and 2D colloidal assemblies of tunable structure and properties.

Growth Habits and Phonon Modes of Nanoparticle Superlattices Qian Chen; University of Illinois at Urbana-Champaign, United States

Growth habits of nanoparticle superlattices dictate major design parameters (for example, symmetry, morphology and surface structure) of crystalline materials and consequently their applications. Using liquid-phase TEM, we show that nanoparticles can follow four different growth habits during self-
assembly as governed by nanoparticle interaction and mass transport, leading to distinct surface morphologies. Meanwhile, lattice relaxations at equilibrium are originated from nanoscopic springs and phonon vibrations, which we are able to map and quantify for the first time using single particle tracking and lattice dynamics theory for topologically-engineered nanoparticle superlattices. Our work paves the way for engineering geometries for applications of mechanical metamaterials.

10:45 AM SF02.06.06 Controlling Coulomb Interactions Among Nanoparticles to Achieve Novel Assembly and Crystallization Binay P. Nayak1,2, Honghu Zhang1, Wei Bu1, Benjamin M. Ocko2, Alex Travesset2, David Vaknin2, Surya K. Mallapragada1,2 and Wenjie Wang2; 1Iowa State University of Science and Technology, United States; 2Ames National Laboratory, United States; 3Brookhaven National Laboratory, United States; 4The University of Chicago, United States

Controlling interactions among nanoparticles is paramount to achieving assemblies vital to technologies seeking to exploit their novel collective properties. Although various techniques have been advanced, robust ones are necessary for upscaling nanoparticle assembly and crystallization. Here, we explore the self-assembly of binary nanoparticle superlattices (BNSLs) at a vapor/liquid interface by grafting gold nanoparticles (AuNPs) with end-charge-polyethylene glycol (PEG). The grafting PEG terminates with either COOH (negatively charged) or NH2 (positively charged) end groups. Lowering the pH increases the positive charge of NH2 (to form NH+ 3) and decreases the negative charge of COO− (to form COOH). Such control facilitates the formation of various two- and three-dimensional ionic-like superstructures of oppositely charged binary constituents either at the vapor/liquid interfaces or in bulk. Unlike traditional ionic crystals, this approach enables manipulation of the relative surface charge between the two constituents. We demonstrate this approach by using surface-sensitive synchrotron-based X-ray diffraction at grazing angles of incidence (GISAXS), X-ray reflectivity (XR), and SAXS, and establish the formation of distinct checker-board square and hexagonal lattice structures also by varying the molar ratios of the constituents. The main results of our study are summarized as follows: 1) For 1:1, 2:1, and 1:4 mixing ratios (−COOH: NH2 terminated-PEG), a checker-board square lattice structure is formed at various pH values. 2) For the 2:1 mixing ratio, lowering the pH transforms the structure from a checker-board structure to a hexagonal superstructure. 3) In the case of extremely low pH, whereas the NH2 terminated nanoparticles are water soluble, the -COOH terminated forms a single-particle hexagonal structure similar to neutral PEG-grafted AuNPs at the vapor/liquid interface. Our results confront zeta-potential measurements that determine the total charge of each particle. This qualitatively allows for a quick prediction of outcome structures based on pH and the molar mixing ratios. SAXS measurements show executive super-ionic structures in bulk consistent with interfacial observations.

Work at Ames National Laboratory is supported by US Department of Energy and Basic Sciences (DOE) DE- AC02-07CH11358, and at NSLS-II, BNL, by DOE DE-SC0012704 and at NSF’s ChemMat CARS by NSF/CHE-1834750.

11:00 AM SF02.06.07 Self-Assembly of Atomically Aligned Nanoparticle Superlattices from Pt–Fe3O4 Heterodimer Nanoparticles Shengsong Yang2, R. A. LaCour2, Yi-Yu Cai1, Yugang Zhang1, Cheve R. Kagan1, Sharon Glotzer1 and Christopher B. Murray3; 1University of Michigan–Ann Arbor, United States; 2Brookhaven National Laboratory, United States; 3Brookhaven National Laboratory, United States

Multicomponent nanoparticle superlattices (SLs) promise the integration of nanoparticles (NPs) with remarkable electronic, magnetic, and optical properties into a single structure. Here, we demonstrate that heterodimers consisting of two conjoined NPs can self-assemble into novel multicomponent SLs with a high degree of alignment between the atomic lattices of individual NPs, which has been theorized to lead to a wide variety of remarkable properties. Specifically, by using simulations and experiments, we show that heterodimers composed of larger Fe3O4 domains decorated with a Pt domain at one vertex can self-assemble into an SL with long-range atomic alignment between the Fe3O4 domains of different NPs across the SL. The SLs show an unprecedented decreased coercivity relative to nonassembled NPs. In situ scattering of the self-assembly reveals a two-stage mechanism of self-assembly: translational ordering between NPs develops before atomic alignment. Our experiments and simulation indicate that atomic alignment requires selective epitaxial growth of the smaller domain during heterodimer synthesis and specific size ratios of the heterodimer domains as opposed to specific chemical composition. This composition independence makes the self-assembly principles elucidated here applicable to the future preparation of multicomponent materials with fine structural control.

SESSION SF02.07: Macromolecular Crystallization and Assembly
Session Chairs: S. Eileen Seo and Hanglong Wu
Wednesday Afternoon, November 29, 2023
Sheraton, Second Floor, Republic A

1:30 PM *SF02.07.01 Directed Self-Assembly of Diblock, Multiblock, Bottlebrush and Rod-Coil Copolymers Caroline A. Ross; Massachusetts Institute of Technology, United States

Block copolymer microphase separation, driven by the chemical incompatibility between the blocks, leads to periodic patterns of spheres, cylinders, gyroids, lamellae and other structures with periods of a few nm and above. The microphase separation of thin films of block copolymers can be directed by topographical or chemical substrate features, leading to well-defined patterns with long range order and/or non-bulk morphologies. This directed self-assembly (DSA) process offers compelling opportunities for the generation of dense patterns with small period which are useful in nanofabrication and nanolithography. The utility of DSA can be enhanced by expanding the range of possible microdomain geometries available, and by developing methods to direct their self-assembly in the out-of-plane direction to make three dimensional structures.

We will describe morphologies created by Si-containing triblock terpolymers, rod-coil copolymers, and bottlebrush copolymers, including zigzags, bends, junctions, tiling patterns and hierarchical structures with two independently tunable periods. As an example, a Janus bottlebrush triblock terpolymer yields layers made up of meshes of one block in a matrix of a second block, separated by layers of a third block. The meshes have sub-20 nm period and various angles, and can be aligned in topographical substrate features. Sequential self-assembly can produce three dimensional structures, including orthogonal mesh patterns, by assembling one block copolymer on another. Additionally, we also describe metal infiltration of block copolymers by immersion in an acid solution of a metal salt, which locks the self-assembled structure, and reversibility of the metallization by immersion in a solution of a complexing agent, unlocking the structure so that it can evolve in response to annealing. We use in situ grazing incidence small angle x-ray scattering to reveal details of the self-assembly process during thermal or solvent vapor annealing. Combinations of novel polymers, templating approaches, and processing techniques yield an extensive array of rectilinear and 3D pattern geometries that can expand current nanofabrication capabilities.
The self-assembly of block copolymers has been widely studied over decades as a potential platform in a plethora of nanotechnological applications. Recently, significant attention has been drawn to the self-assembly of BCP-based supramolecules rather than traditional BCPs, as a more efficient method of tuning the morphologies. While the self-assembly of supramolecules is governed by the competition between minimizing the enthalpy of mixing between the blocks and maximizing the conformational entropy, tuning of morphologies and kinetic behavior are heavily influenced by molecular architecture and processing. Solvent vapor annealing is a versatile processive pathway to obtain highly periodic self-assemblies from high-g block copolymers and supramolecules. However, little evidence is found regarding the kinetic behavior of the order-disorder transition of such assemblies during controlled solvent vapor annealing. Adsorption-desorption isotherm is a method of characterizing host-guest interactions in porous materials. A similar approach can be used to understand the interactions between polymer chains and solvent vapor molecules. The present study is focused on understanding the kinetic factors that influence the morphological evolution using characteristic absorption-desorption behavior of cylinder-forming polystyrene—block—poly (4-vinyl pyridine) block copolymer combined with pentadecylphosphol (PS—b—P4VP(PD)) during solvent vapor annealing. We identify the transition points from kinetically trapped initial phase segregation to periodic horizontal cylindrical structures with long-range order using absorption-desorption isotherms. We further investigate the tunability of grain coarsening and macroscopic film dewetting under continuous flow solvent vapor annealing. Atomic Force Microscopy (AFM) is used to characterize surface morphological evolution. Using Grazing Incidence Small Angle X-ray Scattering (GISAXS), the periodicity (D0) and grain size are quantitatively analyzed.

The properties of synthetic polymers are often tuned with additives. Whilst most additives, like plasticizers, are non-migratory, some are migratory, like lubricants. Blooming and/or bleeding refers to phenomena in which additives in a polymer migrate to its surface; this is a common phenomenon that is important for several industries including food packaging and pharmaceutics, medicine, art, and the production of long-lasting insecticidal bed nets. Many long-lasting insecticidal bed nets for protection against disease vectors are made of poly(ethylene) fibers in which the insecticide is embedded at the time of manufacture. Insecticide molecules diffuse from within the supersaturated polymers to surfaces and become bioavailable to insects, in most cases eventually crystallizing. Recent studies have revealed that contact insecticides can be highly polymorphic. Moreover, insecticidal activity is polymorph dependent, with forms having higher crystal free energy yielding faster insect knockdown and mortality. Consequently, the crystallographic characterization of insecticide crystals that emerge from fibers is critical to understanding net function and improving net performance. Structural characterization of insecticidal crystals on bed net fiber surfaces, let alone their polymorphs, has been elusive owing to the minute size of the crystals that by necessity grow in and on threads, however.

Here we describe surface crystallization of several molecules by phase separation from extruded poly(ethylene) fibers including ROY, paracetamol, flufenamic acid, benzamide, benzil, deltamehrthrin, alpha-cypermethrin, lambda-cyhalothrin and chlorfenapyr. In general, solutes diffuse from the polymer matrix and form amorphous droplets on the surface. With time the system may undergo substantial evolution from droplet coalescence to metastable crystal growth, to recrystallizing as more thermodynamically stable forms, a demonstration of Ostwald’s Rule of Stages. In general, crystallization on the surface of poly(ethylene) resembles growth from vapor phase and is often limited by diffusion mass transport. With the highly polymorphous compound ROY (5-methyl-2-[2-(nitrophenyl)-amino]thiophene-3-carbonitrile) as a proxy for insecticide crystallization, we investigated blooming kinetics and crystallization on the surface of melt-extruded, and cold-drawn poly(ethylene) fibers that had been impregnated with ROY. The blooming rates, tracked from the time of extrusion, were determined by UV-vis spectroscopy after successive washes. Six crystalline polymorphs (of the 14 known) were observed on poly(ethylene) fiber surfaces, and they were identified and characterized by Raman microscopy, scanning electron microscopy, and 3D electron diffraction (3ED). We show both polymorph control and particle size/morphology control. These observations reveal that the crystallization and phase behavior of polymorphs emerging from poly(ethylene) fibers is complex, dynamic, and tuneable. Furthermore, the demonstration that 3D ED can characterize the minute crystals grown on fibers promises a pathway to bed net crystallography and subsequent optimization of bed net performance.
resulting in improved yields for certain pathways. We envision that DNA origami chains could be integrated with scalable assembly methods to build new origami building blocks into a flexible linear chain of linked DNA origami. We then fold these chains into more compact structures in several steps, hierarchical assembly of DNA origami. Inspired by protein assembly, we investigate multi-step folding pathways. Initially, we assemble individual DNA states, enabling rapid and reversible shape transformations of assemblies with high yield. Additionally, we explore strategies to improve the yield of.

We demonstrate the use of DNA barrel monomers as modular voxels to build diverse multi-component assemblies with intricate custom features and connections within hierarchical assemblies. However, challenges remain in achieving structural diversity, rigidity, and programmable reconfiguration. Hierarchical assembly of DNA origami components into larger assemblies offers a pathway to create larger or more complex structures. We then present a universal and robust DNA origami building block to support 2D and 3D hierarchical assembly that combines rigid DNA barrel monomers with rigid connections. The building block is modular and contains 14 directional binding interfaces in 3D, each with multiple DNA strands that can hybridise with connector strands to create rigid connections within hierarchical assemblies.

We demonstrate the use of DNA barrel monomers as modular voxels to build diverse multi-component assemblies with intricate custom features and addressable potentials for material patterning. DNA strand displacement reactions are used to switch connections between flexible and rigid states, enabling rapid and reversible shape transformations of assemblies with high yield. Additionally, we explore strategies to improve the yield of hierarchical assembly of DNA origami. Inspired by protein assembly, we investigate multi-step folding pathways. Initially, we assemble individual DNA origami building blocks into a flexible linear chain of linked DNA origami. We then fold these chains into more compact structures in several steps, resulting in improved yields for certain pathways. We envision that DNA origami chains could be integrated with scalable assembly methods to build new materials with rapid and high-yield reconfiguration.

Bio-Inspired Physical Unclonable Function Labels Fabricated by Self-Assembly Processes Su Eon Lee1, Junhyun Park1, Jang Hwan Kim2 and Bong Hoon Kim1; 1Daegu Gyeongbuk Institute of Science and Technology, Korea (the Republic of); 2LG Chem Ltd., Korea (the Republic of)

The demand for robust verification and recognition techniques is increasing because of the evolution of Internet of Things (IoT) and wireless data storage systems. Although authentications with software systems are prevalent, they are susceptible to external threats like hacking and electronic interference. For these reasons, verification methods with hardware systems using physical unclonable functions (PUFs) have been interested in applying wireless interconnection devices and network-based data servers. The validation process using PUFs relies on the electrical and optical signals generated from micropatterns or randomly oscillating signals in electronic devices, and the verification of these encrypted signatures typically depends on complex and time-consuming measurement instruments.

In this poster, we introduce bio-inspired PUF labels fabricated by self-assembly processes. BCP self-assembly forms randomly oriented nanopatterns (i.e., fingerprint-like lamellar structures) as small as 5 nm across the broad area because of the thermodynamical microphase separation. We fabricate the multi-layered nanopatterns from the randomly oriented BCP templates by stacking a thin layer of the metallic lamella structures via the transfer printing process on non-planar and flexible surfaces for wearable or soft electronic devices. As the purpose of the verification systems, we produce multiple independent keys, utilizing electrical properties, optical dichroism, or Raman signals for high-security rates and fast scan speeds.

In conclusion, we show randomly oriented BCP nanopatterms applied to the PUF labels with robust and secure properties and meaningful encoding abilities, which offer unpredictable signals for identification, utilizing electrical and optical response with fast scan time. Our approach reduces the critical
The addition of small amounts of nanofillers to a polymer matrix has been shown to impart significant changes in mechanical, dielectric, and optical properties. A common challenge in creating these polymer nanocomposites (PNCs) is controlling the dispersion of the nanofillers. Recent work has demonstrated methods to control dispersion and organization of spherical nanoparticles (NPs) in compatible matrices. At sufficiently slow crystallization rates in semicrystalline polymers, the NPs organize in the amorphous regions of the growing spherulites. PNCs with organized NPs have been shown to exhibit improved bulk mechanical properties, but the micromechanical behavior underpinning these has not been fully explored. In this study, in-situ Raman spectroscopy was performed on polyethylene samples under tensile load to explore differences in micromechanical behavior between neat, filled but unorganized PNCs, and PNCs with crystallization-induced particle organization. Crystallization of each sample was characterized in DSC, and organization of PNC samples confirmed by SAXS and TEM. Results show that the addition of fillers leads to a significant change in the distribution of load between the crystalline and amorphous phase. Shift is only apparent in samples that undergo necking (high strain), consistent with previous work on neat polyethylene.

Low Temp Heterogeneous Integration of Ultra-Thin-Silicon Interposer via Transfer Printing and Laser Bonding

Uhyeon Kim, Seungbeom Kim, Junhyung Kim, Agha A. Jan and Seok Kim; Pohang University of Science and Technology, Korea (the Republic of)
characteristics and unique properties. The geometric constraints imposed by the nanometric thickness and interfacial interactions affect the self-assembly process and, in turn, their behaviour. [4,5] In addition, non-planar substrates can further complicate the resultant structure as already observed for block copolymer thin films. [6,7] The combination of geometric effects, i.e. surface curvature, with surface free energy (SFE) may allow more finely controlled self-assemblies. To this end, we have developed a novel approach to prepare substrates with controlled nano-curvature and surface-free-energy (SFE), to be used to investigate how geometric and energetic factors affect the self-assembly of polymeric thin films. [8,9]

In particular, by employing a semi-crystalline model polymer, namely poly-3-hexylthiophen (P3HT), it was observed that the crystals follow the surface curvature only in the presence of an energetic gain.[8]

Here, from the structural characterization via synchrotron radiation grazing incidence X-ray diffraction (GIXRD) and the morphological characterization via atomic force microscopy (AFM), we will demonstrate a non-conformal coverage, after the polymer equilibration, showing that the crystallization strongly depends on the surface curvature. The results suggest the polymer accumulation in the interstices between the particles for the lowest curvature, leading to an in-plane crystal growth. The increase in curvature improves the nucleation probability, leading to shorter crystals on both interstices and curved portions. Moreover, we demonstrate that the crystalline fraction is strongly curvature-dependent, as the crystallization only occurs when the distance between two neighbour particles is higher than the lamellar folding period. Finally, the in-situ structural characterization during thermal cooling shows a variation in the crystallization temperature (Tc) as a function of the substrate geometry, with a decrease in the onset of the crystallization with respect to the flat substrate. These results highlight the role played by the substrate in the crystallization process, suggesting that the geometric factors affect the crystalline structure itself, with the formation of distorted crystals following the surface curvature. The reported work provides a novel and easy method to modulate the structure of polymer films by exploiting geometric distortion and interfacial interactions with possible effects on the functional properties of the polymer film. This correlation sheds more light on how these factors influence the polymer film crystallization and could allow the determination of the crystallization enthalpy and its related loss when a nanometric strain is applied. A deeper understanding of this behaviour could pave the way for the development of finely tailored crystalline structures via control of the substrate geometry and energy.

Spray Deposited Block Copolymer Thin Films with Solvent Evaporation Controlled Domain Orientation
Semih Cetindag, Beatrice Bellini, Ruipeng Li, Esther Tsai and Gregory Doerk; Brookhaven National Laboratory, United States

With their ability to self-assemble spontaneously into well-defined nanoscale morphologies, block copolymer (BCP) thin films are a versatile platform to fabricate functional nanomaterials such as lithographic nanopatterns, nanoporoporous membranes and optical metasurfaces. An important yet unsolved challenge to wider deployment of BCPs in nanofabrication, however, is combining the desired precise control of BCP assembly with scalable deposition techniques that are applicable to large-area, curved and flexible substrates for high-volume manufacturing. Ultrasonic spraying is a scalable, non-batch casting method with minimal wasted polymer, yet its use in thin film BCP assembly has not been investigated.

Here, we show that the latent orientation (vertical vs. horizontal) of well-ordered cylindrical domains in spray-deposited, optically-smooth thin films of polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP) can be controlled by regulating solvent evaporation kinetics. Faster evaporation during deposition facilitates assembly of vertically oriented cylinders spanning the entire film thickness (100-300 nm) upon subsequent solvent vapor annealing. In comparison, slow solvent evaporation induces assembly of horizontal cylinders, imposing an additional energy barrier for reorientation to vertical cylinders during solvent vapor annealing. Using in-situ characterization by synchrotron grazing-incidence small-angle X-ray scattering (GISAXS), we identify the relevant timescale for polymer vitrification which determines latent cylinder orientation. This dependency on solvent evaporation kinetics is exploited to control cylinder orientation in multiple ways, including substrate heating, forced convection, and solvent formulation. To highlight the scalability and utility of the spray casting technique, an exemplar application using spray deposited self-assembled patterns on curved surfaces will also be described.

Funding: This research was conducted at the Center for Functional Nanomaterials (CFN) and the National Synchrotron Light Source II (NSLS-II), which are U.S. Department of Energy (DOE) Office of Science User Facilities, at Brookhaven National Laboratory under Contract No. DE-SC0012704. S.C., R.R., and G.S.D. were supported by a DOE Early Career Research Program grant.

SESSION SF02.09: Materials Surfaces I

Controlling Structural Changes in 2D Magnets using In Situ Microscopy and Machine Learning Techniques
Julian Klein and Frances M. Ross; Massachusetts Institute of Technology, United States

Electron beam patterning raises exciting prospects for modifying the crystal structure and hence physical properties of 2D materials, and has been explored for several 2D materials in single or few-layer form. Here we examine the opportunities arising from patterning thicker, more robust crystals of 2D semiconducting magnets, intriguing materials in which the local ordering of spins determines both the magnetic properties and the optical response. CrSBr is one such material, having layers with alternating magnetic moment and a structure in which Cr atoms located in their own columns are separated by columns of mixed S and Br atoms. For 10-50nm thick multilayer crystals, we find that broad-area irradiation by electrons reorganizes CrSBr into a new structure, which is also van der Waals-bonded but with a layer orientation and calculated magnetization that are rotated by 90° from the initial direction.

Further structural changes can be generated if we irradiate the structure along rows of Cr atoms to open local gaps, changing the calculated interaction
between magnetic atoms. Extending to the ultimate objective of controlling the position of individual Cr columns requires the use of machine learning techniques to track column positions, direct the beam and evaluate whether the desired modification has been achieved. We will describe strategies for achieving this goal and for understanding the process by which the Cr atoms are rearranged. We conclude by discussing correlative techniques to measure the optical and magnetic properties of the modified material, and the more general opportunities arising from patterned recrystallization of multilayer van der Waals bonded magnetic materials for spin-based and optical quantum devices.

9:00 AM SF02.09.02
Mechanism and Kinetics of Topochemical Etching for Synthesis of 2D MXenes from Layered MAX Phases
Mark Anayee, Ruocun (John) Wang, Stefano Ippolito, Mikhail Shekhirev and Yury Gogotsi; Drexel University, United States

MXenes represent a rapidly growing family of 2D transition metal carbides and/or nitrides, which exhibit unique combinations of properties, including metallic conductivity, hydrophilic surface chemistry, redox-active surface, and plasmonic behavior that make them attractive as electrodes for pseudocapacitive energy storage to coatings for electromagnetic interference shielding, transparent conducting displays for optoelectronics, conductive yarns for functional textiles, implantable electrodes for medicine, and many other applications.

MXenes are typically derived via selective etching of atomically thick ‘A’ layers from precursor layered MAX phases using HF-based aqueous etchants. However, the chemical etching process is only somewhat optimized for one composition, and is nonetheless often slow, with low-yield, and results in defects in the materials. Thus, understanding the fundamental mechanism and kinetics of the etching reaction is needed to rationally explore etching of yet-to-be synthesized MXene compositions and optimize etching of existing MXene compositions. Despite their importance, such studies have been challenging because of the atomic thickness of the A-element layers being etched and the aggressive etchants that hinder in situ studies.

Here, we spatially track the etching front in 3D (using analytical setups for tracking byproduct gas evolution), 2D (using cross-sectional imaging of partially etched particles), and 1D (using in situ optical microscopy and profilometry of single particles). Thus, we show the role of surface oxide and binary carbide impurities on the nucleation of etching, and we discovered a layer-by-layer growth process for the etching front. From kinetic modeling, we show that etching varies from reaction-limited to diffusion-limited for various MAX compositions. Overall, our work enables rational high-throughput optimization of synthesis for all MXene compositions, scaling up synthesis towards industrial levels, and tailored synthesis for specific applications.

9:15 AM SF02.09.03
Dynamics of Advanced Low-Dimensional Materials by Low-Voltage Atomic-Scale TEM Experiments
Ute A. Kaiser; University of Ulm, Germany

To create next generation functional low-dimensional materials, it is a growing demand in materials sciences to understand their formation mechanisms as well as their structural and electronic properties at the atomic or molecular scale. Some of the most challenging tasks nowadays are related to energy storage, nano-catalysis or battery materials.

A unique type of transmission electron microscopes operating at electron energies between 80keV and 20keV was developed, which allows to undercut most of the materials knock-on damage thresholds and enables sub-Angstrom resolution in an 4000x4000 pixels sized image, single-shoot image down to 40keV by correcting not only geometrical but also the chromatic aberration of the imaging lens [1-3]. This instrument is used for the in-situ studies presented here. Before we discuss several in-situ TEM experiments, we develop a detailed understanding of the electron beam - 2D specimen interactions:

- Density functional theory molecular dynamics we show that excitations in the electronic system can form vacancies through ballistic energy transfer at electron energies, which are much lower than the knock-on threshold for the ground state. We propose a two-step vacancy formation process as combination of elastic and inelastic events, evaluated also by an U-net-based fully convolution neural network (FCN) [4].

Based on this knowledge, we discuss the dynamics of properties of point, line and extended defects in various transition metal - dichalcogenides and – phosphor dichalcogenides [5-8]. Optical measurements are performed independent of the TEM experiment. To relate optical and TEM results we demonstrate proof-of-principle experiments in which we transfer electron-exposed defect-characterized TMD flakes from a TEM grid to arbitrary substrates and relate the subsequently performed photoluminescence and transport signals to the defect structure [9].

Furthermore, we present in-situ studies of a miniaturized electrochemical cell, where reversibly single-crystalline bilarayer graphene is lithiated and delithiated in controlled manner using an electrochemical gate confined to a device protrusion [10] and report on the Li crystal nucleation and growth during lithiation and Li-O formation and amorphization during delithiation. We generate further incapsulated metal-atom-dimers within single-walled carbon nanotubes and observe the dynamics of single metallic bond formation by exact measurements of the interatomic distance [11].

At the end we show that the approaches of graphene encapsulation and lowering the electron accelerating voltage (here from 300kV to 120kV) can be successfully applied for imaging 2D organic materials at the molecular level [12-14].

Surface Dynamics of Atomically Controlled Electrodes for Clean Energy
Magali Lingenfelder; EPFL, Switzerland

Our society faces a critical challenge in shifting from a reliance on carbon-based energy to sustainable renewable sources. A key step towards achieving clean energy lies in developing efficient catalysts that can convert chemical energy into electricity or use electrons to generate chemical energy.

In our research group, we tackle these challenges by creating customized materials that draw inspiration from nature (biomimicry) and combine principles from interfacial chemistry and surface physics. For this presentation, I focus on the process of photosynthesis as inspiration for the design, characterization,
and dynamic nature of functional interfaces that drive energy conversion processes such as CO₂ electroreduction and water splitting on the surface of Earth-abundant materials.

I will also discuss the application of cutting-edge scanning probe microscopy and Raman spectroscopy under electrochemical conditions, which allows us to visualize dynamic processes at the nanoscale (operando imaging). Additionally, I will highlight our use of unconventional strategies that leverage the assembly of chiral molecular layers and two-dimensional materials to enhance electrocatalytic conversion processes. (References: Nanoletters, 2021, 21, 2059; Nature Commun., 2022, 13, 3356, IJC 62, 11, 2022).

10:45 AM *SF02.09.05 Interfacial Liquid Water on Graphite, Graphene and 2D Materials Ricardo Garcia; Consejo Superior de Investigaciones Científicas, Spain

Solid-water interfaces have a prominent role in a variety of fields such as surface science, geochemistry, electrochemistry, energy storage or molecular and cell biology. Liquids near a solid surface form an interfacial layer where the molecular structure is different from that of the bulk. Yet the molecular-scale understanding of the interactions of liquid water with solid interfaces is unsatisfactory for the lack of high-spatial resolution methods. Here I will present an AFM-based method that provides atomic-scale resolution images of solid-liquid interfaces.

The presentation is divided in three sections. The first section is an introduction to the relevance of solid-liquid interfaces. The second section, presents the features and capabilities of 3D-AMF [1-3] to image with atomic resolution the three-dimensional interfacial structure of surfaces immersed in aqueous solutions. The third section reports the structure of interfacial water layers on different 2D materials from graphene to a few layer MoS₂; from hexagonal boron nitride to a few layer WSe₂. Those interfaces are characterized by the existence of a 2 nm thick region above the solid surface where the liquid density oscillates [4-8]. The distances between adjacent layers for graphene, few-layer MoS₂, h-BN and pentacene are ~0.50 nm. This value is larger than the one predicted and measured for water density oscillations (~0.30 nm). The experiments demonstrate that on extended hydrophobic surfaces water molecules are expelled from the vicinity of the surface and replaced by several molecular-size hydrophobic layers.

11:15 AM SF02.09.06 Modeling and Experimental Analysis of Vertical and Lateral Growth of 2D Mo₂C Crystals via Chemical Vapor Deposition Goknur Cambaz Buke1, Omer Caylan1 and Tarik Ogurtani2; "TOBB ETU, Turkey; "Massachusetts Institute of Technology, United States; "Middle East Technical University, Turkey

This study investigates the growth of Mo₂C crystals through Chemical Vapor Deposition (CVD) on Cu substrates. The research combines theoretical and experimental approaches to examine both the vertical and lateral growth of Mo₂C crystals. A physico-mathematical model is developed, incorporating bulk and surface diffusivities, as well as solubility gradients for Mo₂C crystal growth. Nonlinear flow equations are used to predict Mo₂C crystal growth rates and the thickness of the copper layer and time, which is then validated through experiments and imaging techniques such as SEM and AFM. The results highlight the significant influence of the copper layer thickness on the height of Mo₂C crystals, while its impact on the lateral dimensions is less critical. The study goes beyond enhancing Mo₂C crystal growth and explores the synthesis of tailored Mo₂C crystals for specific applications. The developed forward model provides a platform for further advancements and exploration of related material analogs. (This material is based on the work supported by the Air Force Office of Scientific Research (award numbers: FA9550-19-1-7048, FA9550-22-1-0358).

11:30 AM *SF02.09.07 Interface and Interlayer Dynamics in 2-D MnO2 via In-Situ Characterization Scott T. Misture; Alfred University, United States

Super capacitor electrodes can be prepared from MnO2 nanosheets exfoliated from highly crystalline powder particles and subsequently flocculated to form porous solid electrodes. Restacking of the 2-D nanosheets in packets of ~5 layers affords high surface area electrodes with highly flexible interlayer spaces for electrochemical activity. The talk centers on the application in-situ and in-operando studies using high energy X-ray diffraction, X-ray pair distribution functions, EXAFS/XANES and Raman spectroscopy. We show that linking electrochemical measurements to local structure characterization results enable us to understand the mechanisms by which charging occurs in supercapacitor electrodes. The data show that the re-stacked 2-D nanosheets go through a phase transition during charge/discharge wherein the interlayer chemistry alters the interlayer stacking in a subtle but detectable manner. The presence vs. absence of interlayer water and electrochemically active ions including Na, K or Rb define the interlayer stacking. Using a combined approach that tracks the Mn oxidation state, the local structures (via PDF and Raman) and charge/discharge electron exchange forms a clear picture of the physical mechanisms at play, including mechanisms of capacity fade.

REFERENCES
Metal halide perovskites are inexpensive semiconductor materials promising for high performance solar cells and light emitting diodes (LEDs) because they are easy to synthesize and tolerant of defects. We developed new methods for synthesizing nanostructures of both three-dimensional (3D) perovskites and two-dimensional (2D) Ruddlesden–Popper (RP) layered perovskites, including vapor phase epitaxial growth on crystalline inorganic substrates and general solution growth of 2D RP layered perovskites nanosheets at the air-water interface. More chemically unstable and less soluble 2D perovskites could also be crystallized at the interface of aqueous-nonaqueous solutions. We further create novel and arbitrary heterostructures, such as 2D/3D perovskite, vertical and lateral 2D heterostructures, with high quality interface and tunable band alignments. Various structural characterization and time-resolved spectroscopic methods have been employed to collaboratively study the carrier transfer mechanisms between these well-defined heterostructures of 2D and 3D perovskites. Fundamental understanding of the factors controlling the carrier transfer mechanisms in heterostructures of halide perovskites is crucial for guiding the synthetic strategies to improve properties and device applications.

2:00 PM SF02.10.02
Filament-Induced Crystallization of Ti/HfOx/TiN Film in Neuromorphic Devices Alexandre Foucher1, Baoming Wang2, Teodor Todorov3, John Rozen4 and Frances M. Ross1; 1Massachusetts Institute of Technology, United States; 2Nanjing University, China; 3IBM T.J. Watson Research Center, United States

HfOx films are increasingly under scrutiny for applications in resistive random-access memory (ReRAM) devices. HfOx-based structures have a fast-switching speed, excellent stability, and can be easily integrated in complex devices. However, changes in crystal structure when current and voltage are applied are not well understood and are crucial to guide the rational design of HfOx-based devices. To this end, a Ti/HfOx/TiN stack implemented in nanodevices was studied with in situ scanning transmission electron microscopy (STEM). We observed crystallization of the initially amorphous HfOx films and grain growth of crystals during repetitive switching with increasing applied current and voltage. The formation and growth of crystalline region could then correlate to changes in measured conductance on the sample studied with in situ STEM. In situ electron energy loss spectroscopy (EELS) showed the depletion in oxygen of crystalline phases compared to the initial amorphous HfOx phase. We suggest that this is due to the displacement of oxygen vacancies that concentrate in the crystalline grains and is the cause of the neuromorphic properties of the HfOx film. Oxygen migration toward the Ti/HfOx interface and the importance of crystallization at the interfaces are also discussed. We aim to use this atomistic understanding of crystallization and structural changes of HfOx in Ti/HfOx/TiN to guide the rational design of multilayered materials for electronic applications.

2:15 PM SF02.10.04
Denoising Total Scattering Data using Compressive Sensing Niklas B. Thompson and James Weng; Argonne National Laboratory, United States

Total X-ray scattering measurements performed with high-energy incident photons (> 50 keV), complemented by real-space analysis via the pair distribution function (PDF), is an indispensable tool in determining the local atomic structure of amorphous and nanoscale materials. While the application of PDF analysis to bulk systems is a mature field, there is burgeoning interest in extending its domain of application to more complex sample environments, such as thin films and dilute solutions, with an eye toward in operando measurements under realistic operating conditions. In this setting, the scattering signal originating from the material of interest is typically overwhelmed by the background signal (e.g., from the substrate beneath a thin film, or the solvent in a dilute solution). The successful separation of the intrinsically weak signal of the desired material from the background thus depends on collecting raw data with a high signal-to-noise ratio (SNR), a central challenge in flux-limited X-ray scattering measurements on disordered systems.

Ideally, this challenge can be addressed by simply increasing the measurement time or incident X-ray flux. However, this can result in both radiation damage—altering the structure of the native sample—and limits the time resolution of total X-ray scattering in operando settings. Inspired by recent developments in compressive sensing, we have developed a means of signal denoising based on the responses of many “virtual detectors”, using a single real measurement from an area detector. The technique relies on the sparsity of real scattering images in an appropriate transformation basis, rendering the true signal separable from the (necessarily) non-sparse noise. Our purely computational approach allows the resolution of noisy signals which cannot be easily measured using current detectors without modification of the existing hardware. Based on experiments with both simulations and real data, the resulting virtual measurements behave as though they were independent measurements; by averaging over the virtual measurements, the actual SNR can thus be improved. Effectively, this turns one measurement into an arbitrary number of repeated measurements, thereby allowing for measurements of disordered materials susceptible to radiation damage and rapid kinetic experiments that are otherwise difficult to perform.

Bits to Atoms and Atoms to Bits: Atomic Fabrication in Electron Microscopy Sergei V. Kalinin1, Marc Bellemare2, Aaron Courville3, Jesse Farebrother3, Max Schwarzer2, Pablo S. Castro4, Joshua Greaves5, Maxim Ziatdinov1, Ayana Ghosh4, Igor Mordatch4, Kevin Roccopain4 and Rama K. Vasudevan6; 1University of Tennessee, Knoxville, United States; 2MILA, Canada; 3Google Deep Mind, United States; 4Oak Ridge National Laboratory, United States

The last note left by Richard Feynman stated “What I cannot create, I do not understand.” Building solid state quantum computers, creating nanorobots, and designing new classes of biological molecules and catalysts alike requires the capability to manipulate and assemble matter atom by atom, probe the resulting structures, and connect it to macroscopic world. Until now, the only viable approach for atomic fabrication was the Scanning Tunneling Microscopy, often integrated with the bespoke surface science techniques. Over the last decade, it has been shown that electron beams in Scanning Transmission Electron Microscopy can be used not only to probe structure and electronic properties of materials on atomic level, but also to modify materials on the atomic level. Harnessing electron beam changes for direct atomic fabrication however requires synergy between machine learning methods and microscope control. In this presentation, I will illustrate the progression of automated electron microscopy from real-time data analysis to physics discovery to atomic manipulations. Here, the applications of classical deep learning methods in streaming image analysis are strongly affected by the output of distribution drift effects, and the approaches to minimize those are discussed. The robust approach for real-time analysis of the scanning transmission electron microscopy (STEM) data streams, based on the ensemble learning and iterative training (ELIT) of deep convolutional neural networks, is implemented on an operational microscope, enabling the exploration of the dynamics of specific atomic configurations under electron beam irradiation via an automated experiment in STEM. Combined with beam control, this approach allows studying beam effects on selected atomic groups and chemical bonds in a fully automated mode. We demonstrate atomically precise engineering of single vacancy lines in transition metal dichalcogenides and the creation and identification of topological defects in graphene. The ELIT-based approach opens the pathway toward the direct on-the-fly analysis of the STEM data and engendering real-time feedback schemes for probing electron beam chemistry, atomic manipulation, and atom by atom assembly. We further illustrate how deep kernel learning (DKL) methods allow to realize both the exploration of complex systems towards the discovery of structure-property relationship, and enable automated experiment targeting physics (rather than simple spatial feature) discovery. The latter is illustrated via experimental discovery of the edge plasmons in STEM/EELS. Finally, we demonstrate the use of the reinforcement learmign for real-time control of atomic motion. Jointly, these developments open the pathway for creation and characterization of designed defect configurations and artificial molecules in 2D materials.
Conversion coating, which is precipitated on the surface of a metal material through a chemical reaction, prevents rust and improves coating adhesion. A typical treatment is the phosphate conversion coating treatment, which forms a coating containing phosphate. The iron phosphate conversion coating for steel materials is generally used because of its low-cost and low-sludge generation, although its rust prevention performance is inferior to other treatments. In this treatment, the Fe$^{2+}$ is eluted from the surface of the steel by etching, which is immediately oxidized to Fe$^{3+}$ by dissolved oxygen. Then, Fe$^{3+}$ reacts with OH$^{-}$ and H$_2$PO$_4^-$ in the treatment solution to precipitate a coating composed of Fe$_2$O$_3$ and FePO$_4$ [1]. Therefore, it is essential to understand the dissolution and precipitation reactions of Fe that occur at the interface between the steel and the treatment solution to improve the properties of the coating film. We have previously observed changes in the film structure with film thickness (deposition amount) by X-ray photoelectron spectroscopy and scanning electron microscopy. As a result, it was found that the film is composed of nm-sized particles generated by nucleation and aggregation and that the main component of the coating is FePO$_4$, regardless of the deposition amount[2]. This differs from the component ratio (Fe$_2$O$_3$:FePO$_4$ = 7:3) reported in a previous study [1]. In this study, we attempted to quantitatively analyze the chemical states of the constituent elements by X-ray emission spectroscopy, which is capable of element-selective state separation, to clarify the ratio of coating components according to the deposition amount in more detail. The coatings that completely coated the steel surface comprised approximately 90% FePO$_4$ and 10% Fe$_2$O$_3$. On the other hand, coatings with less than 80% coverage were found to contain little Fe$_2$O$_3$ and 20% FeO. Therefore, a part of Fe$^{3+}$ eluted from the steel surface precipitates as a coating component without oxidizing. In addition, the amount of P content in the coating obtained by X-ray fluorescence analysis was used as the deposition amount of FePO$_4$ and the deposition amount of each component was calculated based on the component ratios obtained. The amount of FePO$_4$ kept increasing with reaction time. On the other hand, the total deposition of iron oxide components increased up to 80% coverage and remained almost constant thereafter. Therefore, the deposition reaction of the coating may vary with the coverage. These results suggest that the iron phosphate conversion coating is deposited by a reaction path different from the conventionally considered steel/treatment solution interface reaction.

In-situ Diffraction-Based Characterization on the Topotactic Reduction of Nickelate Thin Films

Zhenzheng Wei, Kidae Shin, Haoong Hong, Yoeungjae Shin, Robert F. Klie, Arashdeep S. Thind, Yingjie Yang, Frederick Walker, and Charles Ahn; Yale University, United States; Argonne National Laboratory, United States; University of Illinois at Chicago, United States

Square-planar nickelates are a novel class of superconductors, which promise to help unveil aspects about the nature of superconductivity in oxide materials. Their synthesis consists of the growth of a perovskite precursor followed by a topotactic reduction to remove apical oxygen ions. The common reduction process involves annealing in vacuum with CaH$_2$ powder. This ex-situ process is less easily amenable to in-situ measurements of the dynamics of square-planar nickelate formation. To address this challenge, we develop an in-situ process via the deposition of metallic aluminium in ultra-high vacuum (UHV), and we demonstrate the reduction process by reducing NdNiO$_3$ thin films grown using molecular beam epitaxy (MBE). During reduction we characterize the atomic and electronic structure of this class of square-planar nickelates with the *operando* X-ray diffraction facility at beamline 33 ID-E in Argonne National Lab using crystal truncation rod (CTR) and diffraction-based X-ray absorption near edge structure (dXANES). By characterizing the NdNiO$_3$ thin films dynamically during the reduction process, we show that the Ni valence and NdNiO$_3$ lattice constant can be precisely controlled at each step of the Al deposition process, while maintaining the film’s epitaxy and surface morphology. The metal reduction method and in-situ characterization of the reaction stages is straightforward and broadly applicable to oxide reduction.

Work at Yale University was supported by the US DOE, Office of Science, Office of Basic Energy Sciences under award no. DE-SC0019211.
Hybrid materials composed of biomacromolecules and inorganic crystals have exceptional properties and fulfill critical functional requirements of the organisms they produce. These biominerals are known to control proteins that play roles in controlling the crystal polymorph, shape, size, and organization of the mineral constituents. However, the structural details of protein–inorganic interfaces inside biominerals remain largely unknown and are challenging to study because native biomineralization proteins are often intrinsically disordered and function within complex multi-component systems.

Designing well-structured de novo proteins with surfaces that form favorable interactions with inorganic crystals has allowed us to study both how these interfaces promote adsorption and assembly of proteins on existing minerals, and how the proteins template mineral growth. Previously, we have shown that designed helical repeat proteins (DHR) with a periodic array of side chains lattice matched to the mica surface absorbed and assembled into 2D structures at the mica-water interface. The structure of the interfacial assemblies could be modulated by adding protein–protein interfaces in addition to the protein-mica interface. The size, regularity, and stable rod-like shape of these proteins has enabled further study on the effects of solvent and electrolytes on biomaterials at the solid liquid interface and mapping of the angular energy landscape of adsorbed proteins.

Recently, we have shown that specific DHRs that contain designed periodic arrays of negatively charged carboxylate containing side chains promote the direct nucleation of the calcite polymorph of calcium carbonate (CaCO3). This bypasses the formation of vaterite which is seen in the absence of protein, in the presence of a 1:1 serum albumin control protein, and in the presence of a DHR with a similar distance but a different distance between adjacent repeats. Mutational analysis of a protein that promotes calcite formation indicates that activity depends on sidechain stereochemistry and is not driven by charge alone. The calcite nucleating proteins also altered the post-nucleation growth mechanism from classical growth to oriented particle attachment, a mechanism often seen in natural biomineralization processes.

Overall, our research shows the potential of de novo protein design as a powerful tool for studying and manipulating the interfaces between genetically encoded proteins and inorganic crystals, offering exciting prospects for biomimetic materials synthesis.

Sulfated Chitosan Derivatives Modulate the Kinetics of CaCO3 Nucleation by a Systematic Relationship to Interfacial Energy Barrier Brenna M. Knight1,2, Ronnie Mondal1, Nicholas Pietra1, Brady A. Hall1, Kevin J. Edgar1,2, Valerie Vassier Welborn1,2, Louis A. Madsen1,3, James J. De Yoreo4,5, and Patricia M. Dove4,5,1, Virginia Tech, United States; 2Pacific Northwest National Laboratory, United States; 3University of Washington, United States

Organisms use functionalized macromolecules at sites of biomineralization to nucleate and grow diverse CaCO3–organic composites as skeletal structures. Acidic groups (COO–, SO3–, PO43–) are known to impact CaCO3 mineralization but systematic relationships have not been ascertained. Establishing the kinetic and thermodynamic bases for mineralization are fundamental to understanding and replicating control on crystal nucleation and growth in these settings. Of particular importance is how important is the organic matrix in regulating when and where crystals grow. Thus, discerning how functional groups moderate the crystallization of sparingly soluble salts is of first order importance.

Using complementary experimental and theoretical approaches, we first synthesize a series of tailored and characterized chitosan derivatives that present variable degrees of sulfation (DS(SO3–) = 0.1 - 0.8) and sulfate regioisomers (C2N– or C3SO4–). Chitosan provides a simple model for macromolecules in the organic matrix that allows us to measure the dependence of calcite nucleation rate on sulfate density and to determine how this group modulates the energy barrier to crystallization. By quantifying the rate of CaCO3 nucleation onto these materials over a range of supersaturations using established methods, we show rates increase with supersaturation as predicted by classical nucleation theory (CNT). Rates of nucleation onto materials with increasing DS(SO3–) exhibit a stronger dependence on supersaturation, indicating a higher energy barrier to nucleation. Fitting the CNT model to the data, we demonstrate the interfacial energy barrier (γAB) to calcite nucleation correlates with sulfate density by a systematic dependence that is independent of sulfate regioisomer.

We propose that sulfate density creates an increasingly hydrophilic, negatively charged environment at the polysaccharide-water interface to increase the interfacial energy through reductions in γAB. Such an environment would also promote Ca2+ interactions with sulfate, possibly at the expense of carbonate. To test this idea, we conduct a molecular dynamics (MD) study of sulfated chitosan chains that also have varying degrees and positions of sulfation. Each type of polymer is placed in a simulation cell populated with water, NaHCO3, and CaCl2. Polymer equilibrium conformation is first established on GROMACS using a non-polarizable forcefield, following which molecular dynamics simulations are run under a polarizable AMOEBA force field. The trajectory obtained is used to calculate the time-averaged radial distribution functions (RDFs) to ascertain proximity between atoms of interest. Analysis of the MD simulations show the average S-Ca distance decreases with DS(SO3–), indicating stronger Ca-S interactions in the increasingly hydrophilic environment. This is supported by a reduction in the average hydration number of Ca2+ in the N-sulfated and O-sulfated environments of 12.5% and 25%, respectively, compared to the bulk value (8) and by the significantly higher water density about SO3– groups compared to uncharged substituents. The findings from these combined experimental and theoretical methodologies suggest the potential to design biomaterials with localized regions of high/local activity and control crystal placement at near-molecular resolution for advanced applications.

Spatially Controlled Supersaturation of Calcium Phosphate for Controlled Crystal Nucleation and Self-Healing Precipitates Mohsin J. Qazi, Rena Fukuda and Nate J. Cira; Cornell University, United States

Crystal nucleation and growth are widely studied phenomena due to their relevance to a range of disciplines including material science, process engineering, and biology. In order to obtain desirable crystal forms or crystallization dynamics, it is essential to tune parameters like nucleation time, nucleation rate, and growth rate. Supersaturation of material in the crystallizing solution is the first step in the crystallization process, and impacts all these parameters, hence controlling supersaturation is crucial to controlling the overall process of crystallization (1). Some common methods to achieve supersaturation include subjecting a solution to: evaporation, cooling (for materials with temperature-dependent solubility), the addition of antisolvents, and pH change (for materials with pH-dependent solubility). These methods typically result in supersaturation within the primary solution. However, in some systems such as biomineralization or studies probing nucleation dynamics, nucleation is required at specific locations, often outside the region where the primary solution composition can be easily actively controlled. This motivates the development of strategies to create localized supersaturated conditions.

In this study, we present a straightforward approach that enables spatially controlled deposition of precipitated material between two primary solutions (2). Our experimental setup focuses on calcium phosphate (CaP) as a prototypical system, taking advantage of its pH-dependent solubility. By connecting two saturated solutions at different pHs using a gel that allows ion diffusion, we establish a concentration gradient along the gel. The diffusion and reaction of H+ and OH– create a characteristic pH profile along the length of the gel, causing the diffusing calcium and phosphate to become supersaturated and precipitate. Over time, the precipitated band grows denser and forms a barrier that restricts further transport through the gel. We show how this band spontaneously recovers from perturbation, automatically resealing any damage. In addition to experiments, we perform quantitative analysis taking into consideration the diffusion dynamics of all the relevant ions, chemical equilibria, and reaction parameters, to predict the location of the precipitated bands. This work provides a simple physical strategy for creating self-healing precipitates that may be useful in civil engineering, restorative dentistry, and...
enhancing our understanding of mineral deposit formation in the abiotic and living world.

Nucleation and Growth of Minerals on Self-Assembled Monolayers

Minerals are frequently grown in water-based systems in both nature (bioneralisation) and industry. The water may stabilise the interface and potentially hinder or aid the flow of ions to the interface and their attachment. The behaviour of water at these growing interfaces is therefore very important as it will often govern the growth dynamics. Self-assembled monolayers (SAMs) have long been used as substrates and/or templates for the growth of minerals [1] and as model systems for bioneralisation [2]. These organic systems provide arrays of organised head groups that can be functionalised and positioned to generate patterns and specific charge densities. How the water and ions within the solution organise at this interface is very important if we are to understand the nucleation and subsequent growth of minerals at this interface.

We explore a range of models to obtain surface ion concentrations from the simple Gouy-Chapman approximation to the Poisson-Boltzmann equation through to full solutions of the Grahame equation [3,4] including the effects of speciation and changes in activity as a function of local species concentrations. Explicit all atom simulations [5,6] are used to examine the organisation and distribution of ions at these interfaces. Use of a constant chemical potential ensemble [7] allows us to examine the effects of different ionic concentrations using atomistic simulations and so compare results with those obtained using the continuum Poisson-Boltzmann approaches.

We find that certain defects in the SAM structure, which we refer to as active defects, can impair ionic surface diffusion, as well as affect the diffusion of ions in close proximity to the surface feature in question. Our findings suggest that this effect can also lead to such topological features to promote ion clustering and increase local ionic concentration at specific surface sites. The work reported here shows how the presence of small atomic-scale defects can affect the role of a surface in the process of heterogeneous nucleation. We discuss the importance of SAM structures and the solution conditions at the interface on the efficacy of these monolayers as nucleating agents.

Molecular Interaction Forces at Mineral-Electrolyte Interfaces: Insights from AFM Spectroscopy

Frieder Mugele; University of Twente, Netherlands

Colloidal self-assembly and aggregation are controlled by molecular scale interaction forces across (sub)nanometric films of an ambient fluid, often thin water layers of variable salt content and pH. In this lecture, I will give an overview over insights that we have gained using in situ Atomic Force Microscopy (AFM) measurements on the structure of the electric double layer and the resulting nano-scale interaction forces. I will discuss aspects of ion adsorption, hydration, and electrostatic forces for a variety of systems ranging from clay minerals to semi-conducting nanoparticles. In particular, I will illustrate the potential of operando-AFM for the characterization of photocatalytically active materials with a specific focus on facet-dependent surface charges and their role for the separation of photogenerated charge carriers.

Revealing the Molecular Forces that Stabilize Surface Precipitates of Hydroxides by Three-Dimensional Atomic Force Microscopy

Mingxi Zhang1, Benjamin A. Legg2, Youjun Min3 and James J. De Yoreo1,4; 1Pacific Northwest National Laboratory, United States; 2University of California, Riverside, United States; 3University of Washington, United States

Surface charging of solid-liquid interfaces plays a critical role in various chemical processes, such as ion adsorption, particle aggregation, crystal nucleation and growth. Recent work indicates that surface charging can drive the formation of complex laterally ordered surface structures. However, the properties of the resulting heterogeneous charge distributions (and their associated electrical double layer structure) are still poorly understood. Modern atomic probe microscopy offers a promising tool for investigating the behaviors at heterogeneously charged surfaces. In situ high speed atomic force microscopy enables directly imaging of the motion of surface adsorbates at molecular scales; while three-dimensional fast force mapping (3D FFM) allows us to track the tip-sample interaction forces above the surface, aiding in the interpretation of surface charging phenomena through DLVO theory.

Here, the adsorption behaviors of multivalent cations (Mg2+ and Al3+) on muscovite mica has been studied by atomic force microscopy across a range of pH values. At mild pH values, two-dimensional hydroxide films form whose morphology depends on the ion type. For the divalent Mg-hydroxide, it tends to form monolayered large continuous film. For the trivalent Al-hydroxide, it forms monolayered films with a persistent network of gaps, combining positively charged hydroxide islands and negatively charged bare mica regions, which is inconsistent with the prediction of the classical crystal growth model; at even higher pH values, multi-layered gibbsite film growth has been observed, with the upper layers exhibiting similar behavior to Mg hydroxide films that form large continuous sheets. At low pH conditions, it is feasible to image individual ions and clusters and see how the adsorbate populations change with pH. At a pH immediately preceding film nucleation, these ions reveal complex lateral ordering that are controlled by the interplay between ion/ion interactions and ion/substrate interactions.

The links between ion-ordering, film structure, and local surface charge were investigated by using 3D FFM and complementary streaming potential measurements. The results indicate that the coverage and structure of the surface precipitates are strongly influenced by the charged substrate. Also, Al-hydroxide films are more strongly charged than Mg-hydroxide films, supporting the hypothesis that the hydroxide nanostructure is stabilized by
The strong interactions between mineral ions and water molecules can profoundly alter the structure and properties of water molecules at aqueous interfaces[1]. Strong ordering produces density fluctuations, particularly for very flat interfaces (such as mica and calcite)[2]. Diffusion rates of water molecules are greatly reduced from the bulk, leading to the hypothesis that ice-like structure is present. The water often stabilises the mineral surface and configurational interfacial energies obtained from classical molecular dynamics simulations are used to interpret this, even though this ignores entropic effects. Our new methods for calculating interfacial free energies[3], based on using Einstein crystals as a reference state, demonstrate that these effects contribute significantly to the thermodynamics of these interfaces and cannot be ignored.

In this work we examine the aqueous surfaces of calcium sulphate (gypsum, bassanite) and calcium carbonate (calcite, aragonite). We explore the structure and dynamics of water at these interfaces and quantify the enthalpic and entropic contributions to the total free energy. New insights into the competing growth mechanisms of different polymorphs may also be obtained[4]. We will also discuss effects due to the presence of solute ions close to the interface which can alter the activity of interfacial water, induce electrical space charge layers or change the relative stability of different surfaces by disrupting the ordering of the solvent. Our simulations will examine the potential mechanisms of attachment at these surfaces and how the interfacial energy and solution effects these growth processes.

Modeling of Interfacial Growth and Structural Processes and Dynamics of sII Gas Hydrate Systems using Molecular Dynamics and Geometric Techniques
Samuel Mathews, Andre Guerra, Phillip Servio and Alejandro D. Rey; McGill University, Canada

Gas hydrates are inclusion compounds comprising a backbone of water molecules that enclose guest molecules in separate cages. Each volume of hydrate contains 160 volume equivalents of gas. Initially, large scale gas hydrate research was centered around the flow assurance problems they cause in the extraction and transportation of petroleum and its derivatives. Naturally occurring gas hydrates are also studied to satisfy global energy demand: estimates put the total energetic capacity of hydrate reserves at twice that of other fossil fuel reserves combined. Their potential use in the removal of carbon from the atmosphere, carbon capture and storage, and for energy exploitation makes gas hydrates a prime candidate for climate change mitigation research.

Characterizing the interfacial properties of a material that requires intense formation conditions and sublimes rapidly in standard atmosphere is experimentally challenging. Controlling sample purity and system homogeneity is often difficult in devices designed to measure interfacial properties. It is also costly to properly clean apparatus after using additives to study new ones. Finally, rapidly testing different guest molecules, external pressures, surface effects, and extracting meaningful, fundamental information about the atomic and molecular interfacial behaviors is nearly impossible without critical sample disruption. This work uses molecular dynamics as implemented in the Large-scale Atomic/Molecular Massively Parallel Simulator to characterize the temperature and pressure effects on the interfacial tension, energy of interfaces, and growth rate of natural gas hydrates to overcome the complexity of experimentally understanding their performance in extreme environments and prove that theoretical modeling, prediction, and advanced characterization techniques can explain the structural and transport properties that govern hydrate in engineering applications. This project studies the impact of the surface coverings and additives on surface energy, attachment strength, and creation of new nucleation sites in sII gas, and examines the thermal transport across the hydrate/water, hydrate/gas, and hydrate/ice interfaces by calculating the thermal conductivity across the interface. This project also uses geometric analysis techniques to understand the dynamic behavior of the crystalline interfaces, including what specific polyhedral faces tend to face the melting phase and what type of pre-melting dynamics and interfacial thicknesses exist in these systems. It is essential to understand the underlying mechanisms occurring at the molecular level and the nanoscopic behaviors leading to macroscopic properties, thereby clarifying behaviors and phenomena that dominate potential applications of these structures. Our work has shown that there is excellent agreement between sI methane hydrates and experimental values, as well as for sII natural gas hydrates. The hydrates nucleate preferentially with film-shaped nucleation, then cap-shaped, lens-shaped, and homogeneous nucleation. We have confirmed the presence of a novel pre-melting layer at the interface between the structures. We have been able to produce temperature and pressure correlations of surface tension for engineering applications. The excess entropy, adsorption, radial pair distribution function, and charge distribution at the interface were calculated to confirm our findings. The molecular dipole at the interface indicates novel organization of molecules that affects further nucleation and governs the use of surface coverings and additives to control behavior. The interfacial thickness has been characterized to show interface expansion and contraction at certain conditions, as well as showing the fine atomic phenomena that are at play in controlling macroscale properties.

Towards a Holistic Chemistry of Metal-Organic Framework Formation

Hamish H. Yeung; University of Birmingham, United Kingdom

Metal–organic frameworks (MOFs) have established themselves as fantastic materials for fundamental studies and potential applications alike, owing to the almost limitless possibilities that different combinations of metal ion-based nodes and organic linkers offer. Synthesis is typically simple, in the sense that new MOFs can be discovered in one-pot reactions close to ambient conditions within a matter of minutes or hours. However, behind such simplicity lies a great lack of understanding of how MOFs form and why particular phases crystallise under different conditions or even under (seemingly) the same conditions.

Our group has been working to better understand MOF formation using model systems such as the canonical zeolitic imidazolate framework (ZIF) family of MOFs. Although topologically similar to zeolites, relatively few ZIFs have been discovered compared to their inorganic counterparts. Better understanding of the chemistry that underpins self-assembly of metal ions and linkers into ZIFs would enable us to create materials, for example with new topologies or with more precisely positioned functionalities for improved performance in separations, sensing, gas storage and other applications.

A combination of systematic studies, in-situ monitoring and kinetic modelling has enabled us to develop a chemical understanding of phase behaviour, crystallisation rates, particle sizes and reaction yields in two particular hybrid systems: lithium tartrates and zeolitic imidazolate frameworks. This presentation will describe some of our ongoing work in the area, looking into synthetically relevant parameters such as reagent concentration, solvent and pH, and more complex systems such as mixed-metal and core-shell particles.

Inelastic Neutron Scattering Applied to Porous Materials

Anibal J. Ramirez-Cuesta; Oak Ridge National Laboratory, United States

Neutron scattering is uncommon and rare because there are only a handful of places worldwide where it is possible to perform the required experiments. The Spallation Neutron Source at ORNL in East Tennessee is the most advanced pulsed neutron source. The interaction of neutrons with the nuclei provides unique information on light elements (like hydrogen). It distinguishes between neighboring elements and isotopes, complementing X-ray capabilities and photon-based techniques.

In the case of Inelastic Neutron Scattering (INS), the technique is the neutron analog of Raman and infrared spectroscopies. Instead of using photons as the probing beam, a neutron beam illuminates the sample. The penetrating power of neutrons means that with the adequate selection of materials, it is possible to build sample environments that can manage extreme conditions in pressure and temperature without the need for optically transparent windows—giving the technique much versatility. Gas handling experiments are trivial. The main disadvantages of INS are: that measurements usually require cryogenic temperatures, the neutron fluxes are low when compared with photons, and accessing neutron scattering facilities is challenging.

Atomistic computer modeling, particularly DFT, molecular dynamics, etc., is routinely used to interpret and analyze experimental results. The interplay of atomistic modeling and experimental data is unique and allows access to a precious insight into the mechanistic interpretation of the data. Porous materials have space voids where it is possible to adsorb molecules. Trapping these molecules to “store” them or sometimes react chemically is used in many applications.

This paper will present examples of INS spectroscopy applied to small molecule adsorption on porous materials, from zeolites to metal-organic frameworks, highlighting the unique information the technique provides and how computer models are essential to interpret the data.
Metal–Organic Frameworks (MOFs) are crystalline porous materials composed of metal ions and organic ligands. Many reports have described the synthesis of oriented MOF films with high crystallinity and flatness by liquid-phase processes such as layer-by-layer method. Liquid-phase methods often require modification of the substrate surface with self-assembled monolayers and there is a risk of corrosion and contamination of the interface by the solution. By contrast, synthesis by physical vapor deposition is suitable to prevent the degradation caused by solvents and is advantageous for the fabrication of well-defined interfaces and easy patterning for further device fabrication. Until now, oriented thin films of two-dimensional MOFs were fabricated on insulating substrates by physical vapor deposition. However, the oriented three-dimensional MOF films have only been synthesized on metal surfaces, and never on insulating substrates by physical vapor deposition.

In this study, we report the fabrication of (111)-oriented thin films of a three-dimensional-MOF HKUST-1 ([Cu3(BTC)2], BTC = 1,3,5-benzenetricarboxylate) on insulating glass substrates by combining vacuum deposition and annealing in acetic acid vapor. HKUST-1 is expected for device applications because of the tunability in ionic and electronic conductivities by introducing molecules into the pores. We utilized two-step processes for the HKUST-1 thin film fabrication. First, trimesic acid and copper(II) acetate thin films were deposited on the glass substrates as a precursor. Second, post-deposition annealing was performed in air and an acetic acid atmosphere. While the thin film annealed in air showed no peaks corresponding to HKUST-1 in the out-of-plane X-ray diffraction (XRD) pattern, the thin film annealed in acetic acid vapor showed 111, 222, and 333 diffractions, indicating (111)-oriented HKUST-1 films were successfully synthesized on the glass substrate. These results suggest that annealing with the acetic acid vapor facilitates the precursor diffusion and the solid-phase reaction to form HKUST-1 crystals.

Ceramics with high proton conductivity and stability are essential for efficient electrochemical cells, such as fuel cells and electrolyzers. Protonic ceramics that exhibit high proton conductivity at intermediate temperatures (300–600°C), high chemical stability against CO2, H2O, and electrode materials, and practical difficulties for synthesis, are especially of interest for practical applications. Currently, two well-known classes of the protonic ceramics exist: solid oxyacids that exhibit high proton conductivity but decompose at relatively low temperatures (< 200°C) as being dehydrated (e.g., CsH2SO4 derivatives), and perovskite-type refractories that are stable even in dehydrated state but show high conductivity only at high temperatures above 600°C (e.g., BaZrO3-BaCeO3 derivatives). Although efforts to develop thermostable oxyacids and perovskite-type refractories showing high conductivity at the intermediate temperatures have been energetically continued, the protonic ceramics meeting the three properties required for the electrochemical applications have not been developed.

As a new class of protonic ceramics, alkali-proton-exchanged ceramics have been gradually gained attention, and some ceramics in this class (e.g., Li13.9Sr0.1Zn(GeO4)4 and Li2.5Sr0.75Zr1.25(PO4)3) have been suggested to show high proton conductivity and stability. Compared to the perovskite-type materials, the ceramic in this class is believed to exhibit less current leakage by electron holes under high oxygen potential due to donor doping and the incorporation of protons through means other than oxygen vacancy hydration. However, proton conductivities of the alkali-proton exchanged ceramics throughout dense ceramic bodies by a traditional ion-exchange techniques, which involve immersing the alkali ceramics into aqueous acid solutions. The use of water limits alkali-proton exchange processing temperatures to below 100°C, thereby restricting the thermal acceleration of mass diffusion, and usually, only porous or powder-form alkali ceramics are applied.

To overcome this challenge, here, we propose a new but simple method to synthesize the dense alkali-proton-exchanged ceramics using molten long chain fatty acids heated above 100°C. A homemade reaction vessel were developed for stable, uniform, and efficient ion exchange using fatty acids at high temperatures. A case study on Al-stabilized cubic garnet-type Li7La3Zr2O12 (LLZ) shows that the alkali-proton exchange occurs more than 300 µm deep through LLZ dense bodies under optimum conditions, and 91 % exchange can be achieved with only 8 h of treatment. The conductivity of the proton-exchanged LLZ and its potential for the applications will be discussed with DFT calculations.
A major interest in the use of Metal Organic Frameworks (MOFs) is the simultaneous capture and destruction of toxic chemicals and chemical warfare agents. Catalysis typically occurs at defect sites in the MOF crystallite. An unexplored avenue for defect formation in UiO-67 MOFs is through temperature activation. Here, we use a combination of Fourier transform infrared spectroscopy and density functional theory (DFT) techniques to understand the impact of thermal activation on the concentration and strength of Lewis acid defects (Zr=O sites) in UiO-67. Ultra-high vacuum methods are employed to eliminate atmospheric contaminants. We devise a new method to allow vibrationally active probe molecules to diffuse through the MOF and preferentially adsorb to internal sites, providing insight into the structure and properties of internal MOF sites. Through the use of CD3CN, whose ν(CD) mode is Stark active, and DFT calculations, we assign the presence of three distinct Lewis acid sites which evolve as a function of pretreatment temperature. Following dehydroxylation at 623 K, the Lewis acidity of the MOF appears to increase in both concentration and strength through the loss of capping groups. We additionally show that following CD-CN diffusion into UiO-67, the intensities of the ν(CD) and ν(CN) modes depict nonlinear intensity behavior, complicating the interpretation of diffusion kinetics through UiO-67. Through DFT calculations, we observe that hydrogen bonding of CD-CN to μ-OH groups in UiO-67 significantly decreases the transition dipole moment of the ν(CD) modes, while increasing that of the ν(CN) mode. These results highlight the importance of careful infrared spectra interpretation, as well as the propensity for thermal activation to increase the density and strength of Lewis acid sites.

Metal Organic Frameworks (MOFs) are incredibly versatile porous materials capable of degrading many toxic chemicals. By incorporating organic linker molecules that are photocatalytically active into the MOF it is possible to achieve multiple pathways of degradation. Pyrene based linker molecules, such as 1,3,6,8-tetakis (para-benzonic acid) pyrene (TBAPy) are photocatalytically active when exposed to ultraviolet light and produce singlet oxygen in solution. The highly reactive singlet oxygen molecules then react with toxic species in solution and degrade them into less toxic molecules. This work focuses on determining the efficiency of the photocatalysis reaction for degrading toxic and persistent chemicals, such as pesticides in aqueous solutions.

Medium-Range Order Structure Controls Thermal Stability of Pores in Zeolitic Imidazolate Frameworks Rasmus Christensen, Yossi Bleie, Soren S. Sorensen, Christophe Biscio, Lisbeth Fajstrup and Morten M. Smedskjaer; Aalborg University, Denmark

Metal-organic framework (MOF) classes of materials have shown potential for the barocaloric effect such as plastic crystals but to compete with the efficiencies of current refrigerants, the magnitude of pressure required must be reduced. Metal-organic frameworks (MOFs) are porous, periodic, and crystalline materials that are highly modular due to the many metal and linker combinations possible. Though largely studied for their adsorption properties, several MOFs have been reported to exhibit a breathing effect where large volume changes were observed as a result of pressurising the MOFs with and without guest molecules. Hence, they have been recognised as potential barocaloric materials with the most well-known being MIL-53(Al) which has 1,4-benzenedicarboxylates (BDC) as the linkers reporting a colossal entropy change of 311 J K\(^{-1}\) kg\(^{-1}\) under 16 bar of carbon dioxide gas. The ability to accommodate large volumes changes has been associated with the inherent flexibilities within the ligand that acts as the linker, therefore, this work turns to fumarate linkers which are dicarboxylates like the BDC with a torsional double bond in the centre. Studies on the barocaloric performance of an aluminium-centred fumarate MOF was found to exceed that of the BDC-analogue, making this family of MOFs ideal candidates for further investigation.

This research aims to develop further understanding towards fumarate-based MOFs, in particular, the gallium analogue to the fumarate-linked MIL-53(Al)
Zeolite is an important material widely used in ion exchangers, adsorbents, and gas separation membranes. Many aluminosilicate zeolites have been synthesized by hydrothermal, solvothermal, and solid-phase methods using monomeric or polymeric Al and Si sources, such as alkoxides, fly ash, and kaolinite, in the presence of acids, bases, and structure-directing agents. In recent years, topotactic reactions have been developed to expand the structure from a two-dimensional layered precursor to a three-dimensional structure, and methods to design the structure of the target aluminosilicate have been developed, such as synthesis in which the position of Al atoms in the zeolite can be controlled by additives. Since control of the composition and structure of the target aluminosilicate is expected to enable control of functions, further development of rational structure construction methods based on the composition and structure of the starting materials is an urgent task. Therefore, the use of structurally and compositionally well-defined molecular precursors (MPs) would be reasonable starting materials by connecting their core frameworks. In this presentation, we demonstrated in detail the synthesis of aluminosilicate using molecules with secondary building unit (SBU) -like core structure as MP. Hydrothermal reactions of SBU-like MP without additives gave no insoluble product. On the other hand, the hydrothermal reactions of SBU-like MP with alkali metal cation afforded the zeolite that can be constructed by the core structure of the MP. It should be noteworthy that the hydrothermal reactions using separated Al and Si sources at the same Si/Al ratio, alkali metal cation content, and temperature resulted in several zeolites which could not be constructed by linking the MP core structure. These zeolites are known to be thermodynamically more stable than the zeolite synthesized by the SBU-like MP, and form at higher temperature and higher base-
wave gap. From these experimental results, we confirmed that \((\text{Pt}_{0.2}\text{Ir}_{0.8})_3\text{Zr}_5\) superconductor obeys to weak-coupling BCS model with an s-wave gap. The \(\mu H_c^2\) of \((\text{Pt}_{0.2}\text{Ir}_{0.8})_3\text{Zr}_5\) was estimated from specific heat under various magnetic fields. The estimated value of \(\mu H_c^2\) at 0 K is \(\mu H_c^2(0) = 2.59\) T, which is an intermediate value between the orbital pair breaking limit \(\mu H_c^2 = 1.33\) T and the Pauli-Clogston limit \(\mu H_c^2 = 4.08\) T. Although \((\text{Pt}_{0.2}\text{Ir}_{0.8})_3\text{Zr}_5\) belongs to the non-centrosymmetric crystal structure, its \(\mu H_c^2\) is not larger than the Pauli-Clogston limit, which is different from the case of CePt$_3$Si, CeRhSi$_3$, and CeIrSi$_3$. This indicates that the dominant mechanism determining the \(\mu H_c^2\) of \((\text{Pt}_{0.2}\text{Ir}_{0.8})_3\text{Zr}_5\) is the orbital pair breaking limit, and its ASOC effect is not significant. A similar phenomenon was observed in other non-centrosymmetric superconductors, for example, LaMn$_M$ (\(M = \text{Ir} \) and Rh, \(P = P \) and As) and Mg$_{8}\text{Ir}_{10}\text{B}_{16}$. The crystal structure and elemental composition could be important factors in the strength of the ASOC effect.

8:00 PM SF03.03.06 Superconductivity in In-Doped AgPbBiTe$_3$ Compounds Synthesized by High-Pressure Synthesis Takahiro Sawahara$^1$, Hiroto Arima$^1$, Takayoshi Katase$^2$, Achi Yamashita$^1$, Ryuuji Higashimura$^1$ and Yoshikazu Mizuguchi$^1$; $^1$Tokyo Metropolitan University, Japan; $^2$Tokyo Institute of Technology, Japan

NaCl-type metal tellurides (MTe), such as SnTe, PbTe, and InTe, have been widely studied due to their unique physical properties as topological insulators, thermoelectric materials, and superconductors. SnTe, which is a topological crystalline insulator, shows superconductivity upon carrier doping, and In-doped SnTe has been studied as a candidate material in which topological superconductivity emerges. Therefore, further development of new NaCl-type MTe superconductors is expected to expand material variation. In this study, we used allaying technique to design new MTe superconductors. In our previous report, in SnTe, we revealed that the partial substitution of Sn$^+$ site by (Ag$_2$(Bi$_{1/2}$)$_{3/2}$) results in systematic lattice contraction while preserving the crystal-structure type and the total valence state. From first principles band calculations, a band inversion is predicted, suggesting the possibility of topologically preserved electronic state in the system. Furthermore, AgSnBiTe$_3$ also shows superconductivity by In-doping. Similarly, PbTe, which is a thermoelectric material, shows superconductivity by In-doping. From the analogy between SnTe and PbTe, we considered that AgPbBiTe$_3$ could be synthesized and will exhibit superconductivity.

We investigated the In-doping effects on the structural and physical properties in AgPbBiTe$_3$. Polycrystalline samples of (AgPbBi)$_{1+y}$In$_y$Te ($x = 0$–0.5) were synthesized by high-pressure synthesis, and we confirmed the NaCl-type structure by powder X-ray diffraction. In occupies the M site for all the compositions. From magnetic susceptibility measurements, superconductivity was observed for $x = 0.2$–0.5, and the highest transition temperature was 2.8 K for $x = 0.4$. For $x = 0.4$, the emergence of bulk superconductivity was confirmed by specific heat measurement. In the presentation, we will show the superconducting properties of (AgPbBi)$_{1+y}$In$_y$Te and discuss the In-valence state of In-doped MTe with a NaCl-type structure.

8:00 PM SF03.03.07 Unveiling the Potential of Lanthanide-Doped Oxyfluoride Materials for Efficient Green Upconversion and Their Promising Applications, Sonali Mohanty, Mirijam Lederer, Simona Premcheka, Hannes Rijckaert, Klaartje De Buysser, Els Bruneel, Andre Skirtach, Kristof Van Hecke and Anna M. Kacmanrek; Ghent University, Belgium

The quest for highly efficient upconversion (UC) materials has led to the development of fluoride hosts with low phonon energies, minimizing nonradiative transitions. Among them, NaYF$_4$ doped with Yb$^{3+}$ and Er$^{3+}$ has emerged as a top performer. However, its limited thermal stability hinders its application in certain fields. On the other hand, oxide hosts offer improved stability but suffer from lower UC efficiencies due to higher phonon energies. Hence, the prospect of developing host materials that combine the robustness of oxides with the high upconversion efficiencies of fluorides remains an intriguing avenue of exploration.

Herein, we present a novel approach wherein we successfully synthesize lanthanide-doped oxyfluoride particles. This is achieved through the growth of a NaYF$_4$:Yb$^{3+}$,Er$^{3+}$ layer around SiO$_2$ spherical particles, followed by a high-temperature annealing process, yielding SiO$_2$@YOF:Yb$^{3+}$,Er$^{3+}$ particles. Our primary focus was to exploit these materials as Boltzmann type luminescence thermometers within the physiological range. Nonetheless, we encountered a noteworthy challenge concerning the limited emission observed in the green spectral region of these particles. To address this limitation, we have investigated the effects of introducing various metal ion co-dopants (Gd$^{3+}$, Li$^+$, or Mn$^{2+}$) into the SiO$_2$@YOF:Yb$^{3+}$,Er$^{3+}$ particles. Specifically, we analyze the overall emission intensity and the green to red ratio under 975 nm laser excitation. Beyond their role as ratiometric thermometers, our investigation uncovers the remarkable potential of these materials as carriers for drug delivery applications, following the conversion of SiO$_2$@YOF:Yb$^{3+}$,Er$^{3+}$ particles into hollow YOF:Yb$^{3+}$,Er$^{3+}$ structures, and their evaluation in terms of toxicity towards NHDFs. The investigation highlights the previously unexplored aspects of improving the green upconversion luminescence in YOF:Yb$^{3+}$,Er$^{3+}$ and its potential biomedical applications.

8:00 PM SF03.03.08 Surfactant-Templated Green Synthesis of Porosity-Tailored Silica Nanoparticles for Lithium-Ion Battery and 5G Communication Applications Yeongje Lee, Sanghyeok Bae, Seok Jin Hong and Sunho Jeong; Kyung Hee University, Korea (the Republic of)

In a recent decade, silica nanoparticles have received a significant attention owing to their distinctive chemical/physical properties and potentials in newly emerging applications including 5G communication and lithium-ion battery applications. In this study, we propose an environmentally friendly methodology of synthesizing highly functioning silica nanoparticles with characteristic porous structures. The surfactant-templated sol-gel emulation method enables to adjust the dimension of monodispersed silica nanoparticles and to form dual porous (micro- and meso-porous) internal structures. The composite films, in which the dual porous silica nanoparticles are hybridized with polypeptide polymeric resins, exhibit remarkably low dielectric properties, demonstrating their potential as a substrate material for 5G communication applications. By inducing a carothermal reduction reaction, we can control the stoichiometric ratio of porous silica nanoparticles. This leads to a facile creation of porous SiO$_x$/carbon nanocomposites applicable to anode materials for lithium-ion batteries. The resulting nanocomposites showed an excellent cycling stability (~100% after 500 cycles at 0.5 A g$^{-1}$) and rate capability (554 mAh g$^{-1}$ at 2 A g$^{-1}$), and a high capacity (1330 mAh g$^{-1}$ at 0.1 A g$^{-1}$). Our findings affirm the feasibility of porous structure-designable silica nanoparticles for both 5G communication and battery applications. It would open up new possibilities for meeting the unique requirements across various fields through a simple synthesis method.

8:00 PM SF03.03.09 Crystallographic Structural Control of Manganese Dioxide Nanomaterials for Battery Applications Sanghyeok Bae, Yeongje Lee, Seok Jin Hong and Sunho Jeong; Kyung Hee University, Korea (the Republic of)

Recently, manganese oxides have received tremendous attention as active materials for various types of energy storage devices, owing to their cost-effectiveness and excellent electrochemical performances. In particular, manganese dioxide can be used as an anode material for lithium-ion batteries and a cathode material for aqueous zinc-ion batteries. The MnO$_2$ octahedral building units are assembled into tunnel and layered structures, with a formation of variety types of crystallographic structures. The common synthetic method for synthesizing manganese dioxide particles is a hydrothermal reaction. However, in this synthetic method, it is highly demanding to control precisely the crystal structures of manganese oxides, because of an everlasting heating/cooling time during the hydrothermal reaction. Herein, we report an ultrafast annealing process for controlling sophisticatedly the crystallographic structures of manganese oxide nanoparticles. By controlling the heating rate up to a given temperature and the cooling rate down to a room temperature, the oxidation states and the crystal structures are
adjusted correspondingly depending on ultrafast annealing processing parameters. It will be confirmed that the crystalline structures are controllable precisely in nanoparticles, unlike the case of conventional spin-coating reactors. Based synthesized Nb2O5-based nanocomposites are incorporated inside graphene oxide nanocomposites, allowing for a formation of nanocomposite electrode materials. In this study, for understanding better the electrochemical reaction mechanisms manganese oxide materials, the manganese oxide-based nanocomposites with different crystalline structures will be evaluated and analyzed comparatively as anode materials for lithium ion batteries and cathode materials for zinc ion batteries.

8:00 PM SF03.03.10
The Synthesis of Layered Hexagonal Structure Type of SnS2@rGO as High-Performance Anodes for Lithium-Ion Batteries
Hyerin Yoo1, Wonbin Nam1, Yoon Myung2, Chan Woong Na2 and Jaewon Choi1; 1Gyeongsang National University, Korea (the Republic of); 2Korea Institute of Industrial Technology, Korea (the Republic of)

SnS2-based nanocomposites have garnered considerable attention as a highly promising anode material for lithium-ion batteries due to their unique two-dimensional layered structure, impressive theoretical capacity, and alloy metal properties. However SnS2 suffers from low cycle life stability, inadequate electronic conductivity, and large volume expansion during the charge/discharge process. One suggested solution is introducing carbonaceous materials, such as reduced graphene oxide (rGO). These can improve the electrochemical performances of metal sulfides, such as cycle stability and rate capability by their high electronic conductivity. This study comprehensively analyzed the as-synthesized SnS2 and SnS2@rGO composites using SEM, XRD, XPS, and TEM techniques. Furthermore, Ex-situ X-Ray diffraction tests showed that the SnS2@rGO nanocomposite electrode primarily operates via an anodic mechanism for SIBs. The SnS2@rGO nanocomposite demonstrated enhanced cycling stability and discharge capacity, as evidenced by electrochemical testing (500 mAh/g at 542 mA/g after 300 cycles; 317.9 mAh/g at 100 mA/g after 600 cycles). Meaningful enough, the construction of composites using SnS2 and SnS2@rGO represents a promising strategy for improving the electrochemical performance of LIBs. Also, the CV curves at various scan rates are evaluated to investigate the electrochemical reaction kinetics of the SnS2@rGO, and this process is mainly controlled by capacitive behavior. This work demonstrates the potential of SnS2@rGO nanocomposite as anode materials for LIBs and enhances our understanding of electrochemical storage mechanisms. This research will facilitate the development of diverse energy storage materials based on SnS2.
