Solid-binding proteins are genetically engineered chimera that incorporate one or more solid-binding sequences at defined locations of their framework while retaining native function. These macromolecules are versatile building blocks for the fabrication of hybrid hierarchical materials that derive unique properties from the organization, interplay, and reconfiguration of organic and inorganic units. Here, I will discuss how solid-binding proteins can be combined with self-assembled peptoid nanostructures and pre-synthesized or mineralized inorganic elements to create layered 3D architectures, achieve precise control over nanocrystal size, and build photocatalytic nanocomposites. I will also describe recent progress on the use of thermos-responsive solid-binding proteins to control nanoparticle assembly and disassembly and manipulate the outcomes of biomimetic mineralization.

**Silk-Nanotraps for Selective Molecular Targeting. Understanding Potentials and Limitations of Functional Protein Super-Assemblies** [Alessandra Maria Bossi](#)<sup>1</sup> and [Devid Maniglio](#)<sup>2</sup>; <sup>1</sup>University of Verona, Italy; <sup>2</sup>University of Trento, Italy

We report about the development of tailor-made biomimetics stemmed from merging biology with polymer chemistry and material science. Aqueous-soluble nanotraps that behave as biomimetic receptors were prepared in the form of proteinaceous disordered super-assemblies, fixed by non-natural crosslinking. The specific formation of the nanotrap started from the biocompatible, nontoxic material, already in use in regenerative medicine, that is silk fibroin [1].

Pioneering a paradigm change, the tailor-made molecular recognition was conveyed to the silk nanotrap by the unconventional exploitation of the molecularly imprinted polymers (MIPs) technique, that is a specifically designed strategy to entail molecular recognition to a nanomaterial by means of a template-assisted synthesis [2,3], but herein methacrylated silk fibroin polypeptides were used as macromolecular building blocks. Such MIP synthetic protocol was optimized with the aid of surface response method. The silk-nanotraps, called bioMIPs, were physically and functionally characterized, demonstrating high affinity binding (nM) for the targets and selectivity [4]. Enzymatic degradation of the bioMIPs was studied. The biocompatibility of the nanotraps was confirmed. The nanotraps were further labelled with fluorescent tags and tested for imaging in cell cultures [6]. The bioMIP's synthesis proved a general route for entailing recognition towards proteins or small molecules [4,5], which let foreseen applications in sequestering molecular players in the onset and progression of diseases, to tackle the onset of molecular changes in cells, and opening for translational studies with roles in long term pathologies.

**Molecular Dynamics Simulations of cRGD-Conjugated PEGylated TiO<sub>2</sub> Nanoparticles for Targeted Photodynamic Therapy** [Giulia Frigerio](#), Paulo Siani, Edoardo Donadoni and Cristiana Di Valentini; Department of Materials Science, University of Milano-Bicocca, Italy

Active targeting strategies, exploiting the biological interaction between ligands on the surface of nanoparticles and the cell targets, are known to increase the therapeutic efficacy of cancer treatments with respect to passive targeting strategies that are mainly based on the enhanced permeability and retention effect of tumor tissues. In this respect, the conjugation of nanoparticles with integrin  $\alpha_v\beta_3$ -affine cyclic RGD peptides (cRGD) is a promising approach in nanomedicine to efficiently reduce off-targeting effects and enhance the cellular uptake by integrin-overexpressing cancer cells.

We used atomistic molecular dynamics simulations to evaluate key structural-functional parameters of cRGD ligands conjugated to PEGylated TiO<sub>2</sub> nanoparticles for an effective binding activity towards  $\alpha_v\beta_3$  integrins. An increasing number of ligands has been conjugated to PEG chains, grafted to highly curved TiO<sub>2</sub> nanoparticles, to unveil the impact of cRGD ligand density on its presentation, diffusion, and conformation in an explicit aqueous environment.

We find that a low density leads to an optimal spatial presentation of cRGD ligands out of the "stealth" PEGylated layer around the nanosystem, favoring a straight upward orientation and a spaced distribution of the targeting ligands in the bulk-water phase. On the contrary, a high density favors the clustering of cRGD ligands, driven by a concerted mechanism of enhanced ligand-ligand interactions and reduced water accessibility to the ligand's molecular surface. These findings strongly suggest that the ligand density modulation is a key factor in the design of cRGD-conjugated nanodevices to maximize their binding efficiency to over-expressed  $\alpha_v\beta_3$  integrin receptors.

## 3:30 PM \*SB03.03.02

**Computer Simulations of the Interaction of Anaesthetic Molecules Fentanyl and Propofol with Biological Membranes** [Nora H. de Leeuw](#); University of Leeds, United Kingdom

Computational techniques are well placed to investigate materials and processes in the body that are difficult to access experimentally. In this work we have used all-atom computer simulations to predict the structures and behaviours with biological membranes in the cell of two important molecules in the process to induce anaesthesia, i.e. propofol and fentanyl. The lipid membrane is considered a crucial component of opioid general anaesthesia and detailed atomic-level insight into the drug-membrane interactions could lead to a better understanding how different drugs exert their anaesthetic properties. First, we have investigated the opioid analgesic fentanyl on its own, using extensive umbrella sampling molecular dynamics simulations to study the permeation process into a variety of simple phospholipid membrane models, accurately predicting the permeability coefficients, followed by its interactions with the *Gloeobacter violaceus* ligand-gated ion channel (GLIC). The simulations have identified multiple extracellular fentanyl binding sites, which are different from the transmembrane general anaesthetic binding sites observed for propofol and other general anaesthetics, including a novel fentanyl binding site within the GLIC which results in conformational changes that inhibit conduction through the channel.

The second part of our study explicitly includes the interactions between fentanyl and propofol. General anaesthesia is a multi-drug process and our work provides the first insight into how different components in the anaesthesia process interact with each other in a relevant biological environment. For example, using flooding style and gaussian accelerated molecular dynamics (GaMD) simulations, we show fentanyl acting as a stabiliser that holds propofol within binding sites in GLIC, whereas the simulations were also able to show the pathway by which propofol physically blocks the ion-conducting channel pore, which has previously been suggested as a mechanism for ion channel modulation by propofol.

## 4:00 PM \*SB03.03.04

**Multiscale Mechanics of Cancer Metastasis to Bone** [Dinesh R. Katti](#), Sharad V. Jaswandkar, Hanmant Gaikwad and Kalpana Katti; North Dakota State University, United States

The World Health Organization reported that over one million deaths occur worldwide due to breast and prostate cancer. The majority of these deaths occur due to metastasis of the cancer to distant locations in the body, which for breast cancer and prostate cancer happens to be bone. At the bone site, the cancer cells colonize, proliferate, and have a very detrimental impact on the bone. Clinically, this is manifested as frequent skeletal failures. In order to recapitulate the metastasis process through a realistic testbed, we have developed an in vitro model of bone metastasis using nanoclay bone mimetic scaffolds. Experiments using commercial and patient-derived cancer cell lines to create metastasized tumors indicate significant changes to the morphology of the cancer cells based on the cancer phenotype. Also, depending on the phenotype, the mechanical properties of the cancer cells extracted from the tumors are dramatically altered. Associated with the observed changes, we observe significant changes in gene expressions related to actin and actin depolymerization factor cofilin (ADF/cofilin). Confocal imaging of cancer tumors during cancer progression reveals significant actin dynamics, both quantitatively and spatially. Label-free discrimination of cancer progression using Raman imaging and cluster analysis also reveals actin dynamics and changes to actin-related bands, which could serve as spectral biomarkers for cancer progression at the bone site. Steered molecular dynamics simulations of actin and actin with ADF/cofilin describe the mechanisms of the resilience of actin molecules and depolymerization of actin by ADF/cofilin, critical players in the actin dynamics during the cancer progression. Hence, actin remodeling plays a vital role in cancer metastasis progression and pertains to cellular behavior inside the cell. In order to evaluate the molecular phenomena outside the cell, we investigate the characteristics of integrin molecules. The integrin protein is a mechanotransducer establishing mechanical reciprocity between the extracellular matrix and cells at integrin-based adhesion sites. This

protein plays a critical role in cell-ECM adhesion and cellular signaling. We conducted steered molecular dynamics (SMD) simulations to investigate the mechanical responses of integrin  $\alpha\beta3$  with and without ligand binding for a variety of mechanical loading paths. The ligand-binding integrin confirmed the integrin activation during equilibration by opening the hinge between  $\beta A$  and the hybrid domain. This activation of liganded  $\alpha\beta3$  integrin influenced the molecule's stiffness observed during tensile loading. Furthermore, we observed that the interface interaction between  $\beta$ -tail, hybrid, and epidermal growth factor domains altered integrin dynamics. The deformation of extended integrin models in the bending and unbending directions of integrin reveals the stored folding energy and the directionally dependent stiffnesses of the integrin molecule. Along with experimental data, the SMD simulations were used to evaluate the mechanical properties of integrin and identify the underlying mechanisms of integrin-based adhesion substrates. The investigation of the mechanics of integrin molecules provides new insights into understanding the mechanotransmission between cells, ECM, and the substrate. Overall the mechanotransduction facilitated by integrins to actin remodeling at the cellular insides is a critical molecular phenomenon that exists over a multiscale regime that synergistically creates the metastasis progression of cancer.

SESSION SB03.04: Synthesis, Restoration and Regeneration of Biological Hard Tissues

### 8:30 AM SB03.04.01

**Development of Self-Assembled Organothiol-Based Nanolithography Templates for Biomimetic Synthesis of Calcium Phosphate on Amyloid-Like Amelogenin Nanoribbons** Jayesh Dua<sup>1</sup>, Stefan Habelitz<sup>2</sup> and James J. De Yoreo<sup>1,3</sup>; <sup>1</sup>University of Washington, United States; <sup>2</sup>School of Dentistry, University of California, San Francisco, United States; <sup>3</sup>Pacific Northwest National Laboratory, United States

Tooth enamel is the hardest tissue in the body mainly due to the intricate interwoven structure of highly organized apatite filaments that form it. It has been theorized that unidirectionally aligned (co-aligned) amyloid-like amelogenin nanoribbons (Amel NR) guide the formation of apatite by providing an energetically and stereochemically favorable scaffold for nucleation and transformation of amorphous calcium phosphate (ACP) precursor to hydroxyapatite (HAP). To understand the efficacy with which protein structures direct the nucleation of ACP and the subsequent transformation to HAP, studies have been carried out to quantitatively analyze the nucleation of ACP by self-assembled NRs of the full-length protein as well as varying sequences of peptides made up of protein subsegments responsible for self-assembly and ACP binding. Supramolecular block-copolymer templates with alternating hydrophilic and hydrophobic regions were also used to direct the self-assembly of amelogenin-derived peptide nanoribbons having discrete, spatially separated domains. These domains in turn templated the mineralization of filamentous and plate-shaped calcium phosphate. To create more versatile templates, we are using AFM-based nanolithography to create highly modifiable nanopatterns of novel organothiol monolayers self-assembled on Muscovite Mica. By using AFM probes, we perform Nanografting on monolayers of hydrophobic organothiols on Mica in predetermined patterns and backfill the patterns with hydrophilic thiols. The proposed system is similar to the block-copolymer system in its basic function, but with the capability of modifying the design on-the-fly to study the effects of geometry. While similar thiol systems on metal substrates (like nearly-atomically flat Au substrates) have been extensively studied and are even now used for a multitude of applications, the proposed system offers significantly better reproducibility, reusability, and affordability. Although the proposed system has been developed for the use of templating the growth of Amel NRs, it has the potential to be employed for a variety of other applications by modifying the surface chemistry of the Organothiol headgroups. Additionally, since Mica is the preferred substrate for the study of many soft matter systems, it provides the possibility of the direct study of many of these systems, eliminating the need for the modification of the parent molecule to enable its binding to the substrate. Monolayers of long chain alkanethiols (like the ones used on gold substrates) with average roughness  $\approx 0.2$ nm have already been achieved with extremely adaptable grafting pattern thicknesses ranging from 50 nm-200 nm. By manipulating the spacing and dimensions of the 2D-patterns, as well as the composition of the mineralizing solution, we seek to find understand the controls of scaffold geometry on nucleation and growth rates of the ACP precursor domains, as well as their transformation to HAP. Understanding how manipulating the scaffold geometry affects the fidelity of guided mineralization will move us closer towards the biomimetic synthesis of enamel-like materials.

### 8:45 AM SB03.04.02

**Peptoid-Controlled Synthesis of Hierarchical Composite Nanomaterials** Chun-Long Chen; Pacific Northwest National Laboratory, United States

In nature, biominerals (e.g. bones and teeth) are excellent examples of hierarchical composite materials whose formation and functions are controlled over multiple length scales by high information content biomacromolecules. Inspired by nature, many biomimetic approaches have been developed for the design and synthesis of composite materials. These approaches are attractive because they generate complex, functional materials under mild aqueous synthetic conditions.<sup>1,2</sup>

As one of the most advanced classes of sequence-defined peptide-mimetics, peptoids offer tremendous opportunities for bio-controlled synthesis of hierarchical composite materials,<sup>3,4,5</sup> mimicking protein- and peptide-like molecular recognition. Due to the lack of backbone hydrogen bonding, tuning peptoid-peptoid and peptoid-particle interactions can be done solely by varying side-chain chemistry.<sup>1,5</sup> Peptoids have been exploited as programmable building blocks to assemble into highly ordered nanostructured materials with a variety of morphologies.<sup>3,6</sup> In this presentation, we will report our recent progress of developing self-assembling peptoids for controlled formation and morphogenesis of hierarchical composite nanomaterials. A combination of *in situ* imaging and molecular simulations were used to elucidate the principles underlying peptoid-controlled inorganic crystallization with the ultimate goal of enabling predictive materials synthesis across scales.

**Freeze Casting Peptide-Enabled Biomaterials for Tissue Regeneration** Ulrike G. K. Wegst; Northeastern University, United States

While considerable progress has been made over the past years and decades, the challenge persists to synthesize, ideally off-the-shelf materials and scaffolds, with structural, mechanical, and chemical cues akin to the natural tissue or custom- designed for a desired regenerative outcome. Freeze casting permits to manufacture such complex, hybrid materials with excellent control of structural and mechanical properties. As a cold process, freeze casting additionally offers several pathways to introduce what could broadly be called chemical cues such as growth factors, viral vectors and peptides at several processing steps to enhance the functional properties of the final biomaterial. Chemical cues can be introduced already before the freeze casting step through peptide loading and peptide-functionalized components, such as collagen, chitosan, and nanocellulose for soft and hydroxyapatite and tricalcium phosphate for hard tissues, for example. Alternatively, the hierarchical architecture of the freeze-cast scaffolds can be modified with peptides or peptide-enhanced entities once the structure has been ice-templated and lyophilized (freeze-dried). Freeze casting and related manufacturing techniques therefore hold great promise for the manufacture of peptide-enabled biomaterials.

#### 9:30 AM SB03.04.04

**Biomimetic Strontium Sulfate Mineralization Studied by Multiscale Microscopy and Vibrational Spectroscopy** Andrienne Martin<sup>1</sup>, Jordan Hachtel<sup>2</sup>, Oliver Wang<sup>1</sup>, Dawn M. Raja Somu<sup>1</sup>, Steven A. Soini<sup>1</sup>, Diannelle Lacambra-Rivera<sup>1</sup> and Vivian Merk<sup>1</sup>; <sup>1</sup>Florida Atlantic University, United States; <sup>2</sup>Oak Ridge National Laboratory, United States

In the present study, we investigated the in-vitro crystallization of strontium sulfate (celestite, SrSO<sub>4</sub>) in the presence of organic matter, including the synthetic polymer poly(sodium 4-styrenesulfonate), the poly amino acid poly(L-glutamic acid), the polysaccharide poly(galacturonic acid) and the amino acid L-aspartic acid. In nature, biogenic SrSO<sub>4</sub> occurs in the skeleton of the unicellular plankton organisms Acantharia<sup>[3], [4]</sup>. These biomineral model systems closely mimic fundamental interactions between mineral and organic matrix in living organisms, while eliminating the complexity and heterogeneity associated with biological systems. This investigation enabled a focused fundamental investigation of SrSO<sub>4</sub> crystallization across multiple length scales, as biologically grown minerals often contain a variety of organic molecules in small weight percentages as well as considerable amounts of foreign ions, such as magnesium, which complicate data interpretation<sup>[1], [2]</sup>. Even though all studied biomolecules were included into the growing crystals in high weight percentages, poly(L-glutamic acid) had the most profound impact on crystal morphology. Using Scanning Electron Microscopy and Atomic Force Microscopy, we observed mesocrystalline features on the crystal surface, which are consistent with biomolecule incorporation. Apart from studying the chemistry of the nanocomposites using bulk infrared spectroscopy, we discerned intracrystalline organics at the nanoscale using monochromated Electron Energy-loss Spectroscopy in the Scanning Transmission Electron Microscope<sup>[5], [6]</sup>. By screening the organic-biomineral model systems with synchrotron X-ray powder diffraction<sup>[1], [2]</sup>, we quantified the degree of internal residual strain resulting from biomolecules with diverse functional group chemistry.

**Emulating Nature's Way of Making Materials** James J. De Yoreo<sup>1,2</sup>; <sup>1</sup>Pacific Northwest National Laboratory, United States; <sup>2</sup>University of Washington, United States

From harvesting solar energy to capturing CO<sub>2</sub> to purifying water, living organisms have solved some of the most vexing challenges now faced by humanity. They have done so by creating a vast library of proteins and other macromolecules that can assemble into complex architectures and direct the mineralization of inorganic components to produce materials characterized by a hierarchy of structure. While the high information content contained within the intricate sequences of the proteins is crucial for accomplishing these tasks, self-assembly and mineralization are nonetheless constrained to proceed according to the physical laws that govern all such processes, even in synthetic systems. An understanding of the mechanisms by which biological systems successfully manipulate those laws to create hierarchical materials would usher in an era of materials design to address our most pressing technological challenges. In this talk, I will present the results of recent research using in situ atomic force microscopy and in situ transmission electron microscopy to directly observe interfacial structure, protein self-assembly, and nanocrystal formation in biomolecular and biomimetic systems, including protein-directed nucleation of calcium carbonate and calcium phosphate and surface-directed nucleation of two-dimensional protein assemblies. The results elucidate the mechanisms by which the interface between biomolecules and materials directs nucleation, self-assembly and crystal growth, leading to unique materials and morphologies. The results reveal the importance of surface charge, facet-specific binding, solvent organization, and, more generally, the balance of protein-substrate-solvent interactions in determining how organized materials emerge in these systems.

#### 10:45 AM SB03.04.06

**Degradation of Natural Molecules on Mineral Surfaces** Colin Freeman<sup>1</sup>, Bia Fonseca<sup>2</sup>, Matthew Collins<sup>2,3</sup> and Karina Sand<sup>2</sup>; <sup>1</sup>University of Sheffield, United Kingdom; <sup>2</sup>University of Copenhagen, Denmark; <sup>3</sup>University of Cambridge, United Kingdom

Molecular binding at material interfaces is vitally important within a range of contexts. When a molecule has bound to a surface its structure and that structure of the local solvent can be very different to that in solution which can change its functionality and reactivity. In biology deamidation and hydrolysis are two very common processes to break up peptides and both dependent on water molecules; therefore understanding the behaviour of the solvent molecules is equally important as that of the biologically active binding molecule. These decay processes are very important in a range of scientific fields including archaeology, palaeontology and surface fouling. Peptides extracted from archaeological digs can be used to indicate the diet and patterns of

early humans, while DNA and proteins can be used to provide information on evolution in the fossil record.

We present a combined molecular dynamics and atomic force microscopy study on the binding of biological relevant molecules to calcite mineral surfaces. Our study examines and identifies the key factors involved in the binding of these molecules to the surfaces. We then explore the structural changes in these molecules and how this exposes/shields them from reactive processes that could lead to their decay. Finally we examine the behaviour of the other reactant species (solvent) and determine the role of the surface in enhancing or hindering their contribution to degradation reactions [1]. With this information we are able to comment on recent experimental findings and the potential preservation of different biological molecules.

**Multiplexed Breath Biopsy of Lung Disease by Controlled Chemical Signal Activation** Shih-Ting Wang, Melodi Anahtar, Daniel Kim, Tahoura Samad, Cathy Wang, Sahil Patel, Chayanon Ngambenjwong, Jesse Kirkpatrick, Heather Fleming and Sangeeta Bhatia; Massachusetts Institute of Technology, United States

Breath testing is a fast, non-invasive diagnostic method that can link specific volatile organic compounds (VOCs) in exhaled breath to medical conditions. Complementary to blood and urine assays in clinical disease diagnosis, breath is an informative analyte that can provide real-time information of changes in the body's metabolome affected by disease activity. However, few breath tests are currently used in the clinic to monitor disease due to bottlenecks in biomarker identification and differentiation of endogenous VOCs in complex breath signatures. One approach to overcome this challenge is the in vivo administration of orthogonal exogenous agents with controlled properties that can be expelled from breath upon being metabolized by disease-specific molecular processes. Exogenous agents have been used in clinical breath tests for gastrointestinal and liver diseases and are more recently developed for respiratory disease. As the direct source of breath, the lungs are particularly suited for enzymatic activity-based breath tests. The multiplexed capabilities of designing reliable in vivo probes that release detectable and distinguishable exogenous VOCs are still in the early stages. Here, we report engineered breath biomarkers by protease-sensing nanoparticles for multiplexed detection of dysregulated activities of pulmonary proteases in response to disease and produce volatile reporters that can be detected in the exhaled breath. We show that the nature of proteolytic hydrolysis generating peptide fragments can be engineered to activate and release various types of volatile reporters. Using viral infection and *Alk*-mutant lung cancer mouse models, we show that multiplexed volatile-releasing activity-based nanosensors (vABNs) can detect and dynamically monitor diseases and treatment response.

### 1:45 PM SB03.05.02

**Peptide-Functionalized Graphene Sensors for Selective Odorant Detection** Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Gas sensing based on graphene field-effect transistors (GFETs) has gained broad interest due to their high sensitivity. Further progress in gas sensing with GFETs requires the detection of various odor molecules for applications in environmental monitoring, healthcare, food, and cosmetic industries. To establish an artificial sense of smell with electronic devices by mimicking olfactory receptors, it is desirable to use synthetic molecules with similar functionality. In this work, we designed three new peptides based on a motif sequence in olfactory receptors. These peptides were designed to have two domains: a bio-probe specific to the target molecules and a molecular scaffold [1,2]. The scaffold peptides have the ability to self-assemble into a molecular thin film on GFETs [3].

To demonstrate the biosensing capabilities, we employed limonene, methyl salicylate, and menthol as representative odor molecules of plant flavors. We investigated the conductivity change of GFETs upon binding to odor molecules at various concentrations. The dynamic response of the sensors revealed distinct signatures for each of the three different peptides against individual target molecules. The kinetic response of each peptide exhibited characteristic time constants in the adsorption and desorption processes, which were further supported by principal component analysis. These results demonstrate the selectivity of the designed peptides in detecting odor molecules.

The development of graphene odor sensors using these designed peptides paves the way for future peptide-array sensors with multiple sequences, enabling the realization of an odor-sensing system with higher selectivity. Combining the bio-probe and electrical signal amplification functions, the peptide layer on graphene represents a novel and effective strategy for achieving selective odorant detection under normal atmospheric conditions. This research contributes to the advancement of biomimetic devices and holds potential for various applications in odor detection and identification.

This work was supported by the Cabinet Office (CAO), Cross-ministerial Strategic Innovation Promotion Program (SIP), "Intelligent Processing Infrastructure of Cyber and Physical Systems" (funding agency: NEDO).

### 2:00 PM SB03.05.03

**Polymorphs of Short-Sequence Peptoid Assembly on MoS<sub>2</sub>** Shuai Zhang<sup>1</sup>, Chun-Long Chen<sup>2</sup> and James J. De Yoreo<sup>2</sup>; <sup>1</sup>University of Washington, United States; <sup>2</sup>Pacific Northwest National Laboratory, United States

Peptoid is a biomimetic polymer inspired by peptide, with compatible bio-functions but better thermal and chemical stabilities. It has unique capabilities for creating hierarchical assemblies at solid-liquid interfaces, serving as templates for convincing applications in molecular recognition, fabrication of bio-hybrid materials, (bio)mineralization, energy conversion, storage, and transportation of matter and information, etc.

Recently, we designed short peptoid sequences with assembly capabilities on MoS<sub>2</sub>. Using substrates with different hydrophobicity and adjusting the sizes

of peptoid hydrophobic side chains and the dehydration process, we demonstrated that the peptoid assembly on MoS<sub>2</sub> could have diverse phases, including the monolayer hybrid film with high crystallinity, vesicles, lamella, and single-/multi-strands. We further resolved that these phases can co-exist in a complicated phase diagram and can go through phase transitions between each other. Specifically, the peptoid-peptoid interaction, peptoid-solvent interaction, and peptoid-MoS<sub>2</sub> interaction, mediated by pH, play crucial roles in this polymorph assembly. These results improve the knowledge of designing hierarchical architectures with biomolecules at solid-liquid interfaces. It also provides opportunities to optimize the future performance of 2D van der Waals materials-based devices.

#### 2:15 PM \*SB03.05.04

**Subnanoscale Imaging of Nano-Bio Interfaces by 2D and 3D AFM Imaging Techniques** Takeshi Fukuma; Kanazawa University, Japan

Atomic force microscopy is a powerful technique that can visualize atomic- or molecular-scale structures, dynamics and properties even in liquids regardless of the conductivity of the sample. In the past decade, there has been significant advancement in the in-liquid AFM techniques. Owing to the development of low noise cantilever deflection sensors[1] and small amplitude operation mode, atomic or molecular resolution can be achieved routinely even with dynamic-mode AFM such as frequency modulation[2] and amplitude modulation AFM (FM- and AM-AFM). This allowed us to visualize subnanoscale surface structures of various biological samples[3]. In addition, the tip scanning scheme has been expanded from 2D to 3D[4] and now we can visualize the 3D distribution of water (i.e., hydration structures), organic solvents, ionic liquids and flexible molecular chains[5-7]. These unique capabilities should be particularly useful in the studies of nano-bio interfaces, where biomolecules, water and ions interact with each other to induce various biological phenomena. However, their applications to the studies on biomaterials have yet been limited. In this presentation, I would like to present our recent works to explore applications of high-resolution in-liquid AFM techniques to studies on nano-bio interfaces. Examples include molecular-scale investigations on cellulose[8] and chitin[9] nanocrystals and self-assembled structures of short peptides on graphite[10].

**Atom-Condensed Reactivity Descriptors for the Prediction of Biomaterials Degradation** Isaac Vidal-Daza<sup>1,2</sup>, Anna Bachs-Herrera<sup>1</sup> and Francisco Martin-Martinez<sup>1</sup>; <sup>1</sup>Swansea University, United Kingdom; <sup>2</sup>University of Granada, Spain

Nature has been traditionally mimicked in the design of biomaterials for her capacity to achieve performance, but not that often for her ability to degrade at the end of life. To design materials for degradation as well as performance, molecular degradation needs to be better modelled. Degradation is a complex phenomenon largely dependent on the molecular system, the environmental conditions, and the timescales being considered. A common factor in the degradation process is molecular reactivity, which can be predicted using conceptual density functional theory (DFT). Conceptual DFT reactivity descriptors either quantify the global tendency of a molecule to engage in chemical reactions or the areas of the molecule that would undergo such engagement, but these global and local reactivity descriptors are usually detached. Atomic reactivity is not usually quantified in relation to the global molecular reactivity, and it limits our ability to accurately predict degradation. In fact, quantifying the reactivity of any individual atom within the global reactivity of a molecule, is not a trivial task, and it requires the conjunction of different theories in the framework of quantum chemistry. In this work, we combine a topological analysis of the electron density with a non-arbitrary partition of the molecular space into atomic domains to define topology-based atom-condensed reactivity indexes to predict molecular degradation. High-throughput calculations of these *ab initio* atom-condensed reactivity descriptors enabled the analysis and identification of existing patterns among data, which provides a better understanding of molecular reactivity, and the definition of new indexes that describe the local reactivity of individual atoms, in the global reactivity of target molecules. The data generated can be used to train machine learning (ML) models that predict molecular and biomaterials degradation.

**Peptide Designs for On-Demand Multifunctional Surface Functionalization** Nurit Ashkenasy; Ben Gurion University of the Negev, Israel

The development of high-performance devices demands tailoring the properties of surfaces and interfaces of materials. The control of surface properties can be achieved by attaching organic monolayers to the surface. In this talk, I will discuss the design of peptide-based functionalization layers and show that such functionalization layers exploit unique properties of proteins including diversity, modularity, and multi-functionality. Hence, open the way to design highly tunable and smart surfaces.

In the first part of the talk, I will demonstrate the use of surface binding peptides (SPBs) to tailor the electronic properties of surfaces. The effect of peptide side chains and their backbone connectivity and folding state on the resulting electronic properties will be discussed. I will further show that SPBs can be used to template syntheses of thin films with specifically tailored surface properties in an environmentally friendly approach. The use of such films for volatile organic compound sensing will be demonstrated.

The utilization of the unique properties of peptides for the development of programmable surfaces will be demonstrated in the second part of the talk. I will present the design of a coiled-coil peptide system in which folding and chemical reactivity is responsive to external stimuli. The responsivity of the system facilitates the ability to control the binding of the peptides to the surface and/or their folding state, which affects the surface's physico-chemical properties in a reversible manner. These smart dynamic surfaces enable the realization chemically induced computation elements using the surface properties as the readout. The feasibility of applying this approach in biosensing will be demonstrated.

Overall, our work provides a sophisticated surface engineering approach, based on peptide sequence design, which can be utilized in diverse electronics, biotechnology, and medical applications.

**Complex Biomechanics: From Atoms to Patients** Christian Hellmich, Johannes Kalliauer, Niketa Ukaj and Stefan Scheiner; TU Wien - Vienna

University of Technology, Austria

Complex systems are characterized by an overall behavior which is different from that of the components making up the systems - hence, (nonlinear) interactions between the components play a very important role. Taking an interdisciplinary approach rooted in theoretical and applied mechanics and engineering mechanics, we report on two types of recently studied systems where individual system components (atoms and patients) interact in a way which unfolds very interesting emerging patterns that can be mathematically quantified through concepts arising from (bio-)mechanics: (i) the interaction of atoms within a short thread of DNA, which, as a compound, result in a family of a highly nonlinear beam structures with varying, but always coupled torsion-stretching modes [1]; (ii) the compliance of sets of patients to the lethal effect of SARS-COV-2 [2,3], which follows integro-differential equations reminiscent of those introduced by Boltzmann in the context of creep (or hereditary) mechanics [4]. We conclude that smart classical concepts of applied mechanics and physics continue to show an unparalleled potential for solving pressing global problems in the context of computational modelling of living systems.

**Breast Cancer Detection using Shear Assay Based Creep Compliance and Functional Principal Component Analysis** Jolene Cao<sup>1</sup>, Killian Onwudiwe<sup>2</sup>, Jingjie Hu<sup>3</sup>, Meenal Datta<sup>2</sup> and Winston O. Soboyejo<sup>1</sup>; <sup>1</sup>Worcester Polytechnic Institute (WPI), United States; <sup>2</sup>University of Notre Dame, United States; <sup>3</sup>North Carolina State University, United States

This presents the mechanical responses of live cells that are subjected to shear flow in micro-fluidic channels under *in-situ* observation with optical, fluorescence, and confocal microscopy. The resulting time-dependent deformation of points within the cells is analyzed using Digital Image Correlation (DIC) techniques. These are used to extract deformation and strain maps of the nuclei, cytoplasm, and actin cytoskeletal structures at different stages of cell viscoelastic deformation. The measured temporal variations in strain are analyzed using Functional Principal Component Analysis (FPCA) approaches (from data science) that use time series data to extract critical features from the *in-situ* temporal creep responses of cells subjected to shear stress. Differences in the creep responses of the nuclei and cytoplasm are elucidated along with the local creep properties of the actin cytoskeletal structures of non-tumorigenic breast cells (MCF-10A), less metastatic triple-negative breast cancer (TNBC) cells (MDA-MB-468), and highly metastatic breast cancer cells (MDA-MB-231). The implications of the results are also discussed for the detection of non-tumorigenic and tumorigenic breast cells at different stages of cancer progression.

**Keywords:** breast cancer detection, micro-fluidics, shear assay creep compliance, functional principal component analysis, time series data, cell nuclei, cytoplasm and cytoskeletal structures.

**Deep Learning-Assisted Sensitive Detection of Fentanyl using a Bubbling-Microchip** Hui Chen, Sungwan Kim, Joseph Hardie, Prudhvi Thirumalaraju, Manoj Kanakasabapathy and Hadi Shafiee; Brigham and Women's Hospital, United States

Deep learning-enabled smartphone-based image processing has significant advantages in the development of point-of-care diagnostics. Conventionally, most deep-learning applications require task specific large scale expertly annotated datasets. Therefore, these algorithms are oftentimes limited only to applications that have large retrospective datasets available for network development. Here, we report the possibility of utilizing adversarial neural networks to overcome this challenge by expanding the utility of non-specific data for the development deep learning models. As a clinical model, we report the detection of fentanyl, a small molecular weight drug that is a type of opioid, at the point-of-care using a deep-learning empowered smartphone assay. We used the catalytic property of platinum nanoparticles (PtNPs) in a smartphone-empowered microchip bubbling assay to achieve high analytical sensitivity (detecting fentanyl at concentrations as low as 0.23 ng/mL in phosphate buffered saline (PBS), 0.43 ng/mL in human serum and 0.64 ng/mL in artificial human urine). Image-based inferences were made by our adversarial-based SPyDERMAN network that was developed using a limited dataset of 104 smartphone images of microchips with bubble signals from tests performed with known fentanyl concentrations and using our retrospective library of 17,573 non-specific bubbling-microchip images. The accuracy ( $\pm$  standard error of mean) of the developed system in determining the presence of fentanyl when using a cutoff concentration of 1 ng/mL, was 92.66 $\pm$ 0.3% in human serum (n=100) and 94.66 $\pm$ 1.2% in artificial human urine (n=100).

**Euglena gracilis-Derived Extracellular Vesicles as a Natural Immune Modulator** Saetbyeol Jeon, Hwira Baek and Jin Woong Kim; Sungkyunkwan University, Korea (the Republic of)

Since extracellular vesicles (EVs) possess the same cell therapeutic effect due to its similar characteristics to parent cells, they have emerged as an attractive alternative to cell therapy. Taking advantage of this, a variety of EVs have been developed for tissue regeneration, anti-cancer immunotherapy, and intractable disease treatment. In terms of therapeutic application, microalgae-derived EVs has been of great interest because they contain unique physiologically active substances such as polysaccharides, minerals, vitamins and amino acids. However, most microalgae cells are structured with a strong cell membrane which is not easily cleaved and recombine to form EVs. The derivation of EVs from *Euglena gracilis* (EG), a microalgae species, warrants special attention due to its relatively flexible cell membrane. Moreover, it can be cultivated in substantial quantities, providing a valuable resource for production purpose while mitigating the risk of viral infection. In this study, we introduce an EG-derived EV (EV<sub>EG</sub>) system with an enhanced immune performance.  $\beta$ -1,3-glucan, which is specifically accumulated in EG cells, is a representative substance that activates natural killer cells and macrophages to enhance natural immunity. To efficiently deliver  $\beta$ -1,3-glucan present in the EG to immune cells, the EV<sub>EG</sub> are fabricated by cell extrusion method that

can convert cells into vesicles by sequentially passing several micro-sized pores. Basically, the endocytosis mechanism study on the  $EV_{EG}$  exhibited notable cellular uptake compared to  $\beta$ -1,3-glucan only. We verified that the  $EV_{EG}$  fabricated in this study notably stimulated the mitogen activated protein kinase (MAPK) pathway, resulting in release of inflammatory mediators such as nitro oxide, cyclooxygenase-2 (COX-2) and pro-inflammatory cytokines. The expression level of these immune factors was appropriately leveled to strengthen the immune system, not excessively inducing immune response such as cytokine storms. We also showed that the -1,3-glucan encapsulated in the  $EV_{EG}$ , like other polysaccharides, was readily recognized by receptors such as Dectin-1 and TLR4 present on immune cell membranes. These results highlight that our  $EV_{EG}$  immunomodulatory system has potential for health promotion and disease treatment in various biomedical applications.

**Deep Learning-Assisted Nanoplasmonic Digital Immunoassay for Cytokine Profiling in Immune-Suppressed Patients using Designed Peptide Aptamers** Shuai Wu, Lang Zhou and Pengyu Chen; Auburn University, United States

Cytokine profiling in immune-suppressed patients plays a critical role in understanding their immune status and evaluating the effectiveness of immunomodulatory therapies. However, current immunoassay technologies face challenges in achieving rapid and accurate detection of multiple cytokines over a wide dynamic range. In this study, we propose a novel approach that combines deep learning with a nanoplasmonic digital immunoassay using rationally designed peptide aptamers as probes.

The immunoassay system exhibits three notable features: (i) a simplified high-throughput biosensing chip fabrication process, (ii) an ultrasensitive nanoplasmonic digital imaging technique employing 50nm gold nanocubes (AuNCs) conjugated with antibody-mimicking peptide aptamers as detection probes, and (iii) a rapid and precise deep learning-based image processing method for digital signal analysis.

By utilizing our developed immunoassay, we successfully achieved cytokine profiling with a wide working range of 0.1-10,000 picograms per milliliter (pg/ml) and exceptional detection limits in the femtogram range. This level of sensitivity enables the accurate detection of even trace amounts of cytokines, critical for monitoring immune-suppressed patients.

Our findings demonstrate that this deep learning-assisted nanoplasmonic digital immunoassay, utilizing designed peptide aptamers, holds great potential for precise cytokine profiling in immune-suppressed patients. This innovative approach may contribute to improved clinical outcomes and informed treatment decisions for individuals with rapidly inflammatory disorders and immune suppression.

#### 8:00 PM SB03.06.05

**Electrochemical Activity of Molecular Hybrids: Self-Assembly of (XH)<sub>4</sub> Peptides and Hemin on Graphite Electrodes** Marie Sugiyama, Wei Luo and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

The development of artificial enzymes has gained interest in electrochemical biosensors because natural enzymes have a relatively short lifetime and high cost for practical applications. Peptides with a small number of amino acids compared with proteins can be synthesized and chemically stable, thus they can be a good candidate as an artificial enzyme. Short-chain peptides that self-assemble into fiber-like structures in liquid are known to be catalytically active by forming complex structures with cofactors [1]. These catalytically-active peptides often contain histidine, which plays a role in stabilizing the structure and coordinating with cofactors at the imidazole group on the side chain, enhancing the catalytic activity. In our previous work, we found that catalytic peptides containing histidine exhibited their self-assembly on graphite surfaces and revealed electrocatalytic activity combined with the coenzyme hemin [2]. More recent work showed that newly-designed peptides (XH peptides) consisting of a repeating structure of two amino acids with histidine and another amino acid, "X", also exhibited self-assembly on graphite surfaces. These peptides are a useful tool for understanding the role of the counter amino acid X on their surface self-assembly and in tuning the hydrophobicity of the graphite surface [3].

However, the capability of this XH peptide to immobilize cofactor hemins has not yet been investigated. In this study, we studied the interaction between hemin and the (XH)<sub>4</sub> peptide on the surface of a graphite electrode by atomic force microscopy (AFM). Three counter amino acids, tyrosine (Y), valine (V), and leucine (L), were employed as counter amino acids X for this study, e.g. YHYHYHYH. AFM showed that each peptide formed uniform linear structures with a height of a few nanometers. They also showed a hexagonal symmetry on the graphite surface, which is commensurate with the lattice structures of graphite. When the cofactor hemin was added, dot-like structures with a height of 0.5 nm~1 nm appeared on the peptide nanowires. The peptide with the highest number of particles on the peptide and the smallest particle size was LH<sub>4</sub>, followed by VH<sub>4</sub> and YH<sub>4</sub>. Assuming that the particles on the wire were hemins, the XH peptide can be a suitable scaffold for immobilizing hemin. We also performed the electrochemical measurement to evaluate the hydrogen peroxide reduction capacity of the prepared XH peptide-hemin electrodes, and it was found that these peptides with a simple sequence of XH have enzymatic activity. The observations implied that the activity is closely related to the interactions with the hemin and peptides regarding the surface density of the immobilized hemins and their structural stability.

**Graphene Biosensors for Probing Molecular Interactions of Peptides and RNA Forming Liquid-Liquid Phase Separation** Kantarō Kikuchi, Yui Yamazaki and Yuhei Hayamizu; Tokyo Institute of Technology, Japan

Amyotrophic lateral sclerosis (ALS) is a fatal motor neuron disease affecting both upper and lower motor neurons. Frontotemporal dementia (FTD) is a type of brain disorder with degeneration of the frontal and temporal lobes of the cerebrum. These neurodegenerative diseases share the expansion of GGGGCC hexanucleotide repeats in the C9orf72 gene, identified as a major cause of the diseases [1]. The gene produces dipeptide repeats proteins (DPRs) that cause cell death. These peptides contained arginine (Arg) and counter amino acid in the dipeptide sequence and were found to form liquid-liquid phase separation (LLPS), closely related to their cytotoxicity. A previous report indicated that poly-R is highly charged and interacts with anionic molecules such as RNA but exerts no cytotoxic effect. Poly(PR) and poly(GR), on the other hand, entraps proteins via multivalent interaction in LLPS, impairing protein translation. Thus, it is known that the position of Arg in DPRs profoundly affects the interaction [2]. These findings indicate that the interactions between DPRs and RNA should be unique to form LLPS and entrapment the proteins. However, the understanding of the interactions of DPRs is still limited because of the lack of measurement techniques that can distinguish the weak interactions among them.

In this study, we applied graphene field effect transistors (GFETs) to evaluate the biomolecular interactions. Graphene has excellent electrical properties and high specific surface area and has recently shown promise as an ultra-sensitive biosensor. The interaction between biomolecules in the vicinity of the graphene surface can be detected as an electrical conduction change of graphene. We immobilized RNA on the graphene surface via pyrene anchors, as same in other works, and measured the interactions of RNA with DPRs known to form LLPS. The interactions are measured by incubating the DPRs of interest across the RNA-functionalized surface. Atomic force microscopy (AFM) was used to ensure these surface modifications. In electrical measurements, the peptides interacting with the RNA were quantified by the shift of the charge-neutral points in their gate responses of GFETs, and differences in interactions due to peptide species were discussed. From the results, we succeeded in detecting the difference in interaction with RNA by peptide species with high sensitivity at the nano-molar level. We believe that this result is helpful in quantitatively discussing the effect of small amino acid

domains of biomolecules on LLPS droplet formation, an event that occurs on a microscopic scale.

**Layer-by-Layer Nanoparticles for Dexamethasone Targeted Delivery to Hematopoietic Progenitor Cells** Alfonso Restrepo<sup>1</sup>, Tamara Dacoba<sup>2</sup> and Paula T. Hammond<sup>1,2</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Koch Institute for Integrative Cancer Research, United States

Acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) have particularly dismal patient outcomes, with low 5-year survival rates in adult patients. Outcomes in pediatric patients are more optimistic, mainly due to their ability to withstand more aggressive treatment regimens. Glucocorticoids, although used as a standard treatment, can have severe adverse effects that limit dosing regimens. To address these challenges, directing drugs to hematopoietic progenitor cells implicated in these leukemias via targeted drug delivery therapies would allow for more aggressive and effective treatments, with reduced side effects. Layer-by-layer (LbL) nanoparticles (NPs) are a modular drug delivery system that enables the incorporation of a wide range of charged polymers on the surfaces of a drug-loaded NP core, to tune surface properties, targeting capacity, and biodistribution of NPs. The outer polymers can also be used as scaffolds to conjugate molecules, like antibodies, to aid in targeting drugs to cells of interest. In this work, we developed LbL NPs with dexamethasone loaded in the liposome core and functionalized them with polymers and antibodies to evaluate their targeting capacity to hematopoietic stem and progenitor cells (HSPCs) implicated in AML and ALL.

Dexamethasone palmitate (DXP) was incorporated as part of the lipid bilayer of liposomes using lipid hydration. Drug concentrations were measured via high-performance liquid chromatography (HPLC). Negatively-charged liposomes, empty or encapsulated with DXP, were layered with a cationic polypeptide, followed by a layer of anionic synthetic polymer on top. HSPC-targeting antibodies were then conjugated onto the top polymer layer. NP size and surface charge were monitored throughout the process via dynamic light scattering. NP concentration was determined via fluorescence intensity measurements of dye-conjugated lipids in the liposomal core. A biconchonic acid (BCA) assay was used to assess antibody concentration after purification. NP-cell association studies were conducted via fluorescence-activated cell sorting (FACS).

Antibodies were successfully conjugated to the NPs, with no notable impact on their physicochemical properties when measured over a 2-month period. Furthermore, antibody-functionalized LbL NPs demonstrated preferential association with a relevant myeloid progenitor-like cell line (ER-HOXB8), following 90-minute incubation. In fact, two candidate antibodies had a 1.5-fold increase in NP-cell association compared to unconjugated LbL NPs. For DXP-loaded NPs, it was found that the presence of the drug in the liposomal core had minimal impact on the stability of the NP throughout the layering process, with negligible changes in drug loading. Preliminary longitudinal studies found that the presence of the drug had no notable impact on the colloidal stability of the LbL NPs.

Overall, we have shown that LbL NPs can be functionalized with HSC-targeting antibodies, with a preferential association to relevant cell lines, and that the LbL construction of NPs is unhindered by the presence of DXP in the core. Future work would involve combining the drug-loaded NPs and functionalizing them with the candidate antibodies to ensure that similar preferential association is observed in relevant *in vitro* and *in vivo* models of acute leukemias.

#### 8:00 PM SB03.06.09

**A Molecular Dynamics Investigation of Synthetic Collagen Thermal Properties** Marc Duchatelier and Kristen Rhinehardt; North Carolina Agricultural and Technical State University, United States

Composite biomaterials have been used for various medical applications as they contain specific physical, chemical and mechanical attributes while evading rejection by the body and encouraging proper function. One common material used for such function is collagen. As a triple helical, extracellular matrix (ECM) protein it constitutes approximately 25% of the total dry weight of mammals. The thermal properties of collagen can vary (320-370K) depending on the source, which impacts its physical properties, assembly, and stability. The social, physical, and financial expense of obtaining collagen, as its traditionally harvested from animals, has led to a need for synthetic collagen-like peptides. Synthetic collagen has a greater versatility due to their customizability, but a thorough investigation of their physical, and thermal properties as well as their binding capabilities must be completed prior to their production or use. This can be done by using computational modeling. In this study, we use molecular dynamics modeling to explore the structure and physics of synthetic collagen 1K6F in a solvent environment in response to thermal alterations. Simulations of 2 and 4 peptides showed a notable influence of structural orientation of the strands. Visual analysis of the simulations showed interactions between the strands at low temperatures with some structural disturbance at after 330K. The radius of gyration (R<sub>g</sub>) showed the backbone of the molecule start to fold over time around 20 ns. Further an exploration of the Radius of Fluctuation showed varying wave patterns with amplitudes between 1.5 and 7.5 nm. However, a sinusoidal behavior was noticeable at 320 and 330K indicating a possible transition point. The observed sinusoidal waveform in the atomic fluctuation can be ascribed to the thermal influences within the system. We found that a higher number of hydrogen bonds appear at low temperature as there was increased interactions below 320K, but the peptides appear to go to the process of denaturation as temperature increase to 340K. Furthermore, the assembly behavior and protein binding sites were analyzed through composite simulation of silk and collagen. Our results highlight that the interaction strength of synthetic collagen with silk depends on the proportion of collagen within the system.

#### 8:00 PM SB03.06.10

**Enhanced Detection of Influenza Virus by Viral Membrane Fusion with Membrane Rigidity Modulation of Sialic Acid-Expressing Liposomes** Hongjun Park<sup>1</sup>, Chaewon Park<sup>1</sup>, Geunseon Park<sup>1</sup>, Jong-Woo Lim<sup>2</sup>, Sojeong Lee<sup>1</sup>, Soohyun Chung<sup>1</sup>, Eunjung Kim<sup>3</sup> and Seungjoo Haam<sup>1</sup>; <sup>1</sup>Yonsei University, Korea (the Republic of); <sup>2</sup>Seoul National University, Korea (the Republic of); <sup>3</sup>Incheon University, Korea (the Republic of)

Specific interactions between viruses and host cells provide essential insights into materials science-based strategies to deal with emerging viral diseases. In several viral families, pH-triggered viral fusion is universal and important for understanding the viral infection cycle. Inspired by this process, virus detection has been achieved using nanomaterials with host-mimetic membranes that allow interaction with amphiphilic viral haemagglutinin fusion peptides. Most research has focused on the design of functional nanoparticles with fusogenic capability for virus detection, and there has been little exploitation of membrane rigidity to alter the ability of nanoparticles to interact with the viral membrane and improve their sensing performance. In this study, a homogeneous fluorescent assay using sialic acid-expressing liposomes with tunable responsiveness to external stimuli is developed for the rapid and straightforward detection of an activated influenza A virus. Membrane fusion between the liposome and virus can be easily controlled by varying the membrane rigidity, which is determined by the cholesterol ratio, resulting in fluorescent signals within 30 min and detection of several influenza viruses, including H9N2, CA04(H1N1) and H4N6. Therefore, the designs demonstrated in this study propose underlying approaches to utilize engineered liposomes by modulating their membrane rigidity for the direct and sensitive identification of infectious viruses.

**8:00 PM SB03.06.11****Biomimetic Synthesis of ZnO Thin Films** [Ivan A. Melara](#), Jean-Edward Moise and Kristen Siaw; Gordon College, United States

Biomimetic reaction systems, where small proteins and peptides assist in the growth of inorganic materials, has the potential for making complex structures that are otherwise difficult to achieve. Living organisms use a peptide-inorganic matrix to control the morphology of the inorganic structures. Using this method as inspiration we sought a similar approach for novel materials. Zinc oxide as chosen as the target material due to its many exciting optoelectrical properties. Phage display was performed on ZnO sample and used to identify small peptides with high binding affinity for ZnO. By means of an aqueous based synthesis, these high affinity peptides were added at various concentrations to the solution so growth of the ZnO crystals could occur in the presence of the peptides. In the absence of peptides, the ZnO grows with a long needlelike morphology. When peptides are added to the growth solution they are found to dramatically alter the final morphology of the ZnO substrates. By altering the concentrations of these peptides, the morphology of ZnO nanorods can be controlled, ultimately allowing for the formation of thin films. Through the use of these peptides, we form ZnO thin films on a variety of substrates including glass and flexible PET plastic.

**8:00 PM SB03.06.12****Demystifying The Synthesis and Preparation of Protein-Mimicking Random Heteropolymers** [Hao Yu](#), Ivan F. Jayapurna and Ting Xu; University of California, Berkeley, United States

Random heteropolymers (RHPs) with statistically distributed comonomers along the polymer chains are commonly used as functional materials for achieving biomimetic functionality. This is due to their capacity to replicate protein-like phase behavior and functions. However, unlike many branches of chemistry and biology where structures can be constructed precisely on the molecular level, the inherent stochastic nature of monomer sequences in RHPs raises concerns regarding their high material dispersity and difficulties in chemical characterization. Moreover, while extensive research has been conducted on synthesizing and understanding two-monomer systems, there have been limited studies and systematic guidance on the synthesis of multi-monomer copolymers such as RHPs, which involves complex, interdependent reaction kinetics among multiple comonomers. These knowledge gaps present barriers for researchers outside the polymer chemistry community who seek to create protein-mimicking RHPs with targetable structures and properties.

Towards these prospects, here we conduct a comprehensive investigation into the sequence heterogeneity and compositional drift in a family of 4-monomer-based RHPs. We commenced with experimentally determining the relative reactivities of a repertoire of four methacrylate monomers in reversible addition-fragmentation chain-transfer (RAFT) copolymerization. These underlying kinetic factors dictate the sequence heterogeneity of as-synthesized RHPs. Combining with stochastic sequence simulation, we designed four new RHPs, with each ensemble designed to exhibit different levels of hydrophilicity. Of particular interest is our findings that the purification procedures used during RHPs preparation, including pentane precipitation and dialysis against water, can preferentially eliminate different RHP subpopulations. This selectivity can be attributed to the conformations and apparent solubilities exhibited by these subpopulations, which are due to their particular chemical compositions within the whole RHP ensembles. Additionally, we quantitatively mapped out the trajectory of monomer compositions during the whole RHP preparation process. The predicted RHP cumulative compositions are in close agreement with the experimental results. These results validate the fidelity of predictive modeling and multicomponent RHP copolymerization. There are potentially over 300 commodity methacrylate monomers that are available for synthesizing RHPs materials. These findings are readily applicable to study the structure and sequence of heteropolymers beyond those described in this work. Overall, this work provides critically needed information to design and understand RHPs as functional materials while addressing the concerns related to their sequence heterogeneities.

**8:00 PM SB03.06.13****Computational Investigation of Unique Structural Proteins in Cephalopod Skin** [Arsenij P. Panteleev](#)<sup>1</sup>, Christophe Magnan<sup>1</sup>, Pierre Baldi<sup>1</sup>, Alon Gorodetsky<sup>1</sup>, Andrew Cannon<sup>2</sup>, Albert Kwansa<sup>2</sup> and Yaroslava G. Yingling<sup>2</sup>; <sup>1</sup>University of California, Irvine, United States; <sup>2</sup>North Carolina State University, United States

Cephalopods (e.g., octopuses, cuttlefishes, and squids) are renowned for their remarkable dynamic color-changing and camouflaging capabilities.<sup>2,4</sup> These animals possess a skin architecture wherein different cells or organs known as chromatophores, iridophores, and leucophores modulate the transmission, absorption, and/or reflection of light.<sup>2,4</sup> Interestingly, these cells or organs all contain light-manipulating nanostructures composed of unique high-refractive index proteins called reflectins.<sup>2,4</sup> In our previous work, based on a bioinformatics analysis of the 51 reported reflectins, we had designed a truncated reflectin variant and studied the structure and self-assembly of this polypeptide via a combination of computationally driven experimental methods.<sup>6</sup> Subsequently, we had selected a prototypical reflectin isoform and investigated the structure and hierarchical self-assembly of this protein via multiple computational and experimental techniques.<sup>1</sup> Recently, we have extended these studies to other truncated and full-length reflectins, obtaining extensive new fundamental insight into their structures and functionalities.<sup>3,5</sup> When taken together, our experimentally validated computational findings provide additional insight into the camouflage capabilities of cephalopods and suggest new directions for the development of bioinspired optical materials and systems.

SESSION SB03.07: High-Throughput Methodologies and Data Science  
 Session Chairs: Hanson Fong and Christian Hellmich  
 Wednesday Morning, November 29, 2023  
 Hynes, Level 1, Room 101

**8:00 AM SB03.07.01****Bioinspired Cu<sup>II</sup> Defective Sites in ZIF-8 for Selective Methane Oxidation** [Suman Bhaumik](#)<sup>1</sup>, Siriluk Kanchanakungwankul<sup>1</sup>, Ying Yang<sup>2</sup>, Donald G.

Truhlar<sup>1</sup> and Joseph T. Hupp<sup>2</sup>; <sup>1</sup>University of Minnesota, Twin Cities, United States; <sup>2</sup>Northwestern University, United States

Activating the C–H bonds of alkanes without further oxidation to more thermodynamically stable products, CO, and CO<sub>2</sub>, is a long-sought goal of catalytic chemistry. Inspired by the monocopper active site of methane monooxygenase, a Cu-doped ZIF-8 metal–organic framework is synthesized with 25% Cu and 75% Zn in the nodes and activated by heating to 200 °C and dosing in stepwise fashion with O<sub>2</sub>, methane, and steam. We found that it does oxidize methane to methanol and formaldehyde. The catalysis persists through at least five cycles, and beyond the third cycle the selectivity improves to the extent that no CO<sub>2</sub> can be detected. Experimental characterization and analysis were carried out by PXRD, DRUV-Vis, XANES, EXAFS, SEM, and XAS. The reaction is postulated to proceed at an open-coordination Cu<sup>I</sup> site generated by defects, and the mechanism of methanol production was explicated by density functional calculations with the revMO6-L exchange–correlation functional. The calculations reveal a catalytic cycle of oxygen-activated Cu<sup>I</sup> involving the conversion of two molecules of CH<sub>4</sub> to two molecules of CH<sub>3</sub>OH by a sequence of hydrogen atom transfer reactions and rebound steps. For most of the steps in the cycle, the reaction is more favored by singlet species than by triplets. The singlet pathway consists of both closed-shell singlet and open-shell singlet species. The closed-shell singlet calculations were checked for wavefunction stabilities, to ensure the correctness of the calculations. The reaction mechanism along the singlet pathway goes through open-shell singlets until the final step where it passes through a closed-shell singlet transition state to give rise to closed-shell singlet final product, which is a van der Waals complex of Cu<sup>I</sup> and CH<sub>3</sub>OH. This work provides a bioinspired synthesis of a metal-organic framework, whose defective sites carry out selective methane oxidation to methanol. A biomimetic reaction mechanism is postulated and further validated by density functional theory calculations.

**Deep Learning Analysis of Scattered Light Intensity for Shape Classification of Nanoparticles Measured by Nano Tracking Analysis** Keisuke Yamamoto<sup>1</sup>, Hiroaki Fukuda<sup>1</sup>, Hiromi Kuramochi<sup>1</sup>, Yasushi Shibuta<sup>1</sup> and Takanori Ichiki<sup>1,2</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>Innovation Center of NanoMedicine, Japan

Characterizing particles with sizes below 100 nm, such as peptide or protein-based biopharmaceuticals, necessitates single-particle measurement and multi-parametric analysis to distinguish individual particles. Nano Tracking Analysis (NTA) is a widely used technique for single-particle measurement in liquid samples due to its simplicity. By capturing the scattered light from nanoparticles illuminated by laser light, NTA can measure individual particles [a]. To expand the range of evaluable properties, we are exploring the application of deep learning to the analysis of NTA data. Recently, by utilizing deep learning analysis, we have successfully detected the effect of shape anisotropy, demonstrating the potential for multiparametric analysis of nanoparticles in liquids [b]. In this study, to further enhance our understanding of physical properties, we investigate the potential of shape classification using the luminance information derived from light scattering images of particles measured by NTA.

Experiments were conducted using two types of gold nanoparticles: spherical particles with a diameter of 80 nm and rod-shaped particles with a diameter of 40 nm and a length of 180 nm. The NTA method was employed to capture 100 consecutive frames of images at 100 frames per second. From these images, three types of features were extracted as luminance information: scattered light intensity, cross-sectional area of the scattering pattern, and aspect ratio. Subsequently, a dataset was constructed based on these features.

Our deep learning analysis, utilizing a one-dimensional Convolutional Neural Network (1D-CNN) model, successfully learned all the extracted features. The shape classification accuracy using scattered light intensity was found to be 92%, surpassing the 80% accuracy achieved through shape classification based on Brownian motion trajectories. Moreover, even with a limited number of data frames (20 frames), the accuracy for the analysis based on luminance information reached 85%, compared to 60% for the analysis based on Brownian motion trajectories. These results demonstrate the potential of accurately extracting properties in a shorter timeframe using deep learning analysis of scattered light intensity information acquired by the NTA method. In conclusion, our study showcases the effectiveness of employing deep learning analysis of scattered light intensity for shape classification of nanoparticles measured by NTA. This approach not only enhances the accuracy of particle characterization but also reduces the analysis time. The proposed method holds promise for further advancements in the field of nanoparticle characterization and analysis.

**Mineral: Peptide Interactions: Using Our Understanding of Molecular Interactions to Develop a Time Efficient Biopanning Approach** Carole C. Perry and Valeria Puddu; Nottingham Trent University, United Kingdom

Minerals and biomolecules can interact via a range of binding modalities from electrostatic interactions, through hydrogen bonding to hydrophobic interactions and van der Waals interactions. These binding possibilities lead to a range of biomolecule sequences that can interact with a particular mineral. From our understanding of peptide-mineral interactions gained by extensive, detailed experimental and computational studies we have developed an optimised biopanning approach, utilising multiple chemical eluants that allows the identification and recovery of a wide mineral binder pool in just one or two biopanning rounds.

**A Dynamics-Informed Approach to Prediction of Protein Melting Temperature via Graph Neural Networks** Yen-Lin Chen and Shu-Wei Chang; National Taiwan University, Taiwan

A practical design of biomedical materials requires knowledge of their thermal properties. Melting temperature has a direct influence on molecular stability, functionality, and performance in the case of protein engineering. For example, biosensors and enzymes will only operate as intended within a limited thermal range. As such, the prediction of the thermostability of proteins is a crucial factor with implications in various scientific disciplines and technical applications. This task requires an understanding of the hierarchical organization of proteins, which manifests in a dynamically coupled cellular system. The introduction of machine learning methods to biology brought about astounding breakthroughs, such as the prediction of protein structures by AlphaFold. It is a promising approach to undertaking convoluted relationships in protein science. In this study, we propose a machine learning method for the computation of the melting temperature of proteins, taking into account the amino acid sequence, protein structure, and dynamics. Graphs (as in graph theory) are chosen as our data representation due to their rotational invariance and their intuitive mapping to molecular structures. The sequential, structural, and dynamical information are represented as multigraphs, with residues as its nodes, and various node features and edge connections derived from each of these properties. To process the data, a graph neural network architecture that makes use of message passing layers was designed to accommodate the multiple types of connections. Protein structures were computed by AlphaFold and the dynamics were computed based on the torsional network model (TNM) for training. Hence, the learned features and parameters can be readily applied to protein sequences without known experimental structure, satisfying the goal of aiding the prediction of design proteins. We are also able to identify key domains that contribute to the thermal stability/instability of proteins by computing the graph regression activation map, which is based on the partial derivative of the predicted value with

respect to features on the input nodes. Our method gives insight into the mechanism of natural proteins and provides critical information regarding design proteins.

**Scientific Analysis of Synthetic Collagen Compounds using Computational Molecular Modeling Methods** Jordanne A. Davenport and Kristen Rhinehardt; North Carolina A&T State University, United States

Scientists have proven that the health regimen you follow can have a significant impact on the human body. Collagen is found on multiple parts of the body such as skin, bones, lymphatic, cardiovascular, liver, lung, spleen, and intestinal tissue. (Spano, 2019) Although it is prevalent that people lose 1% of collagen each year, there is a way to improve this by maintaining a healthy diet. "Collagen-derived dietary proteins are most commonly extracted from porcine skin (45%), bovine hide (30%), and the bones of both animals (23%) Chicken (bones) and fish (scales and bones) byproducts are also used as production sources of collagen-derived dietary protein" (Holwerda and Loon, 2022). In this research, a biomodel of three synthetic collagen molecules is used to bind biomarker properties including Aptamers, CNA, and Silk. Pymol is a molecular visualization tool that provides an ethically pleasing environment for a three-dimensional structure of a protein molecule to be cleaned by removing water, removing repeated molecules, and retrieving the model sequences. The results from PyMOL are then incorporated into the Basic Local Alignment Search Tool (BLASTp) to generate alignments between a protein sequence (Wheeler, Bhagwat, 2007). The binding energy is calculated along with a visual model of the structural changes of the collagens reaction to its biomarker using HDock and PATCHDOCK servers. When docking with PatchDock, the results are collected and refined with a software named FireDock to retrieve the binding energies. The best conformations were compared with differing peptides to see which ligand showed the highest affinity. "While enzyme driven crosslinking plateaus at maturation, connective tissue stiffness has been shown to further increase with age and diabetes. This tissue stiffening has been associated with non-enzymatic, oxidative reactions between glucose and collagen which increases with increased plasma glucose end concentrations associated with advanced aging" (Snedeker, 2014). Further research will utilize molecular dynamics to explore conformational space and explicitly treat structural flexibility and entropic effects of synthetic collagen.

**Phytochemical-Enriched Plant Extracts Induce Apoptosis in Bone Metastatic Breast Cancer Cells** Preetham Ravi, Haneesh Jasuja, Dipayan Sarkar, Kalidas Shetty, Dinesh R. Katti and Kalpana Katti; North Dakota State University, United States

The WHO reports that breast cancer is the most common occurring type of cancer with nearly 2.26 million cases being diagnosed each year. Breast cancer is also the second leading cause of cancer-death in women. Majority of the deaths occur due to breast cancer metastasis to bone. Breast cancer cells at bone site experience altered growth and chemoresistance. Furthermore, the infrastructure of the bone is compromised, resulting in skeletal failures in patients. Currently, there is no cure for bone metastasis of breast cancer. There is a shortage of effective therapeutics for bone metastatic breast cancer, due to the reported inefficacy of commercialized drugs at bone metastatic site. There is a need for accurate drug screening cancer models, which recapitulate the bone-metastatic condition, to effectively test potential anti-cancer therapies. In addition, therapies are needed not only to treat the tumor, but to heal bone, with limited side-effects. In this study, we employ a unique 3D *in vitro* nanoclay based scaffold model, as a testbed for bone metastatic breast cancer, to screen three phytochemically-enriched plant extracts (Rhodiola Crenulata, Origanum vulgare, and Vaccinium Macrocarpon). These plant extracts have been tested against primary site breast cancer, however, their efficacy against bone metastasized breast cancer cells is unknown. We evaluated the cytotoxicity of the three extracts on bone metastatic breast cancer using the bone-mimetic scaffolds and compared the results with 2D cultured breast cancer cells (MDA-MB-231 and MCF-7). The cell viability studies showed that breast cancer cells growing, both in 2D and 3D Bone-metastatic cultures, were significantly reduced by increasing dosages of all three plant-extracts. Furthermore, it was observed that these extracts induced apoptosis in breast cancer cells grown in 2D and bone-metastatic culture, through upregulation of pro-apoptotic markers, p53, caspase-3, and caspase-9 and downregulation anti-apoptotic markers. Additionally, the bone metastatic breast cancer cultures experienced increased drug resistance. Lastly, we evaluated the effects of these plant extracts on bone cells, and found that they are unaffected after treatment. Overall, our data indicates that these phytochemically-enriched plant extracts can promote cytotoxicity in bone metastatic breast cancer, while unaffected healthy bone cells. Moreover, these specialty derived compounds can be ideal candidates to be investigated as new therapies to treat bone metastasis of breast cancer.

### 10:30 AM SB03.08.03

**Role of Fluid Induced Shear Stresses in Inducing Bone Metastasis in Prostate Cancer** Kalpana Katti, Haneesh Jasuja, Sharad V. Jaswandkar and Dinesh R. Katti; North Dakota State University, United States

The World Cancer Research Fund International reports that prostate cancer is the second most commonly occurring cancer in men. In addition, 1,414,259 new cases of prostate cancer were reported in 2020. The World Health Organization, reports 375,304 deaths in 2020 due to prostate cancer. The majority of deaths due to prostate cancer result from the cancer relocating to a distant location in the body through the process of metastasis. The bone is a common niche of relocation of prostate cancer metastasis. Prostate cancer that has metastasized to bone is incurable. We have developed a novel nanoclay-based tissue-engineered polymeric scaffold in order to mimic the bone metastasis site through sequentially seeding with hMSCs and cancer cells. The role of blood flow in cellular processes is well known through the effect of shear forces exerted by the fluid. It is also known that the fluid flow provides unique biochemical cues for metastasis. We have designed and fabricated a bioreactor that enables physiologically relevant interstitial fluid-flow for prostate cancer bone metastasis. We have also conducted computational fluid dynamics studies to establish that a fluid flow of 0.05 ml/min recapitulates the physiological condition. We did extensive gene expression and protein evaluation studies on the cellular materials grown with and without the effect of fluid flow. We observe that the interstitial fluid-flow does not alter the CXCR4 level, an important regulator of metastasis and invasiveness of cancer. On the other hand, a large impact of bone proximity on the CXCR4 levels. The bone proximity upregulates CXCR4 levels enabling increased MMP-9 levels. We also investigated the levels of integrins which are important cellular adhesion proteins and found that avb3 integrins and MMP-9 levels are upregulated by fluid-flow causing increased migration under fluid-flow. Hence our studies indicate that avb3 integrins act as potential mechanosensory agents transducing mechanical signals via avb3-MMP 9 signaling to promote flow induced motility of prostate cancer cells. Overall, these experiments describe the significant role of interstitial fluid-flow in prostate cancer metastasis.

**Combining Surface-Enhanced Raman Spectroscopy and Electrokinetics for Bacterial Monitoring in Wastewater** Yirui A. Zhang, Liam K. Herndon, Punnag Padhy, Babatunde Ogunlade, Alexandria Boehm and Jennifer A. Dionne; Stanford University, United States

Wastewater-based epidemiology can monitor population-level infections, provide early warnings about disease outbreaks, and help to control disease spread at the community level [1]. However, bacterial identification in wastewater presents outstanding challenges; notably, current methods [2] to identify bacteria are slow and costly, not suitable for high-throughput screening of diverse bacterial species, and may not work well in the complex wastewater matrix. Here, we develop a new electro-optical method that has the promise to detect a wide range of pathogenic bacteria in wastewater.

We combine surface-enhanced Raman spectroscopy (SERS) [3] and electrified interfaces, further assisted with machine learning models [4] to realize rapid and amplification-free detection of bacteria, at cell concentrations as low as  $10^5$  cells/mL in filtered wastewater. First, we collect SERS from bacteria spiked into filtered wastewater, including *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Escherichia coli*. Here, plasmonic gold nanorods electrostatically bind to the bacteria surface, allowing for rapid biomolecular recognition of the cell surfaces. Additionally, two-dimensional gold microelectrodes are patterned on the sensor surface to apply electrical fields to wastewater, which selectively attracts and enriches bacteria present in the complex wastewater matrices within minutes, driven by dielectrophoretic effects [5]. The enrichment of bacteria is directly observed through microscopy, and Raman signal intensities are increased by five to ten fold under electrical fields for bacterial concentrations ranging from 100 cfu/mL up to  $10^8$  cfu/mL. Such enhancement enables the detection sensitivity to reach environmentally-relevant concentrations (typically below  $10^7$  cfu/mL) with just ten seconds of integration times. Finally, using machine learning, we identify biologically-relevant “fingerprint” Raman peaks describing proteins, nucleic acids, and lipids from bacteria surfaces, and achieve rapid and accurate identification of bacteria species in wastewater. The method has the promise for future label-free detection and prediction of bacterial outbreaks through wastewater. It also opens up new directions for generalized pathogen detection and molecular recognition in a broader range of complex liquid samples including wastewater, blood, and seawater.

**11:00 AM SB03.08.05**

**Peptidic Luminescent AuNCs for Biosensing** Solene Ducarre<sup>1</sup>, Raffaello Paolini<sup>1</sup>, Ester Butera<sup>1</sup>, Dorian Lemasson<sup>1</sup>, Regina Cheichio<sup>1</sup>, Pascale Even-Hernandez<sup>1</sup>, Celia Ravel<sup>2</sup>, Ludovic Jullien<sup>3</sup> and Valérie Marchi<sup>1</sup>; <sup>1</sup>Institut des Sciences Chimiques de Rennes, France; <sup>2</sup>CHU Rennes, France; <sup>3</sup>ENS PSL, France

Gold nanoclusters (AuNCs) appear as a recent class of non-toxic fluorophores. Their brightness, their ultrasmall size (< 2 nm) and large window of fluorescence lifetime (1 ns – 1 ms) and their good biocompatibility make them an attractive alternative as fluorescent probes for biological labeling and bioimaging.

We demonstrated their in vivo targeting ability because of specific peptidic recognition groups (R. Cheichio et al. ACS Nano materials **2023**)

Here we present the direct synthesis of original ultrasmall luminescent peptidic gold nanoclusters sensitive to pH. The versatility of small peptides permits to adjust the emission wavelength and the sensitivity of the emission intensity as well as the luminescent lifetime.

In addition due to their ultra-small size, we demonstrated that these probes are easily internalized into Arabidopsis plant from the roots and the leaf by adjusting the surface charge of the ligands. Their biodistribution in this model plant was evidenced by confocal microscopy. This chemical platform provides AuNC dual nanoprobe with potential sensitivity to the environment for biosensing applications. Such nanostructures offer promising candidates for fluorescent in vivo biosensing and biolabeling.

We also investigated the interaction of AuNC with Extracellular vesicles (EVs) which are well-known membrane-limited particles that are secreted by healthy and cancerous cells. EVs are heterogeneous in size and three subtypes are described depending on the location of secretion: microvesicles, myelinosomes and exosomes. EVs are identified in human follicular fluid as a mode of communication in the ovarian follicle (Neyroud A. S. et al. Int. J. Molecular Sci. **2022**). In addition EVs involved in cell-cell communication are considered as biomarkers for early cancer diagnosis. The analysis of their content thanks to AuNCs nanoprobe could provide informations about the origin and the biological function of the EVs. The EVs labeling with easily detectable nanoparticles could enable the development of a powerful tool for the early diagnosis of specific diseases.

**11:15 AM SB03.08.06**

**Engineering Antigen Binding and Orientation on Alum Adjuvants for Enhanced Humoral Responses and Immunofocusing** Duo Xu and Peter S. Kim; Stanford University, United States

A major challenge in vaccine development, especially against rapidly evolving viruses, is the ability to focus the immune response toward evolutionarily conserved antigenic regions to confer broad protection. For example, while many broadly neutralizing antibodies against influenza have been found to target the highly conserved stem region of hemagglutinin (HA-stem), the immune response to seasonal influenza vaccines is predominantly directed to the immunodominant but variable head region (HA-head), leading to narrow-spectrum efficacy. Here, I will first introduce an approach to controlling antigen orientation based on the site-specific insertion of short stretches of aspartate residues (oligoD) that facilitates antigen-binding to alum adjuvants. I will demonstrate the generalizability of this approach to antigens from the Ebola virus, SARS-CoV-2, and influenza and observe enhanced antibody responses following immunization in all cases. Next, I use this approach to reorient HA in an “upside down” configuration, which I envision increases HA-stem exposure, therefore also improving its immunogenicity compared to HA-head. When applied to HA of H2N2 A/Japan/305/1957, the reoriented H2 HA (reoH2HA) on alum induced a stem-directed antibody response that cross-reacted with both group 1 and 2 influenza A HAs. These results demonstrate the possibility and benefits of antigen reorientation by engineering the interaction between antigens and adjuvants, which represents a generalizable immunofocusing approach readily applicable for designing epitope-focused vaccine candidates.

**11:30 AM \*SB03.08.07**

**3D Inverse Modelling to Extract Local Hydrogel Remodelling and Stress Fiber Structure in Human Diseased Aortic Heart Valve Interstitial Cells** Michael S. Sacks and Toni West; The University of Texas at Austin, United States

Direct assessment of three-dimensional (3D) cell single stress fiber (SF) structure and function remains technically challenging, due to the SF feature size falling well below the resolution of light microscopy. Therefore, computational approaches are needed to estimate the effective structures and contractile behavior of SFs in various states. Herein, we developed a 3D computational model of the contracting aortic heart valve interstitial cells (AVICs) embedded

in 3D hydrogels to estimate their SF orientations and contractile forces. We first utilized our hydrogel inverse model to estimate the local hydrogel mechanical properties. Briefly, this approach produces a spatially varying hydrogel modulus field or profile that minimizes the error between the experimentally measured and simulated hydrogel deformations produced by a contracting AVIC. It was determined that AVICs both degrade the gel by enzymatic processes, as well as locally stiffen the gel by collagen deposition. Next, we developed two finite element based inverse models that utilized a single direction and dispersed orientation SF structures. Both models estimated that the greatest levels of SF forces occurred at AVIC protrusions. The second model estimated that the greatest levels of SF alignment occurred at AVIC protrusions while the AVIC midsection revealed less-aligned fibers. To the best of our knowledge, we report the first fully 3D computational contractile cell models which can predict locally varying stress fiber orientation and contractile force levels. Looking forward, these models may help us obtain an increased understanding of SF function at sub-cellular length-scales and can be incorporated into multi-scale models of tissue/organ function.

SESSION SB03.09: Applications and Devices in Materials and Medicine II

### 8:30 AM SB03.09.01

**Application of eIF4E Protein-Ligand Modeling for Cancer Drug Discovery** Melvin Thu<sup>1,2</sup>, Parth Jain<sup>3,2</sup>, Evan Xie<sup>4,2</sup>, Karin Hasegawa<sup>2</sup> and Yuefan Deng<sup>2</sup>; <sup>1</sup>Great Neck North High School, United States; <sup>2</sup>Stony Brook University, The State University of New York, United States; <sup>3</sup>Bergen County Academics, United States; <sup>4</sup>The Pingry School, United States

The eIF4F complex recruits ribosomal subunits (40S) to initiate translation and is composed of the eIF4E, eIF4G, and eIF4A subunits. eIF4E is the cap-binding protein and binds to the m7GTP mRNA 5' cap. eIF4G is the scaffolding protein in the complex and binds eIF4E. The protein 4E-BPs can bind to eIF4E where eIF4G binds to prevent the eIF4F complex from forming. eIF4F plays a substantial role in cancers since eIF4F preferentially activates the translation of certain mRNAs, encoding proliferation and survival-promoting proteins such as cyclin D1, c-Myc, and VEGF. The pathway involving PI3K phosphorylation of 4E-BPs results in the unbinding of eIF4E from 4E-BPs and the formation of the eIF4F complex resulting in breast, lung, ovarian, and prostate cancers, and the pathway involving Ras phosphorylation of eIF4E results in the formation of an active eIF4F complex resulting in pancreatic, lung, and colorectal cancers.

Our approach to eIF4E inhibition involves designing a compound to restrain the movement of key eIF4E residues involved in the binding of eIF4E to m7GTP, such as W102, W56, and E103, to prevent binding. An issue with m7GTP analogues of similar structure and stronger binding affinity, however, is that many are negatively charged and thus can't pass through cell membranes. Molecular docking simulations can predict binding orientation and binding affinity of the ligand to target, producing samples of many ligand conformations in the target binding region to find the optimal conformation. However, high throughput screening through brute force molecular docking is computationally expensive and limited as there are only 1010 known compounds as opposed to the 1060 total compounds.

In order to design an effective ligand, we first have to study the structure of eIF4E, and investigate how key residues involved in eIF4E binding to m7GTP undergo conformational change with and without m7GTP. We optimize eIF4E models without m7GTP using principal component analysis (PCA) and free energy landscape (FEL) calculations. We performed PCA on the trajectory data of 2gpq, 4tpw, and AF protein sources of eIF4E to transform the set of possibly correlated variables (the positions of the protein atoms) into a set of values of linearly uncorrelated variables (the principal components). We then calculated FEL of the 2gpq, 4tpw, and AF protein sources of eIF4E using GROMACS to identify the most stable conformations of eIF4E. FEL is a graphical representation of the thermodynamically stable states of a protein and the transitions between them where the local minima represent the most stable protein conformations and the barriers represent the transition states. The stable conformations of 2gpq, 4tpw, and AF were then used in molecular docking simulations of the eIF4E-m7GTP complex in order to determine the m7GTP pose with the most favorable binding energy. It was confirmed that m7GTP binds to the W56, W102, E103 residues for all three sources of eIF4E. We then performed molecular dynamics simulations on the docked eIF4E-m7GTP complexes using GROMACS with the CHARMM36 force field and TIP3P water model.

We are currently working on identifying the regions of m7GTP that are interacting with W56, W102, and E103. We will use these results to design compounds to allosterically inhibit eIF4E binding to m7GTP, preventing the overexpression of cancer-causing mRNAs.

### 8:45 AM SB03.09.02

**Viability of a Novel Peptide P12 as an Antithrombotic Agent** Sai Pranav Kota<sup>1</sup>, Richard A. Wong<sup>2</sup>, Samuel D. Coopersmith<sup>3</sup>, Avi Talsania<sup>4</sup>, Pia V. Sodhi<sup>5</sup>, Sharis Hsu<sup>6</sup>, Adam Hansen<sup>7</sup> and Miriam Rafailovich<sup>7</sup>; <sup>1</sup>Cedar Falls High School, United States; <sup>2</sup>Plainview-Old Bethpage John F. Kennedy High School, United States; <sup>3</sup>Casa Grande High School, United States; <sup>4</sup>Sachem High School North, United States; <sup>5</sup>The Brearley School, United States; <sup>6</sup>Valley Christian High School, United States; <sup>7</sup>Stony Brook University, The State University of New York, United States

Medical devices and implants are an ongoing point of research due to their impressive capabilities to enhance and support human infrastructure, but pose major challenges as they must incorporate a biocompatible material that can support endothelialization and prevent thrombosis. Specifically, current cardiovascular devices like stents lack reliable endothelialization and because of exposure to constant contact with blood flow within vasculature, result in life-threatening blood clots. Fibrinogen is a plasma-soluble protein that, once cleaved, results in fibrin monomer polymerization into fibrous clots. Previous studies have demonstrated that most stent materials are subject to fibrinogen deposition and denaturation, which results in conversion into fibrin monomers and polymerization through  $\alpha$ C domain connections [1]. A multitude of possible solutions have been studied by utilizing varying hydrophobic or hydrophilic surface properties, which feature different materials or coatings with limited success. Here, we will explore incorporation of a surface coating using P12, a peptide derived from fibronectin, to prevent thrombosis.

Initial studies provided insight on how P12 is effective for inhibiting the fibrin polymerization process on polystyrene (PS) surfaces. We studied various fibrinogen and P12 concentrations, but ultimately we found that incorporation of P12 during the incubation of 4 mg/ml of fibrinogen, the concentration in blood, on PS surfaces prevented substantial fiber formations. We also analyzed this at the molecular level with low concentrations of fibrinogen and by using Atomic Force Microscopy and simulation technology, we concluded that the hydrophobic nature of P12 allowed it to bind to exposed  $\alpha$ C domains of fibrin on the PS surface. This prevented aggregation of neighboring fibrin monomers and ultimately prevented polymerization into fibers.

Further studies were conducted to overcome the possible negatives of using P12, which includes the uncertainty of P12 reaching the implant or cytotoxic considerations. In order to utilize P12 properly, we investigated using it as a material coating to enhance its effectiveness in a controlled location. We studied this by applying 100  $\mu$ M of P12 solution onto PS surfaces until full coverage was achieved. Fibrinogen solutions of 4 mg/ml incubated the coated surface for one hour. The P12 coating resulted in <1% of the surface containing fibers and adversely, without the coating resulted in >50% of the surface covered in fibers. From this data, we concluded that a coating of P12 is very effective in thrombosis prevention.

Cytotoxicity is another major problem with implementation of a biomaterial coating. We therefore plated fibroblasts on P12 coated tissue culture plastic

(TCP) and added additional P12 to the media to directly test cell survivability. We found that there were no significant differences on P12 coating or adding P12 to cells. These results are indicative of no associated cytotoxicity of the P12 surface. We further investigated this by testing cell adhesion and proliferation on P12 coated polystyrene and found an increase in cell growth and adhesion by the addition of P12 on an otherwise non-biocompatible polystyrene surface. This data concluded that a P12 coating not only rendered surfaces non-thrombogenic and non-toxic, but also enhanced biocompatibility.

Future research will look to investigate the effects of a P12 coating on its ability to support endothelialization and look to create a robust interface that incorporates P12 directly into the matrix of the material chemically so that the coating cannot be degraded or dislodged from the surface.

**Photo-Induced Structural Changes in Oxidoreductase-Inspired Nanogels** Chae Gyu Lee and Tae-Hyuk Kwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Under the reductive conditions in cancer cells, cysteine-containing oxidoreductases, such as thioredoxin (Trx), glutaredoxin (Grx), and protein disulfide isomerase (PDI), accelerate thiol-disulfide exchange reactions through a reversible reaction ( $\text{Cys-S-Cys} \leftrightarrow \text{Cys-SH}$ ), rendering upstream and downstream signaling pathways to maintain redox homeostasis in metabolism-activated cancer cells. In addition, it is difficult to differentiate between tumorous and healthy tissues as the intracellular GSH concentrations of both cell types are approximately 2–10 mM. Therefore, disulfide-bond-based nanocarriers have potential to exhibit cytotoxicity due to the unmanageable drug release in normal cells. This study investigates the spatiotemporally-controlled irreversible degradation of Ir-based photosensitizer (Tlr3)- encapsulating nanogels (IrNG) through the hyperoxidation of resulting intracellular thiols using reactive oxygen species (ROS).<sup>1,2</sup> By mimicking the reversible redox reaction of Trx and Grx, we developed IrNG that maintains the self-assembled nanostructure through hydrophobic interactions and reversible crosslinking between its disulfide bonds and thiols in the absence of light. When a highly cytotoxic Tlr3 was stably encapsulated within IrNG, it exhibited significantly enhanced biocompatibility under normal cellular conditions. However, upon photoirradiation, Tlr3 generated high levels of ROS, irreversibly oxidizing the thiols to induce electrostatic repulsion between the polymer molecules, resulting in the Tlr3 release and induction of cancer cell apoptosis. Therefore, we could obtain substantially increased changes in cell viability and *in vivo* tumor growth regarding the presence and absence of photoirradiation, confirming the manual control of cytotoxic drug release.

**Functional Materials Integrating Synthetic Biological Modules Guided by Machine Learning Algorithms** Candan Tamerler; University of Kansas, United States

Synthetic biology takes the bio-based and bio-enabled approaches to a step further to enable engineering biology in designing and producing materials and processes with previously unattainable functions. Nature has been a source of inspiration in engineering solutions for many. As our understanding of biological materials and structures expanded, mimicking biological systems for innovative engineering solutions has continued with growing intensity. Our group was among the early adapters of biomimetic principles for harnessing design strategies to develop innovative materials. Mimicking the molecular recognition in biological interactions, we have been exploring the smaller protein domains, i.e., peptides as the key fundamental building blocks. Peptides offer to design hybrid biomaterials that can mimic the functions of proteins, generate biomimetic platforms and modulate microenvironment. Using synthetic biology approaches, we expanded the use of peptide-based building blocks as bioactive modules and design bio-hybrid materials with diverse functions addressing medical and industrial applications. We incorporated machine learning (ML) methods to capture distinct peptide functionalities as elements of critical modular building blocks. We adapted experimental and computational approaches demonstrated transparent ML frameworks for identifying relevant peptide structure features for targeted functions. For antimicrobial hybrid materials, we provided a method for selecting secondary structure features in related to antimicrobial peptides and expanded our predictions to design peptides for metals in biology as biocatalysts, metalation tools, and metal chelates in manufacturing and nutritional immunity. Using synthetic modular domains, we developed peptide-metal and peptide-polymer hybrids as integral of biomaterials and developed models for allosteric-dependent effects of selecting spacers to recover domain function activity. We generated knowledge-potential folded structures to discover rough set theory trends which showed to be relevant for recovering bioactivity. Our examples will include utilization of the biological activity imparted by each biomolecule toward prevention of dental and oral diseases as well as restoration of oral health. Engineered modular peptide and enzyme systems will be also provided as synthetic biohybrid material systems applicable to industrial applications. Enabling synthetic biological modular approach guided by ML algorithms offers a fascinating path to reshape our thinking in engineering and represent the functional frontiers to mimic biological systems.

**Sequence-Tunable Materials for Silica Biomineralization** Kaylyn Torkelson<sup>1</sup>, Nada Y. Naser<sup>1</sup>, Xin Qi<sup>2,1</sup>, Chun-Long Chen<sup>3,1</sup>, Francois Baneyx<sup>1</sup> and Jim Pfaendtner<sup>4,1</sup>; <sup>1</sup>University of Washington, United States; <sup>2</sup>Dartmouth College, United States; <sup>3</sup>Pacific Northwest National Laboratory, United States; <sup>4</sup>North Carolina State University, United States

Silica biomineralization is a naturally occurring process wherein proteins direct the formation of complex, hierarchical nanostructures. Knowledge of these proteins and their underlying mechanisms has spurred significant efforts to identify routes for biomimetic mineralization that aims to reproduce the exquisite shapes and size selectivity found in nature. A common strategy to achieve this has been the use of short peptide sequences with chemistry mimicking those found in natural systems, like the use of the silaffin-derived R5 peptide. While progress has been made using peptides for this approach, there are many limitations that have prevented substantial breakthroughs in biomimicry. To advance our ability to use charged macromolecules for silica formation, we propose to use sequence-defined synthetic polymers known as peptoids, or N-substituted polyglycines, that present significant capability for precise tuning of sequence and structure beyond what can often be achieved with peptides alone.

This work will highlight recent developments in computational methods for understanding the relationship between polymer aggregate structure, silica surface, silica surface adsorption, silicate precursor interactions, and morphology in the biomimetic mineralization process. We use molecular dynamics simulations with the metadynamics family of enhanced sampling methods to analyze binding mechanisms and energetics of the R5 system. Next, we

synthesize two R5-inspired peptoids and validate our prediction through characterization using surface plasmon resonance and electron microscopy. This study holds promise for designing new sequences with unprecedented control of the placement of chemical functional groups, thus allowing for further unraveling of silicification mechanisms and eventual design of sequence-defined synthetic polymers leading to the predictive synthesis of nanostructured functional materials.

#### 10:45 AM SB03.09.08

**Modeling Molecular Machines with Dynamic Covalent Bonds using REACTER** Jacob Gissinger; Stevens Institute of Technology, United States

Nanoscale devices are the ultimate in mechanical miniaturization. Molecular machines that perform directional transport of small molecules or filaments are a vital aspect of life, performing key biological functions during cell division and muscle contraction. These biomotors have inspired the creation of synthetic versions of molecular 'walkers' that can move directionally down a molecular track by the application of stimuli (pH and irradiation) in a specific sequence. The reconfiguration of covalent bonds is achieved by two orthogonal bond exchange reactions: disulfide exchange, which is activated in basic environments, and hydrazone exchange, which occurs under acidic conditions. In this work, we simulate the nanoscale dynamics of molecular machines using REACTER, a method for modeling chemical reactions in classical molecular dynamics (MD) simulations. Although external stimuli such as UV light cannot be modeled directly in classical MD simulations, the dynamics of a molecular walker can be captured explicitly by alternately activating the bond exchange and photoisomerization reactions using REACTER. Certain shape-memory polymers operate via similar bond exchange reactions, and a workflow to model shape-memory effects with atomistic resolution is proposed.

### SESSION SB03.10: Virtual Session: Lessons from Biology at the Molecular Dimensions II

SB03-virtual

#### 8:00 AM SB03.10.01

**Zwitterion Functionalization of Polyurethanes via Thiol-ene Click for Antifouling Surfaces—Lessons from Nature** Shantanu P. Nikam<sup>1,2</sup>, Peiru Chen<sup>1</sup>, Karissa Nettleton<sup>2</sup>, Yen-Hao Hsu<sup>1</sup> and Matthew Becker<sup>2</sup>; <sup>1</sup>The University of Akron, United States; <sup>2</sup>Duke University, United States

Inspired by the phospholipids on cell membranes, zwitterionic groups have been widely studied for their antifouling property. Equipped with two oppositely charged groups in the same moiety, zwitterions exhibit properties like super hydrophilicity through ionic solvation and tightly bound hydration layer that enables non-specific protein resistance. Additionally, zwitterionic materials also enhance biocompatibility and reduce immune response. Catheter-associated infections (CAIs) have one of the highest mortality rates among healthcare-associated infections. Besides being a major cause of morbidity and mortality, CAIs also impose a heavy financial burden resulting from prolonged treatment and hospital stays. Increasing cost and health related complications necessitate the research for improving currently employed biomaterials for catheter applications. Creating antifouling surfaces by immobilizing zwitterion molecules on material surfaces has been proved to be a promising strategy. Herein, we investigated zwitterion surface-functionalized thermoplastic polyurethane (TPU) for use in antifouling catheter. The thermoplastic polyurethane was synthesized to have an allyl ether side functionality. Zwitterion surface-functionalization was achieved *via* thiol-ene 'click' chemistry in aqueous conditions. The XPS results confirmed the presence of chemically tethered zwitterion moieties on the zwitterion-TPU surface. The Quartz crystal microbalance (QCM) results show reduced fibrinogen attachment for the zwitterion-TPU when compared to its unfunctionalized controls. The zwitterion-TPU also showed a log scale reduction in bacterial adherence. For *P. aeruginosa* and *S. epidermidis*, the zwitterion-TPU resulted in around a 40% and 50% lower bacterial biomass accumulation, respectively. The fibroblast cell viability of TPU remained unaffected by functionalization with zwitterion thiol. Our results suggest a zwitterion modified TPU is a promising candidate for antifouling catheters.

#### 8:15 AM \*SB03.10.02

**Carbon Nano-Interfaces for Medical and Biological Applications** Roger Narayan; North Carolina State University, United States

Recent studies have evaluated the use of microcrystalline diamond, nanocrystalline diamond, and diamond particles for medical applications. In this talk, materials studies and *in vitro* studies describing the interactions between diamond and medically-relevant eukaryotic cells and prokaryotic cells will be considered. The attachment of eukaryotic cells and prokaryotic cells to diamond surfaces will be considered. In addition, recent developments involving the use of diamond in active medical applications, including electrochemical sensing, will be described. Our recent finding involving diamond surfaces indicate that diamond surfaces may offer significant improvements for the diagnosis and treatment of medical conditions over the next few decades.

#### 8:45 AM \*SB03.10.03

**Multiscale Small Molecule Interactomics and Behavioural Biomimetics using the CANDO Platform** Zackary Falls<sup>1</sup>, William Mangione<sup>1</sup>, Brennan Overhoff<sup>1,2</sup>, Liana Bruggemann<sup>1</sup>, Matthew Hudson<sup>1</sup>, James Schuler<sup>1</sup>, Manoj Mammen<sup>1</sup> and Ram Samudrala<sup>1</sup>; <sup>1</sup>University at Buffalo, United States; <sup>2</sup>Harvard University, United States

Our goal is to understand and engineer small molecule behavior and functionality at multiple scales. We accomplish this by developing technologies to describe small molecule behavior and function in terms of their multiscale signatures, which are utilised to engineer safe and effective chemicals and materials for the betterment of society by discovering optimal probes and therapeutics; generate safer and better chemicals and materials; and promote health, quality of life, and prosperity.

We elucidate the scientific tenets determining small molecule behavior in a variety of contexts, starting from the atomic and macromolecular scales, proceeding to pathways, cells and beyond, eventually reaching the phenotypic and population scales. The tenets are embedded in the form of multiscale signatures, comprising the sub-signatures at each scale, i.e., small molecule-macromolecule, -pathway, -cell and -phenotype signatures. At each scale, we determine the interaction signature using a combination of calculations and measurements, which will be enhanced with relevant information from lower scales.

We developed the Computational Analysis of Novel Drug Repurposing Opportunities (CANDO) platform for shotgun multitarget drug discovery, repurposing, and design, funded in part by a NIH Director's Pioneer Award and multiple NCATS ASPIRE Awards to implement this paradigm and overcome the limitations of traditional single target approaches. The open source platform screens and ranks drugs/compounds for every disease/indication (and adverse event) through large scale modelling and analytics of interactions between comprehensive libraries of drugs/compounds and protein

structures. CANDO is agnostic to the interaction scoring method used; two primary pipelines within the platform allow for rapid screening and assessment of billions of drug/compound to protein interactions with fast bioanalytic docking and machine learning affinity regression protocols. CANDO implements a variety of benchmarking protocols for shotgun repurposing to determine how every known drug is related to every other in the context of the indications/diseases for which they are approved, which enables evaluation of various pipelines and protocols within and external to the platform for their utility in drug discovery. We have performed predictive analytics on the CANDO interaction matrices to classify drug, protein, pathway, disease, and adverse event relationships accurately. The multiple fast and accurate interaction scoring/docking protocols, the proteomic scale, and rigorous all-against-all benchmarking used within the platform make it unique and ideal for the design of novel chemical entities that target a desired proteomic/interatomic space or objective.

CANDO has been extensively validated for drug discovery, repurposing, and design; recent work on COVID-19 shows 25% our top drug candidates having in vitro efficacy including two nanomolar concentration full virus inhibitors of SARS-CoV-2, one of which was ranked #1. We already produced preliminary designs for various indications (such as non-small cell lung cancer, opioid/substance use disorder and pain, and aging) using the design pipelines implemented in CANDO. CANDO is capable of performing analytics on any arbitrary drug/compound, including those chemicals relevant to industrial use such per-and polyfluoroalkyl (PFAS) substances to design safer and better compounds. The most potent designs will be pursued further for development and regulatory approval. Elucidating multiscale signatures of small molecules lends itself to a paradigm-shifting view of small molecule behavior and function that will enable detailed engineering of small molecules for myriad applications. This talk will describe the current state of the CANDO platform and future plans for use in materials research.

#### 9:15 AM SB03.10.04

**Harnessing Gradients for Self-Assembly of Peptide-Based Nanocapsules: A Pathway to Advanced Drug Delivery Systems** Haopeng Li<sup>1</sup>, Xuliang Qian<sup>1</sup>, Harini Mohanram<sup>1</sup>, Xiao Han<sup>1</sup>, Huitang Qi<sup>2</sup>, Guijin Zou<sup>3</sup>, Fenghou Yuan<sup>2</sup>, Ali Miserez<sup>1</sup>, Qing Yang<sup>4</sup>, Tian Liu<sup>2</sup>, Huajian Gao<sup>1,3</sup> and Jing Yu<sup>1,1</sup>; <sup>1</sup>Nanyang Technological University, Singapore; <sup>2</sup>Dalian University of Technology, China; <sup>3</sup>A\*STAR, Singapore; <sup>4</sup>Chinese Academy of Agricultural Sciences, China

Biological systems often create materials with intricate structures to achieve specialized functions. In comparison, precise control of structures in man-made materials has been challenging. Here, we report a serendipitous discovery of insect cuticle peptides (ICPs) spontaneously forming nanocapsules through a single-step solvent exchange process, where the concentration gradient resulting from mixing of water and acetone drives the localization and self-assembly of the peptides into hollow nanocapsules. The underlying driving force is the intrinsic affinity of the peptides for a particular solvent concentration, while the diffusion of water and acetone creates a gradient interface that triggers peptide localization and self-assembly. This gradient-mediated self-assembly offers a transformative pathway towards next-generation drug delivery systems based on peptide nanocapsules.

#### 9:30 AM SB03.09.04

**Biomimetic Dentin Repair: Amelogenin-Derived Peptide Guides Occlusion and Peritubular Mineralization of Human Teeth** Deniz T. Yucesoy<sup>1</sup>, Hanson D. Fong<sup>2</sup>, Sami Dogan<sup>2</sup> and Mehmet Sarikaya<sup>2,2,2</sup>; <sup>1</sup>Izmir Institute of Technology, Turkey; <sup>2</sup>University of Washington, United States

Dentin hypersensitivity, a widespread oral health concern, is primarily caused by the exposure of dentin tubules due to the loss of protective tissues. Despite being a widespread ailment, no permanent solution exists to address this oral condition. Current treatments aim to alleviate pain by employing desensitizing agents or blocking dentin tubules through mineral deposition or solid precipitates, yet these interventions often provide only short-term relief. To restore the structural and mechanical integrity of teeth with lasting durability, there is a crucial need to reproduce an integrated mineral layer that seals exposed dentin while promoting peritubular mineralization. In this study, we introduce a biomimetic treatment that promotes dentin repair, utilizing a mineralization-directing peptide known as sADP5, derived from amelogenin.

The occlusion of dentin tubules is achieved through a layer-by-layer peptide-guided remineralization process, resulting in the formation of an infiltrating mineral layer on the dentin. The structure, composition, and nanomechanical properties of the remineralized dentin were analyzed by cross-sectional scanning electron microscopy imaging, energy dispersive X-ray spectroscopy, and nanomechanical testing. Elemental analysis revealed calcium and phosphate compositions akin to hydroxyapatite. Furthermore, the measured average hardness and reduced elastic modulus values of the mineral layer were significantly higher than those of the demineralized and sound human dentin. Thermal aging experiments provided evidence of the structural integration between the newly formed mineral layer and the underlying dentin, with no physical separation observed. These findings suggest the creation of a structurally robust and mechanically resilient interface that can endure long-term mechanical and thermal challenges commonly encountered in the oral environment.

The peptide-guided remineralization process outlined herein provide a foundation for the development of highly effective oral care products leading to novel biomimetic treatments for a wide range of demineralization-related ailments and offers a potent long-term solution for dentin hypersensitivity.

**4D Printing of Hydrogels with Hierarchical Surface Wrinkling Patterns** [Murat Guvendiren](#); New Jersey Institute of Technology, United States

Additive manufacturing of stimuli responsive materials leads to 3D printed constructs that can adapt their properties in response to an external stimuli. This process is referred as 4D printing. 4D printing is commonly used to fabricate shape-shifting constructs, which change their asprinted shape into a preprogrammed shape post-printing with response to an external stimuli. Although 4D printing of shape-shifting objects have significantly expand the applications of 3D printing, novel ink formulations are needed for 4D printing to create 2D and 3D structures that allow dynamic control of properties beyond shape change. In this study, we present smart inks for material extrusion-based direct ink writing (DIW) printing that display preprogrammed surface wrinkling patterns on 2D and 3D surfaces post-printing, which appear only when exposed to a solvent. Hydrogels displaying surface wrinkling patterns with user-defined order and shape are useful for a range of applications, including microfluidics, flexible electronics, smart adhesives, optical sensors, and cell culture platforms. However, conventional techniques to fabricate wrinkling patterns involve multiple steps and are significantly limited to create hierarchical patterns, wrinkles on 3D and non-planar structure. It is also very difficult to scale-up the manufacturing process and to integrate surface patterning into a continuous manufacturing process. 4D printing is used in this work to overcome these issues. The use of photocurable ink formulations allow us to tailor flow properties and printability by controlling photopolymerization time and partial crosslinking time. The crosslinker concentration is varied to develop distinct ink formulations with preprogrammed wrinkling morphology, including lamellar, peanut and hexagonal patterns. We demonstrate 4D printing of optical devices, solvent sensors, anti-counterfeit devices and high-throughput cell culture platforms.

#### 10:45 AM \*SB04.01.02

**Electronic Hydrogels for Plant and Environmental Monitoring** [Eloise Bihar](#)<sup>1,2</sup>, [Elliot Strand](#)<sup>1</sup>, [Catherine Crichton](#)<sup>1</sup>, [Megan N. Renny](#)<sup>1</sup>, [Robert McLeod](#)<sup>1</sup> and [Gregory L. Whiting](#)<sup>1</sup>; <sup>1</sup>University of Colorado-Boulder, United States; <sup>2</sup>University at Buffalo, The State University of New York, United States

Significant progress has been achieved in the field of electronics dedicated to environmental monitoring in recent decades. Currently, a key challenge lies in establishing an enhanced interface between electronics and living tissues. The proliferation of miniaturized sensors designed for plant and environmental sensing necessitates the development of hybrid sensors that employ cutting-edge techniques and novel organic materials to mitigate the formation of fibrotic tissues.

In this context, we introduce a novel generation of biocompatible and stretchable electronic gels, which showcase remarkable mechanical properties and self-repair capabilities. These gels also exhibit a wide array of functionalities, including exceptional conductivity levels of up to 350 S cm<sup>-1</sup>, high transconductance ranging within the mS range, and high capacitance values of up to 4.2 mF g<sup>-1</sup>. Leveraging the unique characteristics of these electronic gels, we can effectively stimulate or record ionic activities both in vivo and ex vivo, enabling the monitoring of plant electrophysiology or serving as energy storage systems for agricultural monitoring.

#### 11:15 AM DISCUSSION TIME

#### 11:30 AM SB04.01.04

**Achieving Tissue-Like Properties in 3D Printed Conducting Polymer Hydrogels** [Somtochukwu S. Okafor](#)<sup>1</sup>, [Tianran Liu](#)<sup>1</sup>, [Anna P. Goestenkers](#)<sup>1</sup>, [Barbara A. Semar](#)<sup>2</sup>, [Riley Alvarez](#)<sup>1</sup> and [Alexandra Rutz](#)<sup>1</sup>; <sup>1</sup>Washington University in St Louis, United States; <sup>2</sup>Washington University in St. Louis, United States

Conducting hydrogels are sought for integration into bioelectronic devices to impart soft, hydrated, and tissue-like properties. However, the compatibility of these materials with advanced manufacturing and the ability to tailor functional properties for application remain limitedly reported. With regards to structural design, additive manufacturing offers customization and complexity with respect to object shape, dimensions, and internal microstructure. Additionally, materials processing as part of the additive manufacturing procedure can be used to control functional properties important for cell-material interactions and device performance. In this work, we developed methods for 3D extrusion printing conducting polymer hydrogels based on poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS). We demonstrate control of hydrogel properties by careful pre-printing ink formulation and appropriate post-printing processing. Shear-thinning and self-healing hydrogel inks were developed. Consistent rheological (viscosity, storage and loss modulus) and printing properties (mass flow rate, particle size) were maintained by manipulating the gelation kinetics of PEDOT:PSS using temperature. A gel-based support medium enabled fabrication of multi-layered structures after adding a gelation agent to increase structural resolution. Printed PEDOT:PSS hydrogels exhibited tissue-like properties including an elastic modulus of ~5 kPa and water content >99%. When further treated with heat or solvent, a wide range of conductivity (10 – 10,000 S/m) was achieved. Furthermore, hydrogels printed into microporous scaffolds were stable in physiological conditions for at least 28 days, and supported viability and proliferation of seeded human primary cells. Collectively, these results provide methods of fabricating PEDOT:PSS hydrogels that offer customization for various biointerfacing applications with regards to structural design and functional properties.

#### 1:30 PM \*EL05.02/SB04.02.01

**Multifunctional Conducting Polymer Hydrogels for Regenerative Bioelectronics** [Maria Asplund](#)<sup>1,2</sup>, [Sebastian Shaner](#)<sup>3</sup>, [Lukas Matter](#)<sup>1</sup>, [Oliya](#)

Abdullaeva<sup>2</sup>, Jose A. Leal Ordóñez<sup>3</sup>, Anna Savelyeva<sup>3</sup>, Bruce Harland<sup>4</sup>, Brad Raos<sup>4</sup>, Han Lu<sup>3</sup>, Maximilian Lenz<sup>3</sup>, Christian Boehler<sup>3</sup>, Darren Svirskis<sup>4</sup> and Andreas Vlachos<sup>3</sup>; <sup>1</sup>Chalmers University of Technology, Sweden; <sup>2</sup>Luleå University of Technology, Japan; <sup>3</sup>University of Freiburg, Germany; <sup>4</sup>The University of Auckland, New Zealand

Bioelectronic medicine refers to technology which use electrical signals, either recorded from or injected into tissue, for therapeutic effect. To date, the focus of electrical stimulation has almost exclusively been on excitable tissue, such as nerve and muscle cells, which respond to short stimulation impulses. Nevertheless, a much broader range of cells are able to respond to direct current, e.g. many cells change shape, growth or align their migration trajectories in accordance with an applied electrical field. It is hypothesized that such effects can be used to steer regenerative processes, modulate neural function or explain cancer metastasis, however, there is little technology developed that allows for such investigations in complex biological models. In our research we are developing methodologies that would make such exploration possible, in complex cell cultures, in vivo and at later stages also in patients.

Key to success is to identify electrode materials that make it possible to interface intimately with living tissues and deliver direct current without corrosion. The typical noble metal materials have limitations in terms of charge injection and corrosion resilience, and their electrochemistry is in general not well-matched to ionic current stimulation. Meanwhile, conducting polymer hydrogels show great promise as they can transport and deliver ionic current via biocompatible charge injection mechanisms, even in the direct current domain.

In my talk I will showcase how we employ conducting polymer hydrogels for direct current stimulation, and how such technology allows for new discoveries as well as potential future therapies. One such application field is wound healing, where we have used conducting polymer hydrogels to show how direct current stimulation of an *in vitro* epithelial wound model resulted in 3 times accelerated wound closure. Another possibility is spinal cord repair where we are exploring how to integrate electrodes for direct current stimulation in a flexible implantable bioelectronic system. By paying close attention to aspects such as electrode/electrolyte reactions, substrate electrolyte reactions as well as the interplay between the fundamental properties of the conducting polymer hydrogel and polymer-substrate adhesion layers, we hope to build a concept for fully biocompatible and implantable regenerative DC stimulation.

This work was supported by the European Research Council (ERC) grant agreement No. 759655 (SPEEDER) the CatWalk Spinal Cord Injury Trust and the Health Research Council of New Zealand (Project grant and HRC/Catwalk Partnership 19/895). Further support was provided by the center for Innovative Brain Machine Interfacing Technology at the University of Freiburg.

#### 2:00 PM \*EL05.02/SB04.02.02

**Conductive and Biofunctional Hydrogels for Regenerative Living Interfaces in the Nervous System** Rylie Green; Imperial College London, United Kingdom

Neurological disorders affect more than 60 million people every year and constitute a major clinical challenge. Due to the limited cellular turnover and the significant degeneration triggered by neural injury and disease, regenerative therapies constitute a promising strategy to ameliorate the symptoms. Living bioelectronics offer the potential to create living interactions between implants and the endogenous neural system. By providing a tissue engineered scaffolds containing neuroprogenitor (or stem) cells at the neural interface, this approach can grow connections, creating an intimate and regenerative cell-level interface. The major challenge in this technology is the need to support the cells and encourage their development into mature neurons, while creating functional synapses with target tissue. Hydrogels with conductive elements have been designed with degradation kinetics that are matched to neuronal differentiation and wound healing, while also being electrically addressable. Critically, these hydrogels provide biological and topographical cues that promote the survival of cells and ability to produce neurite processes. A system based on PVA and gelatin has been shown to support the differentiation of neuroprogenitor cells into functional neural networks at the interface of bionic devices. The incorporation of gelatin into poly(vinyl alcohol) - norbornene hydrogels (PVA-Gel-NB) was shown to provide biochemical cues that were able to be modified by the encapsulated progenitors, which ultimately integrated into brain tissue. In an alternate injectable system, self assembly peptides (SAPs) were modified to form fibers with conductive cores that supported cells in producing directional growth. The use of electrical stimulation that mimicked the pattern of brain activity experienced *in utero* by the developing mammalian CNS, was subsequently demonstrated to increase the number of mature differentiated neurons. Action potentials have been observed within both of the cell populations, showing their development into appropriate cells types. Ultimately, this work demonstrates the ability to bring bioelectronics and tissue engineering concepts together to produce regenerative neural tissue constructs.

#### 2:30 PM EL05.02/SB04.02.03

**Development of a Hydrogel-Actuated 3D Micro Electrode Array (MEA) for Neural Spheroids and Organoids** Outman Akouissi, Eleonora Martinelli, Luca Liebi, Janer Van der Graaf Mas, Silvestro Micera and Stephanie P. Lacour; Ecole Polytechnique Federale de Lausanne, Switzerland

Organoids and spheroids are versatile tools in research. Their 3D structure can faithfully replicate the complexity and functionality of human organs and tissues, enabling scientists to study biological phenomena in a dish. Specifically, neural organoids and spheroids offer exciting opportunities for understanding neuronal connectivity and exploring neurological disorders. Electrophysiological recordings play a crucial role in assessing these parameters. While micro electrode arrays (MEAs) are commonly used for such measurements, they are mostly limited to 2D (planar) configurations, which do not fully capture the complexity of three dimensional organoids and spheroids.

In this study, we present an intuitive 3D MEA platform based on shape-morphing bilayers to engulf the spheroid and enable recordings from its entire surface. The first layer forms the microelectrode arrays patterned as a thin metal film embedded in polymers such as polyimide and parylene. The second layer consists of a hydrogel membrane covalently grafted onto the MEA and capable of swelling upon immersion in cell culture medium thereby enabling actuation.

By precisely tuning the hydrogel formulation, bilayer thicknesses, and MEA geometry, we successfully designed 3D MEA platforms that accommodate a wide range of tissue sizes and shapes. One device included 32 electrodes, with a radius of 15  $\mu\text{m}$ , distributed onto 4 bilayers folding with a radius of closure 300  $\mu\text{m}$ . To expedite and guide the design and microfabrication process, we conducted comprehensive mechanical and electrical characterization of each component, and developed accurate in silico finite element models. The shape morphing MEAs interface reliably with commercial MEA readout platforms, requiring no additional instrumentation and minimal training.

We aim to study network patterns collected from the volumetric MEA over neural spheroids and hope to collect valuable insights into the connectivity, health, and functionality of neural organoids.

#### 2:45 PM DISCUSSION TIME

#### 3:00 PM BREAK

#### 3:45 PM \*EL05.02/SB04.02.05

**Hydrogel-Based Flexible and Multifunctional Fibers for Next-Generation Neural Interfaces** Seongjun Park; KAIST, Korea (the Republic of

To understand the mechanism underlying the function and dynamics of the nervous system or to treat neurological disorders, it is essential to develop the

techniques capable of modulating and recording a diversity of signals employed by neurons. However, current approaches are limited in terms of effectiveness, side effects, non-specificity, and mechanical invasiveness. Naturally, there is a huge need for new devices or materials allowing for minimally invasive manipulation and monitoring of neural activity. My talk will introduce the complementary strategy to address these challenges with hydrogel-based flexible and stretchable fiber-based probes for interfacing with the brain and spinal cord. This technology enabling the interrogation with neural circuits across their diverse signaling modalities without inducing a foreign-body reaction helps the study of information processing as well as pathologies of the nervous system.

**Development of 3D Hydrogel-Based *In Vitro* Circuits with Cocultures of Human Sensory Neurons and Schwann Cells** Blandine F. Clément<sup>1</sup>, Christina M. Tringides<sup>1</sup>, Vilius Dranseika<sup>2</sup>, Jens Duru<sup>1</sup>, Tobias Ruff<sup>1</sup> and Janos Vörös<sup>1</sup>; <sup>1</sup>ETH Zürich, Switzerland; <sup>2</sup>University of Zürich, Switzerland

Engineered *in vitro* neural networks are promising platforms to rapidly screen drugs and study information flow in the nervous system [1]. While existing polydimethylsiloxane (PDMS)-based microfluidic platforms offer precise architecture and connectivity, the cultured neurons grow inside microchannels on a planar multielectrode array (MEA) substrate in a two-dimensional fashion [2]. To better mimic the native extracellular matrix (ECM) microenvironment, 3D hydrogel scaffolds can be designed so that encapsulated cells can be expected to exhibit more physiological behavior [3].

Here, we propose a hybrid approach by filling the PDMS microstructure with hydrogels to offer both a controlled topology and a physiologically relevant microenvironment to the neuronal culture. First, a gelatin methacryloyl (GelMA) hydrogel was engineered by incorporating ECM components and tuning its mechanical properties to match the native niche environment. The hydrogel material was able to 1) support the growth of human iPSC-derived sensory neurons for more than 9 weeks 2) support co-culture with human Schwann cells where the latter could align along the axons. Next, microchannels were filled with the optimized hydrogel precursor, and after crosslinking, the neurons and glial cells were seeded as pre-aggregated spheroids in desired location(s). This enabled topologically defined growth of neurites in 3D.

By further tuning the hydrogel type and its physico-mechanical properties, the microstructures could be filled and tailored for specific cell types, while the underlying MEA allows for the recording of neuronal activity over time. This platform could offer a promising tool to study cell-cell interactions of single cultures or co-cultures, and to efficiently test the potential of various drugs in a more translational manner.

**Biodegradable Materials for Optoelectronic Neural Modulation and Electronic Medicine** Lan Yin; Tsinghua University, China

Devices built on biodegradable materials possess unique characteristics that enable complete biodegradation in physiological environments, thus eliminating the need for retrieval surgery and minimizing the associated risks of infection. These devices can play a critical role in therapeutic and diagnostic processes, including neural modulation, tissue regeneration, etc. Herein, we introduce materials options and fabrication strategies that enable the development of a biodegradable and flexible optoelectronic device, capable of achieving efficient neural stimulation and functional recovery on peripheral nervous systems. Furthermore, we propose a bioresorbable and self-powered device as electronic medicine for peripheral nerve regeneration. Successful nerve regrowth and motor functional recovery are realized in rodent models. These works provide new insights for modulating neural activities and repairing nerve injuries.

**Reprocessable Ion-Conducting Elastomer Formed by Thiourea-Based Dynamic Covalent Network** Bitgaram Kim<sup>1</sup>, Yeong Je Cho<sup>1</sup>, Dong-Gyun Kim<sup>2</sup> and Ji-Hun Seo<sup>1</sup>; <sup>1</sup>Korea University, Korea (the Republic of); <sup>2</sup>Korea Research Institute of Chemical Technology, Korea (the Republic of)

*The development of ionic conducting elastomer (ICE) with reprocessing capability is desirable to prevent resource wastage and environmental crises. Traditional elastomers with covalent cross-linking pose challenges for reprocessing due to their thermoset properties. To address this issue, a thiourea-based dynamic covalent network was employed to design the ICE. Through an analysis of the interaction between the lithium salt and the polymer chain, LITFSI was selected as the ideal choice. Furthermore, the analysis revealed that the behavior of the dynamic covalent network was influenced by the interactions between the polymer chain and lithium salts, not just the network formation itself. The resulting dynamic covalent elastomer can be reprocessed multiple times using various methods such as hot-pressing and solution processes. It demonstrates good dimensional stability and exhibits an ionic conductivity.*

**Minimally Invasive Bioprinting of Conductive Hydrogel for *In Situ* Liver Regeneration** Yueying Yang and Jianfeng Zang; Huazhong University of Science and Technology, China

*In situ* bioprinting is promising for developing scaffolds directly on defect models in operating rooms, which provides a new strategy for *in situ* tissue regeneration. However, due to the limitation of the printing depth and bioink, bioprinting scaffolds in deep dermal or extremity injuries remains a grand challenge. Here, we present a ferromagnetic intravital bioprinting approach for *in situ* tissue regeneration in a minimally invasive manner. The ferromagnetic intravital bioprinting system is able (1) to measure and identify the geometry of organ defects by micro-CT, (2) to plan a matched printing path, and (3) to deliver multiple bioinks to fabricate scaffolds on defects in a minimally invasive manner. The minimally invasive bioprinter is composed of a ferromagnetic soft catheter robot (FSCR) nozzle that can arrive at the deep dermal (0-150 mm) through a small incision (2-4 mm) and a separated remote magnetic actuation system that numerically controls the movement of FSCR. The hydrogel bioink is designed to be electroactive, self-healing, biocompatible, biodegradable, tissue adhesive and extrusion printable. After 3D reconstruction of the defects with computed tomography (CT), conductive hydrogel scaffold is printed within a partial liver resection of live rat, and *in situ* tissue regeneration is achieved due to the electroactive hydrogel scaffold, promoting the orderly arrangement of fibroblasts and collagen *in vivo*.

**Magnetic Nanogels for Combined Hyperthermia and Chemotherapy of Prostate Cancer** Sofia Patri<sup>1,2</sup>, Thanh T. Nguyen<sup>2</sup> and Nazila Kamaly<sup>1</sup>; <sup>1</sup>Imperial College London, United Kingdom; <sup>2</sup>University College London, United Kingdom

Iron Oxide Nanoparticles (IONPs) are FDA approved for biomedical applications, such as magnetic hyperthermia: IONPs can generate heat as a consequence of their relaxation mechanism after being placed in an Alternating Magnetic Field (AMF). The heat generation is measured in Specific Absorption Rate (SAR) and agglomerations of IONPs, known as NanoFlowers (NFs), have shown to have some of the highest SAR values out of all the variations of this material. The surface of IONPs and IONFs can be modified with an organic coating to increase their biocompatibility. By selecting the appropriate soft material, the organic shell can also encapsulate a cargo and release it over time: this kind of magnetic composite can combine hyperthermia with drug delivery, making it a highly effective treatment against cancer cells. Nanogels, which are hydrogels in the nanoscale, are highly biocompatible and stable in the biological environment thanks to their crosslinked network; more importantly, they can be engineered to respond to an external stimulus. By including a thermo-responsive unit in the nanogel, an increase in temperature will induce a coil-to-globule transition of the chains causing the shrinkage of the nanogel and the expulsion of water along with the encapsulated cargo.

In this multifunctional therapy, we aim to trigger drug release from a nanogel by using the heat generated by the IONFs in an AMF. To improve the stability of the nanocarrier in the physiological environment, we demonstrate the necessity to anchor the nanogel to the IONFs through a surface ligand. The development of functional and stable magnetic nanogels provides a more effective, localized, and precise therapy that combines the benefit of the monotherapies while minimizing their individual drawbacks whilst establishing synergistic actions.

#### 8:00 PM SB04.03.04

**Conducting Hydrogel Based on Novel Polymer Composite PEDOT:DBSA for Bioelectronic Applications** Šárka Tumová<sup>1</sup>, Romana Malečková<sup>1</sup>, Petr Smíšitel<sup>2</sup>, Lubomir Kubáč<sup>3</sup>, Jirí Akrman<sup>3</sup>, Jirí Smilek<sup>1</sup>, Michaela Pešková<sup>4</sup>, Jan Viteček<sup>4</sup>, Martin Vala<sup>1</sup> and Martin Weiter<sup>1</sup>; <sup>1</sup>Brno University of Technology, Czechia; <sup>2</sup>Central European Institute of Technology, Czechia; <sup>3</sup>Centre for Organic Chemistry, Czechia; <sup>4</sup>Institute of Biophysics of the Czech Academy of Sciences, Czechia

Organic bioelectronics represents a potential revolution in medicine as it holds the promise of personalised treatment with reduced side effects compared to conventional pharmaceutical drugs. Despite the big effort dedicated to this field, there are still challenges to be solved. One of them is the form of organic polymers acting as active material, as the commonly used thin films are not very favourable with regard to the tissues that are supposed to be in proximate contact with them. That is mainly due to the dissimilarities in mechanical and physical properties of these two components, which might be an obstacle preventing the formation of a satisfactory interface, thus reducing the efficiency of signal transport. This properties mismatch arises especially from the differences in water content and elastic modulus values. Hence, there is a big demand for a more tissue-like form of these materials as it can significantly promote contact with tissues at the interface, thus reducing the adverse immune responses of the biological system, decreasing the interfacial impedance and enhancing the efficiency of both signal recording and stimulation. Among other structures, hydrogels seem to be the perfect interface to biological tissues due to their structural similarity with the extracellular matrix, tissue-like mechanical properties, water-rich nature, superior biocompatibility, flexibility and adjustable biochemical properties. In this work, we prepared and characterised a conductive hydrogel based on a completely new polymer composite – PEDOT:DBSA. The rheological characterization revealed that the mechanical strength of the hydrogel as well as the gelation time can be easily tailored to the desired application by changing the concentration of cross-linking agent. The electrical properties of the hydrogel were studied using impedance spectroscopy and cyclic voltammetry. It was shown that the total bulk conductivity of prepared hydrogel is 3.8 S m<sup>-1</sup>. The LDH cytotoxicity assay showed a very good biocompatibility of hydrogel compared to that of the culture plastic and glass dish. The structure of the hydrogel was investigated using scanning electron microscopy and was found to be of rough, spongy nature. These results indicate that PEDOT:DBSA hydrogel has great potential for creating an interface between the biological environment and electronic devices used in various fields of regenerative medicine.

**Electrospun Hydrogel Nanoporous Scaffold for Cleaning Ultrafine Contaminants in Semiconductor Manufacturing** Somin Shin, Ji-hun Jeong and Sanha Kim; Korea Advanced Institute of Science and Technology (KAIST), Korea (the Republic of)

In semiconductor manufacturing, chemical mechanical planarization (CMP) process is an essential step where wafers are polished via chemical and physical actions using externally supplied abrasives. After the CMP step, contaminants which include the remained abrasives and wear debris must be strictly removed from the wafer surface to prevent device failure via unintended particles. Accordingly, CMP cleaning always follows right after the CMP step. Post-CMP cleaning is particularly difficult as the contaminants are strongly adhered on the wafer surface due to as they are mechanical compressed during the polishing step. For such challenges, brush scrubbing techniques are widely employed due to their superb cleaning efficiency. The brush cleaning is in general conducted via porous polyvinyl alcohol (PVA) hydrogel brushes which make a physical contact with the wafer therefore can provide sufficient physical removal force to the surface particles for their removal.

The synthetic PVA hydrogel used as the wafer cleaning brushes comprises micropores, and has high swelling capacity against water-based cleaning solutions. The recent challenge arises as the pore sizes of commercial brush products remain in micro-scale whereas the size of the contaminants to be removed is ever shrinking to even few nanometers. Therefore, the existing brush products cannot effectively deliver the sufficient removal forces on ultrafine particles. In this research, we fabricate a PVA hydrogel scaffold comprising nano-scale porosity which can exhibit high effectiveness in particle removal for cleaning ultrafine contaminants. Insoluble polyvinyl formal (PVF), the raw material of cleaning brush, is synthesized via acid catalyzed acetalization of water-soluble PVA with formaldehyde which occurs with crosslinking of PVA chains by modifying hydroxyl groups. We produce nano-scale fibrous sheets using electrospinning process and investigate the effect of PVA/formaldehyde/sulfuric acid weight ratio as well as the processing conditions on the fiber formation. A heat treatment follows after the electrospinning step which reconstruct the fiber mat into a three-dimensional porous scaffold via creating fiber-to-fiber junctions, resulting in suitable mechanical strength and resilience. To verify the correlation between structural scale and particle removal efficiency, we conduct lab-scale wafer cleaning experiments on substrates contaminated with particles of various sizes, from 12 μm to 80 nm, using conventional microporous brushes and fabricated nanoporous scaffolds. We further experimentally verify that the effect of the structural scale is significantly more dominant. Our new hydrogel nanoporous scaffold exhibit outstanding removal efficiency for ultrafine particles, thus can provide an

effective engineering solution for the current limit in post-CMP ultrafine contaminant cleaning which is of-interest in semiconductor manufacturing industry.

#### 8:00 PM SB04.03.06

**Tissue-Adhesive and Anti-Swelling Hydrogel Based Multifunctional Implantable Sensor for Monitoring of Bladder Activity in Overactive Bladder with Surgical-Robot Assisted Laparoscopic Surgery** [Byungkook Oh](#) and Steve Park; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Electrical properties and mechanical properties of a biological bladder tissue provide useful tissue information for preventing disabling condition of urinary systems as clinical treatments. Recently, there has been a great deal in designing implantable electronics that collect tissue information and provide fundamental treatments. However, intrinsic differences between biological tissues and conventional rigid and dry electronics pose problems with unstable interaction between both surfaces and infection of biological tissues. Here, a highly stretchable and tissue-adhesive multifunctional implantable sensor based on structurally engineered islets embedded in ultra-soft hydrogel is developed for real-time monitoring of bladder activity in overactive bladder (OAB) induced rat and anesthetized pig. One critical issue with hydrogel in general as implantable substrates, however, is their eventual change in mechanical properties and electrical properties due to the gradual absorption of biofluids in the body. To overcome the critical issue, an anti-swelling coating technique that can prevent absorption of water and biofluids in the body is developed. This coating technique is applicable to various hydrogels that have low sol-gel transition temperatures, while imposing negligible changes in mechanical properties. Using tissue-like, anti-swelling hydrogel, which can sustain its initial mechanical & electrical properties as a role of an insulating substrate, can bridge sensory systems to biological tissue with robust seamless interaction without infection of tissues. The sensory systems integrated to soft bridging materials (hydrogel) consist of strain sensors (directly printed micro-capsules of EGaIn on an anti-swelling hydrogel substrate) and multi-array electromyography (EMG) sensors (Ti/Au) on structurally engineered ferris wheel-shaped islets that can make it possible to collect tissue information during repetitive micturition of overactive bladder. On the OAB induced rat, stronger signals (change in resistance and EMG root-mean-square) were detected near intra-bladder pressure maxima, thus showing correlation to bladder activity. Moreover, using robot-assisted laparoscopic surgery, the hydrogel-based implantable sensor was placed onto the bladder of an anesthetized pig. During micturition cycle, bladder strain and EMG were monitored. These results confirm that our proposed sensor is a highly feasible, clinically relevant implantable device for continuous monitoring OAB for diagnosis and treatment.

**Highly Stretchable Hydrogel Fiber Fabricated by a Self-Coiling Mechanism Maintaining High Water-Content** [Tao Li](#) and Seon Jeong Kim; Hanyang University, Korea (the Republic of)

Hydrogels, which are polymer networks dispersed in water, are widely used in biomedical fields, among others, because of their excellent mass transfer efficiency and biocompatibility. However, hydrogels with a high water content usually have poor mechanical properties and are easily broken. To address this issue, many researchers have incorporated one or more complementary materials into the polymer network of the hydrogel to limit its swelling. Although this method enhances the mechanical properties of hydrogels, it also limits the water content; therefore this method cannot be applied to improve the mechanical properties of high-water-content hydrogels. We have observed that a jellyfish called *Physalia physalis* preys on fish through its coiled stinging tentacles. Although the body of *P. physalis* has a water content above 95%, the coiled structure still provides high stretchability. In this study, we developed a coiled hydrophilic polyurethane hydrogel fiber with high stretchability and high water content by mimicking the coiled stinging tentacles of *P. physalis*. Dry hydrophilic polyurethane yarns produced by electrospinning were twisted under an applied load. When the twisted dry hydrophilic polyurethane yarn swelled with water, the change in Young's modulus and shear modulus elicited self-coiling within 1 s and resulted in a coiled hydrophilic polyurethane hydrogel fiber. The morphology of the formed coiled polyurethane hydrogel fibers can be tuned by adjusting the twist density and the stress resulting from the load applied during swelling. Compared with non-coiled hydrophilic polyurethane hydrogel fibers, the coiled hydrophilic polyurethane hydrogel fibers prepared by this method exhibited ultrahigh stretchability due to the coiled structure and elasticity of the material. When the coiled hydrophilic polyurethane hydrogel fibers are stretched, the uncoiling of the coiled structure provides stretchability, and the fibers can be further stretched due to the elasticity of the hydrophilic polyurethane hydrogel. In summary, we developed a coiled hydrophilic polyurethane hydrogel fiber that can rapidly swell and self-coil under aqueous conditions and possesses high stretchability, while maintaining high water content. It is expected to be used in biomedical fields for applications such as surgical sutures, drug delivery systems, and tissue regeneration.

#### 8:00 PM SB04.03.08

**Controllable Actuator by Reversible Clustering Transition Composed of Temperature-Responsive Hydrogel** [Jiseong Choi](#) and Seongmin Kang; Chungnam National University, Korea (the Republic of)

Hydrogel-based soft actuators, which can change their shape according to the various environment and has safe for the human body, are being utilized in various fields such as smart windows, etc. Among the hydrogels, N-isopropylacrylamide (NIPAm), due to its swelling characteristics dependent on the critical solution temperature (32 degree), can be used as a suitable actuator for different situations. Additionally, micropillars with high aspect ratio easily are transformed to clustering state under external forces, and both their original state and clustering state are being utilized as actuators. However, micropillars of clustering state once do not naturally de-clustered, having limitation of application by its non-reversible property of clustering state. In this paper, we fabricate micropillars actuator of a reversible clustering transition composed of thermo-responsive poly(NIPAm-co-acrylamide) hydrogels, verifying the potential applications of soft actuators. The actuator is clustered due to the decrease in mechanical properties of hydrogels by water, but it is de-clustered due to the increase in mechanical properties by hot temperature. Based on this phenomenon, we demonstrated the potential applications of micro grippers for capturing and transporting micro particles in water, as well as smart windows capable of reversible transitions in surface transmittance outside the water.

#### 8:00 PM SB04.03.09

**An Efficient Self-Healable and Recyclable Conductive Polymeric Blend with Excellent Mechanical Properties Based on PEDOT:PSS/PU** [Jinsil Kim](#) and Fabio Cicoira; Polytechnique Montreal, Canada

Self-healable conductive polymers have been attracting attention because of the promising advances in electronic devices. Self-healable and conductive coating films are fabricated by blending a conductive polymer, poly(3,4-ethylenedioxythiophene): poly(styrene sulfonate) (PEDOT:PSS) with polyurethane (PU) having excellent mechanical properties. PEDOT:PSS/PU composites are characterized in terms of self-healing properties, recyclable properties, mechanical properties and electrical properties in this study. Polyurethane (PU) is synthesized by reacting with macro diol as a soft segment, isocyanate groups and extender as a hard segment. The two polymers have no noticeable phase separation in blending solutions. The self-healable coating materials exhibit outstanding self-healing capabilities and fast self-healing kinetics and therefore can be used for practical applications like flexible and stretchable electronic devices. The polymeric coating film is cut into two parts completely with a sharp blade then the damaged surfaces are connected under mild temperature for the healing process. The results from experiments exhibit using a mechanical tester to compare the mechanical properties of various compositions of PEDOT:PSS/PU and before and after self-healing processes, respectively. Regarding electrical performance, a cyclic tensile test is

also performed to monitor the elasticity. The electrical conductivity maintains constant electrical conductivity under cyclic tensile stress when tensile stress is loaded up to 30% strain. The PEDOT:PSS/PU-based can be reused, improving the sustainability of electronic devices. All these results revealed that PEDOT:PSS/PU have the potential to enable to development of more sustainable and durable electronic devices by reducing electronic waste and improving the lifespan of electronic components.

#### 8:00 PM SB04.03.10

**Designing Azo-Based Color-Changing Hydrogels by Sensing pH Response** Wei-Ting Chang, Violet Pratt, Neel Joshi and Leila Deravi; Northeastern University, United States

The wide applications for environmental sensing and responsible sensing materials using hydrogels can be excellent candidates across systems in biology. For instance, most living cells elicit pH changes during metabolism which we leverage as an actuator in the design of new pH-responsive hydrogels. We synthesized azo-based monomers from anthranilic acid and followed by azo coupling by the treatment of phenylpiperazine and acyl amide. These monomers can then be polymerized with bis-acrylamide, acrylic acid, and polyacrylamide as an adaptive hydrogel that change shape and color different pH environments. Applications of these gels are explored both with and without cells in different environments.

#### 8:00 PM SB04.03.12

**Hydrogel-Enhanced Supported Lipid Bilayers (SLBs) Offer Greater Stability and Functionality in Bioelectronic Devices** Jordan P. Fitzgerald, Zhongmou Chao and Susan Daniel; Cornell University, United States

Supported lipid bilayers (SLBs) have emerged as an indispensable material to functionalize the surface of bioelectronic sensors that facilitates the exploration of cellular membrane interactions with a wide range of molecules. SLBs accurately mimic the structure, composition, and diffusive properties of natural membranes, providing a biomimetic experimental model. Particularly noteworthy is the compatibility of SLB bioelectronics with electrochemical impedance spectroscopy (EIS), allowing for real-time monitoring of changes in impedance across SLBs. Such measurements provide valuable insights into changes in membrane properties, drug interactions, and the behavior of embedded proteins and channels. However, one drawback of these sensors currently is their vulnerability and limited shelf-life that impedes their broader application.

In this study, we combine hydrogels with SLB bioelectronic devices and show that the usable shelf-life of these devices can be extended significantly. Our approach exploits a range of hydrogels, each with unique characteristics that enhance system versatility. PEGDA, a UV crosslinked hydrogel, enhances the stability of both model POPC SLBs and native component SLBs. Other hydrogels, such as poloxamer based thermally reversible gel, and chitosan based chemically crosslinked gels, show potential for preserving UV- and temperature-sensitive components within the SLBs. Overall, this strategy extends the shelf life of the SLBs from a single day over 45 days, all while preserving the electrical signal integrity and functionality of proteins within the SLBs. This hydrogel-enhanced approach not only facilitates longer sensing periods, but also enables the long-distance shipping of functional SLB-based devices, necessary steps for translation to the field.

In addition to enhancing the shelf life and stability of the SLB-functionalized bioelectronic devices, the integration of hydrogels also boosts their functionality. The hydrogel layer not only facilitates improved stability but also enables the use of cell-free expression of proteins directly into the membrane. This expands the utility of our method, creating opportunities for more comprehensive investigations into the behavior of specific proteins and their responses to various agents within a highly stable, extended-lifespan SLB-based bioelectronic system. This research lays the groundwork for the development of sophisticated hydrogel-enhanced SLB systems capable of operating in complex environments, bringing us closer to the construction of advanced devices such as electrode arrays, sensors, and biomimetic devices, and expanding the scope of bioelectronic applications in biomedical research and beyond.

#### 8:00 PM SB04.03.13

**Thermo-Responsive Emulsion-Embedded Hydrogel Microparticle and Its Application to RT-qPCR** Seoyoung Lee, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Water-oil-water double emulsions (DEs) have been widely used as compartmentalized systems to encapsulate components for controllable and targeted reagent delivery. The components encapsulated in DE could be efficiently released upon various stimuli, such as changes in temperature, light, and chemical environment. Among them, by utilizing the heating as a controllable release stimulus, we herein developed a novel thermo-responsive DE-embedded hydrogel microparticle reactor suitably applicable for one-step quantitative reverse transcription polymerase chain reaction (RT-qPCR), which minimizes the non-specific reaction in the reverse transcription step. For this strategy, we encapsulated target-specific nucleic acid reagents (PCR primers and probes) in DE and subsequently entrapped DE in a micro-sized hydrogel PCR reactor. First of all, we adjusted the surfactant concentrations of DE for enhancing the DNA encapsulation efficiency and optimizing the DNA release efficiency to be maximized in the PCR denaturation step (95 °C) as well as minimized in the reverse transcription step (55 °C). From the perspective of DE itself, DNA encapsulation and release efficiencies at both 95 °C and 55 °C increased and decreased, respectively, with increasing concentrations of hydrophobic surfactant, while they were independent of hydrophilic surfactant concentrations. Moreover, we also investigated the change in DNA release tendency and optimized the surfactant concentrations when DEs were embedded in hydrogel microparticles. As a result, and importantly, the DNA release efficiency of DE entrapped in hydrogel significantly increased about 4 times at 95 °C compared to that of DE itself, indicating that the DEs individually located within the hydrogel are more vulnerable to the release of DNA-encapsulated inner water phases. In addition, 8 CMC of hydrophobic surfactant and 37.5 CMC of hydrophilic surfactant were selected as the optimal conditions where 4.6 μM of DNA reagent was encapsulated, and 40% (1.80 μM) and 9% (0.15 μM) of reagent were released at 95 °C and 55 °C, respectively, demonstrating target-specific reagent delivery on demand. Consequently, under these conditions, we successfully confirmed the operation of one-step RT-qPCR in the thermo-responsive DE-embedded hydrogel microparticle and the developed hydrogel microparticle could be utilized as a powerful point-of-care testing platform for the multiplexed detection of several RNA biomarkers.

#### 8:00 PM SB04.03.14

**Nanoemulsions-Containing Hydrogel Microparticle Array PCR for Multiplex Discrimination of SARS-CoV-2 Variants** Yoon-ha Jang, Eui Ju Jeon, Seoyoung Lee, So Young Jeon, Lan Kyeong Yoon, Seungwon Jung and Sang Kyung Kim; Korea Institute of Science and Technology (KIST), Korea (the Republic of)

Over time, viruses continually produce new genetic variants of themselves. Surveillance is needed to investigate how mutations in viruses affect the transmissibility and lethality of the virus as well as responses against therapeutic medicines [1]. However, whole genome sequencing, which is currently utilized for variant identification, has a limitation in testing a large number of samples, especially in a pandemic situation. Herein, we present rapid multiplex RT-qPCR for SARS-CoV-2 variant discrimination using the TaqMan probe and primer-incorporated network (TaqPIN). TaqPIN is a hydrogel microparticle where target-specific reagents such as primers and probes are preloaded as encapsulated in nanoemulsions [2]. The main challenge is to fabricate TaqPIN because the photoinitiators (PIs) required for curing hydrogel destabilize nanoemulsions and damage the fluorescently labeled probes encapsulated within the nanoemulsion. We found that free radicals generated by PIs damage the probes encapsulated within the nanoemulsions via the infiltration of PIs into the nanoemulsions. We successfully fabricated TaqPIN by using water-dispersible nanoparticles of 2,4,6-trimethylbenzoyl-

diphenylphosphine oxide (TPO) as PIs. We found that fluorescently labeled DNA was well retained in the hydrogel particles even when TaqPIN was subjected to strong agitation, and TaqPIN PCR with the same concentration of sample showed constant Ct values up to 2 months. Finally, we constituted a 9-plex TaqPIN array for the identification of five SARS-CoV-2 variants of concern, including alpha (B.1.1.7), beta (B.1.351), gamma (P.1), delta (B.1.617.2), and omicron (BA.1), and the original Wuhan strain within 40 min. From 76 clinical nasal swab samples, the TaqPIN array RT-qPCR successfully discriminated variants with 95.5% sensitivity and 100% specificity. We envision that the TaqPIN array RT-qPCR can be applied to simple diagnostics to help detect and characterize circulating pathogens.

#### 8:00 PM SB04.03.15

**Towards Multi-Responsive Pluronic F127-Based Copolymer Hydrogels for Engineering Living Materials** [Henrique Sepulveda Del Rio Hamacek](#)<sup>1</sup>, LeAnn Le<sup>2</sup>, Petri-Jaan Lahtvee<sup>1</sup>, Rahul Kumar<sup>1</sup> and Alshakim Nelson<sup>2</sup>; <sup>1</sup>Tallinn University of Technology, Estonia; <sup>2</sup>University of Washington, United States

Engineered living materials (ELMs) are dynamic systems featuring capabilities such as biosynthesis, self-organization, and self-healing<sup>1</sup>. Integrating polymeric matrices (abiotic) and cellular (biotic) components creates materials with novel functionalities and precise responsiveness<sup>2</sup>. Here, we deployed additive manufacturing using extrusion-based 3D printing to develop hydrogels capable of retaining cells for longer periods due to increased toughness, while facilitating better nutrient transport to the cells through improved ionic conductivity.

Initially, we formulated hydrogels containing Pluronic F127-bisurethane methacrylate (F127-BUM), methacrylic acid (MAA), and dimethylaminoethyl acrylate (DMAEA) at different monomer concentrations. We characterized the rheological and mechanical properties of these hydrogels. Rheological results revealed that all hydrogel compositions decreased viscosity with increasing shear rate while maintaining their shear-thinning properties even after multiple cycles of applied shear. These results indicate the potential for creating high-resolution 3D-printed structures. Additionally, temperature ramp experiments demonstrated that the hydrogels exhibited the characteristic Pluronic F127 temperature-dependent behavior<sup>3</sup>, with decreased gelation temperatures upon MAA and DMAEA addition to the precursor mixtures.

Subsequently, tensile mechanical tests were conducted to evaluate the toughness and elasticity of the newly developed hydrogels. The results showed that the hydrogel composition with equimolar concentrations of MAA and DMAEA exhibited a 50% increase in elongation at break compared to control hydrogels consisting solely of F127-BUM. This material could also be elongated up to 600% of its original size, while the modulus of elasticity decreased by 35% compared to the control. These effects were attributed to the disruption of electrostatic interactions between MAA and DMAEA, which carry opposite charges at neutral pH. The formulated hydrogels demonstrated the necessary mechanical properties for cell-loading applications.

Finally, we loaded bakers' yeast ( $10^7$  cells/g of hydrogel) into the selected hydrogels and analyzed their viability, metabolite production, and morphology during cultivation at 50 rpm and 30 °C. The hydrogel with MAA and DMAEA enabled cell retention for longer than previously reported for F127-BUM hydrogels with the same initial cell concentration<sup>4</sup>. Additionally, the cells remained metabolically active throughout the cultivation experiments.

In conclusion, this work demonstrates the potential of the developed hydrogel platform, featuring enhanced mechanical properties and improved ionic conductivity, for the additive manufacturing of ELMs. This platform holds promise for applications in bioengineering and highlights the importance of advanced materials in creating functional ELMs with enhanced capabilities.

**Molecular Dynamics Simulation of Free-Formed Nanocomposite Hydrogels** [Emily Sun](#)<sup>1</sup>, Shoumik Saha<sup>2</sup>, Jose Nicasio<sup>2</sup>, Dilip Gersappe<sup>2</sup> and Miriam Rafailovich<sup>2</sup>; <sup>1</sup>Westford Academy, United States; <sup>2</sup>Stony Brook University, The State University of New York, United States

Hydrogels are crosslinked polymer networks that can absorb and retain large quantities of water within their structures. Typically made of hydrophilic polymers, their swelling ability gives these materials properties of both solids and liquids alike. Recent studies highlight that combining hydrogel materials with clay-based nanofillers and charged solvents results in a hydrogel with enhanced properties. However, little is known about the theoretical mechanism of the gel's network formation. Here, we explore a system of free-floating polymer chains, clay-based nanofillers, and solvent to determine the specific conditions for a stable network formation, and optimal rheology of the gel. The aim of this study is to produce the strongest hydrogel, which can then be used for soil-strengthening applications.

We performed coarse-grained molecular dynamics with the LAMMPS software. Our polymer chains were constructed using the Kremer-Grest model, which defines bond interaction via the finitely extensible nonlinear elastic (FENE) potential. Other pairwise interactions between monomers were modeled by using the simple 12-6 Lennard Jones potential. We implemented this model for different polymer concentrations of N=300, 600, and 900, with varying distributions for their attractive regions, or "stickers," which were placed uniformly every 5th, 9th, and 14th monomers (5, 3, and 2 stickers). We turned on attractive interaction between stickers, which let polymer chains connect to undergo network formation. The polymers' dynamics were calculated through diffusion coefficients, gathered from mean-squared-displacement (MSD) values. We calculated stress auto-correlation (SAC) to determine the point at which our system forms a gel. We further ran shearing tests and polymer chain orientation during the shearing process will determine the specific shear thinning properties of our system. Our results show that by proper choice of polymer architecture we can design networks that can be used for soil amendment purposes.

**Utilizing Bioprinting for Hydrogel-Based Electric Double-Layer Capacitor Fabrication** [Bianca Seufert](#) and Arash Takshi; University of South Florida, United States

While electric vehicles are slowly bringing in a new era of eco-friendly transportation, the mass production and use of Li batteries have raised serious concerns about their impacts on the environment. Hence, supercapacitors that are able to be charged and discharged at high rates with high power densities and a long cycling stability are potential alternatives to batteries. There are three different types of supercapacitors: electric double-layer capacitors (EDLC) supercapacitors, pseudo-supercapacitors, and hybrid-supercapacitor. For the scope of this paper, however, only EDLCs will be discussed. Using biocompatible materials, supercapacitors are a viable charge storage device for implantable electronic sensors. This paper addresses a new approach to supercapacitor fabrication using a bioprinting method. A series of experiments were conducted to derive a conductive bioink capable of being implemented as a viable material for energy storage devices. This bioink in conjunction with a gel electrolyte were utilized for the fabrication of supercapacitors in a

planar structure. This study utilizes the testing methods of Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) using the VersaStat 4 Potentiostat to measure the capacitor response. Devices with capacitances as high as 53.52  $\mu\text{F}$  were fabricated and tested. The results of this study show the feasibility of using the bioprinting method for fabricating prototype storage devices.

**Turgor Pressure Reinforces Mineral-Based Composites** [Ran Zhao](#) and Esther Amstad; École Polytechnique Fédérale de Lausanne, Switzerland

Nature fabricates hard functional materials from soft organic scaffolds that are mineralized. To overcome the brittleness of inorganic components, biominerals are arranged in hierarchical structures and sometimes develop local compressive or tensile stresses. For example, the precipitation of hydroxyapatite minerals leads to contractile stresses in collagen fibrils, and eventually reinforces mechanical properties of bones<sup>[1]</sup>. The fibril contraction comes from the dehydration of the polymer matrix, even though it happens in a hydrated environment. Similarly in plant cells, osmotic pressure is used to stiffen leaves by exploiting a strong turgor pressure<sup>[2]</sup>. Osmotic pressure is well-known to change the mechanical properties of living biological materials. Nevertheless, this strategy has thus far not been leveraged in mineral-based composites. This shortcoming might in part be related to the inferior mechanical behavior of synthetic composites compared to natural counterparts due to the limited structural control over different length scales.

Here, we demonstrate a mineral-based composite whose strength and stiffness can be repeatedly adjusted through osmotic pressure driven swelling and deswelling of confined hydrogels. Specifically, we employ a synthetic porous matrix with a similar degree of structural control from the nanometer up to the centimeter length scale made from an emulsion-based, 3D printable ink<sup>[3]</sup>. Those pores in the matrix are back-filled with a hydrogel, which can generate internal compressive or tensile stresses triggered by osmotic pressure gradients. The matrix can selectively bind certain cations such as  $\text{Ca}^{2+}$  ions, which can serve as mineralization sites upon addition of  $\text{CO}_3^{2-}$ . The hydrogel contractions induced through the mineral precipitations and osmotic pressure gradients lead to a synergetic control over the mechanics of the composite. This work provides an exciting concept for enhancing mechanical properties of mineral-based composites through turgor pressure similar to biological systems, which can be used as soft actuators or intelligent devices for underwater applications.

**Nanoengineered Ink for Designing 3D Printable Flexible Bioelectronics** [Akhilesh K. Gaharwar](#); Texas A&M University, United States

Flexible electronics require elastomeric and conductive biointerfaces with native tissue-like mechanical properties. The conventional approaches to engineer such a biointerface often utilize conductive nanomaterials in combination with polymeric hydrogels that are crosslinked using toxic photo-initiators. Moreover, these systems frequently demonstrate low signal accuracy, poor biocompatibility and face trade-offs between conductivity and mechanical stiffness under physiological conditions. To address these challenges, we introduce a class of shear-thinning hydrogels as biomaterial inks for 3D printing of flexible bioelectronics. These hydrogels are engineered through a facile vacancy-driven gelation of  $\text{MoS}_2$  nanosheets and naturally derived polymer. Due to shear-thinning properties, these nanoengineered hydrogels can be printed into complex shapes that can respond to mechanical deformation. The chemically crosslinked nanoengineered hydrogels demonstrate twenty-fold rise in compressive moduli and can withstand up to 80% strain without permanent deformation, meeting human anatomical flexibility. The nanoengineered network exhibits high conductivity, compressive modulus, pseudo-capacitance and biocompatibility. The 3D printed crosslinked structure demonstrate excellent strain sensitivity and can be used as wearable electronics to detect various motion dynamics. Overall, the results suggest that these nanoengineered hydrogels offer superior mechanical, electrical, and biological characteristics for various emerging biomedical applications including 3D printed flexible biosensors, actuators, optoelectronics, and therapeutic delivery devices.

### 9:00 AM \*SB04.04.03

**Conducting Polymer Hydrogels for Hydrogel Bioelectronics** [Hyunwoo Yuk](#); SanaHeal, Inc., United States

Electrical interfacing with biological tissues for interrogation and modulation of living systems – or bioelectronics – is one of the most important modes of communication between artificial machines and biological organisms. In conventional applications, bioelectronic interfacing has relied on conventional electrodes and devices made of metals and engineering solids like plastics and elastomers. However, the stark dissimilarity between biological tissues and conventional device materials has posed great challenges for long-term bioelectronic interfacing with living systems, especially for implantable devices. To address these challenges, electrically conductive hydrogels – polymer networks infiltrated with large amounts of water with electrical conductivity – have been substantially studied in the last decades owing to their unique advantages including tissue-like mechanical properties and high water contents, favorable electrical properties, and in vivo biocompatibility. However, conducting polymer hydrogels has faced several key challenges in their practical uses including poor electrical and mechanical properties in physiological environments, unreliable integration within devices and to the target biological tissue, and difficulties in small-scale fabrications into functional devices. In this talk, several advances in conducting polymer hydrogels to address these challenges will be discussed toward the vision of hydrogel bioelectronics.

### 9:30 AM SB04.04.04

**Skin-printable, Self-adhesive and Bio-based Hydrogel for the Bioelectronic Interface** [Jia Xi Chen](#)<sup>1</sup>, Yi Xin Zhang<sup>1</sup>, Terek Li<sup>1</sup>, Zia Saadatnia<sup>1</sup>, Milos Popovic<sup>2,1</sup> and Hani Naguib<sup>1,1</sup>; <sup>1</sup>University of Toronto, Canada; <sup>2</sup>University Health Network, Canada

Inspired by the customizability of injectable hydrogels in the medical field as cell cultures and engineered tissues, a conductive and 3D-printable hydrogel based on bio-polymers is developed to interface between the skin and medical devices during rehabilitation treatments of surface functional electrical stimulation (sFES). The sFES treatment involves delivering electric currents through the skin to induce muscle contraction, with clinical evidence supporting the ability of sFES treatments to restore voluntary motor functions in previously paralyzed patients. However, physiological differences in muscle distribution and body curvatures among individuals require sFES treatments to be personalized. Therefore, to increase the accessibility of sFES rehabilitations by enabling remote sessions and shape-configurable electrodes universal to all patients, the authors developed a novel material capable of being adapted to any shape and size, with self-adhesive and electrically conductive properties to ensure conformity to body morphology and to guarantee sFES signal stability. As the electrodes are single-use, the hydrogel is made from naturally occurring, biocompatible, and eco-friendly polymers that are easy to fabricate and process. Carboxymethyl cellulose is adopted as the matrix for its water solubility and mechanical properties, along with poly(3,4-ethylene-dioxythiophene) polystyrene sulfonate (PEDOT:PSS) as the conductive additive and mussel-inspired polydopamine as the adhesive additive. A mild and biocompatible gelation method exploiting hydrogen bonding is implemented by adding phytic acid, with *in situ* formation of the extruded hydrogel taking place minutes after being 3D-printed onto the skin. The gelation process is examined with FTIR spectroscopy, which confirms the molecular interactions between bio-polymer components, scanning electron microscopy, which ensures the macroscopic morphology of the formed hydrogel, and rheological measurements over time, which characterizes the printability of the precursor ink. The pre-gel solution exhibits tailorable viscosity, allowing for facile processability and shape-configurability. Adhesive and electrical properties of the hydrogel are studied in contact with porcine skin over time. Although the self-adhesion of the hydrogel is two folds lower than commercial tissue adhesives, the interfacial electrical impedance is improved by an order of magnitude compared to commercial hydrogel electrodes. The sFES performance of the printable and conductive hydrogel is further assessed with a developed handheld 3D printer, a lightweight instrument to extrude the hydrogel ink in uniformly deposited layers with shape fidelity of mm-thick resolutions. Compared to conventional sFES electrodes of both hydrogel and metal-electrolyte gel systems, the printable hydrogel electrodes can induce muscle movement during sFES with better precision and accuracy, improving the efficiency by 10% when stimulating eye closure to the orbicularis oculi muscle. The printable and conductive hydrogel created for wearable purposes may be adapted for other applications involving bi-directional communications of electric signals across the bioelectronic interface, such as surface electromyography and surface electrocardiography.

#### 9:45 AM SB04.04.05

**PEDOT:PSS Hydrogel Based Wearable Biosensor Utilizing Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Lactate Detection** Yuchen Shao<sup>1</sup>, Luiz Marcelo<sup>2</sup>, Lixin Zhang<sup>1</sup>, Manisha Gupta<sup>1</sup> and Dipanjan Nandi<sup>1</sup>; <sup>1</sup>University of Alberta, Canada; <sup>2</sup>Monterrey Institute of Technology and Higher Education, Mexico

Poly (3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) is a conductive polymer with excellent electrical conductivity, good processibility and biocompatibility. Hydrogels have the advantage of soft, flexible and non-toxicity with cells and tissues. A combination of PEDOT: PSS and a hydrogel offers unique conductivity and mechanical properties, applying an alternative approach for biosensing applications.

In this work, we developed a PEDOT:PSS hydrogel based 3D printed organic electrochemical transistor (OECT) for lactate sensing, since OECTs offer high transconductance, low operation voltage and compatibility with aqueous environments. Optomec Aerosol Jet 5X 3D printer is used to fabricate the biosensors on the flexible Kapton substrate. Au was chosen as the metal contact, Pt as the gate with polyimide as the insulator layer. PEDOT:PSS hydrogel is drop casted on Au as the channel material. For PEDOT:PSS hydrogel, it was synthesized by mixing with dimethyl sulfoxide (DSMO) to improve the conductivity under vigorous magnetic stirring for 24 hours, then drop-casted 0.2uL solution on top of the channel for a printed OECT device and was placed into the oven under 60°C for another 24 hours to generate the partially formed gel. After that, 3 times cyclic annealing was applied for the device for 30 minutes at 130°C. Finally, the device was put under -20°C for 12 hours and took out for extra 12 hours, repeating 2 times. The unfunctionalized device exhibits a transconductance up to 110 mS and is compared to the printed PEDOT:PSS based device. Further, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX), bovine serum albumin (BSA) and gelatin help realize the functionalization of the device. The functionalized lactate sensor can be preserved in PBS solution under 4°C for over one month. Spike tests on the PEDOT hydrogel-based lactate sensor was performed and achieved a sensitivity range between 100uM and 10mM. In addition, the combination of the printed PEDOT:PSS channel with drop-casted PEDOT:PSS hydrogel exhibited better performance of the device. The results for this device will be presented along with the material characterization.

**Stimuli-Responsive Polymers as Precursors to Conductive Hydrogels** Laure V. Kayser; University of Delaware, United States

Electronically-conductive hydrogels, composites of crosslinked and water-swollen polymers with a conducting material (polymer or inorganic nanoparticles) can address the mechanical and electronic mismatch between electronic devices and biological systems. While several methods have been reported to prepare these conductive hydrogels, several issues have to be addressed to enable their translation in bioelectronics. These issues include: (1) the increase in elastic modulus at high loading of conducting material, (2) the irreversibility of the gelation mechanism, which complicates the delivery and potential removal of the conductive hydrogel *in vivo*, and (3) the difficulty in controlling the micro- and macro-structure of the conductive hydrogels for applications in tissue engineering and wearable electronics. In this talk, I will share our progress towards addressing these issues through the use of synthetic chemistry, particularly using novel stimuli-responsive conducting polymers. In the first part, I will discuss the use of thermo-responsive conducting polymers that displays a reversible sol-gel transition close to body temperature, thereby enabling injectable conductive hydrogels. The second part will be focused on achieving spatiotemporal control by using photo-active polymers to simultaneously photo-catalyze the polymerization of a conducting polymer and photo-crosslink its supporting matrix. This approach has great potential for 3D printing conductive hydrogels with a controlled microstructure and high resolution using light.

#### 11:00 AM \*SB04.05.02

**Programmable Materials, Structures and Devices for Next Generation Intelligent Machine** Jiyun Kim; Ulsan National Institute of Science and Technology, Korea (the Republic of)

In recent times, virtual intelligence has made significant strides, reaching and even surpassing the functional and cognitive abilities of humans, owing to advancements in computing power and novel operational methodologies. Meanwhile, physical objects or machines in the real world strive to imitate the forms and functions of specific living organisms, such as humans, cheetahs, and octopuses. However, they still lag behind in terms of intelligent and adaptive functions, necessitating the exploration of innovative mechanisms and approaches.

Therefore, our research group aims to develop an integrated robotic platform that possesses the ability to program its morphology, physical properties, interface, and function. This robotic paradigm requires innovation at all levels of the system, including materials, components, architectures for their integration, manufacturing processes, data processing, and operation. In this talk, I will introduce research categories and recent research outcomes from our group. These include (1) the development of programmable robotic components using smart materials such as multifunctional 3D sensors, soft tensile valves, digital metamaterial, and soft end effectors, (2) the exploration of novel algorithmic architecture including tensegrity, lattice metamaterial, and folding-based structures, (3) the exploitation of manufacturing methods realizing the architectures and functions including intuitive pen-drawing and 3D/4D printing, and (4) the excavation of machine design and operation methodology using artificial intelligence for shape-shifting task, in-situ function programming, and robot/HMI device design and operation. Through these works, we aim to blur the boundaries between the virtual and tangible world and, more importantly, between humans and the environment, thereby sharing our vision for the future physical environment for humans.

#### 11:30 AM SB04.05.03

**Highly Transparent Conducting Ionic Hydrogels of Double Network Structure for Deformable Electronics** Jinhwan Yoon; Pusan National University, Korea (the Republic of)

Highly deformable soft electrodes have garnered significant attention due to their potential to drive innovation in wearable electronics and soft robotics. To render the soft electrodes, stretchable, conductive, and transparent polymer networks have been studied extensively, but fulfilling these requirements remains challenging. In this work, we developed double-network ionic hydrogels of high transparency and stretchability due to the finely tuned network structure and transparent electrolyte. Based on the high performance of the ionic hydrogels, electroluminescent devices were achieved with an inorganic phosphor emission layer, which exhibits high luminance under extreme deformation. The remarkable transparency of the ionic hydrogels further enabled the fabrication of novel electroluminescent devices of tandem structures, allowing color variation by independent control of each emission layer.

#### 11:45 AM SB04.05.04

**Repeatably Autonomously Self-Healing Ultra-Stretchable PAAMPSA/PANI/PA Conductive Polymer Complex as Strain Sensor** Colton Duprey<sup>1</sup>, Yang Lu<sup>2</sup> and Evan K. Wujcik<sup>1</sup>; <sup>1</sup>University of Maine, United States; <sup>2</sup>Georgia Institute of Technology, United States

Wearable strain sensors should be comfortably adhered to the skin and capable of monitoring human motions with high accuracy/sensitivity while remaining robust with excellent durability/longevity. However, it is challenging to develop electronic materials that possess the properties of skin—compliant, elastic, stretchable, and self-healable while also having a high enough conductivity for adequate sensitivity. This work demonstrates a new regenerative polymer complex composed of poly(2-acrylamido-2-methyl-1-propanesulfonic acid), polyaniline, and phytic acid as a skin-like electronic material. The type-2 (zip) templated polymerization of aniline in the presence of poly(2-acrylamido-2-methyl-1-propanesulfonic acid) with phytic acid as a P-type dopant exhibits ultrahigh stretchability (1935%), repeatable autonomous self-healing ability (repeating healing efficiency >98%), quadratic response to strain ( $R^2 > 0.9998$ ), and linear response to flexion bending ( $R^2 > 0.9994$ ), mechanically outperforming current reported wearable strain sensors. Sensitive strain-responsive geometric and piezoresistive mechanisms of the material owing to the homogeneous and viscoelastic nature provide excellent linear responses to omnidirectional tensile strain and bending deformations. Furthermore, this material is scalable and simple to process in an environmentally friendly manner, paving the way for the next-generation flexible electronics.

#### SESSION SB04.06: Multifunctional Materials

**All-Aqueous Hierarchical Hydrogels for Microfluidics** Anderson Shum<sup>1,2</sup> and Yafeng Yu<sup>1</sup>; <sup>1</sup>University of Hong Kong, Hong Kong; <sup>2</sup>Advanced Biomedical Instrumentation Centre, Hong Kong

Hydrogels have demonstrated promising applications across fields, ranging from delivery of actives, to cell cultures, and to wound protection. Hydrogel designs have focused on the constituent molecules and molecular interactions via modifications of the molecular identities and structures. Hierarchical structures within the hydrogels can also be manipulated by structuring the precursor solution before hydrogel formation. The precursor solution can be directed via the use of microfluidic techniques, achieving underlying hydrogel architectures with different properties. Besides its use for designing and modifying hydrogels, microfluidic devices can also be made formed by hydrogels, rather than traditional elastomer-based materials. In this talk, I will share our works at the interface between hydrogels and microfluidics, and will discuss the potential functions and properties of the resultant hydrogels and microfluidic devices.

#### 2:00 PM SB04.06.02

**Acid-Crystallized PEDOT Nanoparticles: Scalable and Biocompatible Fillers for Highly Conductive Hydrogels** Joshua Tropp and Jonathan Rivnay; Northwestern University, United States

Conductive hydrogels are widely used in bioelectronic applications due to their flexibility, biocompatibility, and conductivity. Conductive hydrogels have been leveraged to improve the biocompatibility of electrodes, act as transducing elements within biosensors, and as conductive scaffolds for cells to promote tissue regeneration. While the unique properties of conductive hydrogels make them a promising material for bioelectronics, achieving high conductivity while maintaining mechanical compliance remains a significant challenge. To meet these requirements, functional- $\pi$  electron systems (conjugated polymers, carbon nanotubes, graphene, etc.) are typically dispersed within natural or synthetic biomaterials to afford conductive hydrogels. A significant challenge in the field remains the required high nanomaterial loadings to achieve significant conductivity; however, at such loadings the conductive hydrogels become prohibitively rigid for bioelectronic applications. Unlike 2D thin-film applications that leverage the long-range ordering of

nanomaterials such as conjugated polymers to achieve significant charge percolation, the 3D, complex, and tortuous structure of hydrogels prevents such material alignment, creating a barrier toward highly conductive soft hydrogels. To overcome this limitation, PEDOT nanoparticles have been developed, which behave as three-dimensional seeds for charge percolation throughout the hydrogel. By carefully controlling nanoparticle surface chemistry and morphology via acid treatment, dispersible and highly conductive particles were afforded. Unlike other carbon nanomaterial fillers, the intrinsic dispersibility of the PEDOT nanoparticles enabled direct incorporation within hydrogels at high loadings ( $> 100 \text{ mg mL}^{-1}$  of precursor), as well as deposition via spray coating and 3D printing without added surfactant or chemical modification. Upon sufficient particle loading, charge percolation is achieved throughout the hydrogel, affording organic gels with high conductivity ( $> 1 \text{ S cm}^{-1}$ ) without deleterious hydrogel stiffening. PEDOT nanoparticles were incorporated within various synthetic and natural biomaterials, demonstrating compatibility with common crosslinking modalities (photopolymerization, ionic, thermal, Schiff base). The scalability, conductivity, and biocompatibility of the acid-crystallized PEDOT nanoparticles make them attractive fillers for hydrogels/biomaterials for bioelectronic applications.

### 2:15 PM SB04.06.03

**From Conducting Hydrogel to Semiconducting Hydrogel** Dingyao Liu, Yan Wang and [Shiming Zhang](#); The University of Hong Kong, Hong Kong

Thin-film semiconductor-based devices have revolutionized the field of microelectronics. In the realm of biomedical applications, conducting hydrogels have rapidly gained prominence due to their mechanical and biocompatible nature with biological systems. The realization of semiconducting hydrogel materials holds significant value within the field of bioelectronics for developing advanced biologics[1]. Advancing towards flexible and stretchable semiconducting hydrogels can enable direct applications at the interface of soft biological systems [1].

However, the development of semiconducting hydrogels presents challenges, primarily due to the thin-film nature of semiconductors, which are generally less than 1 micrometer in thickness. In contrast, hydrogels tend to have greater thicknesses and struggle to achieve good semiconductor properties.

The advent of organic electrochemical transistors (OECTs) has introduced a new paradigm that can be a powerful testbed to evaluate the performance of a semiconducting hydrogel. In this report, we present the development of the PEDOT:PSS semiconducting hydrogel and its application in the development of OECTs [2]. Furthermore, we provide our insight on how to define a semiconducting hydrogel when using OECT as a testbed. Finally, we delve into the development of stretchable semiconducting hydrogels and explore how they can revolutionize applications in the field of biomedical research.

### 2:30 PM \*SB04.06.04

**Conducting Polymers Biointerfaces for Bioelectronics** [Jadranka Travas-Sejdic](#); University of Auckland, New Zealand

Conducting polymers (CPs) have been widely used as electroactive biointerfaces in applications such as electrically stimulated tissue engineering and flexible organic bioelectronics. In this talk, several different approaches to advanced electroactive biointerfaces based on conducting polymers will be presented.

The first approach addresses the issue of poor solubility and processability of CP by functionalization of CPs with various moieties, and, in particular, by grafting of CP backbones with polymeric sidechains. That enables modification of optoelectronic, physical and mechanical properties of the CPs and their use as biomimetic biointerfaces, e.g. responsive to stimuli, intrinsically stretchable and self-healing[1].

The second approach addresses the issue that electrodes used in tissue recording and stimulation are commonly 2D and made of rigid conducting materials, and as such cannot adequately probe the actual 3D cell environment within tissues and/or have a significant mechanical mismatch with biological tissue.

Our approach to overcome that is based on a precise fabrication of individually addressable, high aspect ratio, soft and flexible 3D CP-pillar microelectrode arrays by means of 'direct 3D writing'. Such 3D microelectrode arrays could be employed in a variety of applications, from biological sensing to recording and electrically stimulating cells and tissues[2], with the array design easily adjustable.

The third approach to electrochemically addressable biointerfaces is based on flexible, microporous, electrochemically switchable membranes that can selectively and efficiently capture, and then non-destructively release, cancer biomarkers, such as cancer cells-shaded extracellular vesicles (EVs)[3] and rare cancer cells[4] The platform allows for the EVs and cells to be captured from large volumes of complex biological samples and released into clean and small volumes of buffers - suitable for further analysis, for example, for medical diagnostics.

**Conductive Hydrogels for Multimodal Bioelectronic Interfaces** [Ivan Minev](#)<sup>1,2,3</sup>; <sup>1</sup>Leibniz Institute for Polymer Science, Germany; <sup>2</sup>Technische Universität Dresden, Germany; <sup>3</sup>The University of Sheffield, United Kingdom

Hydrogels are attracting attention as materials for bioelectronic implants because they may solve some long-standing challenges encountered at the tissue-electrode interface. This will require appropriate viscoelasticity, hydration, bioactivity and dual electronic-ionic conductivity. Apart from improved integration with brain tissue, hydrogels may enable electrodes with superior charge injection capacity and capability for neuromodulation beyond the electrical domain (e.g. using biomolecules).

In this talk I will present our efforts to combine Glycosaminoglycans and the conductive polymer PEDOT into interpenetrating network hydrogels that are soft, conductive and bioactive. The material system is highly tunable offering control over electrical and mechanical properties. Furthermore the hybrid material has enabled us to sequester and release small proteins such as growth factors. The release profiles can be electrically tuned. The released proteins are bioactive and can influence cells in culture.

With this work we aim to advance the possibility to engineer synthetic bioelectronic materials that emulate some aspects of the extracellular matrix and may enable applications in next-generation tissue-mimetic bio interfaces.

#### 4:00 PM SB04.06.06

**Conducting Polymer Hydrogels for Soft and 3D Bioelectronic Interfaces** [Alexandra Rutz](#); Washington University in St. Louis, United States

Hydrogels are insoluble polymer networks swollen with water (>90% water by mass) and are used widely in biomedical applications for their similarities to native extracellular matrix. For bioelectronics, there are many efforts to build devices based on these materials to achieve tissue-matching stiffness and other tissue-inspired properties in order to improve the biointerface. For making electrodes and other device components based on semiconducting materials, conjugated polymers can be gelled into electronically conducting hydrogels. Such methods include simple mix-and-cast techniques, similar to other methods used widely in traditional (non-conducting) hydrogel processing. We have investigated conducting hydrogels based on the conjugated polymer poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) fabricated by mixing in a gelling agent, ionic liquid. We have studied how the hydrogel precursor formulation and other fabrication variables of this method affect gel properties, such as swelling, conductivity, and elastic modulus. Further, we have evaluated the potential of these PEDOT:PSS hydrogels for biointerfacing applications and have found that these gels when processed appropriately are stable *in vitro* and support mammalian cell culture. Finally, we are developing these conducting polymer hydrogels for compatibility with additive manufacturing to grant structural control of these soft bioelectronic interfaces. Such techniques provide manipulation of dimensions and microporosity, important for assembling these hydrogels into functional devices and optimizing tissue integration.

**Ultra-Soft Semiconducting Hydrogels for Tissue-Like Organic Electrochemical Transistors** [Yahao Dai](#) and Sihong Wang; University of Chicago, United States

The rapid development of wearable/implantable electronics over the past decade opens the next era of human-integrated biosensors in pursuit of higher sensitivity and more seamless tissue-electronics interfaces. Transistor, especially organic electrochemical transistor (OECT)-based biosensor has attracted considerable attention as an advanced biosensing platform due to their high built-in amplification and water-compatible operation. To achieve the intimate biointerface and acquire the biological signal with the highest possible accuracy, the most ideal approach is to prepare the semiconducting materials with tissue-level softness and stretchability, and directly interface with the tissue surface. However, so far no semiconducting material is able to provide modulus even close to the tissue level due to the general paradox that semiconductors rely on stronger intermolecular interactions to facilitate charge transport. In this research, we proposed a novel material design strategy for developing a gel-like semiconductor that is able to simultaneously provide low modulus, high stretchability/elasticity, and high hole mobility. This is achieved by incorporating a secondary hydrogel matrix into a semiconducting polymer network for enhancing the water uptake to soften the composite, and utilizing solvent treatment to form strong percolation between polymer semiconductors to resist the negative effect of swelling. We further use ultra-soft semiconductors to fabricate gel-like OECTs with desired mechanical and electrical performance for human integration, and demonstrate its capability as the advanced platform for biosensing applications.

**Developing Multifunctional Hydrogels with Tissue-Like Properties for Improved Cell-Material Interfaces** [Christina M. Tringides](#)<sup>1,2</sup>, [Blandine F. Clément](#)<sup>1</sup>, [Marjolaine Boulenger](#)<sup>1</sup>, [Vilius Dranseika](#)<sup>3</sup>, [David J. Mooney](#)<sup>2</sup> and [Janos Vörös](#)<sup>1</sup>; <sup>1</sup>ETH Zurich, Switzerland; <sup>2</sup>Harvard University, United States; <sup>3</sup>UZH, Switzerland

Biomaterial scaffolds have emerged as a tool to build 3D cultures of cells which better resemble biological systems, while advancements in bioelectronics have enabled the modulation of cell proliferation, differentiation, and migration. Here, we first describe a porous conductive hydrogel with the same mechanical modulus and viscoelasticity as neural tissue. Electrical conductivity is achieved by incorporating low amounts (<0.3% weight) of carbon nanomaterials in an alginate hydrogel matrix, and then freeze-drying to self-organize into highly porous networks. The mechanical and electrical properties of the material can be carefully tuned and used to modulate the growth and differentiation of neural progenitor cells (NPCs). With increasing hydrogel viscoelasticity and conductivity, we observe the formation of denser neurite networks and a higher degree of myelination. Similarly, fibroblasts can be incorporated into the scaffolds and cell migration can be modulated through the application of exogenous electrical stimulation, for applications to wound healing. To investigate the functionality of neural systems, both *in vitro* and *in vivo* platforms can be realized. By placing a polydimethylsiloxane (PDMS) microstructure on an underlying multielectrode array (MEA), we can then explore different materials and techniques to integrate hydrogels into the PDMS microstructures and can facilitate the growth of neuronal networks in 3D. Additionally, implantable surface electrode arrays can be fabricated, with the ability to record from the brain and heart with enhanced tissue conformability and minimal damage to the biological organs. The described biomaterial platforms can be used to investigate neuronal development and disease progression.

**Superstrong Electronic Hydrogel Actuators (ECO)** [Mahiar M. Hamed](#); KTH, Sweden

Intelligent systems combine sensing, actuation, and computation to achieve complex tasks and functions. Soft electrically controlled multifunctional materials, especially hydrogels, are the most promising materials for such systems as they are as adaptable as biological systems yet compatible with advanced systems through electronics.

We describe an electroactive hydrogel fabricated from cellulose nanofibrils from trees, and conductive nanomaterials, like CNTs or 2D MXenes. These nanoparticles self-assemble into an anisotropic composite networks with an open mesoporous structure that can hold lots of water and be highly permeable to substances in their surroundings. The anisotropy of the network allows high expansion in one direction while maintaining very high strength and high electric conductivity in the other.

The electrochemical charge/discharge of the conductors in the hydrogels controls the internal salt concentration and consequently their osmotic swelling. This allows direct electrically controlled actuation where around 700 water molecules expand/contract the structure for each ion/electron pair inserted/de-inserted at only  $\pm 1$  volt, resulting in up to 300% electroosmotic expansion, with very high pressures reaching 1 MPa.

This mode of electronic actuation has not been shown before. We call these electroosmotic (ECO) actuators. Our ECO hydrogel actuators have emergent properties not present in any previously known soft material. ECOs allow formonolithic integration of sensors and many other functions into the same composite, rendering a new form of smart soft material not achievable with other materials systems.

**Long-Term Durable and Ultrasensitive Multiple-Crosslinked Ionic Hydrogel Sensors with Multi-Functions for Wearable Electronics** Byeong Su Kang<sup>1</sup>, Jin-Young Yu<sup>1</sup>, Jeong Hun Kim<sup>2</sup> and Seongmin Kang<sup>1</sup>; <sup>1</sup>Chungnam National University, Korea (the Republic of); <sup>2</sup>Electronics and Telecommunications Research Institute, Korea (the Republic of)

Hydrogels are considered promising for wearable devices because they are soft, flexible, stretchable, and biocompatible. However, existing hydrogels suffer from poor strength, weak and one-time adhesion, non-self-recovery, water evaporation, ice crystallization, and low sensitivity, and these problems have been only partly solved previously. We propose the one-pot synthesis of a multiple-crosslinked poly(2-(methacryloyloxy)ethyl)dimethyl-(3-sulfopropyl)ammonium hydroxide-co-acrylamide (P(SBMA-co-AAm) multifunctional hydrogel to overcome these limitations. The synthetic route provided elasticity, self-healing, and transparency, and the incorporation of glycerol and NaCl ions provided moisture stability (e.g., water retention) and antifreeze properties. Zwitterionic SBMA contributed to the increased gauge factor, resulting in high sensitivity and an ability to detect human movements at a strain of 800%–1600%, making the hydrogel sensor practical. The sensor retained its properties after even 300 cycles, indicating its durability and reliability for long-term applications.

#### 8:00 PM SB04.07.02

**Multi-Crosslinked Hydrogel-Based Needle Structure Capacitance Sensor with High Sensitivity and Stability** Byeongsu Kang<sup>1</sup>, Jeong Hun Kim<sup>2</sup> and Seongmin Kang<sup>1</sup>; <sup>1</sup>Chungnam National University, Korea (the Republic of); <sup>2</sup>Electronics and Telecommunications Research Institute, Korea (the Republic of)

The hydrogel-based sensor has better elasticity than the existing elastomer sensor, so the distance between the two electrodes can be reduced. Also, since the amount of change in contact area is also large, the amount of change in capacitance is excellent. Especially, by adopting a micro needle structure that can maximize the change in contact area, the change in capacitance is increased. However, the previous hydrogel-based sensor lacks recipe research to create a structure, and adding a structure reduces stability and repeatability, limiting its application as a sensor. In this paper, poly(acrylamide-co-N, N'-methylenebisacrylamide) multifunctional hydrogel can overcome the aforementioned limitations. Then, by making a hydrogel-based sensor with a micro needle structure, high sensitivity is sought by adjusting the amount of N, N'-methylenebisacrylamide. In addition, by adding sodium dodecylbenzenesulfonate lauryl acrylate, the stability of the structure that does not interfere with sensitivity is increased. This hydrogel-based sensor is a human-friendly material that can be applied not only to the biomedical measurement field, but also to fields where existing elastomer sensors are applied, such as robots, hydraulic pressure measurement, and aviation.

#### 8:00 PM SB04.07.03

**Robust Integration of Highly Conductive Hydrogels with Stretchable Electronics for Skin-Interfaced Bioelectronics** Hyun Su Lee and Dae-Hyeong Kim; Seoul National University, Korea (the Republic of)

Skin-interfaced bioelectronics mounted on human skin has the potential to revolutionize next-generation medical diagnostics and healthcare. To achieve this goal, designing a compliant and stretchable device is highly desirable for device reliability and long-term user comfort. In the material aspect, the limitations of conventional functional device components that originate from rigid and obtrusive interfaces must be overcome by materials with intrinsic softness and stretchability. Conductive hydrogels that possess tissue-level softness owing to their water-rich nature, can be an alternative option. Generally, for the fabrication of hydrogel-based, skin-interfaced bioelectronics, a hydrogel film is cut and placed onto an electrode. However, during device operation, large amount of water inside the hydrogel film tends to form a slippery surface rather than a robust interface between human skin and electronic device. Such poor integration capability could cause the lack of reproducible device performances, difficulty to scale up, and the loss of intimate physical/electrical contacts, which leads to critical problems in signal sensing and electrical actuation from/to human tissue. Here, we suggest direct polymerization and in-situ chemical-integration of hydrogel onto stretchable electronics as a methodology for enhancing the hydrogel-device interface of skin-interfaced bioelectronics. Highly conductive functionalized hydrogels are polymerized inside stretchable wells placed on a multichannel electrode array. The hydrogels are stably immobilized to the electronic devices during fabrication, and the robust interface contributes to the reliable measurement of bio-signals and effective electrical actuation on tissues. The demonstration shows that the direct polymerization and in-situ chemical-integration of hydrogel are key steps towards the realization of practical skin-interface bioelectronics based on functionalized hydrogels.

#### 8:00 PM SB04.07.04

**Self-Healing Stretchable Li-Ion Battery Based on a High-Voltage Hydrogel Electrolyte** Peisheng He<sup>1</sup>, Jong Ha Park<sup>1</sup>, Chao Fang<sup>1</sup>, Anju Toor<sup>2</sup> and Liwei Lin<sup>1</sup>; <sup>1</sup>University of California, Berkeley, United States; <sup>2</sup>Georgia Institute of Technology, United States

Safe and deformable batteries that can be conformally embedded onto irregular surfaces of electrical systems and human body are desirable for wearable electronic applications due to low user friction. Commercial state-of-the-art Li-ion batteries are packaged in rigid hermetic sealing materials that are not deformable. State-of-the-art deformable Li-ion batteries reported in research articles show fast degradation due to severe performance problems such as the penetration of moisture and the leakage of toxic and inflammable electrolytes. Here we report a non-toxic, aqueous hydrogel electrolyte instead of its organic counterpart that is demonstrated to: 1) enable highly safe operations due to its non-toxic and non-flammable nature; 2) alleviate the moisture penetration problem from outside environment; 3) have a high-voltage working window of ~2.8V; and 4) allow the construction of stretchable batteries by using elastic polymer packaging materials instead of rigid hermetic seals. In the prototype tests, fabricated batteries have shown good stretchability (50% strain) and flexibility (radius of curvature < 2mm) to enable conformal attachments to a wide range of geometric surfaces. The prototype battery also shows outstanding cyclic stability, retaining ~90% of the original capacity after 100 cycles for over 2 months in the ambient environment without using any rigid hermetic sealing package. Finally, a prototype battery with a self-healing elastomer package remains functional after being punctured by a needle 5 times at different locations through the package. Furthermore, it can recover >90% of its capacity after being cut through by a razor blade and subsequently healed at 70 for 10 minutes. Such safe and highly stretchable batteries would be useful for several wearable electronic applications such as blood glucose monitoring, heart rate monitoring, temperature monitoring, wireless charging, smart clothing, etc.

#### 8:00 PM SB04.07.05

**Highly Sensitive Flexible Sensors using Autonomously Self-Healable and Temperature-Tolerant Eutectogel** Jinyoung Lee and Jeong Sook Ha; Korea University, Korea (the Republic of)

With the increased demand for advanced wearable electronics, hydrogel-based devices have attracted enormous attention. Hydrogels have many advantages such as excellent flexibility, biocompatibility, ionic conductivity, and self-healing property, adequate for wearable devices. On the other hand, hydrogel-based devices exhibit limit in the performance due to the freezing and evaporation of water in the polymer network at low and high temperatures, respectively. To address such a thermal instability issue, there has been extensive effort on replacing the water within the hydrogel network with ionic liquids of low vapor pressure and high ionic conductivity. However, most ionic liquids are expensive and toxic to hamper the practical application to wearable devices. Therefore, research on deep eutectic solvents, mixtures of two or more components characterized by significant depressions in melting points compared to their neat constituent components, has been recently activated. Deep eutectic solvents show properties similar to those of ionic liquids as well as additional advantages of low-cost, non-toxicity, biocompatibility, and biodegradability. Furthermore, eutectogels having polymer networks composed of deep eutectic solvents have demonstrated the high potential application to wearable devices.

In this paper, we report on the fabrication of resistive-type strain and pressure sensors based on newly synthesized autonomous self-healing and temperature-tolerant eutectogel. Our synthesized eutectogel is prepared by UV polymerization of acrylamide with trehalose and phytic acid as crosslinkers, and choline chloride, glycerol and a small amount of water as solvents. In addition to the inherent low melting point of deep eutectic solvent, inclusion of bio-derived trehalose and phytic acid makes abundant hydrogen bonding, resulting in improved anti-freezing and anti-drying properties. Also, the dynamic hydrogen bond interactions between the polymer network and trehalose, phytic acid, and glycerol endowed the eutectogel with self-healing properties. The synthesized eutectogel exhibits high stretchability (>300%), temperature-tolerance, and good self-healing efficiency (>90%) after 24 hours at room temperature. By incorporating conducting polymer onto the eutectogel, highly sensitive resistive-type strain and pressure sensors are fabricated for detecting bio-signals after attachment onto a finger or wrist. The eutectogel-based wearable sensors demonstrate stable signal detection over a wide temperature range even after repetitive self-healing, thereby expanding their potential application to wearable electronics with longevity under extreme conditions.

**Topology-Based Dual Lock-and-Key Structures for Hydrogel Self-Assembly in Macroscopic Supramolecular Assembly** Eunseok Heo, Hye Been Koo and Jae-Byum Chang; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Macroscopic supramolecular assembly (MSA), which refers to the assembly of building blocks at a macroscopic scale, holds great potential for the fabrication of ordered bulk structures. Thanks to the high design flexibility of the building blocks and the precise controllability of the assembly process, MSA has found applications in a wide range of fields, including the fabrication of tissue scaffolds, soft actuators, and more. Additionally, among the candidates for building blocks, hydrogels are highly favored due to their easily tunable properties and diverse type with different characteristics. In MSA, two challenges need to be addressed to achieve a high level of assembly: enhancing the precision of assembly and increasing the number of orthogonally matching pairs. To date, despite numerous attempts, none have effectively tackled both challenges simultaneously. In this study, we introduce topology-based design criteria for achieving precise and selective self-assembly of hydrogel building blocks. We suggest a unique design approach termed “dual lock-and-key structures.” In this design model, only topologically matching pairs can be assembled with exceptional precision. Through the implementation of dual lock-and-key structures, we establish principles for the selection of multiple orthogonally matching pairs. We demonstrate the selective assembly of both simple one-to-one matching and complex one-to-many assemblies. Moreover, by harnessing the easy property tunability of hydrogel, we synthesize DNA-mimicking single-stranded structures, which hybridize into double-stranded structures with sequence-specific arrangements. Finally, we present a hydrogel logic gate system, consisting of a YES gate, an OR gate, and an AND gate. Utilizing the high selectivity of our dual lock-and-key structures, the desired outputs are exclusively obtained when the appropriate building blocks are assembled, following the logic of each gate: YES, OR, and AND.

#### 8:00 PM SB04.07.07

**Conducting Polymer Granular Hydrogel Bioinks for 3D Printed *In Vitro* Bioelectronic Devices** Anna P. Goestenkers, Tianran Liu, Somtochukwu S. Okafor, Lianna Friedman, Riley Alvarez and Alexandra Rutz; Washington University in St. Louis, United States

Conjugated polymers have recently been used in their hydrogel form for the creation of soft bioelectronics with improved cell interfacing and the potential for enhanced measurement and stimulation of cellular activities. Cell-encapsulating hydrogels offer a truly 3D culture environment and when designed appropriately can be used as bioinks for 3D printing which grants spatially controlled deposition of cells and materials simultaneously. We developed a bioink based on the conducting polymer poly(3,4-ethylene-dioxythiophene):polystyrene sulfonate (PEDOT:PSS) by creating a granular hydrogel form. Emulsion methodology was developed to fabricate PEDOT:PSS hydrogel microparticles (microgels) with high circularity and monodispersity. Filtration techniques were used to size select microgels with diameters between 10 and 60  $\mu\text{m}$ . When centrifuged to remove significant water, the conducting polymer microgels achieved dense packing characteristic of a granular material state. Increasing centrifugal force decreased the void fraction of the material which increased conductivity. Rheological investigations confirmed shear-thinning and self-healing properties, both ideal for 3D bioprinting for extrusion and ability to keep shape, respectively. Granular PEDOT:PSS hydrogels were in fact 3D printable via pneumatic extrusion and formed various 3D configurations. Evaluation of the material's printability in the granular state also revealed that increased centrifugal force facilitated better printability as evidenced by increased maximum filament length and filament diameter better matching the chosen nozzle diameter. Structural stability of the material within an aqueous environment for up to three months was achieved using a collagen hydrogel overlay. Human dermal fibroblasts encapsulated and cultured within the granular hydrogel showed high cell viability over fourteen days demonstrating cytocompatibility. This developed conducting granular hydrogel bioink exhibits balanced properties of printability, conductivity, and cellular responses for the additive manufacturing of future in vitro bioelectronics.

#### 8:00 PM SB04.07.08

**Extracellular Matrix-Compatible Additive Manufacturing of Bioactive, Conducting Polymer Hydrogel Electrodes** Tianran Liu, Somtochukwu S. Okafor, Anna P. Goestenkers, Sandra Montgomery, Riley Alvarez and Alexandra Rutz; Washington University in St. Louis, United States

Hydrogels of conducting polymers provide a soft and hydrated alternative to metal for interfacing electronic devices with biological systems. To fabricate devices based on conducting polymer hydrogels, the material is often patterned alongside bioinert and stiff substrates such as plastics and elastomers which lead to poor cell-material interactions. In order to further promote device integration with cells and tissue, one strategy is to utilize bioactive materials, such as mammalian extracellular matrix (ECM) components, as the substrate material to present a tissue-like microenvironment to cells. However, traditional semiconductor manufacturing is anticipated to impair the bioactivity of these natural materials. Here, we demonstrate methods for mild temperature additive manufacturing of highly conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) hydrogels with collagen substrates. Various types and concentrations of gelation agents were investigated to enable sufficient working time after addition to colloidal dispersions and to result in a water-stable hydrogel network once fully crosslinked. Among gelation agents tested, ionic liquid was found to be suitable for extrusion-based printing while an acidic surfactant enabled deposition by jetting due to low surface tension and appropriate viscosity. After room temperature gelation and treatment, hydrated PEDOT:PSS prints exhibited conductivity as high as 37.2 S/cm and were stable in cell culture conditions for at least 28 days. To complete the device, a top layer was fabricated by casting a collagen slurry onto the PEDOT:PSS prints which had a sacrificial material deposited on top to protect the intended electrodes from coverage. Once the collagen layer formed, the sacrificial material was removed with 36 °C water, leaving an unaltered

PEDOT:PSS surface for direct biointerfacing. Since the fabrication methods were developed with mild temperatures and processing, the structure and bioactivity of the collagen are believed to be maintained, as evidenced by the support of fibroblast culture that reached confluency and sustained high viability for 28 days. This methodology offers a promising strategy for rapid prototyping soft, hydrated, and bioactive electronic devices that support cell attachment and proliferation.

#### 8:00 PM SB04.07.09

**A Zwitterionic Hydrogel-Based Heterogeneous Fenton Catalyst for Efficient Degradation of Persistent Organic Pollutants** Ian S. Chen, Devashish Gokhale and Patrick Doyle; Massachusetts Institute of Technology, United States

Persistent organic pollutants (POPs) are industrial, pharmaceutical, or commercial byproducts that are highly resistant to degradation and decomposition in the environment, while causing significant health and environmental damage even in small concentrations. Significant existing research aims at destroying the POPs in an environmentally safe and cost-effective manner, but challenges remain in destroying POPs at environmental concentrations in scalable and sustainable processes. Many current approaches to degrading POPs require extreme reagents and conditions. One promising candidate, however, for the removal of POPs is the photo-Fenton reaction, where iron(II) ions catalyze the decomposition of hydrogen peroxide, in the presence of UV light, into highly reactive hydroxyl radicals that readily attack organic compounds, including POPs. Fenton oxidation is promising because iron(II) and hydrogen peroxide are low-cost, environmentally-safe materials, and because the process can target a broad range of POPs.

However, the photo-Fenton reaction requires the presence of water-soluble iron(II) ions that are difficult to reuse. As such, methods that immobilize the iron as a catalyst can be constantly reused, while also eliminating the need for further treatment steps to remove iron from water before it can be used. Unfortunately, existing solutions require challenging reaction conditions; due to the higher efficiency of the Fenton reaction at lower pHs, many catalysts require a low pH (usually around 3) to regenerate iron(II) ions, which is unrealistic for large-scale wastewater treatment and can damage the catalyst itself. Furthermore, due to the non-selectivity of the Fenton reaction, catalysts using common polymers such as polyethylene or polyvinyl alcohol to encapsulate iron (II) or iron oxide (in the form of nanoparticles) often degrade easily due to the susceptibility of the polymer to the photo-Fenton reaction, also releasing nanoparticles into the environment. Other attempts at supported catalysts reduce the surface area and limit kinetics.

To address these issues, we developed an iron(II)-incorporated, zwitterion-based hydrogel catalyst. By complexing the iron(II) ions within a zwitterionic hydrogel, we allow for the photo-Fenton reaction to run efficiently at neutral and even slightly alkaline pHs. Furthermore, due to the high oxidation state of the zwitterions and the saturated backbones, the hydrogel is highly resistant to attack by hydroxyl radicals. A zwitterionic backbone helps us make highly porous materials that bind individual, complexed ions, allowing us to maximize both the effective functional area and rate of pollutant transport within the catalyst. POPs quickly and rapidly diffuse into the catalyst, where they rapidly decompose. Experiments at environmentally relevant concentrations showed that our catalyst was able to degrade 85% of a solution of ethinyl estradiol (a xenoestrogen and common POP) within 1 hour, with near 100% degradation within 24 hours. Furthermore, we observed near 100% degradation of dichlorophenol (a common industrial byproduct) and around 70% degradation of perfluorooctanoic acid (a common perfluorinated pollutant). These results show significant promise for our hydrogel as an efficient and environmentally-safe strategy for rapid water purification of POPs.

#### 8:00 PM SB04.07.11

**Air-Permeable Hydrogels with High Water Content** Xiao-Yun Yan, Shucong Li and Xuanhe Zhao; Massachusetts Institute of Technology, United States

Hydrogels have gained immense popularity as the interface between biological tissues and the environment due to their exceptional properties and unique features. For biomedical applications like long-term signal monitoring, drug release, or pathogen blocking that necessitate continuous epidermal or tissue adhesion, free water and air exchange between the body and its surroundings become crucial. However, despite their excellent water permeability, hydrogels have over an order of magnitude lower oxygen permeability compared to other 'dry' soft materials (e.g. silicone rubber). This poor oxygen permeability in hydrogels is an intrinsic problem caused by the dense polar hydrogen-bonded network, which has long been a challenge to overcome. Herein, we present a strategy that achieves high oxygen permeability without compromising water content. The key to this approach is the fabrication of interconnecting microchannels within the bulk hydrogel material. More importantly, we demonstrate that the designed materials exhibit high oxygen permeability, allowing for long-term wear without causing itchiness or other uncomfortable sensations.

#### 8:00 PM SB04.07.13

**Tough and Recyclable Phase-Separated Supramolecular Gels via a Dehydration-Hydration Cycle** Xiaohui Xu and Rodney Priestley; Princeton University, United States

Hydrogels are compelling materials for emerging applications, including soft robotics and autonomous sensing. Mechanical stability over an extensive range of environmental conditions and considerations of sustainability, both environmentally benign processing and end-of-life use, are enduring challenges. To make progress on these challenges, we designed a dehydration-hydration approach to transform soft and weak hydrogels into tough and recyclable supramolecular phase-separated gels (PSGs) using water as the only solvent. The dehydration-hydration approach led to phase separation and the formation of domains consisting of strong polymer-polymer interactions critical for forming PSGs. The phase-separated segments acted as robust, physical crosslinks to strengthen PSGs, which exhibited enhanced toughness and stretchability in its fully swollen state. PSGs are not prone to over-swelling or severe shrinkage in wet condition and show environmental tolerance in harsh conditions, i.e., organic solvents with pH between 1 to 14. Finally, we demonstrate the use of PSGs as strain sensors in air and aqueous environments.

#### 8:00 PM SB04.07.14

**An Elastomer with Giant Strain-Induced Crystallization** Chase Hartquist<sup>1</sup>, Shaoting Lin<sup>2</sup>, James H. Zhang<sup>1</sup>, Shu Wang<sup>1</sup>, Michael Rubinstein<sup>3,4</sup> and Xuanhe Zhao<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Michigan State University, United States; <sup>3</sup>Duke University, United States; <sup>4</sup>Hokkaido University, Japan

Strain-induced crystallization prevalently strengthens, toughens, and enables an elastocaloric effect in elastomers. However, the crystallinity induced by mechanical stretching in common elastomers (e.g., natural rubber) is typically below 20%, and the stretchability plateaus due to trapped entanglements, impeding performance for advanced applications. We present a new class of elastomers formed by end-linking then deswelling star polymers with a low fraction of defects and no trapped entanglements, which achieve strain-induced crystallinity of up to 50%. The deswollen end-linked star elastomer (DELSE) reaches an ultra-high stretchability of 12.4-33.3, scaling beyond the saturated limit of common elastomers. The DELSE also exhibits a high fracture energy of 4.2-4.5 kJ/m<sup>2</sup> while maintaining low hysteresis. The heightened strain-induced crystallization and stretchability synergistically promote a high elastocaloric effect with an adiabatic temperature change of 9.3 °C at 54 °C, compared with 3.5 °C at 54 °C in natural rubber.

#### 8:00 PM SB04.07.15

**Advancing Protein Synthesis and Applications with a Recyclable Genomic DNA Hydrogel Platform in Cell-Free Expression Systems** Hyangsu Nam<sup>1,2</sup> and Jong Bum Lee<sup>1</sup>; <sup>1</sup>University of Seoul, Korea (the Republic of); <sup>2</sup>Harvard University, United States

Proteins have the most dynamic entities, performing the diverse role of macromolecules in the body, functional interaction network-based biochemical reactions within a cell or from an organ. Recombinant protein-based therapeutics provide an important breakthrough in biomedical biotechnology. Recent technical advances in cell-free protein synthesis (CFPS) offer several advantages over cell-based expression systems, including easy modification to favor protein folding, increased non-toxicity, and capability for high-throughput strategies due to small reaction volume and short synthesis time. Herein, we fabricated the genomic DNA hydrogel (GD-gel) using the dual single-strand circular plasmids employed in cell-free protein expression synthesis. By complementary rolling complementary circle amplification (cRCA) with multi-primers, the genomic hydrogel exhibits a significantly enhanced productivity yield of protein. This synthesis platform has the potential to develop biotechnological in sensing, therapeutics, and diagnosis.

In our study, inspired by the previous DNA hydrogel using a rolling circle amplification technique, we describe a strategy to synthesize genomic DNA hydrogel (GD-gel) via self-assembly of elongated DNA strands encoding multimeric genomic sequences. To achieve the self-assembly of genomic hydrogel, we applied rolling circle chain amplification (RCCA) with the dual single-stranded circular plasmids. Importantly, GD-gel only consists of numerous tandem repeats of genomic DNA strands by the rolling circle amplification from the plasmid DNA template. This approach allows the genomic DNA itself not only to create a hydrogel structure but also to become a medium for protein expression in GD-gel. Hence, our GD-gel is likely to enable a new route for cell-free protein production via self-assembly of multimeric genomic DNA.

**8:00 PM SB04.07.16**

**A Versatile Conductive Ternary Polymer Complex Nanocomposite Sensor with Repeatable, Rapid, Autonomous Self-Healing and Unprecedented Mechanical Properties** Colton Duprey and Evan K. Wujcik; University of Maine, United States

Wearable sensors, stretchable electronics, and many soft robotics materials must have a sufficiently high balance of conductivity, stretchability, and robustness. Intrinsically conductive polymers offer a critical step toward improving wearable sensor materials due to their tunable conductivity, soft/compliant nature, and ability to complex with other synergistic molecules (i.e., polyacids, small molecule dopants). The addition of nanofillers offers the potential to improve the conductivity of polymers for soft robotics and wearable applications, while it also affects and improves the self-healing and mechanical properties of the material. The development of a robust polymer nanocomposite material that offers ultra-stretchability, an autonomous self-healing ability, and enhanced electronic properties has eluded researchers. Here we show an aqueous polyaniline [PANI]:poly(2-acrylamido-2-methylpropane sulfonic acid) [PAAMPSA]:phytic acid [PA] ternary polymer [TP] complex synthesized with silver nanowires (AgNW) to form a polymer nanocomposite with high electronic sensitivity, unprecedented mechanical properties (a maximum strain of 4693% at ambient humidity; ~52 RH%), and repeatable, autonomous self-healing efficiencies of greater than 98%. The AgNW TP complex has an engineering strain higher than all hydrogel and other polymeric sensor materials, in which the interface between the polymer matrix and the AgNW is hypothesized to be integral for the formation of an active conductive network. To illustrate the remarkable sensitivity, the material was employed as a biomedical sensor (pulse, voice recognition, motion), topographical sensor, and high sensitivity sensor.

**8:00 PM SB04.07.17**

**Engineering a Reverse Thermo-Responsive, Cross-Linkable, Biodegradable Liquid Embolic Agent for Brain Aneurysm Treatment** Lamia Ayaz<sup>1</sup>, Hannah Feng<sup>2</sup>, Ruoxi Jin<sup>3</sup>, Ann Lee<sup>4</sup>, Sheldon Liu<sup>5</sup>, Evan Pang<sup>6</sup>, Jiarui Peng<sup>7</sup>, Grace Qiao<sup>8</sup>, Ruth Pereira<sup>9</sup>, Robert Wong<sup>9</sup>, Aaron Sloutski<sup>9</sup>, Chandramouli Sadasivan<sup>9</sup>, Daniel Cohn<sup>10</sup> and Miriam Rafailovich<sup>9</sup>; <sup>1</sup>Howard High School, United States; <sup>2</sup>Torrey Pines High School, United States; <sup>3</sup>Beijing National Day School, China; <sup>4</sup>Seoul International Day School, Korea (the Republic of); <sup>5</sup>Stuyvesant High School, United States; <sup>6</sup>Mission San Jose High School, United States; <sup>7</sup>East Lyme High School, United States; <sup>8</sup>The Experimental High School Attached to Beijing Normal University, China; <sup>9</sup>Stony Brook University, The State University of New York, United States; <sup>10</sup>The Hebrew University of Jerusalem, Israel

Cerebral aneurysms are balloon-like dilations in intracranial arteries that can rupture, leading to fatal hemorrhagic stroke. The majority of current aneurysm treatments involve the implantation of catheter-based endovascular coils and meshes, but they result in unfavorable primary outcomes in at least 20% to 30% of cases [1]. This project aims to develop an injectable, controllably cross-linkable, durable, and multi-functional liquid embolic agent (LEA) using F88-DMA polymer that allows for the body's natural mechanisms to heal the aneurysm with personalized biodegradation.

As temperature increases and reaches physiological temperatures, F88-DMA micelles group together and entangle, resulting in mechanically strong physical gelation. Chemical crosslinkers ammonium persulfate (APS) and tetramethylethylenediamine (TEMED) enhance the long-term stability of the hydrogel, while iohexol acts as a contrast agent.

In order to develop a pluronic-based polymer system that is deliverable in vivo, cold, radiopaque F88-DMA must be injectable through a microcatheter. Gelation must occur at the optimal time and temperature so as not to solidify prematurely or remain liquid within the aneurysm. Various concentrations of F88-DMA and TEMED were tested in vitro to determine the optimal concentration for injectability. Rheology results displayed that a higher concentration of F88-DMA lowers gelation temperature, and this correlation was further confirmed with differential scanning calorimetry for all three concentrations of F88-DMA (27%, 30%, and 33%). Additionally, higher concentrations of TEMED were found to increase the maximum shear modulus and decrease the crosslinking time of F88-DMA gel. To simulate interventional treatment, the LEA was injected into a brain aneurysm model, suggesting 29% F88-DMA to be the most injectable concentration that, when crosslinked, would remain in the aneurysm for prolonged periods of time.

Upon gelation and crosslinking, hydrogels swell in situ due to thermodynamic forces, posing a significant risk for compression or rupture. F88-DMA hydrogel swelling was demonstrated to be dependent on polymer concentration ( $p = 0.019695$ ), and the addition of iohexol significantly decreased swelling over the course of 3 days. Furthermore, hydrogels submerged in flowing saline exhibited less swelling than those submerged in static saline ( $p = 0.0001$ ), an improved durability that originates from the entangled properties of the micelles.

The durable embolic agent must also allow for vascular remodeling and endothelialization in a controlled manner. Thus, cell adhesion and porosity are vital. Imagery of fibrinogen-soaked gel suggests that natural levels of fibrinogen make the cross-linked F88-DMA cell adhesive enough, providing no need to incorporate cell adhesive materials. Sodium phosphate heptahydrate was effectively employed to control pre-determined porosity that initiates the wound healing process.

After the aneurysm has healed, the pluronic implant must be controllably biodegradable. The biodegradability of the LEA is a function of the patient-specific wound healing process such that the blood vessel returns completely to its original healthy state. Naturally occurring enzymatic F88-DMA degradation is currently being investigated with lactide.

Future studies will involve injecting this gel into rabbit models to examine its effects in vivo and determine rates of endothelialization post-injection.

#### 8:00 PM SB04.07.19

**Multi-Scale Chemical Insights into The Static and Dynamic Behaviour of Metallo-Polyelectrolyte Gels** Seneca J. Velling<sup>1</sup>, Pierre J. Walker<sup>1</sup>, Seola Lee<sup>1</sup>, Connor M. Gallagher<sup>2,2</sup>, Michael D. Schulz<sup>2,2</sup>, Zhen-Gang Wang<sup>1</sup> and Julia R. Greer<sup>1,1</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>Virginia Tech, United States

Metallo-Polyelectrolyte Complexes (MPEC) in the gel state represent a class of multifunctional, weakly ionizing materials with intriguing properties deeply rooted in their coordination chemistry and metal ion exchange. We provide a comprehensive exploration of the underlying chemical principles governing MPECs, with a primary focus on the profound effects of metal ion valency and system pH on bonding thermodynamics, association-dissociation kinetics, and global polymer morphology and their regulation of overall gel behaviour. Employing quantum density functional theory (DFT), we estimate the binding energy between the metal cations and the polymer backbone. Hard mono-, di-, and trivalent metal ions exhibit bidentate bridging coordination environments by carboxylate groups and aqua/hydroxy ligands as verified using FTIR, giving stoichiometric charge balance to the complexes. This results in a range of binding energies of -1 to -8 eV. We corroborated these findings with Isothermal Titration Calorimetry (ITC) to probe the solution-phase binding of metal salts to poly(acrylic acid). We demonstrate that the impact of association kinetics at the molecular level propagates to macroscopic behaviour, with higher valency metal ions distinctly influencing relaxation dynamics, thereby increasing gel stiffness and extending the plateau modulus. The role of proton activity in the solution and gel phases – which systematically modulates polyanion charge sparsity and, accordingly, metal binding sites for the formation of these dynamic bonds – can be readily explained using our theoretical treatment. This treatment is in good agreement with our experimental exploration of the MPEC phase space (dissolution, homogeneous gel, and phase separated metal-rich vs. metal-poor gel phase). Guided by theory, our experimental observations unveil the profound influence of pH on polymer relaxation. As charge sparsity decreases, MPEC gels transition towards behaviour reminiscent of monovalent gels, accompanied by critical alterations in network topology. These findings underscore a competition for polyanion (RCOO<sup>-</sup>) association between weakly-bound monovalent species in the buffer (eg. Na<sup>+</sup>), strongly-bound, higher-valency metal species (M<sup>n+</sup>), and the drive for carboxylate protonation when pH < pK<sub>a</sub>. This intricate interplay between metal ion valency and pH-regulated charge sparsity fundamentally governs the global thermomechanical response of solvated MPEC gels: from binding site availability to bond dynamics and overall gel morphology. Local chemistry, therefore, has a profound influence on overall thermal, mechanical, and electrical response of metal cross-linked systems. The assumption – and critical role – of solvent in the gel system cannot be overlooked. Our implicit solvent approaches, taken together with DFT and experimental findings on the collective metal-ligand and metal-aqua/hydroxyl ligand complexation character, explain well the bulk-scale observations in the gel phase, providing mechanistic insights into the polymer-metal interactions, transport, and phase-behaviour. This work unravels the intricate & entangled chemistry underpinning MPEC gels, offering critical insights into their valency-driven, pH sensitive, solvent-dependent global responses.

#### 8:00 PM SB04.07.21

**Unusual Temperature Dependence of Water Sorption in Semi-Crystalline Hydrogels** Xinyue Liu<sup>1</sup>, Lenan Zhang<sup>2</sup> and Evelyn N. Wang<sup>2</sup>; <sup>1</sup>Michigan State University, United States; <sup>2</sup>Massachusetts Institute of Technology, United States

Water vapor sorption is a ubiquitous phenomenon in nature and plays an important role in various applications, including humidity regulation, energy storage, thermal management, and water harvesting. In particular, capturing moisture at elevated temperatures is highly desirable to prevent dehydration and to enlarge the tunability of water uptake. However, owing to the thermodynamic limit of conventional materials, sorbents inevitably tend to capture less water vapor at higher temperatures, impeding their broad applications. Here, an inverse temperature dependence of water sorption in poly(ethylene glycol) (PEG) hydrogels, where their water uptake can be doubled with increasing temperature from 25 to 50 °C, is reported. With mechanistic modeling of water-polymer interactions, this unusual water sorption is attributed to the first-order phase transformation of PEG structures, and the key parameters for a more generalized strategy in materials development are identified. This work elucidates a new regime of water sorption with an unusual temperature dependence, enabling a promising engineering space for harnessing moisture and heat.

**Rubbery Bioelectronics** Cunjiang Yu; The Pennsylvania State University, United States

Electronics that can seamlessly integrate with human body could have significant impact in medical diagnostic, therapeutics. However, seamless integration is a grand challenge because of the distinct nature between electronics and human body. Conventional electronics are rigid and planar, made out of rigid materials. Human body are soft, deformable and curvilinear, comprised of biological materials, organs and tissues. This talk will introduce our solution to address the challenge through the recent development of a new class of electronics, namely rubbery electronics. Rubbery electronics is constructed all based on elastic rubber electronic materials of semiconductors, conductors and dielectrics, which possesses tissue-like softness and mechanical stretchability to allow seamless integration with soft deformable tissues and organs. Rubbery electronic materials (semiconductors, conductors, dielectrics) and device innovations set the foundation. This presentation will describe the development the recent advances of rubbery electronics and rubbery bioelectronics. As a platform technology, rubbery electronics could address many challenges in biomedical research and clinical studies.

**Fabrication of Multi-Material Stimuli-Responsive Microstructures via Photografting of Functional Microgels to Elastomeric Supports** Ruiguo Yang and Stephen A. Morin; University of Nebraska – Lincoln, United States

Hydrogels are functional polymeric materials with stimuli-responsive properties applicable to a wide range of applications including soft electronics and robotics, three-dimensional cell culture, tissue engineering, and adaptive optics. Accordingly, the diversity and reported use cases of these materials has grown tremendously over the past decade, however, the microfabrication of multi-material, hydrogel-based devices remains a challenge. We report a

simple microfabrication strategy that enables the facile production of fixed arrays of stimuli-responsive hydrogel microstructures with dynamic microactuation functionality. Our approach relies on a soft, stretchable chemical template which directs the assembly of prepolymer droplets into ordered arrays and presents the surface chemical moieties needed to photograft the hydrogel to the support, simultaneously. Specifically, we achieve three critical operations in one seamless fabrication scheme: (i) Mechanically driven assembly of prepolymer solutions into ordered arrays is executed using stretchable wettability patterns; (ii) Photoinitiated free radical polymerization is used to drive crosslinking of the prepolymer into hydrogel networks; and (iii) Reactive moieties of the wettability patterns result in photografting of the microgel structures directly to the support substrate. To demonstrate the pragmatic utility of our approach and the functionality of fixed microgels in liquid phase applications, we designed, fabricated, and operated microgel arrays with stimuli-responsive (e.g., solvothermal and chemical) microactuation functionality inside microfluidic chips. Our strategy overcomes the limitations of existing fabrication techniques that produce poorly adherent materials and require complicated processing schemes. We envision many technologies, for example, liquid phase soft microactuators, stimuli-responsive 3D cell culture platforms, and micro/optofluidic chips, will directly benefit from the reported strategy.

#### 9:30 AM \*SB04.08.04

**Hydrogel Bioelectronics, Bioacoustics and Biophotonics** Xuanhe Zhao; Massachusetts Institute of Technology, United States

Whereas human tissues and organs are mostly soft, wet and bioactive; machines are commonly hard, dry and abiotic. Merging humans and machines is of imminent importance in addressing grand societal challenges in health, sustainability, security, education and joy of living. However, merging humans and machines is also extremely challenging due to their fundamentally contradictory properties. At MIT Zhao Lab, we exploit hydrogels to form long-term, high-efficacy, multi-modal interfaces and merger between humans and machines. In this talk, I will discuss hydrogel bioelectronics, bioacoustics, and biophotonics. Specifically, I will discuss examples including nonfibrotic hydrogel bioelectrodes, hydrogel ultrasound couplants that enable wearable imaging, and hydrogel optical fibers that replace rigid optical fibers. I will conclude the talk with a vision for future human-machine convergence aided by materials science and artificial intelligence.

**A Conductive Hydrogel with Tuneable Mechanical and Rapid Self-Healing Properties** Damia Mawad and Nhi Tra; University of New South Wales, Australia

The optimal physical and biological characteristics of a scaffold for tissue engineering include biocompatibility, tissue-like mechanical properties, and a hydrated and porous environment. Hydrogels, 3-dimensional crosslinked polymeric networks, feature many of these characteristics, and thereby, are considered excellent scaffolds for tissue engineering [1]. However, scaffolds tailored for electro-responsive tissues such as neural and cardiac tissue would also benefit from electrical conductivity [2], which has been shown to provide enhanced cell growth and differentiation [3]. Other favourable properties include self-healing [4], providing the scaffold with mechanical and electronic stability under strain, and self-adhesion, enabling the placement of the scaffold at the targeted tissue site in a minimally invasive approach [5]. Here, we report the fabrication and characterisation of a conductive, adhesive, and self-healing hydrogel for tissue engineering applications. We fully characterise its physical and electronic properties. We show that the hydrogel is porous, has high swelling ratio and tuneable mechanical properties, and exhibits very rapid self-healing. We also demonstrate that it is electroactive in physiological buffer and exhibits both ionic and electronic conductivity. Further, its self-adhesion indicates a facile placement on tissues. Coupled together, these properties indicate that the hydrogel with its individual biocompatible components is a suitable scaffold for cell growth and differentiation.

**Tunable Conductive Hydrogels via Simultaneous Photo-Mediated Polymerization and Crosslinking** Dan-My Nguyen, Chun-Yuan Lo, Taewook Choi, Zachary Swain, Yuhang Wu, Charles Dhong and Laure V. Kayser; University of Delaware, United States

Conductive hydrogels, particularly those containing poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS), have gained popularity in bioelectronic interfaces for their mechanical properties close to that of human body and their electrical properties suitable for electrical recording and stimulation. To minimize the invasiveness of conductive hydrogels for bioelectronics, alternative fabrication methods to the common blending approach have been developed, including the photo-gelation of conducting polymers in aqueous environments. However, the photo-catalyzed formation of conductive hydrogels with complex structures is still a challenging task, as the conductive polymers absorb UV light at a similar wavelength, thereby preventing crosslinking. A photo-mediated method for obtaining conductive hydrogels with good conductivity, tunable mechanical properties, and flexibility akin to human body is still lacking.

We developed an approach that combines the simultaneous photo-crosslinking of a polymeric scaffold and the photo-catalyzed polymerization of a conducting polymer under light irradiation. This approach involved the copolymerization of coumarin-containing monomers with sodium styrene sulfonate to yield water-soluble poly(styrene sulfonate-co-coumarin acrylate) (P(SS-co-CoumAc)). Under UV irradiation (365 nm), a transparent, non-conducting solution of P(SS-co-CoumAc), 3,4-ethylene dioxothiophene (EDOT) and ammonium persulfate transforms to a dark blue, electronically conducting hydrogel. The formation of the conductive hydrogel relies on the simultaneous covalent photo-crosslinking of P(SS-co-CoumAc) and the photo-catalyzed oxidative polymerization of EDOT. The resulting conductive hydrogels exhibit both ionic and electronic conductivity to reach bulk conductivity up to  $9.2 \text{ S m}^{-1}$ . They possess tunable elastic moduli (around 10 MPa), and display a reasonable strain at break (up to 16%). These photo-generated conductive hydrogels have the potential to enable the formation of 3D networks with controlled microstructure and offer new possibilities for applications in bioelectronics, including surface electromyography (sEMG).

#### 11:15 AM SB04.08.07

**The Effect of Multivalent Interactions on the Electrostatic Stability of Poly(*N*-isopropylacrylamide) Nanogels** Yuchen Zhu<sup>1</sup>, Jiaxin Hou<sup>1</sup>, Dominic Gray<sup>2</sup>, Tom O. McDonald<sup>2</sup> and Ahu Gumrah Dumanli<sup>1</sup>; <sup>1</sup>University of Manchester, United Kingdom; <sup>2</sup>University of Liverpool, United Kingdom

Poly(*N*-isopropylacrylamide) (PNIPAM) nanogels are promising responsive colloidal particles that can be used in pharmaceutical applications as drug carriers. With an attempt to understand the stability of the PNIPAM-based drug carriers in complex chemical environments, in this work, we investigated the temperature-dependent morphological changes and agglomeration dynamics of PNIPAM nanogels in the presence of mono- and multi-valent cationic electrolytes. Our work provides new insights on the deswelling, flocculation and aggregated morphology of PNIPAM nanogels over a range of electrolyte

concentrations and temperatures revealing the threshold of stability and spontaneous agglomeration states. To complement our results on flocculation of these colloidal particles, we also implemented a Debye screening model that accounts for the shielding effect of multivalent cationic electrolytes on these nanogel systems. We demonstrated that, while the order of deswelling ability of the electrolytes follows the trend  $\text{AlCl}_3 > \text{MgCl}_2 \geq \text{CaCl}_2 > \text{KCl} \geq \text{NaCl}$ , the nanogels reach a minimum hydrodynamic diameter at 10 mM in all electrolyte solutions. The flocculating ability trend and the response time to form aggregates follow a similar order to the deswelling behavior. Interestingly, our statistical analysis on the SEM and TEM images of the PNIPAM nanogels supported our hypothesis on the presence of a shell-like layer around the nanogels with varying density in the electrolyte solutions as compared to those in aqueous medium, and the shell softness of nanogels became harder in multi-valent electrolyte solution than in monovalent system. Furthermore, the retention of the thermo-induced size reversibility for the  $\text{Na}^+$  and  $\text{K}^+$  below 10 mM and for the  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  below 1 mM indicates the effective destabilization of the electrolyte system with multivalence following the Schulze–Hardy rule, except for  $\text{Al}^{3+}$ . In terms of surface charge screening effect, cations with a higher valence shortened Debye length to a greater extent and this ability was found to be in the order of  $\text{Al}^{3+} > \text{Mg}^{2+} > \text{Ca}^{2+} > \text{K}^+ > \text{Na}^+$ .

### 11:30 AM SB04.08.08

**Precision Mechanical Enhancement and Patterning of Hydrogels using Photo-Click Chemistry** Jun H. Park<sup>1,2</sup>, Patrick J. Grimes<sup>1</sup>, Henry E. Symons<sup>1</sup>, Mark S. Workentin<sup>2</sup>, Sebastien Rochat<sup>1,1</sup> and Pierangelo Gobbo<sup>3</sup>; <sup>1</sup>University of Bristol, United Kingdom; <sup>2</sup>The University of Western Ontario, Canada; <sup>3</sup>University of Trieste, Italy

Hydrogels have vast biomedical applications due to their highly tuneable properties, such as biocompatibility, adhesion, permeability, viscoelasticity, and stiffness. These extraordinarily adaptable materials can be engineered to be stimuli-responsive by carefully selecting the crosslinking monomers or polymers that make up the hydrogels. A stimulus that allows for excellent spatio-temporal control is light, and the translucent nature of hydrogels is complementary to its use in these materials. There are various photoactive moieties that have been incorporated into photo-responsive soft materials, however, there are very few systems utilising photo-click reactions to modify the mechanical properties of hydrogels.

Click chemistry has become an established category of reactions characterized by rapid, selective, high yielding, and atom economic transformations that require minimal purification and can be carried out under mild conditions. In 2004, Bertozzi and coworkers established a bioorthogonal, click reaction called the strain-promoted alkyne-azide cycloaddition (SPAAC) by modifying the copper-assisted alkyne-azide cycloaddition (CuAAC) using strained alkynes.<sup>[1]</sup> These alkynes are more reactive and do not require cytotoxic copper catalysts due to ring strain and bond angle deformation. To circumvent degradation and unwanted side reactivity of the strained alkyne, a cyclopropenone-masked dibenzocyclooctyne (*hv*DIBO) moiety was developed, capable of facile deprotection to the strained alkyne using ultraviolet light.<sup>[2]</sup> The rapid deprotection can be performed *in situ* and the resulting alkyne is then free to selectively react with an azide *via* a SPAAC. Along with its great stability and simple deprotection, the application of *hv*DIBO onto soft materials introduces precise spatial control due to the sensitivity of the cyclopropenone group to 350 nm UV-A light.

In this communication, the fabrication of photo-responsive hydrogels incorporating *hv*DIBO and azide moieties will be discussed. Photo-click crosslinking reactions between these groups to mechanically strengthen soft materials will be highlighted. The spatio-temporal control of the photo-click reaction was employed to photo-pattern the surface of hydrogels and to study the kinetics of the materials' strengthening. A recently developed methodology designed to study the mechanical properties of soft materials with a micro-indenter was applied. Microindentation analyses were used to spatially characterize viscoelasticity and height profile changes of these hydrogels, and to determine the reaction order kinetics of the photo-click reaction.<sup>[3]</sup> These analyses aim to relate chemical processes with mechanical measurements. Overall, these photo-responsive hydrogels can be readily strengthened and patterned through clean, facile photo-click chemistry, allowing for exciting potential applications in actuation, soft robotics, biointerfacing, and biomimetic materials.

**DNA-Polymer Hybrids for Responsive and Repeatable Gating in Nanostructures** Kimberley Callaghan<sup>1</sup>, Shelley Wickham<sup>2</sup> and Amanda Ellis<sup>1</sup>; <sup>1</sup>The University of Melbourne, Australia; <sup>2</sup>The University of Sydney, Australia

Deoxyribonucleic acid (DNA) is a remarkable molecule, responsible for cellular information storage, exhibiting unique chemical structure and interactions. These properties have enabled its applications in drug delivery, research tools, and novel materials, with many more potential applications as yet unrecognised. This project aims to develop responsive DNA-polymer hybrid materials capable of sensing and responding to environmental stimuli. These materials will capitalise on the dynamic properties of DNA, whilst utilising the favourable material properties of polymeric materials.

In this work, a DNA-polymer hybrid material was designed to form an aqueous hydrogel upon stimuli addition to generate a gate within a DNA-origami nanostructure to form a biological circuit board. The hydrogel was constructed from an acrylamide backbone, with pendant DNA functionality incorporated. DNA oligonucleotides with polymerisable acrydite handles were doped into the polymerisation reaction, resulting in sporadic incorporation of the DNA motifs.

The DNA motifs used were designed to gate the hydrogel structure under orthogonal stimuli. The stimuli investigated included: temperature, through a self-complementary sequence able to form inter-strand duplexes at lower temperatures; pH, via a i-motif formation involving Hoogsteen base pairing between two cytosine bases in which one is protonated below pH 5 with dissociation upon deprotonation above pH 7; and, a metal ion bridge, using silver ions to bridge two cytosine bases followed by addition of a cysteamine ligand to dissociate the strands. The stimuli chosen all generate transient intermolecular interactions and as such can be cycled repeatedly, allowing for multiple opening and closing cycles of the gates without the need for replacing DNA-polymer components or damaging DNA-origami structures. By integrating the dynamic properties of DNA with the favourable characteristics of polymeric materials, these nanoscale systems offer a solution for the limitations of traditional electronic devices.

SESSION SB04.09: Hydrogels and Energy

**Multifunctional Zwitterionic Hydrogels as a Platform for the Rapid and Simultaneous Elimination of Organic and Inorganic Micropollutants from Water** Devashish Gokhale, Andre F. Hamelberg and Patrick Doyle; Massachusetts Institute of Technology, United States

The removal of micropollutants from water is made difficult by their chemical diversity, low concentrations, and slow uptake by industrial adsorbents. Traditional adsorbents, like activated carbon and ion-exchange resins, are effective in eliminating only specific classes of micropollutants, necessitating the use of multiple unit operations that sequentially treat water. At the same time, slow kinetics require the unit operations to have long residence times and be much larger to effectively eliminate micropollutants. Here we present a new multifunctional zwitterionic porous hydrogel platform for the single-step bulk absorption of both organic and inorganic micropollutants from water. Shifting from traditional surface adsorbents to hydrogels greatly increases the effective functional area, while allowing us to retain the same process-level equipment that has been well studied in the context of conventional adsorbents. A facile synthesis allows easy functionalization of the hydrogels for eliminating multiple micropollutant classes, while also allowing a measure of selectivity. The hydrogels can be synthesized in several form factors for specific applications, including microparticles for use in packed beds, or tablets for treating water in a glass or canteen. Transport of micropollutants within the hydrogels is sped by ion-conducting zwitterionic backbones, while encapsulated micelles speed the transport of uncharged organics. The zwitterionic hydrogels are shown to remove six chemically diverse micropollutants (including BPA, xenoestrogens, and other organics, and lead and other metals) at least 10 times more rapidly than a commercial activated carbon/ion exchange resin mixture, and 100 times faster than other multifunctional adsorbents reported in literature. Zwitterionic hydrogels treat complex micropollutant mixtures, including in the presence of background hardness. Lower compressibility, extremely rapid mass transport, and high stability make our materials highly scalable for real world applications. We demonstrate the use of a prototype packed bed filter with a practical residence time and containing zwitterionic hydrogel microparticles to clean highly contaminated water to below regulatory limits for a period of two weeks.

#### 2:00 PM SB04.09.03

**VOCs-Responsive Hydrogel Electrode based on Changes in Chain Mobilities for Multi-Protection** Youna Kim and Jinkee Hong; Yonsei University, Korea (the Republic of)

Every year, exposure to volatile organic compounds (VOCs) causes fatal accidents including dyspnea and explosions. Personal protection equipment (PPE), such as VOCs sensors to monitor indoor air quality and masks to prevent inhalation of VOCs, is needed to prevent VOC exposure. However, single-functional PPE leads to inconvenience for workers as they must wear multiple pieces of PPE. Therefore, PPE must have the versatility to check not only air quality but also the health condition of workers.

PPE combined with wearable electronics could provide multifunctionality with human health monitoring including strain and motion signals and VOCs detection. The electric materials for wearable electronics should be lightweight, flexible, and stretchable. Hydrogels are attracting attention in wearable electronics because of their flexibility, stretchability, and conductivity. However, it has weak mechanical strength and suffered the deterioration of conductivity and shape shrinkage due to moisture evaporation. Furthermore, few studies have controlled the mechanical and electrical properties of hydrogels due to VOCs exposure except for color changes. In order for VOCs-responsive hydrogels to exhibit various VOC-sensing performances, like actuation and electrical changes, an understanding of polymer behavior caused by VOCs must be investigated.

In this study, we designed a VOC-responsive polymer network (VRN), a wearable electronics that can change its mechanical and electrical properties through VOC reaction. Through a solvation effect by different chemical affinity, the inter/intramolecular interaction and arrangement between polymer chains could be controlled. Based on the solvation effect, we considered (1) the control of polymer chain mobility and hydrogen bonding within VRN and (2) the chemical affinity between the VRN and VOCs.

To control the VRN network, VRN is composed of polyvinyl alcohol (PVA) as hydrophilic semicrystalline and deep eutectic solvents (DES) as ionic liquids. DES is used as a processing and conductive additive to increase the entangled polymer chains and inhibit hydrogen bonding between polymer chains. Accordingly, VRN shows ionic conductivity and stretchability, which can be used for strain-responsive electrodes.

After VOCs exposure, the increased hydrogen bonding and chain relaxation energies affected not only mechanical properties but also the electrical resistance of VRN. A relative resistance change ( $\Delta R/R_0$ ) of VRN is increased by 50% when VRN is exposed to VOCs vapor. The peak voltage based on the triboelectric energy generator (TENG) system decreased by 30% due to VOCs exposure. VRN can be applied to PPE in various forms such as fiber and spray coating.

In addition, we studied the VOCs responsive mechanism of polymer chains using rheological and Raman analysis. We expect VRN to propose VOCs-responsive mechanisms and technologies needed to move towards advanced PPE.

**Ingestible Electronic Interfaces for Neuromodulation** Khalil Ramadi<sup>1,2,3</sup>, <sup>1</sup>New York University Abu Dhabi, United Arab Emirates; <sup>2</sup>New York University, United States; <sup>3</sup>Massachusetts Institute of Technology, United States

Neuromodulation is emerging as a novel approach to treat both neurological and non-neurologic diseases. However, the brain and nervous system are extremely heterogeneous, where cell types and functions vary on scales from sub-millimeters to centimeters. This heterogeneity presents a major obstacle for targeted modulation and interrogation of specific neural structures. This talk will describe non-invasive, ingestible toolkits for high spatial and temporal resolution targeting of neural circuits.

#### 4:00 PM SB04.10.02

**Kinetic Control Dictates the Operation of PEDOT:Lignosulfonate Thin-Films for Biosensing at Physiological pH** Alex C. Tseng<sup>1</sup>, Tomasz Rebis<sup>2</sup> and Toshiya Sakata<sup>1</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>Poznan University of Technology, Poland

Integrating electrically conductive and redox polymers (RPs) is a promising approach for sustainable development of high-performance electrical and electrochemical materials, not only for energy storage but also for bioelectronics and biosensors. Lignosulfonates (LS) exemplify a particularly green materials selection, being low cost and biorenewable, yet readily providing phenolic groups to access (*ortho*-)quinone redox (i.e., reversible proton coupled electron transfer, PCET) and sulfonic acids for polyanionic doping of conductive polymers (CPs). When blended with oxidatively stable PEDOT (poly(3,4-ethylenedioxythiophene)), remarkable specific capacity (170 F.g<sup>-1</sup>) was reported in acidic conditions (0.1 M HClO<sub>4</sub>) [1] despite significant loading of electrochemically inactive components.

Besides enhancing pseudocapacitance, quinone PCET may be further leveraged to serve as an electrochemical interface between technological devices and biological catalyst cycles [2]. However, in the mild pH conditions amenable to biology, it is well known that *ortho*-quinones exhibit limited stability towards redox cycling. Several possible explanations been offered up over the years, for instance: microstructural changes inhibiting proton diffusion [1,4], dissolution of the redox polymer [3], hydroxylation to higher order polyphenols [2], phase separation of CP and redox polymer [5], and cross-linking by the formation of ether linkages [6] or phenyl dimerization [7].

These varied conclusions are likely views of the same fundamental property of *ortho*-quinone RPs—filtered through a range of fabrication and experimental conditions—which is that reversible quinone PCET is a kinetically controlled process. Future biological applications, therefore, require an understanding of how and when alternate electrochemical pathways become activated by the scarcity of protons in physiological conditions. Hence, we investigated the pH-dependent behaviour of PEDOT:LS thin-films via *in-situ* UV-Vis spectroelectrochemistry, charge transport characterization in an electrochemical transistor, and thermodynamic/kinetic analysis by the Laviron method. Our results paint a surprising picture: PEDOT, typically considered to be a “transparent” conductor serving simply as a wire to enhance electron transfer with quinones, is implicated in the formation of strongly bound complexes that appear to stabilize semiquinone radicals. Accordingly, previously observable PEDOT and quinone states are removed in proportion from measurement on experimental timescales. This kinetic process is mediated by the effective overpotential vs. PCET as a function of pH and polarization, and thus informs the optimal operating conditions for biosensing using PEDOT:LS.

**Waterproof and Gel-Free E-Textile Wearable Systems for Exercise Physiology and Maternal Health** Junyi Zhao, Chansoo Kim and Chuan Wang; Washington University in St. Louis, United States

Textile-based electronic systems have emerged as a promising platform for noninvasive and comfortable human-machine interfaces in various applications. These systems integrate multiple technological capabilities such as sensing and wireless communications, making them suitable for daily wearables and physiological monitoring in sports and clinical settings. This work presents a novel E-textile system consisting of printed on-textile electrodes and add-on conductive microfibers, enabling gel-free motion-artifact-tolerant recording of multiple physiological signals, including ECG and EMG from both skeletal and smooth muscles. More specifically, the base layout consists of a screen-printed array of poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS), and the fluffy microfibers coated with PEDOT:PSS are stacked on top. The vertically oriented hairy microfibers offer exceptional conformal and robust contact with the skin, while the spreading-out microfiber electrodes substantially increase the effective contact area. As a result, the contact impedance between the electrode and skin is significantly reduced, enabling comfortable all-day wear under dry conditions without the need for ionic gels. To ensure the durability and functionality of the textile, a self-assembled monolayer (SAM) of trichloro(1H,1H,2H,2H-perfluorooctyl) silane is vaporized as a superhydrophobic coating. This treatment preserves the natural physical properties of the textile while maintaining the intrinsic conductivity of the electrodes. Additionally, a portable mini-circuitry was designed and manufactured to enable multi-channel recording and wireless communications. These advancements contribute to the seamless integration of the E-textile system into everyday life and expand its potential applications. This study explores the application of E-textile systems in real-life scenarios, including strenuous exercise and clinical studies. The study begins by demonstrating the robustness and stability of the E-textile system using E-jersey and E-shorts during a 15-minute cycling training session. Remarkably, the recorded signals remained clear and free from motion artifacts, even in the presence of intense sweating, with a signal-to-noise ratio of approximately 30 dB. Real-time monitoring also allowed for additional real-time data analysis, including heart rate and muscle output. Next, the waterproof capability of the system was tested by creating an E-swimsuit with electrodes placed facing the swimmer's back. Throughout the 12-minute swimming training, the fully submerged E-swimsuit consistently delivered reliable ECG recordings, demonstrating its resilience and suitability for aquatic environments, even when encountering water flows, showcasing its strength and suitability for aquatic environments. Finally, the textile-based E-patch with electrode arrays was employed in clinical studies to monitor maternal health. Multiple pregnant subjects were monitored, capturing multichannel maternal-ECG and uterine-EMG signals. The recorded multichannel uterine-EMG signals were further processed to generate noninvasive and high-resolution three-dimensional (3D) electromyometrial images, providing unique insights into uterine behavior and offering a means of predicting the risk of potential preterm birth. These findings emphasize the versatility and potential of wearable E-textile systems in a wide range of real-world applications. The E-textile systems are specifically designed for convenient and comfortable wearing, paving the way for professional sports tracking and personalized healthcare advancements.

#### 4:30 PM SB04.10.04

**Materials Design of Functional Gels to Realize 3D Artificial Skin Device based on Extrusion-Based 3D Printing** Woohyeon Shin<sup>1,2</sup>, Hui Ju Choi<sup>1</sup> and Kyeongwon Chung<sup>1</sup>; <sup>1</sup>Kyungpook National University, Korea (the Republic of); <sup>2</sup>Ulsan National Institute of Science and Technology, Korea (the Republic of)

Due to unique properties such as biocompatibility, flexibility, and conductivity, hydrogels are widely investigated in various applications, including tissue engineering, E-skin, wearable, and ionic devices. Especially, in the field of E-skin devices, hydrogels are recognized as one of the promising materials due to their flexibility and capability to realize various sensing functionalities. Still, there are challenges that need to be addressed: the structural freedom of devices. Most E-skin devices have been demonstrated with simple structures such as blocks or films due to the demand for complicated multi-layer structures or limitations in the fabrication process. Especially, because body parts with various shapes and movements (e.g., fingers, elbows, and shoulders) are under massive fatigue by strains in various directions and amounts, it is important to realize artificial skin devices with complex 3D structures that are optimized for the targeted body part.

To realize complex 3D structures of hydrogel via extrusion-based 3D printing, we systematically investigated the correlation between materials design and their characteristics including gelation properties, rheological characteristics, and 3D printing processability. From the investigation, we successfully presented the material design window based on the rheological parameter ( $G' < 2500$  Pa and  $\tan \delta < 0.2$ ) to prepare target-oriented 3D structures of the hydrogel via extrusion-based 3D printing.

Based on the defined material design window, we successfully prepared functional hydrogel 3D structures to demonstrate novel artificial skin devices that can detect accurate touch points and spontaneously heal mechanical damage. Ring-shaped and fingertip-shaped artificial skin devices have been successfully prepared to fit the finger model. Furthermore, like human skin, artificial skin devices provide accurate location information for arbitrary touch points without complex device fabrication or data processing.

In hydrogel-based 3D e-skin devices, it is also important to address the inherent drying and freezing problems of hydrogel for practical application. As an approach to these problems, we presented organohydrogel systems via solvent displacement and investigated the correlation between solvent system design

and the material properties of organohydrogels. By investigating the rheological properties and ion conductivity of the gels, we provided insights for preparing optimal organohydrogels for various processes and applications. Based on the defined solvent system design, we prepared organohydrogels that show excellent drying resistance even over 1,000 hours and exhibit superior freezing resistance by showing no phase transition down to  $-60^{\circ}\text{C}$ . Furthermore, the 3D artificial skin devices are demonstrated based on the organohydrogels, and the artificial skin devices successfully provide the exact position of touchpoints over time and show excellent operation capability even at temperatures below  $0^{\circ}\text{C}$  without losing flexibility.

SESSION SB04.11: Skin and Tissue-Interfacing Hydrogels II

**Electrically Induced Shape Memory Hydrogels in Biomedical Applications.** Georgios Mikalef, Arjan Sall, Zoe Schofield, Atif Shahzad, Patricia P. Esteban and Liam Grover; Healthcare and Technologies Institute, United Kingdom

Here we report the development of a novel shape memory hydrogel that changes shape on exposure to an electrical field. This material has been designed to enable the minimally invasive administration of a novel sensor system to monitor real-time changes in blood pressure. The hydrogel will encapsulate a sensor coil and protect against biological interference during measurement. Real-time blood pressure measurement will enable the diagnosis and monitoring of conditions as hypertension and cardiomyopathy, which place a significant financial burden on healthcare systems worldwide.

Polyelectrolyte (PE) hydrogels can exhibit a shape memory effect upon exposure to an electrical current, caused by ions that sit within its structure. PE gels are naturally found throughout the body where they are often associated with oppositely charged molecules. One such example is in the aggrecan, which interacts strongly with collagen in cartilage. PE hydrogels have already been used extensively as biomaterials. Their structure has made them ideal scaffolds for tissue engineering, novel drug delivery systems, soft robots particularly in artificial muscle and actuators, smart fabrics, and implantations for minimally invasive surgeries.

Since hydrogels can exhibit poor mechanical properties, we have made efforts to reinforce the shape-memory polymer structure. We explored 2 different formulations have been synthesised containing the smart material 2-acrylamido-2-methylpropanesulfonic acid (AMPs) and either Polyethylene Glycol Diacrylate (PEGDA) or acrylamide. The mechanical performance and chemical structures of these materials have been evaluated. Finally shape memory testing has been performed to determine the effect of curing on the material's ability to change shape.

Further testing will include direct contact cytotoxicity testing to determine cell viability as well as surface modification whereby protein adsorption will be implemented to fix the device and so reduce migration upon implantation.

#### 9:15 AM DISCUSSION TIME

#### 9:30 AM \*SB04.11.03

**Healable and Stretchable Conducting Hydrogels for Epidermal Electronics** Fabio Cicoira; Ecole Polytechnique de Montreal, Canada

Soft and conductive materials with long-term stability have attracted interests in the field of epidermal bioelectronics due to their conformal contacts with skin and the ability to acquire bio-signals for long-term use. Applications include monitoring of vital signs (e.g., electrocardiography (ECG), electromyography (EMG), and electroencephalography (EEG)), measurement of body temperature and blood pressure and detection of analytes in bodily fluids. ECG, EMG, and EEG are typically achieved with metal (ground strap, bar, or cup) or, in most cases, Ag/AgCl gel electrodes. However, rigid metal electrodes are unable to withstand bending or stretching, which can result in skin damage or irritation and lead to high signals noise, whereas Ag/AgCl gel electrodes can lead to skin irritation due to strong adhesion on the skin and are prone to signal degradation in long-term use due to the drying of the gel. Therefore, there is a strong demand for soft conductive electronics that can form conformal interfaces with biological tissues for long-term use without leading to skin damage and irritation.

Various types of conductive soft materials have been used for on-skin electronics, in form of films, bio-inspired adhesives, fabrics, and hydrogels. Conductive hydrogels are promising candidates for epidermal electronics because of their conformal contact with the skin, high water content (70-99%, similar to tissues), ease of processing, tunable electrical and mechanical properties, and biocompatibility. Conductive hydrogels may be obtained from pure conductive polymers, e.g., poly(3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS), polypyrrole (PPy), or polyaniline (PANI), or, in most of cases, by mixing conductive materials (e.g., conducting polymers, nanoparticles, nanowires, nanosheets, carbon nanotubes (CNTs), and graphene) with polymers, such as poly(vinyl alcohol) (PVA), poly(acrylic acid) (PAA), poly(acrylamide) (PAAM), or polyurethane (PU). A hydrogel prepared by mixing a PEDOT:PSS aqueous suspension with 0.1 M  $\text{H}_2\text{SO}_4$  exhibited a conductivity of  $\sim 9 \text{ S/cm}$  after further concentrated sulfuric acid treatment. Our group reported a hydrogel obtained by blending PEDOT:PSS into a PVA/borax system, which showed remarkable compliance on skin, outstanding plastic stretchability (10000% strain), self-healing, high adhesion on porcine skin ( $1.96 \text{ N/cm}^2$ ), and low compressive Young's modulus ( $\sim 4 \text{ kPa}$ ). Electrodes based on this hydrogel have demonstrated high-quality recordings of ECG and EMG signals.

Tannic Acid, a natural polyphenol, has been widely used to prepare hydrogels from mixtures with PAAM/kaolin, silk fibroin, PVA/PAAM, and CNT/PVA/glycerol. Moreover, TA exhibits biocompatibility and antibacterial, antioxidative, and anti-inflammatory properties, which can be exploited for medical applications, such as wound healing and infection treatments. Polyvinyl alcohol (PVA)-borax hydrogels are widely studied for biomedical applications due to their biocompatibility, biodegradability, water solubility, easy processing and self-healing properties.

Herein, we report conductive organohydrogels obtained from aqueous mixtures of PEDOT:PSS, EG, and TA and PVA, which showed a low compressive Young's modulus of  $\sim 20 \text{ kPa}$ , high electrical conductivity as well as anti-freezing and water retention properties. Our gels were showed self-healing ability and were used to prepare epidermal electrodes for ECG and EMG recordings, which showed similar performance to that of commercial Ag/AgCl gel electrodes, even after storage in ambient air for 1 week. We also demonstrated the use of gel electrodes as human-machine interfaces to control the opening and closing of a robotic hand in real time. The simple fabrication, high conductivity, and mechanical properties make our gels highly promising for applications in bioelectronics.

#### 10:00 AM BREAK

**10:30 AM \*SB04.11.04*****In-Vivo* Polymerization of Conjugated Polyelectrolytes in Plants and Animals** Eleni Stavrinidou; Linkoping University, Sweden

Leveraging the biocatalytic machinery of living organisms for in-vivo fabrication of functional bioelectronic interfaces enables seamless integration of devices in tissue and formation of biohybrid systems. Previously we have demonstrated that plants can polymerize conjugated oligomers in-vivo forming conductors within their structure. We showed that the polymerization is enzymatically catalyzed by endogenous peroxidases, and we developed a series of conjugated oligomers that can be enzymatically polymerized in physiological conditions. The conjugated polyelectrolytes integrate within the plant cell wall structure adding electronic functionality into the plant that is then explored for energy storage. Recently we demonstrated intact plants with electronic roots that continue to grow enabling plant-biohybrid systems that maintain fully their biological processes. The electronic roots are used to build supercapacitors and biohybrid circuits to power low power electrochemical devices. Furthermore, we have extended this concept into an animal model system. We demonstrated that Hydra, an invertebrate animal, can polymerize intracellularly conjugated oligomers in cells that expresses peroxidase activity. The conjugated polymer forms electronically conducting and electrochemically active domains in the  $\mu\text{m}$  range integrated within the hydra tissue. Our work paves the way for self-organized electronics in plant and animal tissue for modulating biological functions and in-vivo bio-fabrication of hybrid functional materials and devices.

**11:00 AM SB04.11.05****Hydrogel for Multiplexed Multiscale Imaging and Phenotyping of the Human-Organ-Scale Biological Tissues** Juhyuk Park<sup>1</sup>, Ji Wang<sup>1</sup>, Webster Guan<sup>1</sup>, Lee Kamentsky<sup>1</sup>, Nicholas Evans<sup>1</sup>, Jeffrey Stirman<sup>2</sup>, Xinyi Gu<sup>1</sup>, Chuanxi Zhao<sup>1</sup>, Minyoung Kim<sup>1</sup>, Seo Woo Choi<sup>1</sup>, Clover Su-Arcaro<sup>1</sup>, Yuxuan Tian<sup>1</sup>, Dae Hee Yun<sup>1</sup>, C. Dirk Keene<sup>3</sup>, Patrick Hof<sup>4</sup>, Matthew Frosch<sup>5</sup> and Kwanghun Chung<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>LifeCanvas Technologies, United States; <sup>3</sup>University of Washington, United States; <sup>4</sup>Icahn School of Medicine at Mount Sinai, United States; <sup>5</sup>Harvard Medical School, United States

Understanding the intricate chemoarchitectural details and regional-specific functions and dysfunctions of the human brain poses a formidable challenge in holistic brain imaging and phenotyping. While recent advancements in tissue clearing and labeling techniques have made significant strides, the lack of scalability, thermos-mechanical robustness of tissues, imaging resolution, and cost-effective immunolabeling protocols limit their applicability in multiplexed human brain mapping at various scales. In this study, we present a pioneering hydrogel-based tissue processing technology called mELAST, which transforms biological tissues into soft, tough-elastic, reversibly expandable tissue-hydrogel hybrids, in tandem with mechanical devices and chemicals. Leveraging mELAST, we achieved multi-round immunolabeling and multiscale expansion imaging of volumetric human brain tissues, enabling the comprehensive capture of cytoarchitecture, microenvironment, and synapses within the human brain. We applied the mELAST pipeline to conduct a comparative study of Alzheimer's disease in the human brain, further unraveling neuroscientific enigmas. With mELAST, we anticipate a significant advancement in our ability to navigate deep within the human brain afflicted by pathologies, shedding light on crucial neuroscientific challenges.

**11:15 AM SB04.11.07****Intraoral Hydrogel-Graphene Biosensors for *In-Situ* Detection of TNF- $\alpha$  in Human Saliva** Shaoting Lin; Michigan State University, United States

Technologies that enable in-situ monitoring of biomarkers in human saliva in oral cavities are highly desirable for timely diagnosis, early intervention, and personalized treatment of oral diseases. Existing efforts have been mostly focused on flexible electronics made of rigid materials, which inevitably suffer significant challenges in interfacing soft tissues due to their contradictory properties. Hydrogels, polymer networks infiltrated with water, share similar mechanical and physiological properties as biological tissues, regarded as an ideal material candidate to form long-term, high-efficacy, multi-modal interfaces between electronic components and biological systems. In particular, the recent developments of tissue-adhesive hydrogel patches have shown great success in forming rapid and tough adhesion between wet tissues and electronic devices in various organs, but these efforts have not been implemented in oral cavities. In this work, we focus on developing an intraoral hydrogel-graphene biosensor that can achieve highly sensitive, specific, and durable detection of human tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) in human saliva. The design of hydrogel-graphene biosensor is based on an integration of selective-permeable hydrogel and graphene-based sensing probe, which enables sensitive and specific detection of low-concentration TNF- $\alpha$  in human saliva. This work will not only hold the promise of enabling rapid diagnosis of conditions such as recurrent aphthous stomatitis (RAS), periodontal disease, and oral cancer, but also facilitate the planning of medical treatment policies and evaluation of treatment efficacy.

**11:30 AM SB04.11.08****A Damage-Mapping, Self-Healing Electronic Skin for Surgical Simulation Training** Samuel E. Root and Zhenan Bao; Stanford University, United States

Modern facilities for surgical education make use of inanimate models to simulate surgical tasks. Such models provide trainees with the opportunity to practice and receive feedback on the procedural and motor skills required to perform complex surgeries with expert-level competency. Existing models for surgical simulation rely heavily upon thermoset polymers such as silicones or hydrogels, which deteriorate after single or repeated use. Such disposable models are expensive—especially those with physically realistic properties—and incur a prohibitive cost for training programs, limiting opportunities for students to practice with high fidelity models. Moreover, evaluating the performance of trainees on surgical tasks is difficult and requires direct observation by an expert or the use of motion tracking software. There is a need to develop surgical simulation models with realistic physical properties and functional capabilities mimicking that of living tissue including, i) the ability to heal from damage, and ii) the ability to sense and transduce mechanical stimuli including forces, pressures, rates and depths of incisions and punctures. Over the past decade, advances in the science of dynamic polymeric materials (*i.e.*, polymers that are cross-linked with reversible bonds, such as hydrogen bonds) have enabled the molecular design and device integration of stretchable, conductive, self-healing composites. We have recently reported a strategy for improving the functional self-healing efficacy of multi-layer laminate composites through the molecular design of a pair of dynamic polymers with immiscible polymer backbones (poly(dimethylsiloxane) and poly(propyleneglycol)) but identical dynamic bonding units (a mixture of bisurea-based hydrogen bonding units). These polymers have a strong, adhesive but thermodynamically restricted interface, which results in an autonomous alignment and healing phenomenon, whereby polymer chains directionally diffuse to minimize the interfacial free energy when multi-layered stacks are damaged and misaligned. In this presentation, I will discuss our current efforts building upon this work towards the design of a damage-mapping electronic skin capable of sensing processes such as punctures with needles, scalpels, or sutures—and self-healing to undergo many operational cycles. We have developed a scalable compositing, compression-molding, and layer-based assembly process for fabricating multi-layer soft electronic films. We have implemented a voltage-based sensing mechanism for mapping the location and depth of needle punctures and surgical incisions. Finally, we demonstrate how these electronic skins can be integrated with surgical simulation technology, including rolling the films into vein-like tubes capable of sensing needle punctures for intravenous access training. Overall, we propose that there are many opportunities for bio-mimetic functional materials and device design within surgical simulation technology, including hybrid self-healing hydrogel-elastomer devices.

SESSION SB04.12: Chemistry-Focus of Hydrogels

**Conductive or Injectable Hydrogels for Conformal Tissue-Device Interfacing** Dae-Hyeong Kim<sup>1,2</sup>; <sup>1</sup>Institute for Basic Science, Korea (the Republic of); <sup>2</sup>Seoul National University, Korea (the Republic of)

Recent advances in soft electronics have attracted great attention due to its potential applications to personalized health-monitoring and point-of-care devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations and drug delivery in feedback therapies. Ultra-flexible and stretchable bioelectronic devices have a low system modulus and intrinsic softness, and have a potential to solve these issues. However, locally incomplete contacts are still found in skin-device interfacing and they reduce the sensing efficiency and therapeutic efficacy of the soft bioelectronics. Composites of polymers, nanomaterials, and hydrogels are particularly promising material candidates for solving such issues and achieving ideal biotic-abiotic interface. In this talk, the unique strategies in the synthesis of conductive or injectable hydrogels, their seamless integration with soft bioelectronics, and wearable and/or implantable device applications are presented. These efforts are expected to address unmet clinical challenges.

**2:15 PM SB04.12.03**

**Tuning the Surface Chemistry of 3D Graphene Hydrogels by Covalent Functionalization: A Flow Chemistry Approach** Antonino Biagio Carbonaro<sup>1</sup>, Daniele Fumagalli<sup>2</sup>, Valentina Greco<sup>1</sup>, Antonino Gulino<sup>1</sup>, Valentina Pifferi<sup>2</sup>, Luigi Falciola<sup>2</sup> and Alessandro Giuffrida<sup>1</sup>; <sup>1</sup>University of Catania, Department of Chemical Sciences, Italy; <sup>2</sup>University of Milan-La Statale, Italy

Recently, three-dimensional porous graphene architectures, such as hydrogels and aerogels, have received increasing attention in the scientific literature due to their unique structural, chemical and physical properties. Combined with the well-studied brilliant properties of graphene-based materials, 3D graphene structures find applications in bioelectronics, sensing and energy storage. The meso- and macroporous structure of hydrogels and aerogels allows to overcome some limitations of 2D graphene materials, such as the re-stacking of monolayers, which confers unique properties due to the high active surface area of well-defined 3D graphene architectures. Most applications of graphene hydrogels and aerogels are based on the interaction between the porous carbon structure with molecular species, in the gas or liquid phase. In this context, functionalization strategies that allow the control of surface speciation would be highly welcomed. Functionalization methods for graphene hydrogels include non-covalent approaches where the guest species are physisorbed onto the porous structure during the gelation process. However, this approach can have many disadvantages, such as molecule slippage, and they are difficult to control compared to a covalent functionalization strategy. Keep this in mind, in this work we would like to shed light on the chemical behaviour of graphene hydrogels; in particular, according to the flow chemistry concepts, we propose a facile covalent functionalization strategy through Diazonium Salts Chemistry. The samples were extensively characterized by micro-Raman and ATR-FTIR spectroscopy, X-ray Photoelectron Spectroscopy (XPS), Scanning Electron Microscopy (SEM) and BET. In addition, the electrochemical performances of the 3D porous graphene hydrogel and aerogel structures were investigated by Cyclic Voltammetry (CV), Differential Pulse Voltammetry (DPV) and Electrochemical Impedance Spectroscopy (EIS), focusing on the electrochemical sensing properties of the 3D self-standing structures.

**2:30 PM SB04.12.04**

**Host-Guest Chemistry for The Design of Functional Polymer-Nanoparticle Hydrogels** Stephane Bernhard, Lauritz Ritter, Marco Müller, Giovanni Bovone, Elia Guzzi, Wenqing Guo and Mark W. Tibbitt; ETH Zurich, Switzerland

Polymer-nanoparticle (PNP) hydrogels are a class of injectable nanocomposites based on physical interactions between polymers and nanoparticles (NPs). (1) Due to the shear-thinning and self-healing behaviour provided by the reversibility of the polymer-nanoparticle interactions, they have been used in the biomedical field as injectable biomaterials or inks for additive manufacturing. (2-3) Current PNP hydrogels however cover a narrow range of functionality and can be built from a restricted pool of available building blocks due to the constraint presented by the limited versatility of the cross-linking interactions. Here, we present the use of a supramolecular motif based on host-guest interactions for the design of versatile and functional PNP hydrogels.

In this work, two approaches based on cyclodextrin (CD) host-guest interactions were used for the design of PNP hydrogels. In a first approach, alpha-cyclodextrin ( $\alpha$ CD) was added to a cellulose- and PEGylated-NP-based hydrogel, to decouple mechanical properties from building blocks via polypseudorotaxane formation. The addition of  $\alpha$ CD enabled the exchange of the polymer and nanoparticle for varied biopolymer with secondary cross-links or inorganic nanoparticles with conductive or magnetic characteristics. In a second approach, beta-cyclodextrin ( $\beta$ CD) was used in combination with azobenzene, a photo-responsive guest for the design of light sensitive hydrogels. For this purpose, a host-functionalized polymer ( $\beta$ -CD hyaluronic acid) and guest harboring block copolymer (PEG-*b*-PLA) NPs were synthesized.(5) The presence of the photoresponsive host-guest complex resulted in reversible gelation of the hydrogel via illumination at various wavelengths of light. This work demonstrates how supramolecular interactions can be used to engineer versatile and functional polymer nanocomposite biomaterials and substantially increase the utility of this class of materials.

**10:30 AM \*SB05.01.01**

**Modulation of Cell Signaling with Magnetic Nanomaterials** [Polina Anikeeva](#); Massachusetts Institute of Technology, United States

Magnetic fields offer unprecedented access to signaling processes deep within the body due to the low conductivity and negligible magnetic permeability of biological matter. Magnetic fields with a diversity of spatio-temporal characteristics can be transduced into stimuli perceived by biological receptors via tailored magnetic nanomaterials enabling remote modulation of cell function. In this talk, I will highlight physical principles guiding magnetic nanomaterials design with the goal of transducing magnetic fields into mechanical, thermal, chemical, and electric stimuli. I will further describe how these magnetic nanomaterials, coupled with biological mediators, can enable wireless modulation of cell signaling, organ physiology, and animal behavior. Finally, I will discuss strategies to deliver magnetic nanomaterials to specific cells and organs in the body laying a foundation for minimally invasive implant-free and surgery-free bioelectronic interfaces.

**11:00 AM SB05.01.02**

**Directed Assembly Behavior of Optoelectronic Peptide Biomaterials for Excitable Systems** [Ze-Fan Yao](#), Yuyao Kuang, Emil Lundqvist and Herdeline Ann Ardoña; University of California, Irvine, United States

Organic conjugated materials are known to have molecular design-tunable optoelectronic properties while exhibiting intrinsic flexibility and the ability to form soft networks, which are suitable for biological interfacing. To better utilize these properties towards interfacing with living systems, more efforts are required to render biocompatibility and other physiologically relevant characteristics to these materials. Here, we design, synthesize, and characterize  $\pi$ -conjugated peptides with controllable assembly-disassembly behavior in aqueous solutions and directed anisotropic assembly on surfaces for biointerfacing. The peptidic segments serve as a biomimetic template for the stimuli-driven self-assembly process of  $\pi$ -conjugated monomers in aqueous solutions and on nanostructured polymeric surfaces. In solution, the supramolecular assembly and disassembly processes of the designed peptides can be accessed through a carbodiimide-fueled approach that instructs their self-assembly and hydrolysis-induced disassembly. On polymeric surfaces that have anisotropic topography and have chemically analogous  $\pi$ -conjugated chains as the central core of our peptide monomers, the resulting self-assembled optoelectronic peptides can be directed to form 1-D nanostructures on the surface nanofeatures. These peptide-modified surfaces present bioadhesive cues towards achieving cellular anisotropy, therefore providing a potential opportunity for directional stimulation of excitable cells. By having the capability to generate photoinduced currents, substrates bearing these assembled optoelectronic  $\pi$ -conjugated units offer the possibility of light-controlled behavior of excitable cells. In summary, this presentation will discuss the engineering of optoelectronic peptides that form controllable supramolecular structures capable of modulating the behavior of excitable cells and tissues via light.

**11:15 AM SB05.01.03**

**Bioadhesive Polymer Semiconductors and Transistors for Intimate Biointerfaces** [Nan Li](#) and Sihong Wang; University of Chicago, United States

Integrating biocompatible electronic devices with living biological tissues is emerging as a highly promising avenue for achieving the real-time measurement of biological signals with high spatiotemporal resolutions for biological studies and health monitoring. Polymer semiconductors-based transistors (e.g., organic electrochemical transistors (OECTs)) as an advanced sensing device, are highly desired for direct electrical biointerfacing due to their low operation voltage, mixed electron-ion conduction, and high sensitivity. To interface with wet and dynamically moving tissues, developing intrinsically bioadhesive polymer semiconductors can significantly improve the devices' conformability on tissue surfaces and signal acquisition sensitivity.

In this talk, I will present the design of a BioAdhesive polymer SemiConductor (BASC) film by creating a rationally designed polymer network with interpenetrating semiconducting polymers and adhesive brush polymers. The BASC films can form robust and rapid adhesion with bio-tissues (e.g., heart, lung, spleen) under gentle pressure, while providing high charge-carrier mobility. We further fabricate a bioadhesive OECT with the BASC as the active channel and demonstrate its use for reliably monitoring electrophysiological signals on an isolated rat heart and in vivo muscles.

**11:30 AM SB05.01.04**

**MXene Hydrogels as Soft Bioelectronic Interfaces** [Raghav Garg](#)<sup>1</sup>, Stefano Ippolito<sup>2</sup>, Spencer R. Averbeck<sup>1</sup>, Yury Gogotsi<sup>2</sup> and Flavia Vitale<sup>1</sup>;

<sup>1</sup>University of Pennsylvania, United States; <sup>2</sup>Drexel University, United States

Biological tissues and organs, such as the cardiac tissue and the brain, are mechanically soft and exhibit viscoelastic behavior. Real-time diagnosis and treatment of diseases of such electrically active tissues requires continuous electrophysiological monitoring stimulation. This has been achieved through implantable bioelectronic platforms. However, current implantable bioelectronics are composed of mechanically rigid materials such as metals (Au, Pt), metal oxides (IrOx), and semiconductors (Si). The large mechanical mismatch between the target tissues and the bioelectronics interfaces has been a bottleneck for chronic clinical applications. Although metal nanoparticles and carbon nanomaterials have been leveraged to fabricate electrically conductive hydrogel bioelectronics, they are limited by their electrochemical functionality, biocompatibility, and processability. Here we leverage safe liquid-phase processing of two-dimensional  $Ti_3C_2T_x$  MXene to fabricate MXene-based hydrogels for implantable bioelectronic interfaces. We achieve a high-density network of MXene flakes by directly crosslinking individual MXene flakes using transition metal ions. The matrix-free structure of the MXene hydrogels endows them with high electrical conductivity and low electrochemical impedances, thus facilitating their integration into soft bioelectronics for electrophysiological recordings with high signal-to-noise ratio. The capacitive nature of  $Ti_3C_2T_x$  further allows the hydrogels to exhibit high charge injection capacities for safe delivery of electrical stimulation to target tissues. Finally, we demonstrate modulation of the mechanical properties of the packaged hydrogels by altering the composition and degree of cross-linking of the alginate-based insulation. Our results underscore the application of MXene-based soft bioelectronics in studying neural function and disease pathologies, as well as developing neuromodulation paradigms.

**11:45 AM SB05.01.05**

**Optimizing the Pore Structure of 3D Conducting Polymer Scaffolds for Bioelectronic Devices** [Rachana Acharya](#), Douglas van Niekerk, Aimee Withers and Roisin Owens; University of Cambridge, United Kingdom

The integration of 3D tissue-engineered microporous scaffolds based on conductive polymers (CPs) into bioelectronic devices have led to the possibility of dynamic monitoring of biological phenomena through electrical measurements. The 3D structure and morphology of the porous scaffolds mimics the topographical features of human physiology, while the electrically conductive nature of the polymers allows for electrical measurements for label-free monitoring and live-sensing of cells. 3D scaffolds based on the polymer poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) prepared by the freeze drying process have been the focus of many studies and well integrated into bioelectronic devices such as electrodes[1] and organic electrochemical transistors[2].

The freeze-drying process involves freezing the aqueous dispersion of the conducting polymer, followed by the sublimation of the ice crystals by lowering the pressure in the system, leaving behind a porous network of the conducting polymer. This porous network is representative of the physiological tissue structure, making the ice nucleation and crystallization a crucial component of the scaffold fabrication process. A deeper understanding of the freeze drying process and a higher degree of control on the freezing parameters will help establish the correlation between the material properties of the scaffolds and the biomimetic tissue engineering requirements for optimum cell culture platforms.

Three different freeze drying protocols were employed, with a pre-cooling treatment used before the freeze-drying process. Two different pre-cooling rates, 0.5 °C/min and 1 °C/min along with a control protocol with no treatment were designed to prepare different scaffold types. Within each protocol, the freezing rate was varied between 0.2 °C/min and 1 °C/min and the thermal profile of the aqueous dispersion was recorded during the entire fabrication process.

The influence of the different protocols and freezing rates on the pore size and structure was examined by scanning electron microscopy and micro-computed tomography. Pores of circular and elongated ellipses were observed by SEM and a pore size distribution (the longest dimension of the ellipsoid) between 80 µm and 220 µm was measured. It was observed that a higher cooling rate generated larger pores with more elongated pore morphology as well as a wider pore size distribution. The pre-cooling treatment with 0.5°C/min cooling rate was most useful in generating scaffolds with a more homogenous pore structure and a pore size of approximately 100 µm.

The different scaffolds were incorporated into electronic devices such as transmembrane electrodes to characterize the electrical properties and evaluate the reproducibility of the scaffolds prior to cell culture. No significant change in the electrochemical impedance spectra was observed despite the large difference in porosity of the different scaffolds. In addition, the different scaffolds were used to host and monitor biological cells like fibroblasts and endothelial cells. Cell growth and proliferation in the different scaffolds was also monitored by immunofluorescence microscopy. It was observed that a pre-cooling protocol and a freezing rate of 0.5°C/min helps to fabricate scaffolds with an optimized, uniform and homogenous pore morphology. This design protocol is highly beneficial in reducing the random artifacts of the nucleation process and generating scaffolds highly conducive to cell growth and survival and to create a versatile bioelectronic platform for studying in-vitro cell models.

**3D Bioelectronic Models of Gut, Brain and Lung** [Roisin Owens](#); University of Cambridge, United Kingdom

Physiologically relevant in vitro human models are urgently required to bridge the gap between over-simplified 2D in vitro models and ill-suited animal models, for drug discovery and disease modelling. Bringing together principles of materials science, tissue engineering, 3D cell biology and bioelectronics, we are building advanced models of the gut, brain (neurovascular unit) and the lung. In the case of the gut and NVU, our aim is to elucidate the role of microbiota in the gut-brain axis communication, a particularly challenging system to model with lab animals. In the case of the lung, our interest is in modelling the air-liquid interface to more accurately study lung disease.

Our models are based on the use of electroactive scaffolds which can host tissues, but also monitor their formation, and later their status when challenged with a pathogen or target molecule. Our strategy is to build a stromal layer with the scaffold and layer epithelial or endothelial models on top, preserving tissue stratification. Our most recent work has adapted these scaffolds to the well-known Transwell format, to allow continued access to both apical and basal aspects.[1] As well as traditional readouts such as immunofluorescence, or biochemical analyses of media, our continuous electrical monitoring readouts from our electroactive scaffolds gives us real-time data on the tissue health.

**Harnessing Protein Engineering and Bioelectronics for Sensory Perception on a Chip** [Eleanor Best](#), Zhongmou Chao, Poompol Buathong, Peter Frazier and Susan Daniel; Cornell University, United States

As humans, our perception of the world relies on the function of our powerful sensory organs. Olfaction in particular is well-documented as a biosensing modality across species, as dogs and insects have been shown to detect the early onset of disease or even harmful substances as part of airport security protocols. As specific ligands bind to their corresponding sensory receptors, they trigger a unique combination of activated neurons that are interpreted downstream. By merging interspecies sensory systems with bioelectronics, we can create a novel biosensor and simulate sensory perception on a chip. Whilst previous platforms have leveraged gas sensors for compound detection, our system instead employs carefully selected mammalian and insect proteins to replicate and enhance sensory perception. By using innovative protein engineering techniques and deliberately designed electronic devices, we have created a fully customizable approach to sensory perception in a way that carefully combines nature's original biosensors with synthetic biology. This unique platform provides a novel approach to the conventional biosensor with immense potential for security and medical applications.

**Deformable Composites: From Photostimulation to Living Bioelectronics** [Bozhi Tian](#); University of Chicago, United States

The field of electronic and photonic biointerfaces continues to evolve, with flexible and living composites playing a key role in advancing the development of multifunctional devices such as sensors and modulators. Our research focuses on creating non-genetic approaches for biological modulation and sensing across different length scales. This presentation will provide insights into some of our recent projects. This includes our work related to photostimulation within clinical environments. We have made new progress in the development of a nanoporous/non-porous heterojunction, exemplifying the level of precision and control achievable in bioelectronic therapies. We have also developed a granular system aimed at focal adhesion in bioelectronics and other interfaces for regenerative medicine. Additionally, we have begun exploring the integration of living cells with wearable bioelectronic devices, a new direction within the sphere of living bioelectronics. Our primary goal is to transition these basic studies of modulation tools into applicable clinical practices, with the potential to influence therapeutic strategies and improve patient outcomes. As I conclude the presentation, I will highlight our future research directions. These are designed to further contribute to the extensive field of biological modulation and sensing, with a specific focus on applications that could have a significant impact in the clinical setting.

#### 3:45 PM SB05.02.05

**Tissue-Embedded 3D Stretchable Nanoelectronics for Multimodal Charting of the Human Stem Cell-Derived Organoids** [Ren Liu](#), Qiang Li, Zuwan Lin, Xin Tang and Jia Liu; Harvard University, United States

The development of human induced pluripotent stem cells (hiPSCs) technology has revolutionized the field of disease modeling and holds immense potential for personalized regenerative cell therapies. A comprehensive understanding of stem cell-derived tissues and organoids requires advanced multimodal techniques capable of capturing cell functions with high spatiotemporal resolution in three-dimensional (3D) tissues, profiling numerous genes in recorded cells, and performing multimodal computational analysis. However, none of the existing technologies fulfill these requirements. In this presentation, I will begin by introducing the development of soft, stretchable mesh nanoelectronics that mimic the physical and mechanical properties of biological tissues. We can distribute these stretchable tissue-like bioelectronics throughout the entire 3D organoids by their organogenetic processes. By establishing seamless and noninvasive connections between electrodes and cells, we can achieve long-term stable electrical contacts with progenitor or stem cells, capturing the emergence of single-cell action potentials. This facilitates continuous, long-term recording from various types of 3D organoids during their development.

Next, I will demonstrate how this technique enables the long-term stable mapping of human 3D cardiac microtissues for the characterization of their functional maturation. Specifically, I will discuss an example in which stretchable mesh electronics were embedded with hiPSC-derived cardiomyocytes (hiPSC-CMs) and hiPSC-derived endothelial cells (hiPSC-ECs). By developing machine learning-based pseudotime trajectory inference of the long-term cardiomyocyte electrical signals from multiple samples, we can quantify the electrical phenotypic transition path during development. Our results showed that hiPSC-ECs drive remarkable hiPSC-CM electrical maturation via multiple intercellular pathways.

Finally, I will discuss our efforts to combine in situ single-cell RNA sequencing with flexible bioelectronics, a methodology we term "in situ electro-seq". This technique allows us to link cell molecular gene expression with electrical activities. Specifically, I will discuss how in situ electro-seq enables systematic and simultaneous investigation of single-cell electrophysiology and gene expression across hiPSC-CMs during their development. Additionally, I will discuss the potential of using in situ electro-seq to create spatiotemporal multimodal maps in electrogenic tissues, thereby potentiating the discovery of cell types and gene programs responsible for electrophysiological function and dysfunction.

#### 4:00 PM SB05.02.06

**Bioelectronic *In Vitro* Cell Membrane Models for Investigating Intestinal Host-Pathogen Interactions** [Reece McCoy](#)<sup>1</sup>, Jeremy Treiber<sup>2</sup>, Alberto Salleo<sup>2</sup>, George G. Malliaras<sup>1</sup> and Roisin Owens<sup>1</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>Stanford University, United States

The early stage of pathogen-related diseases often depend on the initial interaction between the pathogen, or its secretions, and the host cell membrane. Interfacing cells with electronics allows for quantitative real time monitoring of barrier integrity. Organic electronics coupled with electrochemical impedance spectroscopy (EIS) are used to probe host-pathogen interactions directly with enterocyte plasma membranes using native supported lipid bilayers which are representative of apical and basolateral surfaces of the intestinal epithelium.

PEDOT:PSS is used in both microfabricated planar electrode arrays which can support the formation of supported lipid bilayers. The Caco-2 adenocarcinoma cell line is used to develop a model that reflects in vivo conditions. Cells are differentiated and polarised for 21 days and chemical vesiculation induced to extract small membrane vesicle biopsies of the apical and basolateral surfaces before being used to form supported lipid bilayers. Fluorescence microscopy is employed to confirm bilayer fluidity with fluorescence recovery after photobleaching (FRAP). EIS is used to determine the

impedance of the bilayer across frequencies and models are fit to the data to extract resistance and capacitance values. The ADAM10-receptor mediated effects of *Staphylococcus aureus* alpha hemolysin toxin is demonstrated and found to be highly dependent on the epithelial membrane surface it encounters. The presence on the receptor in the apical bilayer potentiates the effect of alpha hemolysin leading to a pronounced decrease in membrane resistance compared to the basolateral bilayer.

Organic bioelectronics are used to monitor bilayer and barrier impairment caused by pathogens and their secretions. EIS coupled with conventional biological techniques can be used help elucidate pathogen invasion mechanisms and aid discovery of potential therapeutics.

**Multiscale Material Engineering of a Conductive Polymer/Liquid Metal Platform for Stretchable and Biostable Human-Machine-Interface Bioelectronic Application** Huanan Zhang; University of Utah, United States

Liquid-metal-based stretchable bioelectronics can conform to the dynamic movements of tissues and enable human-interactive biosensors to monitor various physiologic parameters. However, the fluidic nature, surface oxidation, and low biostability of the liquid metals have limited the long-term use of bioelectronics. Here we have developed a rationally designed material engineering approach to overcome these challenges in liquid metal bioelectronics. To our knowledge, this is the first demonstration of stretchable, leak-free, and highly conductive gallium-based bioelectronic devices with exceptional biostability and electrochemical properties. We first utilized unique gallium oxide properties to create 3D microscale wrinkled structures on the gallium surface. Then, gold nanoparticles and biostable poly(3,4-ethylenedioxythiophene) were successively deposited on the wrinkled liquid metal surface. We demonstrated this multilayer encapsulation material could conform to the stretching deformation and showed excellent environmental stabilities while maintaining high electrical properties. Electromyographic measurements were used to evaluate the bioelectrical performance of the stretchable electronics, and the results demonstrated the encapsulated liquid metal device could outperform bare liquid metal devices. Finally, a sensory feedback study demonstrated our liquid metal bioelectronic device could record precise physiologic signals to control robots for mimicking dexterous hand gestures. This study opens the possibility of chronic liquid-metal-based stretchable bioelectronics.

#### 4:30 PM SB05.02.08

**Conformable Multimodal Sensory Facemask for Decoding Biological and Environmental Signals** Jin-Hoon Kim and Canan Dagdeviren; Massachusetts Institute of Technology, United States

Facemasks are considered to be a key instrument in reducing exposure to viruses and other environmental hazards such as air pollution. Current wearable electronics applicable to the facemask have been designed only to monitor biological information such as breathing patterns. However, it remains difficult for the public to assess the status of their facemasks with regard to wearing habits and fit quality. In this work, we developed a widely-deployable, conformable, miniaturized sensory interface, which seamlessly attaches onto the internal side of any user-supplied facemask without compromising fit and protection quality, along with a user-interface capable of interpreting a participant's mask-wearing behavior under various use-case scenarios. Multimodal signals from a variety of sensors were wirelessly transmitted to a server through a custom-made mobile app. Based on the collected data, it was shown that various biological signals related to the signature of infectious diseases could be monitored while determining the fit status of the facemask without using a conventional mask fit tester. A machine learning algorithm was further used to enable the reliable decoding of the facemask position. The novelty of this work lies not only in the system integration, but also in the development of devices which provides real-time mask fit and position analysis, which may benefit medical institutes, industries and the general public in selecting proper facemasks and maintaining a desired mask fit. Additionally, our work could be deployed to multidisciplinary studies such as human behavioral and social sciences to analyze the fit change in real world situations.

#### 4:45 PM SB05.03.08

**Paper-Based Wearable Patches for Real-Time, Quantitative Lactate and Temperature Monitoring** Elisabetta Ruggeri<sup>1</sup>, Giusy Matzeu<sup>1</sup>, Giulia Guidetti<sup>1</sup>, Andrea Vergine<sup>2</sup>, Marco Lo Presti<sup>1</sup>, Giuseppe De Nicolao<sup>2</sup> and Fiorenzoomenetto<sup>1</sup>; <sup>1</sup>Tufts University, United States; <sup>2</sup>Università degli Studi di Pavia, Italy

Wearable sensors are establishing themselves as options for real-time continuous health monitoring in health care and wellness. In particular, the use of flexible interfaces that conform to the skin have attracted considerable interest for the extraction of meaningful physiological and pathological information through continuous and painless sampling and analysis of biofluids. In contrast, conventional techniques for biomarkers analysis are difficult to adapt to real-time portable monitoring due to their invasive sampling protocols, biosample preparation and reagent stabilization. In this work, we present shelf-stable, non-invasive, paper-based colorimetric wearable lactate and temperature sensors. These sensors exploit the ability of silk to control the concentration, print, and functionally preserve labile transducing biomolecules in the format of a shelf-stable digital patch for optical readout. This novel approach overcomes major challenges associated with the commercialization of colorimetric wearable sensors (e.g., enzyme thermal instability, narrow sensing range, low sensitivity, and qualitative response) by showing a combination of unprecedented stability (i.e., up to 2 years in refrigerated conditions), wide sensing range, and high sensitivity. Additionally, real-time quantitative signal readouts are achieved using machine learning-driven image analysis enabling physiological status evaluation with a simple smartphone camera.

SESSION SB05.03: Poster Session I: Biohybrid Systems and Devices

**Large-Area Photo-Patterning of Initially Conductive EGaIn Particle-Assembled Film for Soft Electronics** Gun-Hee Lee; KAIST, Korea (the Republic of)

Eutectic-gallium-indium particle (EGaIn\*) is considered one of the promising conducting materials for soft electronics due to its enhanced mechanical stability and stable conductance under strain compared to bulk EGaIn. However, its practical applicability has thus far been limited due to the challenges of achieving electrical conductivity and the incompatibility with well-developed fabrication strategies. Here, we report materials and manufacturing methods that allow large-area multi-layered patterning of 'polystyrene sulfonate (PSS)-attached EGaIn\* (EGaIn\*:PSS)' thin-film with the conventional cleanroom process. PSS enhances the stability of EGaIn\*, which allow uniform thin-film coating and photographic lift-off at a wafer-scale down to 10 μm features of varying thicknesses. Using dimethyl sulfoxide as the solvent during lift-off induces cohesion between EGaIn\*:PSS, resulting in initial electrical conductivity without an additional activation process. Demonstrations of stretchable display, wearable multilayer pressure sensing systems, and soft

artificial finger validate the versatility and reliability of this manufacturing strategy for soft electronics.

#### 8:00 PM SB05.03.02

**Multifunctional Intelligent Wearable Devices using Logical Circuits of Monolithic Gold Nanowires** SangHoon Hong, TaeYeon Kim and Sei Kwang Hahn; Pohang University of Science and Technology (POSTECH), Korea (the Republic of)

Although multifunctional wearable devices have been widely investigated for healthcare systems, augmented/virtual realities and telemedicines, there are few reports on multiple signal monitoring and logical signal processing by using one single nanomaterial without additional algorithms or rigid application-specific integrated circuit (ASIC) chips. Here, we develop multifunctional intelligent wearable devices using monolithically patterned gold nanowires for both signal monitoring and processing. Gold bulk and hollow nanowires show distinctive electrical properties with high chemical stability and high stretchability. In accordance, the monolithically patterned gold nanowires can be used to fabricate the robust interfaces, programmable sensors, on-demand heating systems and strain-gated logical circuits. The stretchable sensors show high sensitivity for strain and temperature changes on the skin. Furthermore, the micro-wrinkle structures of gold nanowires exhibit the negative gauge factor, which can be used for strain-gated logical circuits. Taken together, this multifunctional intelligent wearable device would be harnessed as a promising platform for futuristic electronic and biomedical applications.

#### 8:00 PM SB05.03.03

**From Network to Channel—Crack-Based Strain Sensors with High Sensitivity, Stretchability and Linearity via Strain Engineering** Wanyi Wang and Youfan Hu; Peking University, China

High-performance stretchable strain sensors are indispensable for mechanical deformation detection in electronic skin applications such as health monitoring and human-robot interfaces. Thus far, achieving a stretchable strain sensor with a high sensitivity that works linearly over a wide working range is still a great challenge. Among various applicable working mechanisms of strain sensors, crack-based strain sensors have the advantages of flexible material selection, easy fabrication, and high sensitivity. Here, we propose a universal strain engineering strategy that introduces an inhomogeneous spatial distribution of stress, which results in a distinguished crack density distribution in space and a critical state of crack propagation behavior between network and channel morphologies. By controlling the occurrence of the critical state, strain sensors are capable to perform high sensitivity, stretchability, and linearity simultaneously. The strain sensors can be tuned to realize a gauge factor of 690.95 in a linear working range of 0-40% ( $R^2 = 0.993$ ) or a gauge factor of 113.70 in a larger linear working range of 0-120% ( $R^2 = 0.999$ ). Intraocular pressure monitoring has been demonstrated based on these sensors to show their great application potential.

#### 8:00 PM SB05.03.04

**Stimuli Recognition by Polydiacetylene using Hyperspectral Microscopy** Jiali Chen and Kaori Sugihara; The University of Tokyo, Japan

##### Introduction

Polydiacetylene (PDA)-based chem/bio sensors have garnered significant attention due to their exceptional biocompatibility and ability to respond to various signals, such as heat, pH, force, light, and biomolecules. They exhibit visual blue-to-red color changes and fluorescence emission. However, the poor reproducibility of PDA sensors has hindered their practical implementation. The varying structures of PDA, even under identical synthesis conditions, make it challenging to achieve consistent and highly sensitive responses during mass production. Hyperspectral microscopy, initially developed for geology exploration and earth morphology observation, provides precise spectral analysis at the pixel level with high spatial and spectral resolutions. Recent advancements in detector and computing technology have expanded its applications to fields like agriculture, food, and medicine. In this work, we employed hyperspectral microscopy to visualize the inconsistent distribution of PDA structural domains, which contributes to the poor reproducibility and variations in PDA responses. Additionally, these mixtures of PDA structures exhibit distinct blue-to-red transition pathways upon stimulation, indicating their potential for stimulus identification.<sup>1</sup>

##### Method

We utilized hyperspectral microscopy to capture detailed spectral information at the sub-crystal level of PDA, allowing differentiation among various PDA structures. Using spectral classification techniques, such as spectral angle mapper, we created distribution maps of PDA structural domains within bulk crystals. Moreover, we developed a pixel transition tracking method using MATLAB to quantitatively monitor the colorimetric response of these structural domains. Based on these technologies and discoveries, we observed that PDA exhibits different response patterns to various stimuli, such as heat and pH. Our aim was to comprehensively understand the dynamic transition pathways associated with PDA structural domains and their response patterns to stimuli.

##### Result and Discussion

We uncovered mixtures of PDA structural domains within blue and red bulk crystals, which explain the main source of poor reproducibility in traditional PDA sensors. It was the first time that hyperspectral microscopy was applied to examine the non-uniform property of PDA sensors, and we developed a new interpretation tool to track their transition pathways. Different structures of PDA displayed varying affinities to stimuli, leading to unique transition patterns specific to the type of stimulus applied. This indicates that the stimuli leave a potential fingerprint on PDA. The observed good reproducibility holds promise for PDA to serve as an identification array for molecules in the future.

#### 8:00 PM SB05.03.05

**Skin-Like Multimodal Sensors Based on Iontronics and Piezoelectricity** Liren Wang<sup>1,2,3</sup>, Peter Zalar<sup>4</sup>, Yuanyuan Zhou<sup>1,3,1</sup> and Naoji Matsuhashi<sup>1,3,2</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>Keio University, Japan; <sup>3</sup>Institute of Industrial Science, The University of Tokyo, Japan; <sup>4</sup>Holst Centre / TNO, Netherlands

The skin possesses softness, stretchability, and the ability to sense a variety of environmental signals, including temperature, slow deformation (static strain), and rapid vibration (dynamic strain). Previous attempts to mimic skin with multimodal sensors have been limited by their multimodal sensing capability<sup>[1]</sup> and interference between different types of signals<sup>[2]</sup>. In this work, we demonstrate a skin-like multimodal sensor capable of sensing three outputs - temperature, static strain, and dynamic strain - using a soft piezoelectric and ionic composite material. Our sensor is constructed by sandwiching the ionic and piezoelectric composite between a pair of silver-nanowire-based stretchable conductors. Electrochemical impedance provides readings of temperature and static strain, while piezoelectricity measures dynamic strain. We have systematically investigated the influence of ionic conductivity and elasticity of the composite on sensitivity and stretchability. The high conductivity of the silver-nanowire-based stretchable electrodes had a negligible effect on the signal readout. The sensor provided accurate strain-insensitive temperature signals (error ~0.28°C) under 50% strain, and a modest longitudinal

piezoelectric coefficient ( $d_{33}$ ) of  $\sim 10$  pC/N. Our sensors display skin-like softness and multimodal sensing capability, features which are highly beneficial for human health monitoring and robotic skin applications.

**Decoding Silent Speech Commands from Articulatory Movements Through Soft Magnetic Skin and Machine Learning** Penghao Dong and Shanshan Yao; Stony Brook University, The State University of New York, United States

Silent speech recognition is a promising technique to restore spoken communication for individuals with voice disorders and to facilitate intuitive communications when the acoustic signal is unreliable, inappropriate, or undesired. However, the current methodology for silent speech faces several challenges, including bulkiness, obtrusiveness, limited portability, and susceptibility to interferences. In this work, we present a wireless, unobtrusive, and robust silent speech interface for capturing and decoding speech-relevant movements of the temporomandibular joint. Our solution employs a single ultrasoft magnetic skin placed behind the ear for wireless and more socially acceptable silent speech recognition, greatly alleviate concerns associated with existing interfaces based on face-worn sensors, including large number of sensors, highly visible interfaces on the face, and obtrusive interconnections between sensors and testing unit. Through optimizations in material composition, sensor structure, and sensing location, we present a lightweight wireless sensor that can conform to the skin surface to capture subtle movements induced by speech. With machine learning-based signal processing techniques, good speech recognition accuracy is achieved (92.7% accuracy for phonemes, 85.6% for word pairs from the same viseme group, and 96.7% for sentences/phrases). Moreover, the reported silent speech interface demonstrates robustness against noises from both ambient environment and user's daily motions. Finally, we illustrate the great potential in assistive technology and human-machine interactions through two proof-of-concept demonstrations – silent speech enabled smartphone assistant and drone control.

#### 8:00 PM SB05.03.09

**An Advanced Dermal Tissue-Embedding Mesh Sensor for High-Resolution IL-6 Detection** John T. Williams<sup>1</sup>, Hanie Yousefi<sup>1</sup>, Xudong Ji<sup>1</sup>, Hope Burks<sup>2</sup>, Jonathan Rivnay<sup>1</sup> and Shana Kelley<sup>1,2</sup>; <sup>1</sup>Northwestern University, United States; <sup>2</sup>Chan Zuckerberg Biohub Chicago, United States

In this study, we explore the development and application of a highly sensitive, high temporal-resolution dermal tissue-embedding mesh sensor. We functionalize this sensor using molecular pendulums developed by J. Das *et al.* to measure the concentration of Interleukin-6 (IL-6), a key biomarker in skin inflammation. Miniaturized organ models, including organoids and spheroids, serve as powerful platforms for investigating human physiology and pathology *in-vitro*, and bioelectronic sensors effective, complementary tools for monitoring them. Current bioelectronic sensor technologies provide insights into thermal, electrophysiological, optical, and oxygenation parameters within these models, yet robust and high-fidelity biochemical sensors remain a significant gap. Our device bridges this gap, offering microsecond resolution in the detection and tracking of IL-6 proliferation and movement. This work paves the way for high-resolution interrogation of skin inflammation, significantly enriching our understanding of inflammation, and providing a powerful tool for potential drug efficacy assessment.

#### 8:00 PM SB05.03.10

**Poly Vinyl Alcohol and Carbon Nanotube Based Scaffolds for Engineered Biosensors** Ryan E. Jaworski and Isaac Macwan; Fairfield University, United States

Biosensors are analytical devices that can turn biological responses into electrical signals which can be very useful in the diagnostics of numerous diseases. This work looks into the fabrication of an impedance based biosensor using electrospun Poly Vinyl Alcohol (PVA) and Carbon nanotubes (CNTs) to be used in conjunction with bacteriorhodopsin contained in a purple membrane. Dispersions of PVA are created with and without CNTs in deionized (DI) water, which are then utilized to synthesize porous electrospun nanofibrous scaffolds with fiber diameters ranging from 150nm to 250nm. The detection technique utilized for the fabricated biosensor is through the quantification of electrochemical impedance via the Electrochemical Impedance Spectroscopy (EIS). The parameters for both electrospinning and EIS are carefully optimized to achieve porous nanofibrous scaffolds having expected fiber diameter, porosity and impedance. The parameters which are optimized for the electrospinning process include the flow rate, collection distance, voltage, viscosity of the polymer CNT solution, and the type and configuration of the collector. Similarly, the parameters for the EIS include optimum potential of the applied small ac signal in mV, frequency range, electrolyte concentration and the type of electrodes and their configuration. This careful optimization of the parameters would enable the fabrication and the dynamic response of the designed biosensor to be able to hold its integrity through the entire process of characterization and testing. Two different forms of CNTs are used, which are single-walled carbon nanotubes (SWNTs), and multi-walled carbon nanotubes (MWCNTs). The two different SWNTs used in this study have a (6, 5) chirality and also mixed metallic and semiconducting chirality to assess the differences in the biosensor performance based on the type of SWNT and its comparison to the MWNTs. The synthesized scaffolds are also characterized through atomic force microscopy (AFM) and scanning electron microscopy (SEM), and compared to control samples without CNTs. The synthesized scaffolds are then tested for performance through the detection of a light sensitive protein bacteriorhodopsin (BR), which is a membrane protein found in Archaea, most notably Halobacteria. The primary function of the protein is in its use as a proton pump across the cell membrane and its novel characteristic to detect light of different wavelengths make it attractive for application in optical memory. Although this is a specific example, these scaffolds can accommodate different types of analyte for biosensors in many applications.

**Fabrication of a Partially Porous Microneedle Array Through Stepwise Integration of Porous and Non-Porous Poly(glycidyl methacrylate)** Hiroyuki Kai<sup>1,2</sup> and Akichika Kumatani<sup>3,4,2</sup>; <sup>1</sup>Toyo University, Japan; <sup>2</sup>Tohoku University, Japan; <sup>3</sup>The University of Tokyo, Japan; <sup>4</sup>Presto, Japan Science and Technology Agency, Japan

The microneedle array, a two-dimensional array of small needles with the height of a few hundreds of micrometers, are being actively studied for the application for minimally invasive transdermal drug delivery and biosensing. Among microneedles of various structures, porous microneedles have the advantages that they have large specific surface area that can be advantageous for high drug loading on the internal pore surface as well as highly sensitive biosensing taking advantage of high electrode area.

Porous polymer microneedle arrays made of crosslinked poly(glycidyl methacrylate) (PGMA), pioneered by Nishizawa's group, have advantages such as easy fabrication by photopolymerization in a mold and tunability of the properties by molecular design [1] as well as capability for functionalization by organic chemistry to fabricate functional microneedles such as organic/inorganic hybrid microneedle electrodes [2]. The existing porous PGMA microneedle arrays are porous throughout the microneedle body: both the base substrate and needles are homogeneously porous. Therefore, the amount of drug and sensor molecules interfaced with skin and biological fluid cannot be controlled, which prevents the quantitative control of drug release and

reproducible amperometric biosensing. Considering the porous PGMA microneedles for quantitative applications, spatial control of porosity in the microneedle body is important. Monomers (glycidyl methacrylate, and trimethylolpropane trimethacrylate, and triethylene glycol dimethacrylate) are photopolymerized by the irradiation of ultraviolet light in the presence of a photoinitiator to obtain crosslinked PGMA. In the presence of poly(ethylene glycol) (PEG) as a porogen (a template material to make pores), polymerized PGMA has macropores with the diameter of  $\sim 1 \mu\text{m}$  [3]. Therefore, control of addition of the porogen can be utilized to obtain spatially controlled porosity.

In this study, we present a two-step process for creating a porous PGMA microneedle array with a two-section structure: a porous needle section and a non-porous substrate, both made of PGMA. First, the monomer solution mixed with the porogen was poured into an elastic mold of a microneedle array and excess solution over the needle section was removed by carefully scraping on the mold, followed by the polymerization by ultraviolet light irradiation to fabricate porous needles. Then, the monomer solution without the porogen was poured over the polymerized needle section in the mold and polymerized to fabricate a non-porous base substrate. After the removal of the fabricated microneedle array from the mold, the needle section was in a white opaque color resulting from macroporous structures of PGMA and the base substrate was colorless and transparent, indicating PGMA in the substrate was non-porous. The two sections were integrated well and no significant breaking of needles was observed. Water absorption properties of the fabricated microneedle arrays were measured by immersing them into water and measuring the change in total mass. The amount of water absorbed by the partially porous microneedle array was significantly smaller than the homogeneously porous microneedle array, yet higher than homogeneously non-porous microneedle array. The developed two-layer, partially porous microneedle array is potentially useful for quantitative control of drug delivery and reproducible biosensing.

**Highly Accurate Multiplexed Nanoplasmonic Detection of MicroRNAs using Splinted Ligation** Sihwa Joo<sup>1</sup>, Younju Sung<sup>2</sup>, Na Rae Jo<sup>3</sup>, Yong-Beom Shin<sup>2</sup> and Mina Lee<sup>1</sup>; <sup>1</sup>Korea Research Institute of Standards and Science, Korea (the Republic of); <sup>2</sup>Korea Research Institute of Bioscience and Biotechnology (KRIBB), Korea (the Republic of); <sup>3</sup>Korea Institute of Machinery and Materials (KIMM), Korea (the Republic of)

MicroRNAs (miRNAs) are short, non-coding single-stranded RNAs that regulate gene expression by binding to mRNAs. Because miRNAs are abnormally expressed in cancer cells, they have been considered an important cancer biomarker. However, the short length and high homology of miRNAs make them difficult to detect accurately. In this study, we developed a highly accurate miRNA detection method using a multi-channel localized surface plasmon resonance (LSPR) sensing platform. miRNAs were labelled with a DNA probe using splinted ligation and immobilized on a gold nano-truncated cone (GNTC) array chip fabricated by nanoimprinting. After enzyme-assisted precipitation was performed, the LSPR spectral shift was measured as a function of miRNA concentration. Three miRNAs (miR-34c, miR-99a, and miR-125b) were sensitively detected with the limit of detection ranging from 1.8 to 26.1 fM. Single nucleotide variation (SNV) was clearly discriminated with high contrast. In addition, several miRNAs could be simultaneously detected in the multi-channels of a GNTC chip with high quantitative accuracy. Furthermore, we demonstrated the clinical applicability of our method by accurately detecting miRNAs in total RNA samples extracted from cancer cells.

#### 8:00 PM SB05.03.14

**Biocompatible Silk Films for Transient Tactile Sensors** Donggeun Lee<sup>1</sup>, Jeong Woo Chae<sup>2</sup>, Sang Min Won<sup>2</sup> and Wi Hyoung Lee<sup>1</sup>; <sup>1</sup>Konkuk University, Korea (the Republic of); <sup>2</sup>Sungkyunkwan University, Korea (the Republic of)

Research interests in naturally derived polymers with flexibility, stretchability, foldability, transparency, transiency, biocompatibility, and biodegradability has recently received much attention. In addition, the emergence of transient electronics, which are decomposed, absorbed, and disappear after operating for a certain period, can supplement the demerits caused by the survival of implanted devices. These technologies rely heavily on the flexibility, stretchability, biocompatibility, and biodegradability of the used biomaterials. This report presents strategies for utilizing both silk fibroin and silk sericin extracted from silk cocoons of *Bombyx mori* and fabricating silk-based sensors that detects capacitive touching motion and resistance change form mechanical deformation of the sensors. Decomposition and flexibility in humid condition were controlled by annealing fibroin film. Sericin extracted from cocoons in the process of producing fibroin was used to make an adhesive with good biocompatibility. Furthermore, a conductive silk composite was produced through hybridization with tungsten nanoparticles and was used as a piezoresistive/capacitance sensor. The sensitivity of conductive silk composite was confirmed through EEG and EOG tests. The flexibility of wholly silk based sensors was confirmed by measuring the changes in resistance at various bending condition. Acknowledgement: This work was supported by Korea Institute for Advancement of Technology (KIAT) grant funded by the Korea Government (MOTIE) (P0012770) and grant from the Basic Science Research Program of the National Research Foundation of Korea (NRF) funded by the Ministry of Science and ICT (2023-00208902).

#### 8:00 PM SB05.03.15

**Impedance-Based Polymer Microneedle Patch Sensor for Continuous Interstitial Fluid Glucose Monitoring** Honglin Piao, Jaehyun Kim, YongHo Choi, Heon-Jin Choi and Dahl-Young Khang; Yonsei University, Korea (the Republic of)

Early diagnosis and control of blood glucose is essential for effective prevention and management of diabetes-related complications. This study aims to develop a microneedle-type glucose sensor patch for minimally invasive, painless and continuous glucose monitoring. In situ monitoring of glucose concentration in interstitial fluid using polymeric microneedle arrays is the method used in this study. The experimental section included four subsections, namely substrates fabrication, sensor fabrication, and characterization of the glucose sensor based on microneedle patches. The experimental findings demonstrate the successful penetration of cylindrical microneedles into skin tissue with minimal force, reaching a depth of approximately 520  $\mu\text{m}$ . The microneedle sensor was produced with high precision using the CMOS process, and the immobilization of glucose oxidase was confirmed through phase angle changes. After conducting long-term tests, the sensor was found to be effective for up to 7 days. Glucose concentration measurements were conducted using the developed sensor, resulting in fitted curves with a mean slope of -27.18 and a mean intercept of 197.27. Random glucose concentration tests were conducted, and the range of values obtained shows strong correlation with those obtained from commercially available glucose detectors. MARD ranges from -0.5% to 11.97%. These results suggest the potential for the microneedle sensor to be used as a reliable and accurate tool for glucose monitoring. The study provides a promising approach for developing a wearable and minimally invasive and painless glucose sensor for continuous glucose monitoring.

#### 8:00 PM SB05.03.16

**Wireless, Highly Sensitive Biosensors on Contact Lenses for Intraocular Pressure Monitoring** Te Xiao; Waseda University, Japan

Glaucoma is one of the common eye diseases to cause a risk of blindness in severe cases. To prevent the blindness by glaucoma, real-time monitoring of intraocular pressure (IOP) becomes particularly important. The contact lenses built-in IOP sensor can contact continuously with the eye, so they are

superior to other IOP measurement system in that it can measure constantly. Many researchers have been working on making wireless smart contact lenses that can detect intraocular pressure. By embedding LCR resonators<sup>[1-2]</sup> in the contact lenses, which can generate changes in inductance, capacitance, or resistance of the pressure sensors, and receiving signals through transmission coils, the purpose of real-time wireless detection of intraocular pressure is achieved. However, the development of smart contact lens remains a challenge, including wireless sensor sensitivity, transparency, durability, and safety. Here we demonstrate the use of a wireless and highly sensitive IOP monitoring system on pig eyes that is comfortable while wearing. The IOP monitoring system consists of a stretchable gold antenna sensor printed on a moist and soft contact lens for IOP detection. The wireless IOP data reception is made of a reader circuit resonated at 1.39 GHz. We designed a horseshoe-shaped gold antenna, which was then printed on commercially available contact lenses through electrochemical bonding, using poly(3,4-ethylene dioxythiophene) film as an adhesive glue. The printed stretchable IOP sensing lens can be stretched and twisted, which is impossible using a conventional loop antenna<sup>[3]</sup>.

#### 8:00 PM SB05.03.17

**An Electric Contact Lens for Non-Mydriatic Near-Infrared Fundus Imaging** Yang Cui; Waseda University, Japan

Ophthalmic fundus imaging has become an important technique for the diagnosis and treatment of eye diseases<sup>[1]</sup>. An ideal imaging system should have portability, low cost, and high resolution for the remote monitoring of eye health at home; however, the conventional imaging systems are large and heavy and can only be used in hospitals.

To solve this problem, we demonstrate a non-mydriatic near-infrared (NIR) fundus imaging system with light illumination from an electric contact lens (E-lens)<sup>[2]</sup>. We designed a wireless power transfer system that can be bound to the contact lens and don't block the eye view<sup>[3]</sup>, and a near-infrared LED is embedded on the contact lens and can be powered wirelessly to light up. The E-lens can illuminate the retinal and choroidal structures in the eyes. The irradiated light is reflected at the layered structures of the fundus, and subsequently, the reflected light passes through the pupil of the eye lens to capture the images with a portable NIR camera.

Because of the strong light scattering effects in the fundus tissue, the captured images are blurred. Therefore, we reconstruct the images with a depth-dependent point-spread function to suppress the scattering effect that eventually visualizes the clear fundus images of the retinal and choroidal vasculature<sup>[4]</sup>. This method showed superior image reconstruction results compared to other common methods such as high-pass filtering. The proposed imaging system provides a new method for remote monitoring with increased functionality, it makes the portable eye health care possible.

#### 8:00 PM SB05.03.18

**Stretchable Microelectrode Arrays for Brain Spheroid Electrophysiology** Eleonora Martinelli<sup>1</sup>, Camille L. Delgrange<sup>1</sup>, Ivan Furfaro<sup>1</sup>, Loris Gomez Baisac<sup>2</sup>, Adrien Roux<sup>2</sup>, Luc Stoppini<sup>2</sup> and Stephanie P. Lacour<sup>1</sup>; <sup>1</sup>Ecole Polytechnique Federale de Lausanne, Switzerland; <sup>2</sup>Haute Ecole du Paysage, d'Ingenierie et d'Architecture, Switzerland

Human neural spheroids, i.e. 3D cellular aggregates composed of neurons and glial cells, are a compelling biological model to study neuronal communication both in physiological and pathological conditions. We propose the design of a perforated and stretchable microelectrode array (MEA) to monitor the electrophysiology of brain spheroids under static and dynamic mechanical loading. This is a relevant neuroelectronic system to investigate the consequences of traumatic brain injury (TBI).

The MEAs are prepared with thin-film technology using a platinum thin film sandwiched between two 1 μm thick polyimide films. Stretchability is engineered by design introducing patterns of micron scale, Kirigami-like Y-shaped cuts on the whole MEA surface.

Each MEA hosts 8 Kirigami-patterned recording electrodes (diameter = 70 μm), and a macroscopic ground electrode to probe one brain spheroid (spheroid diameter = 500-1000 μm). Electrode contacts are coated with electrodeposited PEDOT. The coating conformably follows the profile of the Kirigami-patterned electrodes independently of electrode size and reduces the electrochemical impedance at 1 kHz by 60 folds (n = 24, diameter = 70 μm).

Next, the permeability of the perforated MEAs is quantified as a function of pattern designs and perforation methods; this is to ensure sufficient nutrient and oxygen exchange at the air-liquid interface of the brain spheroid.

The electromechanical properties of the MEAs are then evaluated when subject to uniaxial elongation at a constant speed (100 μm/s). The strain parameters are aligned with typical TBI loadings (5-35%). Kirigami-patterned PEDOT-coated electrodes sustain strains up to 10% without showing significantly increased electrochemical impedance amplitude, while patterned platinum electrodes sustain strains only up to 5%. Similar results are shown with cyclic stretching. The electromechanical properties of the MEAs are also evaluated when subject to fast mechanical loading comparable with TBI impacts (elongation speed 1-2 m/s).

Next, the ability of the Kirigami-patterned electrodes to record neural activity from brain spheroids is verified. The MEA is mounted on a fluidic platform to allow for cell culture media change and the brain spheroids are integrated into the system. Spontaneous neural activity from the brain spheroids is reliably recorded for up to 5 days.

This work paves the way for studying the effect of mechanical loading on neural activity in 3D *in vitro* brain models.

**Whole-Cell Biosensing and Remediation of Arsenic using Magnetically Separable E. Coli: Towards Sustainable Materials for Water Treatment** Eric J. Sorge, Jingge Chen, Megan Kizer and Vicki L. Colvin; Brown University, United States

The World Health Organization (WHO) identifies arsenic as a carcinogenic toxin with exposure limits in drinking water set as low as 10 ppb. Arsenic is abundant in the Earth's crust and its prevalence in groundwater originates from natural causes as well as anthropogenic activities. Millions of people around the world, especially those in rural areas, are exposed to dangerous levels of arsenic in their water supply each year. Preventing human exposure to arsenic with accessible, inexpensive, and sustainable technology is crucial. We describe a strategy for sensing and removing arsenic from drinking water that exploits the bioaccumulation of arsenic by engineered bacteria and its detection using a whole-cell biosensor (WCB). A gene coding for a chimeric protein with two different arsenic binding domains was transfected into wild type *E. coli*; the resulting microbes could reduce arsenic concentrations in

water samples containing up to 500 ppb to our instrument detection limit (~ 10 ppt) within 60 minutes. These microbes remain alive while bioaccumulating arsenic and thus we refer to them as 'living sorbents'. While the dry-weight sorption capacity of these biomaterials is less than commercial inorganic arsenic sorbents, their arsenic affinity and selectivity is much greater. As a result, it is possible to reduce even very low levels of arsenic to acceptable levels using reasonable sorbent loadings.

These organisms may be further engineered to detect arsenic through optical reporters, thus providing an important integrated solution to the problem of arsenic in drinking water. Environmental arsenite binds to the ArsR transcription regulator, a protein that is central to the arsenic bioaccumulation capability described earlier. This same protein may also be applied to upregulate a reporter protein with fluorescent or luminescent properties. Whole cell biosensors should indicate the presence of arsenic at the extremely low levels relevant to meeting global exposure standards, on the order of ppb. Such sensitivity can be achieved through signal amplification strategies such as the use of engineered positive feedback or the application of multiple optical reporters.

Because these living sorbents use proteins evolved for arsenic sequestration, the material performance is independent of local water chemistry. The technology can be applied without customization to a particular site, and is notably independent of silicate and phosphate concentrations. Unlike inorganic sorbents which must be transported to a given site, these WCBs can be stored as dehydrated powders and later reconstituted on-site to levels appropriate for water treatment. Reversible attachment of iron oxide particles to the *E. coli* allows for magnetic capture of the biomass and the production of drinking water with no measurable contamination. This biological approach, employing regenerative and biodegradable materials, provides a sustainable alternative to conventional, inorganic sorbents for arsenic removal.

#### 8:00 PM SB05.03.23

**Ultrafast Light-Activated Polymeric Nanomotors** Jianhong Wang, Hanglong Wu, Jingxin Shao and Jan Van Hest; Eindhoven University of Technology, Netherlands

Synthetic micro/nanomotors have been extensively exploited to achieve active transportation over the past decade. This interest is a result of their broad range of potential applications, from environmental remediation to nanomedicine. Nevertheless, it still remains a challenge to build a fast-moving biodegradable polymeric nanomotor. Here we present a light-propelled nanomotor by introducing gold nanoparticles (Au NP) onto biodegradable bowl-shaped polymersomes (stomatocytes) via electrostatic interactions. These biodegradable nanomotors show controllable motion and a very high velocity of up to  $125 \mu\text{m s}^{-1}$ . This unique behavior was explained via a thorough three-dimensional characterization of the nanomotor, particularly the size and the spatial distribution of Au NP, with cryogenic transmission electron microscopy and cryo-electron tomography. Our in-depth quantitative 3D analysis revealed that the motile features of these nanomotors were caused by the nonuniform distribution of Au NPs along the axial direction of the polymersome. This study could offer a new perspective for designing robust biodegradable soft nanomotors, thereby facilitating their applications in a bio-friendly manner.

#### 8:00 PM SB05.03.24

**Fabrication of Water-Resistant Materials using Nanofiber Membranes Inspired by Penguin Feathers** Ryosuke Kawasaki<sup>1</sup>, Daisuke Ishii<sup>1</sup>, Yosuke Zaito<sup>2</sup> and Masanori Kurita<sup>2</sup>; <sup>1</sup>Nagoya Institute of Technology, Japan; <sup>2</sup>Port Nagoya Public Aquarium, Japan

When diving, penguins do not get wet due to the feathers that cover their skin, and emperor penguins dive to a maximum depth of 564 meters. This is probably due to the penguin's feather density, which is the largest among birds, the hierarchical microstructure of its feathers with gaps of up to 17  $\mu\text{m}$ , and surface-modifying fat secreted by the tail blubber gland. Even with the feathers without the fat removed by organic solvents, contact angles were as high as about 130°. When a water pressure resistance was measured of surface modified feathers and wire meshes with various pore sizes by self-assembled monolayers, the smaller the pore size and the smaller the surface free energy, the better the water resistance. This result suggests that water repellency and water resistance are synergistic effects of microstructure and surface modification.

This study aimed to fabricate water-resistant materials using nanofiber membranes by electrospinning, inspired by the mechanism of penguin feathers. Polyacrylonitrile (PAN) nanofiber membranes fabricated in previous studies had problems with water absorption. A high surface free energy of PAN causes capillary action within the pores of the nanofiber membrane. Therefore, to improve the water absorption phenomenon, we investigated methods of reducing the pore size by heat pressing and changing to a polymer with low surface free energy. The experimental conditions for the electrospinning were a drum collector rotation speed of 15 rpm, a needle diameter of 0.41 mm, a feed rate of 0.10 ml/min, an applied voltage of 20 kV, and a distance between a collector and needle of 10 cm. Samples of heat pressing were yarned from a 12.5 wt% N,N-dimethylformamide (DMF) solution of PAN, and were pressed under three conditions: room temperature (25°C), glass transition temperature (T<sub>g</sub>) of PAN (104°C), and 150°C. A hydrophobic polymer nanofibers were spun from DMF solution of Poly(vinylidene fluoride) (PVDF) (15, 20, 25, and 30 wt%). Static contact angles, water absorption, and wetting behaviors of the nanofiber membranes were discussed.

As a result, water absorption was observed in the nanofiber membrane pressed at room temperature, but no water absorption was observed in the heated press at or above the glass transition temperature. The fibers were not adhered each other pressed at room temperature, resulting in capillary action. On the other hand, the fibers pressed over T<sub>g</sub> were adhered each other. Then pores of the nanofiber membranes became smaller and capillary action did not take place. The contact angles of the pressed nanofiber membrane at over T<sub>g</sub> were about 70°. It is considered that the difference in pressing temperature over T<sub>g</sub> has no effect on the surface structure. In the case of PVDF, only beads were formed at 15 and 20 wt%, which resembled "electrospray", and 25 and 30 wt% resulted in fibers, although some beads were formed. The beads were probably caused by aggregation on the collector side because the solvent was not fully volatilized. The PVDF nanofiber membrane did not show water absorption, and the contact angle was about 140°. The contact angle of smooth PVDF was about 85°, suggesting that the microstructure of PVDF improves hydrophobicity. These results indicate that the combination of microstructure and low surface free energy has potential for superhydrophobic fabrics and will contribute to the development of new water resistance mechanisms.

#### 8:00 PM SB05.03.25

**Elucidating Biosensing Mechanism of Aptamer Modified Extended-Gate Field-Effect Transistor Biosensor** Sunghyun Park and Jayoung Kim; Yonsei University, Korea (the Republic of)

Extended-gate structure biosensors offer a promising field-effect transistor (FET) architecture for point-of-care applications by physically separating the sensing region from the transistor. However, few studies have investigated the sensing mechanism of FET biosensors (not limited to extended-gate structure), but rather have shown excellent label-free sensing performance. Herein, we demonstrate the biosensing mechanism of the aptamer modified extended-gate FET biosensor by modulating the dielectric properties and charge properties on the surface of the gold extended-gate. In the extended-gate FET structure, we can consider two capacitors in series: an extended-gate and a FET, which leads to the phenomenon of capacitive coupling. To show how the capacitive coupling between these two components affects the biosensing performance, we vary the capacitance values by modulating the electrode size of extended gates. Furthermore, by modifying an aptamer on the extended-gate surface for selective recognition of biomarkers and connecting it in series with a FET, the sensing performance can be explained by the capacitive coupling effect, and we further compare the results with those obtained by modulating surface charge and dielectric properties to gain insights into the sensing mechanism of the aptamer modified extended-gate FET biosensor. This

in-depth investigation enhances the understanding of the biosensing mechanism in FET biosensors, provides insights for additional amplification strategies, and improves the sensitivity of FET biosensors.

#### 8:00 PM SB05.03.26

**Establishment of a Quantitative Method for Comparing The Surface Properties of Natural and Synthetic Leather** Kazuya Uchida and Daisuke Ishii; Nagoya Institute of Technology, Japan

Natural leather is produced by processing the hides of cattle, pigs, and other by-products of the meat industry. Therefore, it is a sustainable material that makes effective use of by-products. However, the metallic salts used in the "tanning" process of converting animal skins into natural leather can cause environmental problems such as water pollution and health hazards to the worker. Although vegetable tanning is an alternative tanning method that does not use metallic salts, the proportion of metal salt tanning is still high in industrial materials. Synthetic and artificial leathers are also becoming popular, but it is difficult to replace natural leathers because the characteristics of synthetic and artificial leathers have not been imitated.

Therefore, we aim to solve this problem by reducing the use of natural leather by focusing on the wettability of the surface of the leather and creating synthetic leather that has properties like natural leather. At first, the surface characteristics of each leather material such as wettability and frictional force were compared quantitatively. Based on the results of these comparative evaluations, we will establish guidelines for the development of synthetic leather with surface properties as close as possible to those of natural leather. The differences in surface properties between commercial natural leather and synthetic leather covered by polyurethane were due to differences in wettability and surface and cross-sectional microstructure. Static contact angle measurements were performed using 10  $\mu$ L of distilled water to compare wettability. In addition, microscopic contact angle measurements were also performed to evaluate the behavior of absorbing a 30  $\mu$ L water droplet. To clarify the relationship between these wettabilities and surface structures, the surface microstructures were observed by scanning electron microscopy (SEM). The cross-sectional microstructures were also observed, considering the contribution of not only the surface but also the cross-sectional structure to the water absorption behaviors.

As a result, the SEM observation revealed bubbles in resins and regular structures on the surface of the synthetic leather, and a fluffy structure with non-woven fabrics protruding from the surface of the artificial leather. These microstructures, which differ from the surface of the natural leather, have affected surface wettabilities. In the cross-section, the natural leather showed a tendency for the structure to become rough from the outer to the inner surfaces. On the other hand, a structural gradient was not observed for the other materials, suggesting that the structural gradient affects water absorbency. The static contact angle results showed that natural and synthetic leathers had similar contact angles, although their surface structures differed according to the SEM images. The highest value was obtained for the artificial leather, which is thought to be due to its fluffier surface, which allows for a larger air layer and a more effective pinning effect than the other materials.

Finally, observation of water absorption behavior showed that the contact angle decrease rate of natural leather was greater than that of the other materials, suggesting that it has superior water absorption properties. It was thought that the gradient-like structure was responsible for the superior water absorption property. In the presentation, details of surface properties such as frictional force and mechanical properties, as well as quantitative evaluation methods for comparing the properties of each leather material will be established, and guidelines for the development of alternative materials will be explained.

#### 8:00 PM SB05.03.27

**Design and Fabrication of Sustainable Manufacturing of Neural Electrode Array for In Vivo Recording** Pei-Ling Chen<sup>1</sup>, Szu-Ying Li<sup>2</sup>, Pochun Chen<sup>1</sup>, Kuang-Chih Tso<sup>3</sup>, You-Yin Chen<sup>2</sup> and Jun Ohta<sup>3</sup>; <sup>1</sup>National Taipei University of Technology, Taiwan; <sup>2</sup>National Yang Ming Chiao Tung University, Taiwan; <sup>3</sup>Nara Institute of Science and Technology, Japan

Increasing requirements for neural implantation are helping to expand our understanding of nervous systems and generate new developmental approaches. It is thanks to advanced semiconductor technologies that we can achieve the high-density complementary metal-oxide-semiconductor electrode array for the improvement of the quantity and quality of neural recordings. Although the microfabricated neural implantable device holds much promise in the biosensing field, there are some significant technological challenges. The most advanced neural implantable device relies on complex semiconductor manufacturing processes, which are required for the use of expensive masks and specific clean room facilities. In addition, these processes based on a conventional photolithography technique are suitable for mass production, which is not applicable for custom-made manufacturing in response to individual experimental requirements. The microfabricated complexity of the implantable neural device is increasing, as is the associated energy consumption, and corresponding emissions of carbon dioxide and other greenhouse gases, resulting in environmental deterioration. Herein, we developed a fabless fabricated process for a neural electrode array that was simple, fast, sustainable, and customizable. An effective strategy to produce microelectrodes, leads, and bonding pads onto the Parylene C substrate by laser micromachining techniques combined with the drop coating of the silver paste to stack the laser grooving lines. Sequentially, Parylene C was deposited onto the Parylene C substrate to form the insulation layer for the protection of inner circuits. Following the deposition of Parylene C, the via holes over microelectrodes and the corresponding probe shape of the neural electrode array was also etched by laser micromachining. To increase the neural recording capability, three-dimensional microelectrodes with a high surface area were formed by electroplating PEDOT-GO composite. Our eco-electrode array showed reliable electrical characteristics of impedance under harsh cyclic bending conditions of over 90 degrees. For in vivo application, our flexible neural electrode array demonstrated more stable and higher neural recording quality and better biocompatibility as well during the implantation compared with those of the silicon-based neural electrode array. In this study, our proposed eco-manufacturing process for fabricating the neural electrode array reduces carbon emissions compared to the traditional semiconductor manufacturing process and provided freedom in the customized design of the implantable electronic devices as well.

#### 8:00 PM SB05.03.29

**Advancing Soil pH Sensing Through Novel, Stabilized, Screen-Printed Electronics** Catherine Crichton<sup>1</sup>, Elliot Strand<sup>1</sup>, Juan Pablo Cisneros Barba<sup>1</sup>, Nicholas Bruno<sup>1</sup>, John-Baptist Kauzya<sup>1</sup>, Anupam Gopalakrishnan<sup>1</sup>, Madhur Atreya<sup>1</sup>, Eloise Bihar<sup>2,1</sup> and Gregory L. Whiting<sup>1</sup>; <sup>1</sup>University of Colorado Boulder, United States; <sup>2</sup>University at Buffalo, The State University of New York, United States

Soil pH significantly affects agriculture by regulating available nutrients and water-soluble chemicals available to plants, thus driving the need for low-cost, durable soil pH sensors. A few potential solutions include expensive commercial pH sensors and printed sensors that only work in liquid media. Each of these solutions poses its own set of unique challenges perpetuating the affordable soil pH sensing dilemma. Here, we present a novel pH sensor platform based on an array of low-cost, durable, screen-printed electronics for in situ soil sensing. We show the stabilization of the pH-sensitive dye, alizarin, in the printed pH devices allowing for extended sensing periods in soil. We compare different alizarin dye immobilization techniques and electrode configurations and have evaluated the effects of soil pH on sensor durability. This new affordable, stable printed pH system pioneers the development of printed electronics for new alternatives to assess soil pH.

#### 8:00 PM SB05.03.30

**Bioinspired Transdermal Delivery Patches with Multiscale Adhesive Architectures** Jihyun Lee and Changhyun Pang; Sungkyunkwan University, Korea (the Republic of)

Intelligent bioinspired adhesive devices are attracting attention as a tool for the transdermal drug delivery patch. However, there have been many

challenges in delivering drugs from the wrinkled and rough skin surface through the complex stratum corneum into the body. The rough skin surface interferes with the interfacial contact between the drug delivery material and the skin, making close adhesion difficult, which reduces drug delivery efficiency. In addition, the brick-like structure of the stratum corneum, which has a barrier function, is a major obstacle to drug delivery through the skin. Here, we present two strategies to overcome the limitations of transdermal drug delivery based on biomimetics. First, the drug delivery patch, which is designed by combining an adhesive structure that mimics a diving beetle and a drug-loading hydrogel, improves the efficiency of drug delivery through conformal contact. In addition, the asymmetric diving beetle adhesive structure provides directional adhesive performance, enabling hypoallergenic detachment. Second, it is an adhesive interface that provides negative pressure to the skin by mimicking the tentacle of a cephalopod. Negative pressure delivered to the skin induces fine structural deformation of the stratum corneum and creates gaps between the stratum corneum, improving drug delivery efficiency. With the aid of bioinspired adhesive architecture, we demonstrated improved drug delivery efficiency in an *in vivo* model, suggesting a promising development in the medical and skin therapy fields.

**Permeability and Anti-Fouling Performance of Microfiltration Membrane Modified by Hybrid Structured Omniphobic Coating Method** Seonmin Kim, Moon Suk Suh, Churl Seung Lee and Hayoung Choi; Korea Electronics Technology Institute, Korea (the Republic of)

Surface characteristics of polymer membrane plays a significant role in bioprocess such as separation, purification, and so on. Generally, hydrophilicity is recommended for better process efficiencies in various commercial biomedical engineering fields. However, omniphobic properties of these fields could be recommendable for better performance because those properties on the surface is more favorable in many reasons. In this study, we try to modify the commercial polyethersulfone (PES) membrane by combining two different coating procedures: electrospinning and spray coating. Poly(vinylidene fluoride) is used to form the nanofiber mat for the robust roughness by the electrospinning technique and various fluoro-silane materials is applied to modify the chemical properties of the surface by spray coating method. The modified membrane was analysed by scanning electron microscopy for surface morphology and characterized by the measurement of contact angle for anti-fouling properties. We also measured the permeabilities of membrane for water and bovine solution to test anti-fouling ability in a simulated bioprocess conditions.

#### 8:00 PM SB05.03.32

**Wireless, Fully Implantable and Expandable Bioelectronic Platform for Bidirectional Modulation of the Urinary Bladder** Tae-Min Jang, Jeong-Woong Shin and Suk-Won Hwang; Korea University, Korea (the Republic of)

Current standard clinical options for patients with detrusor underactivity (DUA) or underactive bladder -- the inability to release urine naturally -- include the use of medications, voiding techniques, and intermittent catheterization, for which the patient inserts a tube directly into the urethra to eliminate urine. Although those are life-saving techniques, there are still unfavorable side effects, including urinary tract infection (UTI), urethritis, irritation, and discomfort. Here, we report a wireless, fully implantable, and expandable electronic complex that enables elaborate management of abnormal bladder function via seamless integrations with the urinary bladder. Such electronics can not only record multiple physiological parameters simultaneously but also provide direct electrical stimulation based on a feedback control system. Uniform distribution of multiple stimulation electrodes via mesh-type geometry realizes low-impedance characteristics, which improves voiding/urination efficiency at the desired times. *In vivo* evaluations using live, free-moving animal models demonstrate system-level functionality.

#### 8:00 PM SB05.03.34

**Use of PMMA as a Deep UV Photoresist to Produce Patterned Substrates for Surface-Aligned DNA Deposition with Potential Application to Sequencing** Heba Ouerfelli<sup>1,2</sup>, Boheng Cao<sup>3,2</sup>, Ellen Hu<sup>4,2</sup>, Aditi Kiran<sup>5,2</sup>, Selina Zhang<sup>6,2</sup>, Alex Zheng<sup>7,2</sup> and Jonathan Sokolov<sup>2</sup>; <sup>1</sup>Fort Lee High School, United States; <sup>2</sup>Stony Brook University, United States; <sup>3</sup>North Hollywood High School, United States; <sup>4</sup>C. Leon King High School, United States; <sup>5</sup>BASIS Independent Fremont, United States; <sup>6</sup>North Hunterdon High School, United States; <sup>7</sup>Stuyvesant High School, United States

As genetic sequencing grows widespread in diagnostics and research, increasing its accessibility has become all the more necessary. Current next-generation sequencing (NGS) technologies entail the large-scale assembly of complete sequences from short, free-floating DNA fragments, resulting in high computational costs. Researchers have attempted to address this issue through long-read or third-generation sequencing, extending the length of the contiguous DNA fragments to tens of kilobase pairs. However, repetitive regions of the DNA still limit the ability of software to reassemble unique sequences. Ordered DNA fragmentation is an important tool in reducing the computational bottleneck of rearranging scattered strands in solution. The foundation of our approach lies in the integration of biological materials with a synthetic polymer, creating a novel abiotic-biotic system.

In this work, we explore the use of 996K molecular weight poly(methyl methacrylate) (PMMA)-coated silicon wafers as a suitable substrate for developing suspended DNA segments. The suspended segments provide steric clearance for the application of Tn5 transposases to fragment and label surface-immobilized long DNA molecules. PMMA was used as a deep-UV photoresist to produce latent patterns, followed by DNA deposition and photoresist development. Despite the tendency for UV-exposed PMMA to become more hydrophilic (unfavorable to DNA stretching on surfaces), we were successful in finding a combination of exposure and development times to achieve surface immobilization of long DNA strands such as those of mice genomic DNA and ligated lambda DNA. Initial experiments testing Tn5 activity will also be discussed. The broader implications of this work are a novel and exciting biohybrid way forward in ordered DNA fragmentation for lower-cost sequencing.

#### 8:00 PM SB05.03.35

**Impact of Rhizobium Tropici-Produced EPS on Bermuda Grass Root Growth** Haaris Alam<sup>1</sup>, Isana Alicea<sup>2</sup>, Ashritha Kalakuntla<sup>3</sup>, Elise Ngo<sup>1</sup>, Brinley Dai<sup>4</sup>, Jerry Gao<sup>5</sup>, Tei Kim<sup>6</sup>, Tony Guo Feng Tung<sup>7</sup>, Yiwei Fang<sup>8</sup>, Aaron Sloutski<sup>8</sup>, Marcia Simon<sup>8</sup>, Jay Gao<sup>8</sup>, Miriam Rafailovich<sup>8</sup>, Steve Larson<sup>9</sup> and Fengxiang Han<sup>9</sup>; <sup>1</sup>Portola High School, United States; <sup>2</sup>Patchogue Medford High School, United States; <sup>3</sup>Ed W. Clark High School, United States; <sup>4</sup>Experimental High School Attached to Beijing Normal University, China; <sup>5</sup>Beijing No. 80 High School, China; <sup>6</sup>Stanford Online High School, United States; <sup>7</sup>Shanghai High School International Division, China; <sup>8</sup>Stony Brook University, The State University of New York, United States; <sup>9</sup>US Army Corps of Engineers, United States

Erosion control is imperative to soils vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is provided by extracellular polymeric substances (EPS): hydrated microbial biopolymers whose high water-holding capacity, entrapment of nutrients, and resistance to environmental stressors can elevate soil fertility. EPS also promotes aggregate formation, which helps maintain a soil's structural integrity. A more indirect benefit of EPS in soil is its ability to enhance subterranean root growth. This corresponding increase in root mass or length can stabilize topsoil and aid in erosion control. However, the specific mechanism by which EPS benefits root growth was studied by different research groups with partial success. This project aimed to further investigate the influence of EPS produced by *Rhizobium tropici* bacteria (RT-EPS) on Bermuda grass, particularly on its root growth. By gaining a deeper understanding of this impact, a more effective approach for the fabrication and deployment of RT-EPS can be developed, which will be used on large scale applications to minimize the soil damage caused by extreme weather conditions. EPS produced from the *Rhizobium tropici* bacteria was used to generate an ethanol precipitate material (EPM). After cell-free biofilms of the bacteria were

generated, the cells were removed by centrifuge and the crude EPM collected through precipitation with ethanol, thus producing two forms of EPM: non-dialyzed and dialyzed (where an additional dialysis step was applied). For the plant study, Bermuda grass seeds were germinated in sand treated with non-dialyzed- and dialyzed- EPM (and water as a control). The plants were grown in one of three conditions in the greenhouse: a controlled chamber, inside the greenhouse, or outdoors. After a 60-day period, gravimetric and length measurements were taken of both the roots and shoots, indicating that EPM treatment increased relative root mass growth. The structure, density, and elemental composition of roots from Bermuda grass specimens grown in sand were analyzed by a Keyence VHX-7000 Microscope. After retrieving images, qualitative and quantitative analyses (nodule counting) found higher root density and greater branching in EPM-treated samples, for both dialyzed and non-dialyzed polymers. Additionally, X-ray fluorescence (XRF) spectroscopy was performed to determine the concentration of biologically important ions in roots with EPM, revealing higher amounts of Ca, K, and P. X-ray diffraction (XRD) was then performed to determine the presence of crystalline structures on top of the roots.

In conclusion, it was observed that the Bermuda grass samples treated with non-dialyzed EPM had the highest root-to-shoot mass ratios and coverage from tertiary branching. These samples also contained higher concentrations of ions that promote root growth, demonstrating enrichment of the nutrient profile. Prospective analysis includes in-depth research on the protein fraction EPM contains, with a focus on their influence on root stem cell differentiation. Further experiments will be conducted to compare the impact of different EPM dialysis procedures (by increasing the dialysis pores) on Bermuda grass root growth. The knowledge obtained from these studies will be utilized to conduct open-field experiments to examine the effect of EPM on large-scale growth, including subsequent soil analysis.

The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-2-0054) in this research.

#### 8:00 PM SB05.03.36

**Structural Modifications of Nano-Sized Hydrogel via Reversible and Irreversible Redox Reactions of Thiols** [Chae Gyu Lee](#) and Tae-Hyuk Kwon; Ulsan National Institute of Science and Technology, Korea (the Republic of)

Cysteine-containing oxidoreductases, such as thioredoxin (Trx) and glutaredoxin (Grx), play crucial roles in maintain cellular redox balance through finely tuned reversible redox signaling pathways. However, elevated levels of reactive oxygen species (ROS), often of exogenous origin, can trigger the irreversible hyperoxidation of cysteine thiols into sulfonic acids ( $-SO_3H$ ), resulting in permanent dysfunction of these proteins. In this study, we present an approach involving a multi-functional nano-sized hydrogel (nanogel, IrNG), encapsulating an iridium-based photosensitizer (Tir3).<sup>1,2</sup> IrNG offers precise control over its nanostructure through reversible and irreversible redox reactions. In the absence of photoirradiation, IrNG maintains its self-assembled nanostructure, even in the presence of high concentrations of reductive glutathione, owing to strong hydrophobic interactions and the reversible self-crosslinking between thiols and disulfides. However, upon the photoirradiation, the disulfide bonds evenly distributed within IrNG undergo hyperoxidation, transforming into negatively charged sulfonates. This transformation results in the rapid degradation of IrNG. The photo-responsive Tir3 generates significant levels of ROS, enabling both spatiotemporally controlled structural modifications in the redox-responsive nanogel and mitochondrial oxidation-mediated cancer cell apoptosis.

**Shear-Reversible Clusters of HIV-1 in Solution: Stabilized by Antibodies, Dispersed by Mucin** [Ayobami I. Ogundiran](#), Tzu-Lan Chang, Andrey Ivanov, Namita Kumari, Sergei Nekhai and Preethi Chandran; Howard University, United States

The behavior of HIV-1 in culture media was tracked with Dynamic Light Scattering (DLS) and complementary atomic force microscopy (AFM) imaging in the presence of lectins, anti-gp120 Antibodies (Abs), mannosidase, and mucin. After excluding the serum contribution to culture media from extracted DLS data, it is observed that there are clusters/ aggregates of about 400-700nm HIV-1 in solutions. The clusters were sheared into single virus particles by filtration but re-clustered back over a short time. It is known that HIV-1 mutates rapidly and is protected by glycan shields of mannose sugars that have challenged the broadly neutralizing of the virus by Abs. In other studies, mannose residues have been reported to be self-adhesive, but it is not known if these mannose adhesions drive HIV-1 to be aggregated in solution, further confounding Ab neutralization. Mannosidase treatment reduced clustering, suggesting the mannose glycan shield is involved in the cluster formation. Mucin molecules (porcine gastric mucin) effectively dispersed HIV-1 clusters, even those stabilized by Abs. It is well known that mucin reduces HIV virulence, but the mechanism has not been clarified. Our findings suggest that mucin reduces HIV-1 virulence by dispersing its clusters, as opposed to the current perspective that mucin aggregates HIV-1.

#### 8:00 PM SB05.03.40

**Impact of Surfactant Properties on Phase Transition and Morphology of Thermoresponsive Polysaccharide Biomaterials** [Rabeya Sharmin Lima](#), Saniya Yesmin Bubl, Katherine Salvatore, Sachin Kamath, Zhiyu Yang and Linqing Li; University of New Hampshire, United States

Understanding the interactions between various surfactants and thermoresponsive polymers is essential for regulating phase transition and controlling polymer aggregation, offering opportunities in producing biomaterials with diverse morphologies and microstructures. Here we developed a new class of dextran-based thermoresponsive polysaccharides by chemically altering the hydrophilic polymer backbone into hydrophobic derivatives. These thermoresponsive materials exhibited robust, reversible phase transitions and tunable lower critical solution temperatures. Photo-initiated radical polymerization permits facile chemical crosslinking and captures phase separation dynamically, leading to the formation of hydrogels with distinct morphologies. We evaluated the effects of various surfactants – such as anionic sodium dodecyl sulfate (SDS), nonionic pluronic F-127, cationic hexadecyltrimethylammonium bromide (CTAB), and zwitterionic 3-[(3-cholamidopropyl) dimethylammonio]-1-propanesulfonate (CHAPS) – on the phase transition and microdomain morphology of polysaccharides. We found that temperature-triggered hydrophobic interactions and phase transition behaviors are regulated by a combination of surfactant charge density, hydrophilic-lipophilic balance (HLB) values, and critical micelle concentrations (CMC). Surfactants with higher HLB values significantly disrupt phase separation above their CMCs. Notably, the non-ionic pluronic F127 surfactant effectively eliminates phase transitions across a wide range of dextran molecular weights and concentrations even below its CMC. Depending on their charge and CMC, surfactants also modify the microdomain size, shape, and number by altering the balance between continuous and dispersed phases. These findings will expand the selection of appropriate surfactants to regulate the polymer/polymer and polymer/solvent interactions to modulate phase-separation and microstructures morphology that may serve as a potential polymeric carrier for cancer drug delivery.

#### 8:00 PM SB05.03.41

**Characterizing Oil-In-Water Emulsions as Muscle and Subcutaneous Adipose Tissue Phantoms for T2 Relaxometry** [Alexa S. Zammit](#), Sydney Sherman and Amena Khatun; Massachusetts Institute of Technology, United States

Tissue microstructure can be indicative of pathology and varying microstructural properties can contribute to inaccuracies in several diagnostic tools.<sup>1</sup> Skeletal muscle is hierarchical and highly organized. Additionally, skeletal muscle is an important reservoir of fluid and can be an early indicator of a

volume overloaded state.<sup>1,2</sup> A recent study demonstrates that point-of-care fluid status determination may be possible with the analysis of T2 relaxometry data collected by a bedside NMR sensor.<sup>2</sup> However, given the clinical setting of the study, fluid overload and a typical fluid state were the only two states available for data collection. Here, oil-in-water emulsions are assessed and characterized on a T2 relaxometer. The properties of the emulsions are compared to dissected murine muscle and subcutaneous adipose tissue after data analysis with a multi-exponential fit. Peanut oil is used in the emulsions, as the NMR signal is comparable to the triglycerides in adipose tissue.<sup>3</sup> Varying the fat fraction of the emulsions by changing the oil to water ratio changes the relative amplitudes of the peaks as determined by the multi-exponential analysis. A comparison of different fat fractions enables us to determine that an emulsion with a fat fraction of 40% can be considered a muscle phantom and an emulsion with a fat fraction of 75% can be considered an adipose tissue phantom. As such, the phantoms can be used as standards for calibration and sensitivity testing for T2 relaxometry purposes.

#### 8:00 PM SB05.03.42

**Bioelectronic Control of Neuronal Activity in Cortical Organoids with Ions and Small Molecules** Yunjeong Park, Sebastian Hernandez, Cristian O. Hernandez, Heather Knight, Hunter E. Schweiger, Houpu Li, Kateryna Voitiuk, Harika Dechiraju, Nico Hawthorne, Elana M. Muzzy, John A. Selberg, Frederika N. Sullivan, Roberto Urcuyo, Sofie R. Salama, Elham Aslankooi, Mircea Teodorescu, Mohammed A. Mostajo Radji and Marco Rolandi; University of California, United States

Cortical organoids are valuable tools for studying brain development, modeling neurological disorders, and testing potential treatments. For these studies, we need to improve the ability to precisely manipulate and modulate the activity of the cortical organoids at a fine time scale in a precise and detailed manner. Here, we have employed a bioelectronic approach with an ion pump, used for selective delivery of ions and neurotransmitters. More specifically, we used these devices to experimentally determine neuronal effects on the organoids with the bioelectronic delivery of potassium ions (K<sup>+</sup>), protons (H<sup>+</sup>), and  $\gamma$ -aminobutyric acid (GABA). This work is important to reflect bioelectronic device potential in exploring neurological disorders and their potential treatments with a level of precision and detail that was previously challenging to achieve.

#### 8:00 PM SB05.03.43

The ability to deliver drugs with precise dosages at specific time points can significantly improve disease treatment while reducing side effects. Drug encapsulation for gradual delivery has opened the doors for a superior treatment regimen. To expand on this ability, programming bioelectronic devices to deliver small molecules enables ad-hoc personalized therapeutic profiles that are more complex than gradual release. Here, we introduce a wearable bioelectronic bandage with an integrated electrophoretic ion pump that affords on-demand drug delivery with precise dose control. In this poster, I will present my contribution to the device fabrication that involves hydrogel synthesis in glass capillaries, testing of the hydrogel conductivity, and device testing. With these devices, delivery of fluoxetine to wounds in mice resulted in a 27.2% decrease in the macrophage ratio (M1/M2) and a 39.9% increase in reepithelialization, indicating a shorter inflammatory phase and faster overall healing. Programmable drug delivery using wearable bioelectronics in wounds introduces a broadly applicable strategy for the long-term delivery of a prescribed treatment regimen with minimal external intervention.

#### 8:00 PM SB05.03.44

**Materials and Strategies for Integrating Chloride Membrane Channels with Bioelectronics** Le Luo, Emily Lee, Yunjeong Park and Marco Rolandi; University of California, United States

Biological membrane channels actively mediate information exchange between cells and have a main role in molecular recognition. The 'iono-electronic' gap between these channels and electronics creates a significant challenge in connecting these channels to electronic devices for efficient signal readout from. To address these challenges, we've combined supported lipid bilayers (SLBs) with Ag/AgCl electrodes to specifically target chloride conducting membrane spanning channels. We use the Ag/AgCl contacts to translate the ionic signal from the Cl<sup>-</sup> ions into an electronic signal at the interface by exploiting the Ag/AgCl electrochemical reaction. With this system, we show that Cl<sup>-</sup> conducting channels and Cl<sup>-</sup> pumping rhodopsins interface better than with other non-selective contacts (Pt) or proton selective contacts (PdH). In the future, this platform can be used to create complementary hybrid devices with membrane spanning channels that are selective to the desired type of ion.

SESSION SB05.04: Engineering Biohybrid Interfaces

Session Chairs: Guglielmo Lanzani and Flavia Vitale

Tuesday Morning, November 28, 2023

#### 8:00 AM SB05.04.01

**Stretchable, High-Modulus Penetrating Microelectrode Arrays for *In Vitro* Intramuscular Electromyography** Qinai Zhao<sup>1</sup>, Ekaterina Gribkova<sup>2</sup>, Yiyang Shen<sup>1</sup>, Jilai Cui<sup>2</sup>, Noel M. Naughton<sup>2</sup>, Liangshu Liu<sup>1</sup>, Jaemin Seo<sup>1</sup>, Mattia Gazzola<sup>2</sup>, John A. Rogers<sup>3</sup>, Rhanor Gillette<sup>2</sup> and Hangbo Zhao<sup>1</sup>; <sup>1</sup>University of Southern California, United States; <sup>2</sup>University of Illinois at Urbana-Champaign, United States; <sup>3</sup>Northwestern University, United States

Three-dimensional (3D) penetrating microelectrode arrays (MEAs) serve as important interfaces with biological tissues in various fields, including neuroscience, tissue engineering, and wearable bioelectronics. These 3D MEAs can penetrate surface layers of tissues, thereby facilitating electrophysiological sensing and electrical stimulation of interior tissues in a minimally invasive manner. Stretchable penetrating MEAs are highly desirable as they can adapt to the deformations of dynamically moving tissues or organs. This adaptability enables stable bioelectronic interfacing,

enhances recording signal quality, and reduces tissue damage. However, fabricating stretchable 3D MEAs with high electrode modulus required for penetration and customized geometries presents significant challenges in materials integration and patterning. In this study, we present the design, fabrication, and applications of highly stretchable microneedle electrode arrays (SMNEAs) for sensing localized intramuscular electromyography (iEMG) signals in vitro. We have developed a hybrid fabrication scheme utilizing molding, microfabrication, and transfer printing, which enables scalable fabrication of SMNEAs with high electrode modulus ( $E = 6.6$  GPa) and device stretchability (80%). Our SMNEAs also offer controllable electrode dimensions and recording areas, and low electrode impedance. We demonstrate the use of these SMNEAs in recording iEMG signals from the buccal mass of *Aplysia*. By inserting a multichannel SMNEA with varying electrode lengths into individual muscle groups of the buccal mass, we achieved high-fidelity, localized iEMG recording during muscle contractions and relaxations. The iEMG signals captured by the SMNEA exhibit distinctive spatiotemporal muscle activation patterns within individual muscle groups of the buccal mass, a level of detail unachievable with surface electromyography (sEMG) using a planar MEA. The high electrode modulus and device stretchability, as well as customized electrode geometries make our SMNEAs potentially useful for local sensing and stimulation of dynamic 3D tissues such as cardiac and neuromuscular tissues.

#### 8:15 AM SB05.04.02

**Biomimetic Designs of Organic Electrochemical Transistors for Human-Interfaced Biosensing and Neuromorphic Computing** Sihong Wang; The University of Chicago, United States

The use of electronic devices for acquiring biological information and delivering therapeutic interventions relies on two aspects: the effective acquisition of physiological information through direct contact with soft bio-tissues, and the high-throughput processing of the acquired data using machine learning. To ensure high-quality signal transductions, the interfaces between bioelectronic devices and bio-tissues must combine signal amplification with stable and conformable contact. Organic electrochemical transistors (OECTs) have been developed as one of the most advanced technologies for high-performance bio-sensing and neuromorphic computing. Moreover, the fastest and most energy-efficient data processing through machine learning is directly on the human body. However, the rigid mechanical properties and the lack of tissue/skin adhesion from transistors largely prevent the formation of such intimate and long-term stable bio-interfaces. In the first part of my talk, I will introduce our material and device designs for introducing three highly important biomimetic properties onto OECT-based biosensors—stretchability, tissue-like softness, and bioadhesive properties. Our rationale designs from the material to the device level allow the realization of these properties with state-of-the-art electrical performance. I will also introduce the strategies and advantages of using these new biomimetic properties in bioelectrical and biochemical sensing. In the second part of my talk, I will introduce our research in imparting intrinsic stretchability onto neuromorphic devices that can provide state-of-the-art computing performance. I will also show the practical applicability of this device for implementing machine-learning computing and algorithms for health data analysis, when the computing hardware is under human-body-induced deformation.

#### 8:30 AM SB05.04.03

**Human Stem Cell-Based Biohybrid Fish** Keel Yong Lee<sup>1,2</sup>, Sung-Jin Park<sup>3</sup>, Herdeline Ann Ardoña<sup>4</sup>, Sean L. Kim<sup>2</sup>, John Zimmerman<sup>2</sup>, Andre Kleber<sup>2</sup>, George Lauder<sup>2</sup> and Kevin K. Parker<sup>2</sup>; <sup>1</sup>Sejong University, Korea (the Republic of); <sup>2</sup>Harvard University, United States; <sup>3</sup>Emory University, United States; <sup>4</sup>University of California Irvine, United States

Biohybrid muscular systems have emerged as a valuable test platform for engineering and studying various physiological features, encompassing ion channels to system-level performance. The integration of muscle cells into simplified synthetic platforms has provided insight into the intricate mechanisms involved. However, the field of biohybrid technology is still in its nascent stages, encountering challenges in attaining system-level structure and performance comparable to their natural counterparts. This study presents a notable breakthrough in biohybrid technology through the development of a human stem cell-based biohybrid fish capable of self-pacing and self-sustaining coordinated locomotion. Taking inspiration from the structural attributes of the sinoatrial node and the multi-layered myocardium, our design incorporates a geometrically insulated cardiac tissue node and muscular bilayer muscle tissues into the biohybrid platform. This integration facilitates spontaneous activation and enables mechano-electrical signaling coupling between the muscular bilayer muscle tissues. The unique biohybrid design empowers the fish to exhibit spontaneous yet coordinated antagonistic muscle contractions, resulting in self-coordinated body-caudal-fin propulsion. Our autonomous biohybrid fish surpasses existing biohybrid muscular systems in terms of speed and longevity. It attains an optimal performance level comparable to natural body-caudal-fin swimmers, signifying a substantial advancement in the biohybrid technology domain. The achievements of this biohybrid fish lay a remarkable foundation for future autonomous biohybrid species capable of exhibiting complex adaptive behaviors. By harnessing the potential of human stem cells and employing advanced biohybrid designs, we are paving the way for a new era of biohybrid systems that closely mimic and potentially surpass the capabilities of their natural counterparts. These advancements hold immense promise across diverse applications, including regenerative medicine, biomimetic robotics, and enhancing our understanding of the fundamental principles governing biological locomotion.

#### 8:45 AM SB05.04.04

**Modular Biomachines Built from Amphibian Stem Cells** Douglas Blackiston<sup>1,2</sup>, Sam Kriegman<sup>3</sup>, Josh Bongard<sup>4</sup> and Michael Levin<sup>1,2</sup>; <sup>1</sup>Tufts University, United States; <sup>2</sup>Harvard University, United States; <sup>3</sup>Northwestern University, United States; <sup>4</sup>The University of Vermont, United States

Living organisms remain more adaptive, robust, and regenerative than any synthetic system yet developed. It is thus promising that engineering has seen a surge in novel fabrication materials over the past decade, including a growing catalogue of biological cells and tissues. These living materials have the potential to overcome several problems faced by traditional engineering programs: they are biodegradable, self-powered, self-motile, self-healing, nanometer sized, and contain an inherent biochemistry. Efforts have largely coalesced around biohybrid designs, combining synthetic scaffolds or components alongside living cells and tissues. In complement to this approach, we demonstrate a method for constructing fully biological machines from embryonic amphibian cells, engineered to exhibit a specific behavior. AI methods automatically design diverse candidate lifeforms in silico to perform a desired function. The best performing simulation is then selected, and a living biological representation is constructed using a novel cell-based toolkit sourced from amphibian stem cell lineages. These self-powered representations are then released into aquatic arenas and tested for transference of in silico behavior. Further, we show that these modular biomachines survive in varied freshwater and saline environments and can be programmed to respond to varied stimuli across their lifespan. These studies lay the groundwork for future large-scale and automated deployment of fully biological constructs capable of a variety of user specified tasks

#### 9:00 AM \*SB05.04.05

**Hybrid-Nanomaterials for Cellular Activity Modulation** Tzahi Cohen-Karni; Carnegie Mellon University, United States

My team's efforts are focused on three major thrusts: (i) synthesis and in depth mechanistic investigation of the unique emergent optical, thermal, electrical and electrochemical properties of novel hybrid-nanomaterials and nanomaterials topologies composed on one-dimensional and two-dimensional building blocks, (ii) application and characterization of hybrid-nanomaterials interfaces with cells and tissue, and (iii) development and engineering of nanomaterials-based platforms to interrogate and affect the electrical properties of tissue and cells such as cardiomyocytes, and neurons, with a specific focus to understand electrical signal transduction in complex 3D cellular assemblies. In this talk I will review our current efforts to control cellular activity

using photoactive hybrid-nanomaterials. Light has proven itself as a powerful tool to remotely modulate cellular activity with minimal invasiveness. We present a safe neural modulation approach with sub- $\mu\text{J}$  incident energy using engineered nanostructured Si, Ge, C (out-of-plane grown graphene), and two-dimensional (2D) transition metal carbides nanoflakes without generating cellular stress. Our approach serves as a powerful toolset for studies of cell signaling within and between tissues and can enable therapeutic interventions. Expanding the material library for safe optical modulation and the systematic evaluation of their biosafety will inspire future clinical translation to achieve remote control of cells/tissue in vivo.

#### 9:30 AM \*SB05.04.06

**Life-Nanomachine Synergism: From Subcellular-Sized Bioelectronic Interfaces to Brain-Like Ultra Energy-Efficient Nanoelectronics** Deblina Sarkar; Massachusetts Institute of Technology, United States

Typical biomedical implants are large (mm-cm in scale) and are highly invasive. To overcome these challenges, we are developing sub-cellular sized bioelectronic devices which are much smaller than the size of even a single cell. These devices can either reside inside a cell or in between cells and provide biological interfacing with high spatio-temporal precision. These can have applications in sensing biological signals as well as modulating them for therapeutics. Going beyond bio-interfacing, I will also discuss how we can learn from biology and build devices that act like the brain for achieving highly energy efficient and environmentally sustainable Artificial Intelligence.

SESSION SB05.05: Photo/electrochemical Processes at Biological Interfaces I

Session Chairs: Herdeline Ann Ardoña and Guglielmo Lanzani

Tuesday Morning, November 28, 2023

Hynes, Level 1, Room 102

#### 10:30 AM SB05.05.01

**Light-Responsive Cationic Membrane-Targeted Dyes for Cell Membrane Stimulation** Chiara Bertarelli<sup>1,2</sup>, Guglielmo Lanzani<sup>2,1</sup>, Valentina Sesti<sup>1,2</sup> and Paola Moretti<sup>1,2</sup>; <sup>1</sup>Politecnico di Milano, Italy; <sup>2</sup>Fondazione Istituto Italiano di Tecnologia, Italy

In the last few decades, photoswitches are being widely studied as a promising tool for photopharmacology. Light-responsive switches offer the possibility of using light as a clean, non-invasive, and spatio-temporally precise tool to trigger cell signalling and control a variety of biochemical functions. In this framework, reversible light-sensitive ligands successfully allow for a selective and reversible stimulation by means of the photoisomerization of dyes freely diffusing or covalently linked to channels, receptors, or other specific binding sites.<sup>1</sup>

Cationic membrane-targeted photochromic materials offer a rather different approach, where the amphiphilic character of the dyes drives their spontaneous partitioning within the cell membrane, with a specific affinity to lipid rafts. The cell signalling is the result of modification of the characteristics of the cell membranes induced by the light-driven conversion of the photoswitch to a metastable isomer.

Here, we show the molecular design of these amphiphilic dyes, which combine different families of photochromic compounds and cationic heads targeting the membrane, spaced by alkyl chains. Moreover, the presence of electroactive substituents allows for a high quantum efficiency in the visible range, modifies the isomerization kinetics and the stability in aqueous environment. Among the classes of switching units, azobenzenes demonstrated to be highly promising, and the most effective has proven to be the azepane- aminoazobenzene pyridinium-terminated Ziapin2.<sup>2,3</sup> Nevertheless, the use of indigos and Donor-Acceptor Stenhouse Adducts (DASAs) have been also explored.

The cationic membrane-targeted azobenzenes have been proven effective in the stimulation of neurons, muscular contraction and in driving optical modulation of bacterial membrane potential.<sup>4,5</sup> Finally, we demonstrate that the number and the structure of the capping head influence the solubility of the dye, the partitioning, and the stability within the cell membrane, rather than the targeting of membrane-bound cell organelles.

#### 10:45 AM SB05.05.03

**Unlocking the Potential and Lessons of 3D Porous Electrodes in Living Biophotoelectrochemical Systems** Linying Shang<sup>1</sup>, Joshua Lawrence<sup>1</sup>, Laura Wey<sup>2</sup>, Bartek Witek<sup>1</sup>, Evan Wroe<sup>1</sup>, Rachel Egan<sup>1</sup>, Alyssa Smith<sup>1</sup>, Silvia Vignolini<sup>1</sup> and Jenny Zhang<sup>1</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>University of Turku, Finland

Living biophotoelectrochemical systems are devices that 'wire' photosynthetic microorganisms (i.e., scalable and sustainable biocatalysts) to 3D-architected electrodes to catalyse reactions for solar-power generation and fuel production using sunlight and water. Despite excellent progress over the last decade, large enhancements in solar-to-charge conversion efficiency are needed to enable real-world applications. One major challenge lies in optimising the bio-electrode interface, where the material and structure of the electrodes play a crucial role.

State-of-the-art electrodes in this field are micro-pillar and inverse opal (IO) electrodes fabricated from indium-tin-oxide (ITO) nanoparticles.<sup>1</sup> Here, we provide important lessons for electrode design by tuning the pore sizes and homogeneity of IO-ITO electrodes, characterising their light management ability, surface morphology, electroactive surface area, cells wiring efficiency, and relating these to their biophotoelectrochemical performance.

Our results indicate that the bare IO-ITO electrodes of different pore sizes (10-42  $\mu\text{m}$  in diameter) managed light similarly and the larger pore-sized IO-ITO gave rise to the highest photocurrent output. Further attempts to boost light utilisation on these electrodes by adding a bio-mimicking reflective layer at the back of the electrode resulted in increased light reflection but did not influence the photocurrent output significantly, implying the light utilisation of the structure has been optimised.

In conclusion, presented is the most comprehensive systematic study in the structure-activity relationship of electrode architecture to biophotoelectrochemical output to our knowledge.

#### 11:00 AM \*SB05.05.04

**Multifunctional Hybrid Interfaces for Energy Applications** [Maurizio Prato](#)<sup>1,2</sup>; <sup>1</sup>Università Degli Studi di Trieste, Italy; <sup>2</sup>CIC biomaGUNE, Spain

Among the most innovative strategies in the energy transition, photo-electrocatalytic splitting of water for the production of "green hydrogen" plays a key role, as it provides an ideal energy carrier, obtained from renewable and circular resources and whose production and combustion fuels the H<sub>2</sub>O/O<sub>2</sub> cycle, activated by sunlight. Currently, hydrogen production is mainly obtained from fossil sources, and in particular from natural gas, through thermochemical processes (reforming/pyrolysis) that generate quantities of carbon dioxide with high environmental impact. The perfect mechanisms of the leaf, realized in an artificial environment, allows for the production of hydrogen as a solar fuel, an ideal solution for sustainable development. In particular, a new catalytic system, based on the combination of perylene bisimides and polyoxometalates, arranged in a hierarchical assembly, offers new opportunities for the biomimetic splitting of water.

**Membrane Targeted Azobenzene Drives Optical Modulation of Bacterial Membrane Potential** [Giuseppe Maria Paternò](#); Politecnico di Milano, Department of Physics, Italy

The possibility to control living matter with exogenous stimuli can have tremendous impact on synthetic biology, medicine and materials science, among others. For instance achieving control over cells behaviour remains a challenge at the interface between living and non-living matter,[1] and would enable the development of new bio-mimetic and bio-enabled materials able to perform tasks.[2] Within this context, bacteria have arisen as "active and actively-controllable materials", exhibiting neuro-like behaviour, extended bioelectric signalling[3,4] and tunable assembly properties.[5] In the last decade, it has been observed that the regulatory element of such an active behaviour is the electrical potential across the membrane, which governs bacteria electrophysiology, metabolisms and bioenergetics.[6] Light can be a powerful tool in these regards, as one can control the membrane potential and, thus, cell function and behaviour remotely and with relatively high spatiotemporal precision. Here, I will show that a membrane-targeted azobenzene can be used to photo-modulate precisely the membrane potential in cells of the Gram-positive bacterium *Bacillus subtilis*. We found that upon exposure to blue- green light, the isomerization reaction in the bacteria membrane induces hyperpolarisation of the potential ( $\Delta V = 20$  mV), within a bio-mimetic mechanism reproducing the initial fate of retinal. Apart from being promising results in the view to photocontrol bacterial motion and assembly behavior in consortia, this approach also highlights the role of previously uncharacterized ion channels in bacteria electrophysiology.[7]

#### 2:00 PM SB05.06.02

**A Membrane-Targeted Push-Pull Azobenzene for the Optical Modulation of the Membrane Potential** [Arianna Magni](#)<sup>1,2</sup>, [Valentina Sesti](#)<sup>1,2</sup>, [Matteo Moschetta](#)<sup>2</sup>, [Giuseppe Maria Paternò](#)<sup>1,2</sup>, [Chiara Bertarelli](#)<sup>1,2</sup> and [Guglielmo Lanzani](#)<sup>2,1</sup>; <sup>1</sup>Politecnico di Milano, Italy; <sup>2</sup>Istituto Italiano di Tecnologia, Italy

In the last years, the use of light as a tool for modulating membrane potential and bioelectricity has emerged as a fascinating opportunity, with the broad aim of establishing life-machine symbiosis that can help in healing disorders and restoring biological functions. An approach to induce light sensitivity in animal cells, which are usually transparent to visible light, is the use of photoactuators. These are photoactive materials that can decorate or localize into the cell membrane and are able to transduce light into a signal that can be processed by the cells. A variety of materials are suitable for the non-genetic optostimulation of cells, ranging from inorganic nanoparticles to organic polymer films and nanostructures. The cell membrane and its electrical potential represent the core of bioelectricity, hence constituting an ideal target for exogenous modulation of signalling. For this reason, we chose a push-pull azobenzene molecule (PP-2Pyr) as a membrane-targeting photoactuator that induces a charge displacement upon isomerization. The work comprises the photophysical characterization of the photoactuator, focusing on the isomerization dynamics, and the evaluation of the photoinduced effects on HEK-293 cells. The focus is on unveiling the photostimulation mechanism, intending to link the photophysical changes occurring in the molecular photoactuator after light absorption, to the biological effects on *in vitro* cell models. The proposed light-driven mechanism

originates from inferences on the molecular partitioning of PP-2Pyr in the two membrane leaflets and on the rearrangement of the charges adsorbed to the membrane due to variations in the molecular dipole moment upon light excitation.

#### 2:15 PM SB05.06.03

**Surprising Enhancement of Extracellular Electron Transfer (EET) from Electroactive Bacteria to Charge Collectors by Fumarate and Further Enhancement of EET by Functionalized Carbon Nanotubes (CNTs)** [Gábor Méhes](#)<sup>1</sup> and Arghyamalya Roy<sup>2</sup>; <sup>1</sup>Waseda University, Japan; <sup>2</sup>Linköping University, Sweden

We are witnessing the convergence of organic electronics with applied microbial electrochemistry for applications of energy harvesting, biosensing, electrosynthesis and others. In other words, biocompatible films made of conducting organic molecules interface electroactive (and other) bacteria in electronic and electrochemical devices, such as microbial electrochemical cells, biobatteries and transistors. Recently we have contributed to these efforts by creating a 3D hybrid bioelectrode based on PEDOT:PSS and *Shewanella oneidensis* MR-1 for enhancing the output of MESs[1], and by the first demonstration of amplification of EET by organic electrochemical transistors [2]. After shortly introducing these two papers, we will discuss two ways EET can be enhanced to yield MESs with electrical performances closer to realistic applications. More concretely, we have been investigating the effect of chemically-functionalized CNTs, as well as the biomolecule fumarate, on the magnitude and temporal dynamics of EET. We observed distinctively different effects on EET based on the chemical agent for functionalization of CNTs, and an unexpected role of fumarate in EET dynamics.

**Seeing the Sound—An Ultrasound-Mediated Intravascular Light Source for Noninvasive Brain Modulation** [Guosong Hong](#); Stanford University, United States

Understanding the inner workings of the brain requires a bidirectional interface that enables causal manipulation and simultaneous interrogation of neural activity. Existing electrical and optical brain interfaces are usually based on implanted devices and invasive procedures that necessarily damage the endogenous brain tissue and constrain the subject's free behavior. To address these challenges, our lab leverages the latest advances in materials science to develop minimally-invasive functional interfaces for monitoring and modulating the brain. Specifically, in this talk, I will present three materials-inspired strategies: 1) light sculpting in the tissue with ultrasound by turning the endogenous circulatory system into an "optical flow battery", 2) an intravascular light source inspired by the biomineralization process in nature, and 3) deep-brain neuromodulation inspired by the infrared sensitivity of rattlesnakes. I will conclude my talk by presenting an outlook on how advances in materials science may facilitate the development of next-generation brain-machine interfaces.

**Integration of Polymers with Synthetic Soft Matter and Biological Matter Towards Sensing** [Alberto Salleo](#); Stanford University, United States

An attractive feature of polymeric mixed conductors is their ability to swell in water thus forming a soft interface amenable to interacting with biological matter. Further, their ability to transduce ionic fluxes into electronic fluxes opens opportunities in sensing. Indeed, one can imagine combining the specificity and sensitivity of biological matter with the functionality of semiconductors in a single hybrid device. In this talk I will describe our work on integrating lipid bilayers, either synthetic or obtained from cell walls to sense a variety of environmental cues. For instance, we demonstrate specific sensing of toxins and viral fusion as well as the detection of opening and closing of selected ion channel. I will describe the surface treatments needed to enable such hybrid interface to retain its functionality as well as modeling of the device response and its limitations.

#### 4:00 PM SB05.06.06

**Vertical Organic Electrochemical Transistors for Enhanced Performance and Circuit Integration** [Antonio Facchetti](#); Northwestern University/Flexterra Inc, United States

Organic electrochemical transistors (OECTs) have been intensively investigated for applications in state-of-the-art wearable electronics and next-generation biosensor technologies due to their outstanding amplification, sensitivity to ionic and ultra-small electrical potential signals, compatibility with roll-to-roll fabrication processing, and low driving voltages. The far majority of OECT studies are based on a device structure comprising coplanar source-drain electrodes in contact with the organic semiconductor. Recently we proposed a new architecture where the electrodes are vertically stacked achieving high transconductance and current on-off ratio for both p- and n-type semiconductors. This vertical OECT architecture (vOECT) is also attracting for dramatically increase transistor density for high-resolution OECT sensors and complementary driving circuits. However, scalable patterning methods for organic semiconductors and optimization of the semiconductor topology for efficient monolithic integration of vOECTs remains technologically challenging, but essential for applications in complex and high-density OECT circuit arrays and multi-functional data analysis. In this presentation we report on the monolithic integration of flexible vOECT arrays for driving high-density (> 7 M OECT/cm<sup>2</sup>) active-matrix complementary logic circuits.

#### 4:15 PM SB05.06.07

**Stand-Alone Conformable Bioelectronics Based on Integrated Internal Ion-Gated Organic Electrochemical Transistors** [Claudia Cea](#)<sup>1,2</sup>, [Zifang Zhao](#)<sup>1</sup>, [Jennifer Gelinás](#)<sup>1</sup> and [Dion Khodagholy](#)<sup>1</sup>; <sup>1</sup>Columbia University, United States; <sup>2</sup>Massachusetts Institute of Technology, United States

Effectiveness of medical treatments can be greatly influenced by individual variations, prompting the need for methods that enable continuous monitoring of physiological signals and personalized responsive delivery of therapeutics. Implanted bioelectronic devices play a crucial role in these methods, but there are challenges that prevent their widespread adoption. The ability to perform these demanding electronic functions in the complex physiological environment with minimum disruption to the biological tissue remains a big challenge. An optimal fully implantable bioelectronic device would require each component from the front-end to the data transmission unit to be conformable and biocompatible. For this reason, organic material-based conformable electronics are ideal candidates for components of bioelectronic circuits due to their inherent flexibility, and soft nature. Here, we present a vertical internal ion-gated organic electrochemical transistors (vIGT) as a high-density, high-amplification sensing component as well as a low leakage, high-speed processing unit. In addition, a novel wireless, battery-free strategy for electrophysiological signal acquisition, processing, and transmission that employs IGTs and an ionic communication circuit (IC) is introduced. We show that the wirelessly-powered IGTs are able to acquire and modulate neurophysiological data in vivo and transmit them transdermally, eliminating the need for any hard Si-based electronics in the implant.

**4:30 PM SB05.06.08**

**Organic Electrochemical Transistors as On-Site Signal Amplifiers for Electrochemical Aptamer-Based Sensing** Xudong Ji and Jonathan Rivnay; Northwestern University, United States

Electrochemical aptamer-based sensors are typically deployed as individual, passive, surface-functionalized electrodes, but they exhibit limited sensitivity especially when the area of the electrode is reduced for miniaturization purposes. We demonstrate that organic electrochemical transistors (electrolyte gated transistors with volumetric gating) can serve as on-site amplifiers to improve the sensitivity of electrochemical aptamer-based sensors. By monolithically integrating an Au working/sensing electrode, on-chip Ag/AgCl reference electrode, and Poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) counter electrode — also serving as the channel of an organic electrochemical transistor, we can simultaneously perform testing of organic electrochemical transistors and traditional electroanalytical measurement on electrochemical aptamer-based sensors including cyclic voltammetry and square-wave voltammetry. This device can directly amplify the current from the electrochemical aptamer-based sensor via the in-plane current modulation in the counter electrode/transistor channel. The integrated sensor can sense transforming growth factor beta 1 with 3 to 4 orders of magnitude enhancement in sensitivity compared to that in an electrochemical aptamer-based sensor (292  $\mu\text{A}/\text{dec}$  vs. 85  $\text{nA}/\text{dec}$ ). This approach is believed to be universal, and can be applied to a wide range of tethered electrochemical reporter-based sensors to enhance sensitivity, aiding in sensor miniaturization and easing the burden on backend signal processing.

**4:45 PM SB05.06.09**

**Soft Polymer for Enhanced Electron Transfer** Rossella Labarile<sup>1</sup>, Danilo Vona<sup>2</sup>, Maria Varsalona<sup>2</sup>, Matteo Grattieri<sup>2</sup>, Melania Reggente<sup>3</sup>, Ardemis Boghossian<sup>3</sup>, Fabian Fischer<sup>4</sup> and Massimo Trotta<sup>1</sup>; <sup>1</sup>Consiglio Nazionale delle Ricerche, Italy; <sup>2</sup>Università degli Studi di Bari Aldo Moro, Italy; <sup>3</sup>Ecole Polytechnique Fédérale de Lausanne, Switzerland; <sup>4</sup>Haute école Spécialisée de Suisse Occidentale, Switzerland

Photosynthetic bacteria are anoxygenic microorganisms with highly versatile metabolism, as they use sunlight to oxidize a broad variety of organic compounds in addition to heterotrophic and photoautotrophic alternative metabolisms. Conductive polymer layers on the surface of several bacterial species have been used to intercept and funnel the electron flow produced by microbial metabolism outside the cells and transfer it to an electronic circuit of a biohybrid device.

Polydopamine (PDA), produced by self-assembly of dopamine, is a very versatile and bioinspired polymer with widespread applications<sup>1</sup> mostly due its ability to adhere and cover surfaces of different chemical composition. The oxidative conditions employed for the formation of this dark insoluble polymer are mild and biocompatible and have inspired scientists to develop novel nanomaterials. Post-functionalization of PDA<sup>2</sup> also enables fine tuning of properties.

Furthermore, the ability of this monomer to self-assemble and polymerize in the bacterial growth medium was considered one of the requirements of the polymer to be used as coating material beside the tunable conductive properties and the flexible structure.

Biocompatibility of dopamine was tested by *in vivo* addition in the growth media of the photosynthetic purple non sulphur *Rhodobacter (R.) sphaeroides*<sup>3</sup> in anoxygenic conditions.

We have used PDA conductive coatings as biotic-abiotic interfaces in biohybrid photoelectrochemical devices through the encapsulation of entire bacterial cells or single components – e.g. photosynthetic reaction center (RC) - of *R. sphaeroides*<sup>4,5</sup>, ensuring electronic communication of the biological component with the electrodes' surfaces in photoelectrochemical cells.

**5:00 PM SB05.06.10**

**Soft and Ultra-Thin Wearable Tactile Interface with Electrical Impedance Tomography for High Spatiotemporal Resolution** Kyubeen Kim, Jung-Hoon Hong and Ki Jun Yu; Yonsei University, Korea (the Republic of)

Wearable tactile mapping devices, a burgeoning area in human-computer interaction, have gained significant attraction due to their wide range of applications. These include interfaces for virtual reality and gaming devices, haptic feedback systems, and artificial skin for medical and robotic applications. Tactile sensors, as a cornerstone of this technology, must achieve high spatiotemporal resolution while maintaining soft mechanical properties to replicate the human sense of touch accurately. This is paramount in creating seamless and immersive user experiences, whether it's in navigating virtual environments or enabling prosthetic devices to mimic real tactile feedback. However, the development of these sensors presents distinct challenges. Current high resolution tactile sensing technologies predominantly rely on inorganic material-based sensors, which, despite offering high spatial resolution and reliability, pose significant limitations. They are inherently brittle and ill-suited to accommodate mechanical deformation, a critical attribute for wearable sensors meant to conform to human skin. On the other hand, soft materials, characterized by a low Young's modulus, are mechanically desirable for wearable tactile systems as they can conform to varied and changing surfaces. However, the fabrication processes for these materials tend to deviate from conventional microelectronics manufacturing techniques. This divergence often results in less sophisticated device structures, hindering the development of advanced and intricate tactile sensing systems.

To overcome these limitations, we propose an ultra-thin tactile sensor offering single-cell based multi-channel array functionality via the application of electrical impedance tomography (EIT). The sensor's stretchable sensing area consists of an elastomeric substrate and encapsulation, alongside a conductive functional layer comprising multi-wall carbon nanotube (MWCNT) layers. With a thickness of just 50 microns, this low-modulus, highly stretchable sensor can conformably adhere to human skin, maintaining robust functionality under applied force and mechanical deformation. The EIT

computational analysis method allows our single-cell device to operate as a multi-channel array by reconstructing high-resolution conductivity changes within the broad sensing area. Piezoresistive effect-induced conductivity changes in the MWCNT-based conductive layer occur when external forces are applied, causing mechanical deformation, bending, and stretching. These changes can be mapped by EIT measurements using surrounding electrodes, achieving high-resolution detection of force applications. This EIT-based soft tactile interface can differentiate external pressures down to a 1 mm scale, and vertical deformation of a few hundred micrometres. We validated our tactile sensor's functionality through two real-time applications: a wearable drone controller and a handwriting recognition interface. Our work illustrates the potential of applying EIT to soft, ultra-thin elastomeric devices for the development of high-performance wearable tactile sensing systems. These systems could find potential applications in healthcare, robotics, and human-machine interfaces, paving the way for more advanced tactile sensors in the future.

SESSION SB05.07: Poster Session II: Functional Soft Materials for Biointerfacing

**Battery-Free, Fully Implantable Optoelectronic System for Programmable Photodynamic Therapy and Tumor Growth Monitoring** In Sik Min, Kiho Kim and Ki Jun Yu; Yonsei University, Korea (the Republic of)

Photodynamic therapy (PDT) is garnering attention as a prominent next-generation cancer treatment modality that utilizes specific wavelengths of light and photosensitizers to target and treat malignant tumors with high selectivity, resulting in minimal side effects and exclusively targeting cancer cells. Photosensitizers, selectively accumulated in cancer cells, transition into an excited state upon exposure to incident light energy. Subsequently, the surrounding oxygen is converted into reactive oxygen species, which serve as the mechanism for destroying cancer cells without inflicting significant damage or pain on normal cells, thus enabling the destruction of malignant tissue. Due to the limited penetration of light into deep tissues within living organisms, conventional PDT has predominantly been confined to epithelial cancers such as skin cancer, bladder cancer, and bronchial carcinoma. Furthermore, light delivery systems for PDT have relied on bulky and expensive laser-based equipment, posing significant constraints on user accessibility. To overcome these challenges, various LED-based fully implantable PDT systems have recently been developed. However, existing fully implantable PDT systems have faced limitations in precise light intensity control and adjustment of PDT parameters, as they are based on passive electronics or simple circuits incapable of performing advanced functions. Moreover, the implementation of wireless systems solely for power delivery has hindered the realization of tumor-related data monitoring based on bidirectional communication systems. Here, we introduce a battery-free and fully implantable optoelectronic system for PDT that enables precise light intensity control and scattered light measurement for tumor growth monitoring. This system involves the insertion of a  $\mu$ -LED probe into the tumor to deliver light of 624 nm wavelength for PDT. The system allows for precise control of LED light intensity from 0% to 100% through wireless user control using a Bluetooth Low Energy communication. Additionally, the system incorporates the capability to monitor tumor growth by measuring the scattering of light within the tumor tissue through an external phototransistor placed outside the tumor. We performed *in vitro* experiments to confirm that the therapeutic effects vary at different light intensities of 0%, 30%, 70%, and 100%, and observed tumor growth inhibition through 624 nm-based PDT performed on a nude mouse model during a three-week *in vivo* experiment. Furthermore, we validated the feasibility of a system for monitoring relative changes in tumor size by measuring the scattered light from the tumor using a phototransistor, through ray-tracing simulation, *ex vivo* and *in vivo* experiments. This wireless electronics-based PDT system holds significant potential for expansion into a multimodal system with diverse functionalities such as a closed-loop system based on simultaneous treating and monitoring system, providing an opportunity to realize an effective and low side-effect cancer treatment while simultaneously collecting valuable feedback data related to the treatment.

#### 8:00 PM SB05.07.02

**The Relationship Between Surface Oxidation States and Antiviral Activity of Nano-Columnar Copper Thin Films** Keisuke Shigetoh, Rie Hirao and Nobuhiro Ishida; Toyota Central R&D Labs Incorporated, Japan

Antiviral coatings capable of inactivating a broad spectrum of viruses are crucial in the fight against viral mutation and emergence. Drawing inspiration from cicada wings known for their mechano-bactericidal properties, this study proposes the use of nano-columnar Cu thin films [1]. These thin films of Cu and its oxides were fabricated on a polymer surface by a sputtering technique, and their virus-inactivate capabilities were tested against both enveloped bacteriophage  $\Phi 6$  and non-enveloped bacteriophage  $\Phi \beta$ . Among the fabricated films, the Cu thin films showed the highest antiviral properties. The Cu thin films diminished the infectious activity of the bacteriophages by five orders of magnitude within half an hour, the  $\text{Cu}_2\text{O}$  thin films reduced it by three orders of magnitude, while the CuO thin films lessened it by less than one order of magnitude. Moreover, the excellent antiviral activity of Cu thin films was confirmed under the pseudopractical conditions using viral solutions that contain contaminating proteins, assuming such as in human saliva. After being exposed to ambient air for a month, the antiviral activity of the  $\text{Cu}_2\text{O}$  thin film dropped by one order of magnitude. Nevertheless, the Cu thin films consistently demonstrated a higher degree of antiviral activity compared to the  $\text{Cu}_2\text{O}$  thin films. A detailed analysis of the surface chemical states via X-ray photoelectron spectroscopy indicated that the fabricated Cu thin films showed slower oxidation to CuO than that of the  $\text{Cu}_2\text{O}$  thin films. Therefore, the formation of CuO possibly worked as a passivation layer for antiviral activity. The significant antiviral activity and oxidation durability of the Cu thin films can have immense practical utility, while their oxidation resistance might be a characteristic property of nanostructured Cu fabricated by the sputtering method. Finally, the antiviral activity of the nano-columnar Cu thin films against infectious viruses in humans was demonstrated by the binding inhibition of the SARS-CoV-2 spike protein to the angiotensin-converting enzyme 2 receptor (ACE2). The cleavage of the disulfide bonds in the spike proteins by copper ions is thought to have led to a significant reduction in binding affinity between spike protein and ACE2. The small mass loading ( $6 \mu\text{g cm}^{-2}$ ) of the Cu thin films ensured transparency and flexibility of the substrates, with a low environmental risk; this is particularly useful for coating applications on disposable masks and filters.

#### 8:00 PM SB05.07.03

**Novel Structural Concept for High-Performance Gold Nanowire Stretchable Electrode Toward Ultra-Flexible Biomedical Applications** Satoshi Takane<sup>1,2</sup>, Yuki Noda<sup>1</sup>, Naomi Toyoshima<sup>1</sup>, Takafumi Uemura<sup>1,2</sup> and Tsuyoshi Sekitani<sup>1,2</sup>; <sup>1</sup>Osaka University, Japan; <sup>2</sup>National Institute of Advanced Industrial Science and Technology, Japan

Gold nanowires (AuNWs) are attractive candidates to develop stretchable/biocompatible electrodes for use in biomedical sensors and neural interfaces. In

this study, we propose a novel structural concept to enhance the strain-conductive performance of stretchable AuNW electrodes, the formation of a “macroscale mesh”-shaped “nanowire-thin film composite” structure in the AuNW electrodes. The AuNW-Au thin film (AuTF) composite electrodes with a mesh structure using an Ecoflex substrate decrease the absolute resistance by 22% and the normalized resistance changes by 24% compared with the AuNW electrode without a composite or mesh structure under 80% strain. Furthermore, our stretchable electrodes, composed of AuNWs, AuTFs, and Ecoflex have excellent biocompatibility and thus have great potential for use in biomedical applications.

Due to the growing demand for biomedical devices that are mechanically/biologically compatible with human organs, stretchable AuNW electrodes have attracted considerable attention because of their stable strain-conductive performance and biocompatibility owing to the nanowire network structure and the chemical inertness of gold, respectively. Although numerous studies have been conducted on stretchable AuNW electrodes, further improvements in the inadequate performance are required for these electrodes to appear in the industrial market.

As performance indicators of stretchable electrodes, two parameters are used to evaluate their strain-conductive properties: absolute resistance and normalized resistance change. Previous studies have suggested unique methods to improve the parameters of stretchable metal nanowire electrodes. For instance, the deposition of metal thin film on metal nanowire electrodes to form nanowire-thin film composite electrodes can reduce the absolute resistance of pristine metal nanowire electrodes over a broad strain range. However, this method may increase the normalized resistance change owing to the mechanical degradation of the metal thin film. In contrast, the formation of a mesh structure over metal nanowire electrodes can suppress the normalized resistance change under tensile strain. However, the formation of the mesh structure decreases the conductive area of the electrodes, which can induce a higher absolute resistance.

In this study, we integrate these two unique but imperfect methods and introduce this novel structural concept to AuNW electrodes to improve both their absolute resistance and normalized resistance change simultaneously for the realization of a high-performance and biocompatible electrode. The AuNW-AuTF composite electrodes with a mesh structure demonstrate 22% lower absolute resistance and 24% smaller normalized resistance change than those of the pristine AuNW electrode without a composite or mesh structure under 80% strain. From the result, we consider the AuTF in the composite electrode facilitates the current flow although the mesh structure decreases the conductive area of the electrode, whereas the mesh structure suppresses the mechanical failure of the AuTF by reducing the tensile stress. Additionally, the AuNWs, AuTFs, and Ecoflex have been previously used in biomedical devices and confirmed to be biocompatible. Therefore, mesh-shaped AuNW-AuTF composite electrodes can be applied to biomedical devices. This novel structural concept which can improve strain-conductive performance is versatile for any type of stretchable metal nanowire electrodes. Using the AuNWs, we developed high-performance, elastic, and biocompatible electrodes suitable for use in biomedical devices. Our findings will accelerate the development of biomedical applications not only in academia but also in industry.

**Silk Fibroin: An Adaptive Natural Surfactant for Aqueous Solution-Processed Nanoelectronics over All Substrates** [Taehoon Kim](#) and Fiorenzo Omenetto; Tufts University, United States

Universal wettability is especially relevant for aqueous solution processing, which has gained prominence due to the growing demand for water-based fabrication of electronic and photonic components. Although water is an ideal solvent in terms of abundance and environmental sustainability, its relatively high surface tension limits its wetting capabilities. Surface pre-treatments, surfactants, or organic co-solvents are commonly used to enable aqueous solution processing. However, these methods have drawbacks, including their potential to impact material composition and morphology, increase costs, and raise environmental concerns. Thus, the development of a practical, versatile, and sustainable strategy for achieving universal wettability of aqueous solvents is of significant importance.

In this study, we present the utilization of silk fibroin (SF), a natural biopolymer, to modulate the interfacial energy landscape of hydrophobic surfaces. By incorporating small amounts of SF in thin-film precursor solutions, we demonstrate its role as an adaptive molecular bridge that enables the deposition of aqueous solutions on otherwise unwettable substrates. The amphiphilic composition of SF chains confers exceptional interfacial energy control, resulting in enhanced wetting behavior. Furthermore, we investigate the vertical self-segregation mechanism of SF during the formation of metal-oxide thin films, which can be harnessed to preserve the electronic properties of the active layers. By combining these effects, we successfully fabricate (opto)electronic structures on substrates with significantly different surface energies using all water-based precursor solutions, without compromising device performance due to the presence of the bioinspired surfactant.

Overall, these results present a comprehensive exploration of SF as a means to regulate the interfacial energy for achieving universal wettability in aqueous solution processing. The findings contribute to the development of practical and sustainable approaches for fabricating electronic and photonic thin films, offering potential benefits in terms of cost, energy consumption, and environmental impact.

#### 8:00 PM SB05.07.06

**Thermo-Responsive Shape Memory Polymer for use in Implantable Blood Pressure Measurement Device** [Arjan Sall](#), Zoe Schofield and Liam Grover; University of Birmingham, United Kingdom

*Hypertension or high blood pressure is a worldwide problem as it has become the leading cause in the growth of cardiovascular disease and premature death. This is especially true in countries of low to middle income [1]. As a result of this it is critical that patient's blood pressure is measured on a regular basis in order to provide the correct treatment. Current methods of blood pressure measurement such as the sphygmomanometer or ambulatory methods in a clinical setting or electronic monitors used at home are either too invasive for the patient, are subject to the general fluctuation of blood pressure throughout the day or are only able to take singular measurements [2][3]. This has produced a need for a method of blood pressure measurement that is non-invasive and is able to provide continuous and reliable blood pressure measurement throughout the day. The focus of this presentation will be the development of a biocompatible shape memory polymer (SMP) that will be used in the fabrication of a blood pressure sensor that will allow a non-invasive implantation of the device into the subcutaneous layer of the wrist.*

*Mechanical characterisation of the current sensor material, polydimethylsiloxane (PDMS), will be presented to provide a reference point for the development of the SMP. The fabrication process of the SMP based on a blend of PDMS and Polycaprolactone will be described, and the systematic variation of the polymer composition will be explained detailing its impact on the shape memory effect elicited, while also comparing the mechanical properties of the SMP formulations to the pure PDMS. The mechanical characterisation carried out will focus on the compressive strength of the material where cyclic loading tests will determine the fatigue behaviour of the SMP and maximum compression tests will allow the calculation of the elastic modulus of the material. This will help determine the longevity of the implant. Aging of the samples using PBS at 37°C and 70°C will assess the ability of the material to withstand prolonged subcutaneous implantation. Dynamic mechanical analysis and dynamic scanning calorimetry will be used to determine the transition temperatures ( $T_g$ ) of each of the SMP formulations with 37°C being the target temperature. Once an SMP with the target  $T_g$  has been produced the shape fixity, shape recovery and recovery rate will be tested. The goal for this project is to create a material that is able to withstand both the mechanical and biological stresses of blood pressure measurement and subcutaneous implantation which will allow the sensor to provide a reliable and consistent blood pressure measurement.*

**Mechanical Characterisation of Bio-Inspired, Multi-Compartment Soft Materials Endowed with Photo-Responsivity** Patrick J. Grimes<sup>1</sup>, Agostino Galanti<sup>2</sup>, Pierangelo Gobbo<sup>2</sup>, Henry E. Symons<sup>1</sup>, Sebastien Rochat<sup>1</sup> and Jun H. Park<sup>1</sup>; <sup>1</sup>University of Bristol, United Kingdom; <sup>2</sup>University of Trieste, Italy

Novel bio-inspired materials are of great interest to both the materials science and synthetic biology communities. The Gobbo group has recently developed “protocellular materials” (PCMs) assembled from protein-polymer protocell units (called proteinosomes) that are annealed into sheets through interfacial strain-promoted alkyne-azide cycloaddition (I-SPAAC).<sup>[1]</sup> Proteinosomes are comprised of a self-assembled, crosslinked nanoparticle membrane with an inherent molecular weight cut off (MWCO) (ca. 40 kDa) that allows the entrapment of cargoes of sufficiently high molecular weight.<sup>[2]</sup> The resultant PCMs formed of a population of covalently bound proteinosomes have been demonstrated to be robust and free standing in water.

The current trajectory of research in this area is towards improving the mechanical properties of the PCM's constituent proteinosomes, such that the resultant PCM can more closely mimic biological cell consortia. Moreover, developing the responsivity of PCMs to physiochemical stimuli is of great interest to allow the use of PCMs in a range of applications, including their potential use as a substrate on which to grow communities of living cells. The characterisation of PCMs has been restricted to confocal and electron microscopy, which, although both powerful techniques, is naturally limiting in the context of mechanical properties.<sup>[1]</sup>

In this communication I will show how a novel photosensitive crosslinker and a reactive thermoresponsive polymer can be combined to generate three-dimensional hydrogel “protocytoskeletons” within the proteinosomes of PCMs. This protocytoskeleton can be disassembled on irradiation, leading to the loss of mechanical integrity of the PCM. The selective disassembly of PCMs can be achieved with high spatio-temporal control on irradiation with UV light, and that disassembly can be monitored through the use of microindentation using a recently developed methodology.<sup>[3]</sup> Moreover, the photolabile proteinosomes of the PCM can be precisely photo-patterned to generate new, complex three-dimensional architectures. Whilst these novel materials are still in the early stages of development, they have the potential to be used in diverse applications from drug delivery to soft robotics.

**Hofmeister Salts Enhance the Water-Responsive Actuation Energy of *Bacillus Subtilis* Cell Walls** Seungrì Kim<sup>1,2</sup>, Haozhen Wang<sup>2,3</sup>, Darjan Podbevšek<sup>2</sup> and Xi Chen<sup>1,2,3</sup>; <sup>1</sup>The City College of New York, United States; <sup>2</sup>CUNY Advanced Science and Research Center, United States; <sup>3</sup>The City University of New York, United States

Water-responsive (WR) materials have attracted significant attention due to their potential applications as high-energy actuators for soft robotics, smart structures, and energy harvesting devices. Recently, the cell walls of *Bacillus (B.) subtilis* have shown a high WR energy density of 72.6 MJ m<sup>-3</sup>, surpassing that of existing actuator materials. In this study, we found that the exceptional WR energy density of the cell walls is attributed to nanoconfined liquids' properties. Furthermore, we discovered that strengthening the hydrogen (H-) bonding network of these nanoconfined liquids could further increase this energy density. To investigate this, we systematically modulated the H-bonding network using Hofmeister salts, specifically potassium sulfate (K<sub>2</sub>SO<sub>4</sub>) and potassium iodide (KI), which respectively strengthen and weaken the H-bonding network. Cell walls treated with a 10 mM K<sub>2</sub>SO<sub>4</sub> solution exhibited a 22.4 % enhancement in energy density, reaching 101.8 MJ m<sup>-3</sup>. However, higher concentrations (30-50 mM) of K<sub>2</sub>SO<sub>4</sub> or any KI solutions led to reduced WR energy densities. These observations highlight the crucial role of the enhanced H-bonding network in achieving high-performance WR materials and emphasize the existence of a certain range of H-bonding strength for optimizing WR performance. Moreover, our study presents a cost-effective and scalable approach that utilizes Hofmeister salts to manipulate and enhance the WR performance of hygroscopic materials.

**Tunable Interface of Polymeric Composite of Electroactive P3HT-MWCNT Thin Film for Bioelectronics Applications** Paola Campione<sup>1,2,3</sup>, Grazia Maria Lucia Messina<sup>1</sup>, Francesca Santoro<sup>3,2</sup> and Giovanni Marletta<sup>1</sup>; <sup>1</sup>University of Catania, Italy; <sup>2</sup>Forschungszentrum Juelich, Germany; <sup>3</sup>RWTH Aachen University, Germany

One of the main challenges in bioelectronics concerns the development of materials able to respond to external stimuli and that are compatible with excitable tissues. In the last decades, conductive polymers (CPs) have been widely studied and developed as electroactive materials for applications in interfacing with biological systems. Their conductive properties allow cells or tissues growth upon stimulation, and their “soft” nature allows to form a better biotic-abiotic interface and reduce the mechanical mismatch between material and cells thanks to the elasticity of polymeric films that is similar to biological tissues [1]. CPs' physical and iontronic-electronic properties can be optimized through the formation of composites enriched with carbon nanotubes or graphene in order to improve electron transport capacity, decrease impedance and increase flexibility. Their biocompatibility can be improved using functionalization methods with biologically active molecules [2] even if the influence of blending agents is still under investigation. The precise control of CP films nano-topography may have interesting effects for biointerfacing and improving the cell-chip coupling for cell activity recording and stimulation, acting on protein adsorption and cell adhesion.

In this work, we report on how to obtain stable electroactive nanocomposite dispersion using semiconducting regioregular poly(3-hexylthiophene-2,5-diyl) (P3HT), with different percentages in weight of multi-walled carbon nanotubes (MWCNT) and how to deposit to form homogeneous thin films. Their morphologies have been investigated by means of atomic force microscopy (AFM) and scanning electron microscopy (SEM), and the attention has been focused on the “cushion” effect due to the presence of the filler in the polymeric matrix that allow an interesting modification in mechanical properties (Young's Modulus), analyzed by nanoindentation with atomic force microscopy (AFM), and the formation of a “softer” interface. Considering the central role of extracellular matrix protein in cell adhesion, their interactions at the interface with our systems were investigated by means of quartz crystal microbalance with dissipation monitoring (QCM-D). Noteworthy, it has been found that thanks to the larger available surface area of the blend thin film that act like a sponge, proteins are adsorbed in a very different way with respect to the bare semiconducting P3HT. Indeed, both the adsorption kinetics and the adsorbed mass are increased for each extracellular matrix proteins. The biocompatibility of the systems with different cell lines has been investigated as well as the effect on cell metabolism. Moreover, the effect of the systems on the variation of the distance between cell and electrode has been analyzed by focused ion beam - scanning electron microscopy (FIB-SEM). The realization of this nanostructured bioelectronic interface represents an example of 2.5D cell culture and promotes the optimization of the cell-chip coupling by tuning the cleft between the membrane of the cell and the electrode, also acting on the formation of the extracellular matrix protein coating that helps cells attach to, and communicate with, nearby cells, and plays an important role in cell

growth, cell movement, and other cell functions.

**Modulating Light Transmission using Particle-Based Displays** Patrick A. Sullivan, Daniel Wilson and Leila Deravi; Northeastern University, United States

E-inks utilize reflected ambient light rather than emitted light to display changes in text or images. As such, they can generate and hold patterns using very low power. Electrophoretic, electrofluidic and electrochromic techniques have been used commonly in this space together with homogenous materials designed specifically adapt to a biased stimulus to create these low power displays. We asked whether inherently asymmetric materials like Janus particles can be similarly used in low energy adaptive display. In this work we investigate methods to synthesize and manipulate the transmissivity of Janus particles made with a metal and a dielectric material. Using custom designed optical chambers, we assayed the effect of electric field on particle rotation which ultimately correlated to a change in the transmission of visible light. Our preliminary results demonstrate a realistic approach to using asymmetric Janus materials as active elements for future display applications.

#### 8:00 PM SB05.07.13

**3D-Printed, Biomimetic, Electroconductive Scaffolds for the Promotion of Axonal Regrowth after Spinal Cord Injury** Liam Leahy<sup>1,2</sup>, Ian Woods<sup>1,2</sup>, Jack Maughan<sup>1,2,3</sup>, Javier Gutierrez Gonzalez<sup>1,2,3</sup>, Michael Monaghan<sup>2,3</sup>, Adrian G. Dervan<sup>1,2</sup> and Fergal O'Brien<sup>1,2,3</sup>; <sup>1</sup>RCSI, Ireland; <sup>2</sup>RCSI and TCD, Ireland; <sup>3</sup>Trinity College Dublin, The University of Dublin, Ireland

Spinal cord injury (SCI) induces paralysis by damaging axons, neuronal processes that carry signals about the body. Injured axons are unable to regrow through the injury site, preventing functional recovery. Electrical stimulation (ES) has shown signs of being capable of inducing neuronal regrowth and support functional recovery. We propose that a tailored, electroconductive scaffold with composition designed to support and direct ES to regrowing axons may help drive them toward their distal targets and restore function. This is a difficult challenge to tackle, as the spinal cord is a complex tissue comprising discrete axonal tracts. An ideal scaffold for this system must mimic the structure of the cord and provide the supportive cell environment of the native extracellular matrix (ECM). To overcome this challenge, ECM-functionalised electroconductive scaffolds designed to mimic the axonal tract structure of the human spinal cord were fabricated by coating 3D-printed polycaprolactone (PCL) with conductive polypyrrole (PPy) nanoparticles and filling the structure with freeze-dried ECM to direct ES to promote neurite outgrowth.

Biomimetic PCL scaffolds were 3D-printed with an Allevi 2 printer to produce uniaxially aligned, interlocking cylindrical architectures, with several channel sizes to match the diameters of human spinal cord axonal tracts. PPy was polymerised *in situ* to form an electroconductive nanoparticle coating on PCL scaffolds, verified via FTIR and SEM imaging. Electroconductivity was measured via the 4-point probe method. Scaffold biocompatibility was assessed by growing neurons on 2D PPy/PCL films and measuring metabolic activity, cellular DNA and neurite outgrowth. Neurotrophic ECM was directionally freeze-dried within scaffold channels to mimic the native spinal cord environment and further promote neurite extension<sup>1</sup>. Neurons were electrically stimulated on ECM-functionalised PPy/PCL and PCL scaffolds using an Ionoptix bioreactor and imaged to assess the effect of ES-induced neurite extension over 7 days.

3D-printed PCL scaffolds of all channel sizes were successfully coated with PPy nanoparticles. Conductivity of the PPy coating was measured at  $15 \pm 5$  S/m, 30 times higher than native spinal cord tissue. PPy/PCL substrates were as biocompatible as PCL, indicating the suitability of PPy coated scaffolds for neuronal tissue engineering. Freeze-dried ECM formed aligned pore structures within scaffold channels, providing a physical guide for neurite outgrowth. No difference in electrical properties or cell activity were measured in scaffolds of various channel sizes, showing scaffolds can be scaled to match native cord structures without losing functionality. Electrically stimulated neurons on PPy/PCL scaffolds showed increased average neurite length and total cellular DNA compared to PCL scaffolds, suggesting ES via a conductive scaffold promotes healthy neuronal growth.

In conclusion, biomimetic 3D-printed electroconductive scaffolds were manufactured and characterized and demonstrated excellent biocompatibility. Scaffolds were successfully scaled to match the sizes of axonal tracts, and electrically stimulated neurons exhibited increased neurite extension within PPy/PCL scaffolds compared to inert PCL controls, showing the potential of the electroconductive scaffold to direct neurite growth. Taken together, these results show that ES applied via ECM-functionalised electroconductive scaffolds drives neurite outgrowth, a key requirement to achieving functional recovery post-injury, highlighting the potential use of this novel combination therapy for SCI repair.

**Nanomaterials and Additive Processes for Transparent and Stretchable Organic Electrochemical Transistor** Takaaki Abe, Teppei Araki, Shoya Matsuda, Naoko Kurihira, Mihoko Akiyama, Takafumi Uemura and Tsuyoshi Sekitani; SANKEN (The Institute of Scientific and Industrial Research), Japan

Flexible electronic devices with optical transparency exhibit biocompatibility and increase the versatility of measurement methods, such as multimodal sensing that enables simultaneous usage in optical, electrical, and ionic methods. In this study, we develop fully transparent and flexible organic electrochemical transistors (OECTs) using transparent conductors of Ag nanowires (AgNWs) and conductive polymers. They demonstrate the feasibility of multimodal acquisition of biological signals. In addition, stretchable materials are newly developed to construct fully transparent and stretchable OECTs, which can contribute to the creation of next-generation medical sensors.

Sensors for use as personal healthcare devices that can measure biological signals continuously and for a long time for the early detection of diseases have been expected [1-2]. OECTs can be used to fabricate circuits suitable for such biological signal measurements owing to their advantages of low operating voltage, mechanical flexibility, and high mutual transconductance [3]. In particular, the high mechanical flexibility decreases the wearing discomfort because flexible biological tissues change their shape. Additionally, if the device has high transparency, it enables multimodal sensing that can utilize electronic, optical, and ionic methods simultaneously, as well as miniaturization through the stacking of devices. Therefore, stretchable and transparent conductors and semiconductor materials for electronic devices can facilitate a new electronic design.

In this study, we develop highly transparent and flexible OECTs using AgNWs and poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) [4]. High bending durability and high visible transmittance (>90%) are achieved by controlling the orientations of the AgNWs used for wiring. Furthermore, additive layering techniques, such as printing and lamination processes, are employed to decrease damage to the nanomaterials constituting the OECT. In addition, these transparent and flexible OECTs exhibit properties comparable to those of conventional opaque OECTs. Consequently, low-noise measurements of brain waves and ion concentrations, as well as simultaneous optical measurements of blood flow and pulse

waves, are feasible and a step toward the quantification of human stress.

Furthermore, stretchable channel materials are developed to create more flexible OECTs. A patterning process of AgNW-based conductors and semiconductors on elastomers is concurrently developed to fabricate fully stretchable and transparent OECTs. In particular, the stretchable conductors and channel materials exhibit durability under 50%–100% strain; thus, they can be used for fully transparent and stretchable sensors for the long-term and multimodal assessment using electrophysiological, optical, and ionic methods.

**Transforming the Brain to Transparent Hydrogels for Long-Range Microscopic Analysis of the Nanoparticles Interactions with Brain Tumors** Maryam Golshahi, Hamed Arami and Layla Khalifehzadeh; Arizona State University, United States

Microscopic analysis of the tumor response to therapeutics reagents such as nanoparticles and chemotherapy drugs is limited to conventional tissue sectioning, which is followed by immunostaining and optical microscopy. Tissue sectioning is destructive and microscopic data obtained from a limited number of thin tissue slices (typically with 5-50  $\mu\text{m}$  thickness) are not representative of the efficacy of the treatment over the entire tumor mass. Microscopic results obtained from a single or limited number of tissue slices can be even more misleading for brain tumors with high levels of heterogeneity such as glioblastoma multiforme (GBM). Therefore, developing methods for microscopic analysis of the whole tumor tissue without any sectioning can be beneficial by providing an overall feedback about the treatment rates at different parts of the tumor mass. This capability can potentially enhance the treatment effects and minimize the probability of the tumor recurrence by optimizing the treatments to target the entire tumor. Here, we used a polymerization method that helps to transform the whole mouse brain to optically transparent acrylamide-based hydrogels without losing the microscopic or nanoscale structure of the tumors at both extracellular and intercellular levels. Orthotopic U87 tumors (human-derived GBM cells with GFP signal) were generated in mouse brains ( $n=3$ ). Therapeutic nanoparticles (gold nanoparticles tagged with Cy5 fluorescent molecules) were injected into tumors stereotactically using a magnetic resonance imaging (MRI) guided approach. Mice were euthanized 24h post-injection and brains were excised and immersed in a monomer solution, followed by a low-temperature polymerization and tissue-clearing technique known as CLARITY. Then, the entire volume of these transparent brains were analyzed using different microscopy techniques, including confocal and light-sheet microscopy. The interaction of the nanoparticles with tumors was investigated using their Cy5 and GFP signals, respectively. We were able to generate three-dimensional maps verifying the distribution of the nanoparticles in tumors and other parts of the brains (e.g., the ventricles). Immunostaining of these brains is a reversible process and a series of staining and microscopies can be used for analyzing different treatment biomarkers (such as cell death, necrosis, and immune response) separately. Expansion of this method will enable more accurate pre-clinical and clinical investigations to evaluate the efficacy of a variety of therapeutic agents and their potential side-effects within the entire tumors and other parts of the brain.

#### 8:00 PM SB05.07.17

**Aptamer-Decorated Prussian Blue Nanozymes for Selective Detection of Dopamine** Han Been Lee, Do Hyeon Kim, Se Hwa Cheon, Chang Hyeon Ha, Su Jeong Lee and Gi hun Seong; Hanyang University, Korea (the Republic of)

Dopamine (DA) is a catecholamine neurotransmitter that plays a significant role in the central nervous and hormone systems of humans. Abnormal levels of DA can lead to various diseases, including Parkinson's disease and depression. While electrochemical measurements have gained considerable attention for their simplicity and responsiveness, the electrochemical detection of DA is easily influenced by the simultaneous presence of ascorbic acid (AA) or uric acid (UA). This is because AA and UA can also undergo oxidation at a potential similar to that of DA. Therefore, it is crucial to develop a sensitive and selective detection method for DA in biological fluids to overcome these challenges.

Colorimetric assays have obtained much attention due to their rapid observation by the naked eye and user-friendly operation. However, assays relying on the reduction of the substrate of DA have limitations in terms of selectivity because substances such as AA and UA, which have a similar structure to DA, also possess the ability to reduce substrates. To address this issue, we employ an aptamer to ensure high selectivity in real samples. Aptamers are molecular recognition components based on nucleic acids. These functional single-stranded nucleic acids can adopt a three-dimensional structure and exhibit exceptional specificity and affinity for target molecules.

Nanozymes, nanomaterials that exhibit enzyme-mimicking activities, have emerged as promising alternatives to natural enzymes like horseradish peroxidase (HRP) due to their exceptional catalytic activity, ease of modification, and remarkable stability. Given their intriguing and practical characteristics, nanozymes have been employed in various biomedical point-of-care applications, including biosensing and immunoassays. Among the different types of nanozymes, prussian blue nanoparticles (PBNPs) have gained widespread use in the field of biosensing and immunoassays. This is attributed to their outstanding peroxidase-like activity, robust stability, and high sensitivity.

In this study, we employed chitosan (CS), a polycationic biopolymer with amine groups in its backbone, to stabilize PBNPs. This resulted in the formation of CS-coated prussian blue nanoparticles (CS/PBNPs), which modified the surface charges of the PBNPs to a positive state. By virtue of the positive charges conferred by CS, the negatively charged dopamine binding aptamer (DBA) could be immobilized onto the CS/PBNPs through electrostatic interactions.

DBA molecules, known for their specific affinity towards DA, were adsorbed onto the surface of CS/PBNPs, leading to the inhibition of the peroxidase-mimicking activity of the CS/PBNPs. However, upon the introduction of a DA sample solution, the DBA molecules on the CS/PBNPs surface strongly bound to the DA, inducing a conformational change in the aptamer and causing its separation from the CS/PBNPs. Consequently, as the concentration of DA increased, more surface area of CS/PBNPs became exposed, resulting in an elevation of their peroxidase-like activity.

In conclusion, we successfully developed an aptamer-based colorimetric assay utilizing CS/PBNPs for the detection of DA in concentrations ranging from 0.25  $\mu\text{M}$  to 100  $\mu\text{M}$ , with a limit of detection (LOD) of 0.16  $\mu\text{M}$ . The recovery results of DA concentrations (0.25  $\mu\text{M}$ , 0.5  $\mu\text{M}$ , and 1  $\mu\text{M}$ ) in spiked human serum were 92.6%, 102.1%, and 103.9%, demonstrating high reproducibility and reliability of the CS/PBNP-based apta-sensor for determining DA levels in clinical applications. Furthermore, compared to typical immunoassays, this aptamer-based nanozyme inhibition/activation assay eliminates the need for a washing step, making it highly practical in terms of reducing assay time and maintaining high sensitivity. Based on its excellent performance, this biosensor holds promise as a valuable tool for the rapid, selective, and sensitive detection of clinically significant small molecules, such as hormones, in practical applications.

#### 8:00 PM SB05.07.18

**Modification of Conductive Surfaces via Tailored Dyes Derivatives for Bacterial Detection** Svenja Herdan<sup>1</sup>, Laurie Neumann<sup>1</sup>, Lea Könemund<sup>1,2</sup>, Rebekka Biedendieck<sup>1</sup>, Hans-Hermann Johannes<sup>1,2</sup>, Dieter Jahn<sup>1</sup> and Wolfgang Kowalsky<sup>1,2</sup>; <sup>1</sup>Technische Universität Braunschweig, Germany; <sup>2</sup>Cluster of Excellence PhoenixD, Germany

The improvement of a biosensor which combines fast and highly sensitive detection of bacteria with easy handling is of great interest, for example, in the fields of medicine or the food industry. In the future, pathogenic bacteria could be detected at an early stage. Conventional methods such as enzyme-linked immunosorbent assay (ELISA) or polymerase chain reaction (PCR) are time-consuming, expensive and require professional expertise. Therefore, a sensor with low costs and fast, reliable results is of great importance.

In previous works, functionalized porphyrins with two different linkers have been synthesized for a bacteria sensing system. The linkers are divided into two different groups: linker **A** which can bind to an electrode (gold or indium tin oxide) and linker **B** which can bind to bacteria. For linker **B** there are two possible bio receptors a peptide group and cysteine group enabled to connect the Gram-negative bacterium *Escherichia coli* (*E. coli*) K12, a common well investigated apathogenic model strain. An analysis with fluorescence-lifetime imaging microscopy (FLIM) could already show a decrease of the fluorescence lifetime of the porphyrin molecule due to changes in their chemical environment or conformation as they have an interaction with cell components of the bacteria cells. These results show that both bio receptors in combination with the porphyrin molecule can be used as a bio linker on an electrode surface for further bacteria detection methods. (Neumann, 2021).

The goal of this research is to extend the existing system. For this purpose, porphyrin was replaced by another dye, boron-dipyrromethene (BODIPY). Reasons for this are that BODIPYs are thermally and photochemically stable, have a higher fluorescence quantum yield (BODIPYs  $\approx$  90%; porphyrins  $\approx$  5%; depending on the substitution of the dyes), are well soluble and chemically stable and they are biocompatible. Furthermore, it should be emphasized that the synthetic effort and thus also the yield loss can be reduced, because only two steps are necessary for the BODIPY linker synthesis and six steps have so far been necessary for the porphyrin linker synthesis. In addition, it is possible to use a boronic acid instead of a peptide or cysteine group for linker **B**. Boronic acids have the property to bind to *cis*-diols, which are located on bacterial cell wall. By adapting linker **B** as previously mentioned, a general sensor could be developed regardless of whether the bacteria are Gram-negative or Gram-positive.

**Key words:** porphyrin, BODIPY, *E. coli* immobilization, biosensing

#### 8:00 PM SB05.07.19

**Mediated Electron Transfer in Bacteria for Charge Generation** Ndepana G. Andrew and Hemali Rathnayake; University of North Carolina at Greensboro, United States

The increase in energy demand led to remarkable research activities on energy generation, storage, and conversion, and many different kinds of nanoscale materials have been explored to harness energy. However, recently microorganisms including bacteria and algae have been shown to display significant roles in developing high-performance probes owing to their abilities to reproduce fast, self-repair, self-assembly, and wide range of biosynthetic capabilities. Among a wide variety of microbes, bacteria have been well studied offering their adaptation to broaden research directions for developing a variety of sustainable energy generation, conversion, and storage systems with either improved or new capabilities and performance.

However, adapting bacteria to develop the aforesaid systems with required performance entails a clear understanding of how bacteria interact with the surface or mediator and how chemical, physical, and intrinsic properties of the “mediator” affect interaction with bacteria to produce expected results and programmable characteristics. The processes of metabolic electron transfer from bacteria to an extracellular mediator and vice versa in diverse exoelectrogenic and non-exoelectrogenic bacteria have been studied but only a few have been investigated in-depth to understand bacteria responses and study their electron transfer processes at their respective biotic interfaces with a variety of organic and inorganic mediators. Electron transfer in bacteria can occur either directly or indirectly, however, only a limited set of bacterial species can transfer electrons directly to the electrodes, most bacteria require an external electron transfer mediator to transfer charges to the electrode for efficient energy generation. Although Various compounds have been tested in the past as exogenous mediators, there are potential classes of compounds that are yet to be explored.

Herein, we gather a new concept of using a metal-organic framework as an external mediator for electron transfer at the interface of *E. coli*, we grow live *E. coli* cells on a functional MIL-88B MOF to construct a charge capacitive bio interface. The aim is to study the interactions at the bio interface and employ these interactions to generate a charge-capacitive smart interface for energy storage and study the metabolic electron transfer mechanism at the bio interface resulting in the generation of energy at the bio interface. In theory, the MIL-MOF will stimulate the bacteria's metabolic electron transfer processes by modulating charge injections at the *E. coli*/MOF interface to generate charge capacity through electron transfer processes. So far from our preliminary result, we obtained a charge capacity of 399 Fg<sup>-1</sup> at a scan rate of 5 mV/s generated at the *E. coli*/MOF interface as compared to 195 Fg<sup>-1</sup> generated at the *E. coli* (control) interface only at the same scan rate. Our results suggest the potential of MIL-88B MOF as an external mediator in facilitating electron transfer at the *E. coli* interface to generate a higher charge capacity twice the magnitude of *E. coli* charge capacity.

This study proposes that by combining the distinctive functionalities of living bacteria with biocompatible abiotic MIL-MOFs, it is possible to create smart interfacial biosystems for charge generation and storage with programmable features.

#### 8:00 PM SB05.07.20

**The “SLIC” Idea: Superhydrophobic Lubricant Infused Composite (SLIC) is a Non-Toxic, Inexpensive Polymer Composite Coating that Prevents Biofouling** Thomas LeFevre, Joseph Daddona, Wilaiwan Chouyok, Stony Akins, George Bonheyo, Curtis Larimer and Raymond S. Adleman; Pacific Northwest National Laboratory, United States

This poster will describe the development and testing of a Superhydrophobic Lubricant-Infused Composite (SLIC) coating that inhibits the attachment of organic and biological matter. Biofouling is the unwanted accumulation of biological material, such as bacteria, algae, mussels, and barnacles, on a surface. Biofouling is an expensive and disruptive problem in many water-related industries such as shipping, hydropower, and aquaculture. Antifouling coatings are commonly utilized to mitigate fouling, but the existing coatings that are effective are also toxic or extremely expensive.

To address the toxicity and expense of existing coatings, SLIC is a PDMS-based coating with several additional ingredients that provide strength, texture, and porosity in the coating. This work will describe the design, selection, and optimization of biomimetic additives designed to provide strength, abrasion resistance, and a surface microstructure that mimics the superhydrophobic texture of natural surfaces such as the lotus leaf. We will outline a process for incorporating lubricant oil into the coating to provide a low surface energy liquid layer, similar to fish slime, that inhibits biological adhesion. The oil can flow into cracks and crevices in the coating, providing a self-healing mechanism when the coating is scratched. SLIC was designed to be an antifouling coating that is tough, long lasting, economical, and toxin-free. It can also be easily customized for specific use cases such as nets that require a flexible coating.

Results of experiments to quantify antifouling performance by exposing varying formulations of SLIC to mussels at different life stages will be presented. Use of a machine learning algorithm to assist in the detection and counting of mussel larvae on surfaces will be described. Results of antifouling performance tests showed that SLIC prevented mussel larvae attachment in static conditions is better than the leading antifouling paint and significantly better than uncoated stone, metal, and plastic surfaces. In summary, SLIC was designed as a high performance low-cost antifouling coating. It can prevent mussel adhesion and other types of fouling while remaining nontoxic.

**8:00 PM SB05.07.21**

**A Smart Coating with Integrated Physical Antimicrobial and Strain-Mapping Functionalities for Orthopedic Implants** Yi Zhang and Qing Cao; University of Illinois at Urbana-Champaign, United States

As the prevalence of orthopedic implants increases within the aging population, these patients become increasingly vulnerable to risks associated with periprosthetic infections and instrument failures. There have been attempts to reduce the risk of infection by modifying the implant surface to impede bacterial adhesion or applying antibiotics to the surface to kill local bacterial populations. But these methods are rarely used due to their own limitations. For instance, coating implant surfaces with hydrophilic molecules or quorum-sensing inhibitors can block bacterial adhesion, but this strategy fails if even a few bacteria manage to attach and form an antibiotic-resistant biofilm. Another significant complication associated with orthopedic implants is aseptic implant failures, which require surgical revisions and affect over 10% of patients. These failures manifest primarily as loosening caused by mechanical shielding or implant breakage due to fatigue failure. Presently, these complications are diagnosed using x-ray or bone scan imaging. However, these techniques only detect gross implant movement, which occurs long after the inception of loosening or implant-related microfractures, even with harmful radiation and high costs.

To address these challenges, we develop the design of a smart-coating foil that can be applied to the surfaces of orthopedic implants. This foil provides both long-term physical bactericidal action and sensitive strain mapping to mitigate both septic and aseptic orthopedic failures. The outer surface of the foil is designed with high-density nanopillars, mimicking the surface nanotopology of cicada wings. These structures exhibit strong mechanical bactericidal effects against bacteria commonly associated with orthopedic implant infections without directly releasing any chemicals. A multiplexed strain-sensing array is integrated into the foil. The high piezoresistive coefficient of single-crystalline silicon ensures accurate detection of strain down to 0.01% experienced by orthopedic implants. The nanometer-scale film thickness allows the foil to bond with the implant surface, while the integration of silicon gauges with multiplexing transistors enables strain mapping across the implant surface. This can assist in the detection of early-stage spinal fusion and pedicle-screw loosening, guiding patient-specific care and early intervention against aseptic instrument failures. The strain-mapping array and mechano-bactericidal nanostructures both showed excellent biocompatibility and long-term stability in vivo.

**8:00 PM SB05.07.22**

**Specific Protein Metalization in Cell-Derived Extracellular Matrix via Antibody-Guided Bioteplating for Utilization in Hydrogen Production and Sensing** Chang Woo Song and Jaewan Ahn; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

In nature, there is a myriad of hierarchical biological structures consisting of various proteins that are challenging to replicate by artificial synthetic methods. To exploit such complex structures in material science, bioteplating has attracted great attention over the past decades, wherein exotic functionalities from inorganic materials were able to impart into the biological scaffolds by electroless plating or physical vapor deposition of metal. However, the biological architectures used in prior reports were stereotypical and ordinary with the lack of ways to manipulate their morphological features such as porosity, alignment, and organization, limiting their usage in more broad fields. To this end, we propose the cell-derived extracellular matrix (ECM) is an excellent option to be used as a template for achieving diverse biomimetic architectures. ECM has evolved into intricate mesh structures intertwined with various fibrillar protein assemblies to conduct mechanical support of cells, assist in the proliferation and migration of cells, and transport the signal to the cells. Because of these important biological roles of ECM, a variety of ECM have been created with customized morphological and chemical characteristics, especially for cell biology, pharmacology, and tissue engineering. Despite already developed diverse protein assemblies in ECM, there was no attempt to use them as a biological scaffold for metalization. To use a specific ECM protein as a template, we introduced 1.4-nm nanogold-conjugated antibodies and labeled them to a specific protein called fibronectin within the ECM, and then the nanogold acted as the nucleation sites for Au growth. The metalized ECM could be electrically conductive after thermal sintering or second metal growth (e.g., Pd and PdPt alloy) with additional functionality. Following the deposition of PtNPs, the fabricated conductive biocomposite showed catalytic activity in the hydrogen evolution reaction (HER), maintaining its stability for up to 500 repeated cycles. In addition to hydrogen production, the electrically conductive biocomposites by the second metal growth demonstrated the prominent hydrogen sensing performance at room temperature.

**8:00 PM SB05.07.23**

**A Photo-Patternable Stretchable Gold Conductor by Electroless Plating Process** Hinata Mitomo<sup>1,2,3</sup>, Keita Suzuki<sup>4</sup>, Katsuya Tennichi<sup>5</sup>, Yuanyuan Zhou<sup>1,2,3</sup> and Naoki Matsuhisa<sup>1,2,3</sup>; <sup>1</sup>Research Center for Advanced Science and Technology, The University of Tokyo, Japan; <sup>2</sup>The University of Tokyo, Japan; <sup>3</sup>Department of Electrical Engineering and Information Systems, The University of Tokyo, Japan; <sup>4</sup>Tanaka Kikinzoku Kogyo K.K., Japan; <sup>5</sup>EEJA Ltd., Japan

Stretchable gold thin-film electrodes exhibit superior biocompatibility and conductivity. In previous studies, stretchable gold thin films have typically been prepared by thermal evaporation<sup>1,2</sup>. However, to maintain high stretchability, the sheet resistance was limited to an order of 10 Ohm/Sq. Moreover, it is crucial to minimize gold waste resulting from deposition in unnecessary areas.

In this study, we present highly stretchable and conductive gold electrodes fabricated by a photo-patternable electroless plating process. Our gold thin film exhibited a remarkably low sheet resistance of 0.25 Ohm/Sq. at 0% strain and 2.7 Ohm/Sq. at 50% strain. The film remained highly conductive, even under a 200% strain. These electrical and mechanical characteristics were preserved when the gold was patterned to a resolution of 100 μm. Fabrication began by spin-coating a primer polymer layer, which adheres gold nanoparticles from the colloid solution. Deep ultraviolet exposure can deactivate the capacity to capture gold nanoparticles, enabling patterning. Subsequent electroless plating allowed the gold nanoparticles to grow into a uniform film with a thickness of 200 nm. We controlled the aforementioned plating conditions to regulate microcrack formation under strain, and obtained the high stretchability of our gold. The high conductivity and patternability of our stretchable gold pave the way for the development of stretchable, high-density electrodes for electrophysiology measurements, and stretchable antennas for wireless wearable electronic devices.

**8:00 PM SB05.07.24**

**Design and Characterization of Magnetically Controlled Minicell-Driven Biohybrid Microswimmers for Targeted Drug Delivery Applications** Saadet F. Baltaci Demir<sup>1,2</sup>, Irina Kalita<sup>3</sup>, Birgul Akolpoglu<sup>1,4</sup> and Metin Sitti<sup>1,4,5</sup>; <sup>1</sup>Max Planck Institute for Intelligent Systems, Germany; <sup>2</sup>University of Stuttgart, Germany; <sup>3</sup>Max Planck Institute for Terrestrial Microbiology, Germany; <sup>4</sup>ETH Zürich, Switzerland; <sup>5</sup>Koc University, Turkey

Bacteria-based biohybrid microswimmers, combining motile bacteria cells with synthetic materials, have emerged as promising vehicles for alternative therapeutic applications such as active drug delivery. However, existing biohybrids face many limitations that hinder their translation to clinical applications considering the poor penetration ability through the barrier or tissue, biostability and limited payload capacity. Here, we propose a magnetically controllable drug-loaded biohybrid microswimmer driven by a bacterial outer membrane vesicle, referred to as minicell, which offers unique capabilities such as enhanced penetration capability thanks to its sub-micron size and long-term stability with self-propulsion because of its non-dividing but metabolically active nature. Additionally, minicells exhibit a large drug encapsulation capacity compared to traditional nanocarriers. In this study, we fabricated motile minicells produced by engineered *Escherichia coli* strain inducibly expressing a biotin display system on their surface, enabling us to

benefit from the robust biotin-avidin interaction with streptavidin-coated magnetic nanoparticles onto the micelles. We optimized the production of self-propelled micelles via several purification methods and investigated their growth and motile behavior in various culture and physiological media over time. We showed the magnetic control and guidance of micell-driven biohybrids by an external magnetic field, and compared their 2D swimming motility with and without applying uniform magnetic fields. Furthermore, we optimized the loading efficiency of the chemotherapeutic drug doxorubicin into the micelles and demonstrated the time-dependent release of the drug molecules. Overall, the micell-driven biohybrid design proposed here offers a magnetically guided active drug-carrying nanosized platform for targeted delivery while preserving its motility and durability during the extended application period.

#### 8:00 PM SB05.07.25

**Designed Nanoparticle-Polymer Conjugates as Nucleants for Multiple Protein Types** Xiaoting Guo and Vicki L. Colvin; Brown University, United States

Determining the three-dimensional structure of proteins is crucial for understanding their function, but the limited ability to form protein crystals suitable for X-ray diffraction has become a bottleneck problem in this field. Through the control of nanocrystal and protein interactions, it is possible to both enhance the nucleation of protein crystals as well as create three-dimensional structures of nanoparticles within the protein crystals. The length of polymers (e.g. poly(ethylene glycol) bound to a nanocrystal surface can mediate protein interactions with the nanocrystal-polymer conjugates: specifically, longer polymers at the nanoparticle surface allow for more protein association with conjugates.

We showed that the addition of AuNP-PEG to hen egg white lysozyme (HEWL) led to an increase in the number of crystal hits across a wide range of crystallization conditions. The compared result in crystallography indicates with the incorporation of conjugate system, protein structures can be dissolved with the existence of the nano-nucleant inside the protein matrices. Surprisingly, the incorporation of AuNP-PEG inside the crystals did not affect their quality. The statistical values listed in Table 1 for the AuNP-HEWL co-crystal remained consistent with those obtained for the pure HEWL crystal, indicating that the addition of AuNPs did not alter the crystal properties in any way.

AuNP-PEG can also be used as a general nucleant for different protein species. 5 illustrate a comparison of hit counts for eight proteins, namely Ferritin, Proteinase K, Thaumatin, p-HSA, Concanavalin A, Glucose Isomerase, Insulin, and Xylanase, based on 48 screening conditions. The results indicate that the addition of AuNP-PEG increased the number of hits in each protein species compared to the control group without the presence of AuNP solution. The potential of AuNP-PEG to affect liquid-liquid phase separation (LLPS) of FUS-LC proteins was also investigated, which plays a crucial role in understanding the formation and solubilization of protein droplets in cellular processes. The addition of AuNP-PEG to FUS-LC led to an acceleration of LLPS and the formation of more condensates.

Within the protein-nanoparticle conjugate co-crystals, we further demonstrated that the incorporation and arrangement of nanoparticles at regular distances within the protein crystal is reflective of the fact that the protein crystal nuclei form on the nanoparticle surface; for lysozyme, these nuclei have been studied via both light scattering and diffraction. Most studies find that they consist of four or more lysozymes with dimensions near 9 to 18 nm. In the presence of nanoparticles, these proto-nuclei form in and around nanoparticle-polymer conjugates that can themselves have polymer shells as thick as 30 nm. This would suggest that incorporated nanoparticles could have as much as 40 to 50 nm of surface polymer and protein surrounding them, giving rise to a lower limit for the interparticle separations that is in good agreement with that found from the radial distribution function (e.g. 47 nm). The composites grow when these protein-nuclei encounter other similar structures and begin to crystallize, leading to the formation of composite crystals. Anisotropic materials align due to the faster spreading of proteins along the a-b face of crystal during growth which causes the preferential orientation of the rods perpendicular to the c-axis.

#### 8:00 PM SB05.07.26

**Strain Dependency of Charge Transport of Stretchable Conjugated Polymers** Seung Hyun Kim and Kilwon Cho; Pohang University of Science and Technology, Korea (the Republic of)

Stretchable polymer semiconductors have attracted significant interest for their potential in flexible and stretchable electronics. However, there remains challenging work in controlling the strain-induced properties of conjugated polymers (CPs), such as crystallinity, morphology, and charge transport properties. Herein, we delve into the contribution of microstructures to their mechanical and electrical stretchability. To achieve stable electrical properties during deformation, specific structural requirements are discussed, such as the inclusion of a less-rigid donor moiety between diketopyrrolopyrrole (DPP) acceptors. This addition reduces crystalline packing, thereby significantly enhancing the mechanical deformability of the CP films. Furthermore, the multiscale structural and electrical analyses revealed that a less-rigid backbone allows for the strain-induced flattening of the polymer chains. The flattening of polymer chains reduces the activation energy barrier for hopping transport to 38 meV at 80% strain. Consequently, strain-induced alignment and conformational changes of polymer chains provide favorable pathways for charge transport, resulting in a significant increase in hole mobility of up to 180% under an 80% tensile strain. We believe that our study on the strain-induced structural changes in CP films, ranging from molecular to mesoscale, would contribute to a better understanding of the strain dependency of charge transport of stretchable conjugated polymers.

#### 8:00 PM SB05.07.27

**Fabrication and Characterization of Electrospun PU and Vapor Phase Polymerized PEDOT:Tos Fibers for Flexible Electronics** Jiaxin Fan, Jinsil Kim and Fabio Cicoira; Polytechnique Montreal, Canada

Soft conductive materials have gained considerable attention owing to their vast potential in wearable sensors, biomedical devices, and flexible displays. The successful implementation of high-performance flexible electronics requires exploring suitable materials with superior electrical and mechanical properties.<sup>1</sup> Poly-(3,4 ethylenedioxythiophene) (PEDOT) doped with various counterions has been extensively studied for flexible and stretchable electronics due to their ambient stability and solution processability. Additionally, their electrical conductivity and mechanical properties can be further tailored by blending with additives based on the application requirements.<sup>2</sup> PEDOT-based materials are also compatible with various fabrication and processing techniques, such as drop-casting, spin-coating, printing, and electrospinning. Among various techniques, electrospinning offers unique advantages, including a straightforward setup, versatile material choice, scalable production, tunable fiber properties, and compatibility with various substrates. Electrospun nanofibers exhibit desired properties for soft electronics.<sup>3</sup> For PEDOT-based materials, the spinnability can be improved by adding carrier polymers.

In this study, we focus on the preparation of conductive fiber mats based on a mixture of polyurethane (PU) and PEDOT doped with tosylate (PEDOT:Tos). The fabrication process involved electrospinning the mixture of PU and oxidant, iron (III) p-toluenesulfonate (tosylate), followed by vapor phase polymerization (VPP) to obtain PEDOT:Tos. PU was utilized as both carrier polymer and an additive for enhancing the electrical and mechanical properties. The resulting fibers have an average diameter of ~ 800 nm. An average sheet resistance of  $16.4 \pm 1.5$  k $\Omega$ /sq was obtained for the PU/PEDOT:Tos fiber mat after VPP. To investigate the influence of different electrospinning solution mixtures and conditions, we analyzed the morphology, electrical conductivity, electrochemical behaviors, and mechanical properties of the fiber mats fabricated with various spinning solution mixtures and fabrication conditions. Preliminary demonstration of utilizing the conductive fiber mats for flexible electronics will also be presented. This comprehensive investigation provides insights into optimizing and engineering the properties of fiber mats for their application in soft electronics.

**Silent Speech Interface using Wearable Strain Sensors Based on Crystalline Silicon Nanomembrane** Kiho Kim, Taemin Kim, Kyowon Kang and Ki Jun Yu; Yonsei University, Korea (the Republic of)

The Silent Speech Interface (SSI), which uses non-verbal forms of communication like sign language, provides a promising alternative for those unable to vocalize. This technology interprets intended words by monitoring facial muscle and skin movements during verbal communication. Notably, SSI benefits from wearable sensors that use surface electromyography (sEMG), as it doesn't necessitate constant video surveillance in a fixed setting. However, conventional sEMG electrodes face issues related to signal quality, such as low signal-to-noise ratio and interelectrode interference, obstructing the precision of facial mapping.

In this study, we have developed an innovative SSI incorporating epidermal strain sensors made from crystalline silicon nanomembrane (SiNM). These sensors, thanks to their piezoresistive properties, are considerably more sensitive than standard metal foil-based strain gauges. Each sensor includes two strain gauges placed perpendicularly to measure biaxial strain independently. We attached four sensors to four facial regions with the greatest areal changes, as identified by vision recognition.

We selected 100 English words at random from the Lip Reading in Wild benchmark set and trained 100 strain data sets for each word on a deep-learning-based classifier. To evaluate the classification performance of our system, we used a 5-fold cross validation which resulted in an average accuracy of 87.53%. In the same validation, a 4-channel sEMG system of identical dimensions ( $< 0.1\text{mm}^2$ ) to our unit strain gauge exhibited only 41.53% accuracy due to its low SNR caused by high impedance. We also conducted an experiment with 200-word classification to check the effect of spatial resolution on accuracy. Under identical conditions, the 16-channel and 8-channel systems showed 81.87% and 71.63% accuracy, respectively. This demonstrates the potential for this technology to support everyday conversation in the future.

**Soft Transparent Microelectrodes based Multimodal Devices for Biointerfacing** Luyao Lu; The George Washington University, United States

Optically transparent microelectrodes are important technologies that can integrate with tissues and allow light to transmit in both directions for co-localized and crosstalk-free electrical recording, optical imaging, and optogenetics. Existing transparent microelectrodes rely on external optical fiber, camera, or microscope setups for optical biointerfacing. In this talk, I will discuss several of our recent examples of soft transparent microelectrodes based multimodal optoelectronic devices enabled by new concepts in materials, micro- and nano-fabrication techniques, and engineering designs. Those innovative devices integrate microscale light-emitting diodes, photodetectors, with transparent microelectrodes on a chip. They are designed in flexible formats and allow for stable, high-fidelity, high-content electrical and optical recording and modulation of many important cellular parameters (intracellular calcium dynamics, metabolic activity, biopotentials, etc.) across different spatiotemporal resolutions. We envision those multimodal devices will open up new windows to understand important biological processes at the cellular, tissue, and organ levels with high spatiotemporal resolution and selectivity.

**8:15 AM SB05.08.02**

**Bio-Inspired Multiple Tactile Sensing System for Simultaneous and Real-Time Perception** Bo-Yeon Lee, Seonggi Kim, Sunjong Oh, Youngdo Jung and Hyuneui Lim; Korea Institute of Machinery and Materials, Korea (the Republic of)

A human can intuitively perceive and comprehend complicated tactile information. Because the cutaneous receptors distributed in the fingertip skin receive different tactile stimuli simultaneously, and the tactile signals are immediately transmitted to the brain. Although many research groups have attempted to mimic the structure and the function of human skin, it remains a challenge to implement human-like tactile perception process within one system.

In this work, we developed a real-time and multimodal tactile sensing system, mimicking the function of cutaneous receptors and the transmission of tactile signals from receptors to the brain, by using multiple sensors, a signal processing and transmission circuit module and a signal analysis module. The proposed system is capable of simultaneously acquiring four types of decoupled tactile information within a compact system, thereby enabling differentiation between various tactile stimuli, texture characteristics, and consecutive complex motions. This skin-like three dimensional integrated design provides further opportunities in multimodal tactile sensing systems.

**8:30 AM SB05.08.03**

**Advancing High-Performance Printed Soft Mechanical Sensors Through Microstructure Control of Conductive Composites** Yi-Fei Wang, Ayako Yoshida, Yasunori Takeda, Tomohito Sekine, Daisuke Kumaki and Shizuo Tokito; Yamagata University, Japan

Soft mechanical sensors have emerged as highly desirable components for the next generation of biomedical devices, wearable electronics, and soft robotics [1]. Their inherent flexibility and stretchability enable seamless integration onto soft and irregular surfaces, empowering them with advanced sensing capabilities for a wide range of external mechanical stimuli. Recently, conductive composites have garnered significant attention in the research community as promising materials for soft mechanical sensors due to their cost-effectiveness, ease of processing, and the ability to tune their electromechanical performance [2]. A key aspect of achieving high-performance sensors lies in the effective control of the conductive composite's microstructure, as it directly impacts its electromechanical properties [3]. For instance, introducing microcracks in the conductive film significantly enhances its strain sensitivity, while constructing a conductive layer with a porous structure or micropatterning surface is commonly employed to achieve

high sensitivity in pressure sensors. However, previous approaches have often relied on complex material synthesis and expensive manufacturing processes, presenting scalability challenges and severely limiting their practical applications.

This report highlights our recent progress in materials design aimed at controlling the microstructure of conductive composites to realize high-performance printed soft mechanical sensors. We have developed a novel brittle-stretchable conductive network that generates controllable microcracks, resulting in high sensitivity to applied strain while maintaining a large working range [4]. This innovative approach successfully overcomes the trade-off between sensitivity and sensing range commonly encountered in stretchable strain sensors. We have also successfully formulated a novel printable ink by mixing PDMS, CB, and a deep eutectic solvent (DES). This ink spontaneously forms a microporous conductive architecture without the need for complex processing [5, 6, 7]. Leveraging this composite, we have achieved highly sensitive pressure sensors and low hysteresis stretchable strain sensors using straightforward manufacturing techniques. Furthermore, we have utilized thermally expandable microspheres to create irregular microdome surfaces, facilitating the easy fabrication of flexible printed pressure sensors with superior reliability and uniform performance. When compared to previous studies, our approaches offer significant advantages: (i) simple ink preparation without the need for complex materials synthesis; (ii) compatibility with printing technologies, ensuring superior scalability, patternability, and cost-effectiveness; and (iii) easy microstructure control in conductive composites, resulting in soft mechanical sensors with exceptional performance in terms of sensitivity, working range, reliability, and uniformity. We are confident that these achievements will provide valuable insights into materials design and microstructure control of conductive composites, thereby advancing their practical applications in the field of soft electronics.

**Engineering Flexible Electronics for Monitoring Epithelial Integrity *In-Vitro* and *Ex-Vivo*** [Sophie Oldroyd](#), Sarah Barron, David Bulmer and Roisin Owens; University of Cambridge, United Kingdom

Inflammatory bowel disease (IBD) is a widespread condition, with a forecasted prevalence of 1.1% by 2025 [1]. It presents with chronic symptoms such as abdominal pain and diarrhoea and is characterised by a leaky gut barrier, which has increased permeability due to changes in localisation of tight junction proteins [2]. However, a detailed understanding of the disease pathway is limited, and current methods of assessing gut tissue health *ex vivo* are impeding progress in the field. The techniques need re-designing in the modern era given advancements in technology. This work presents flexible bioelectronic devices that permit real-time recordings of changes in gut tissue. The ability to assess gut health in living tissue is important in establishing and monitoring phenotypes associated with gastrointestinal diseases.

All-planar conformable devices with multiple working electrode sizes (from 25 to 1000  $\mu\text{m}$ ) and an internal counter/reference electrode (CE/RE) were fabricated using previously developed techniques [3]. On the bottom, and between each of the layers, parylene C was used for insulation. Conductive tracks, outlines, and contact pads for the electrodes were formed using photolithography and gold deposition. Electrodes were coated with PEDOT:PSS, a conducting polymer used to increase volumetric capacitance. The electrodes were characterised by electrochemical impedance spectroscopy (EIS) and brightfield microscopy. *In-vitro* testing utilized a human colonic epithelial cell line, Caco-2. The cells were grown on Transwell® inserts and differentiated for 21 days. The ability of the device to measure barrier integrity, perturbations, and recovery in real-time was assessed via the transient addition of EGTA. The devices were tested *ex-vivo* on small intestine and colonic tissue from wild type-C57Bl6 male mice. Cell viability was confirmed with confocal microscopy and staining. Extracted transepithelial resistance values, based on simple equivalent circuit models, were confirmed against the gold standard methods for *in-vitro* and *ex-vivo*, using the EVOM3™ and Ussing Chambers respectively.

This work highlights the first instance of an all-planar flexible electronic device that can monitor epithelial barrier function and perturbations at the air liquid interface. The mechanical flexibility of the device allows for direct and conformable contact with biological surfaces, to provide a quantifiable electrical readout under physiological conditions. The multi-electrode design established a minimum electrode radius (400  $\mu\text{m}$ ) needed to capture the epithelial properties, and chemical disruption, of colon cell lines and mouse colon tissue. The sensing area achieved is one order of magnitude smaller than previously reported, highlighting the increased sensing efficiency of the design. The device achieves comparable sensitivity with a planar CE/RE compared to an external CE/RE. As this device was the first of its kind, readouts were validated against gold standard TEER measurements, which showed comparable trends with a reduction in measurement error. We confirm the device is biocompatible and does not negatively affect the barrier properties under study. Future work could look to apply this technology for spatially mapping local and real-time changes in epithelial barrier properties for toxicology and drug screening applications.

**Multimodal Flexible Fiber Antenna Sensor for Physiological and Environmental Sensing** [Merve Gokce](#)<sup>1</sup>, [Eilam Smolinsky](#)<sup>1</sup>, [Louis van der Elst](#)<sup>1</sup>, [Creasy Clauser Huntsman](#)<sup>2</sup> and [Alexander Gumennik](#)<sup>1</sup>; <sup>1</sup>Indiana University Bloomington, United States; <sup>2</sup>Cook Medical Technologies, United States

The real-time monitoring of a patient's health condition during medical operations is crucial to the patient's comfort, safety, and treatment success. While there are many advanced biomedical devices on the market that monitor various physiological parameters, they are limited with respect to sensitivity, accuracy, compatibility, and durability. It is vital to improve physiological monitoring limitations to minimize potential trauma, discomfort, and complications after surgery. Fiber device technology enables the designing of fiber-embedded sensors that provide higher sensitivity, accuracy, and spatial resolution through its complex cross-sectional geometry and material properties [1]. Thermally drawn polymer fibers offer high flexibility, durability, and better compatibility, making integrating fiber sensors into fabrics and biomedical devices easier [2]. Here we present the first sub-terahertz fiber antenna sensor capable of high spatial resolution, high sensitivity, and large dynamic range physiological monitoring and cyber-physical interfacing. The sensitivity and spatial resolution of the fiber sensor are high enough for practical operations such as integrating the flexible fiber sensor into medical devices. The fiber sensor monitors physiological and environmental signals in real-time, where the sensing

modality, either physiological or environmental, is defined by the electronics used to control the order of the mode coupled to the fiber sensor. While the high sensitivity of the fiber sensor is derived from its unique geometry, materials, and unique manufacturing approach [3], its spatial resolution results from the frequency decomposition of the reflected signal off the sensing point along the fiber and thus is the function of the operation bandwidth. Our multimodal flexible fiber sensor is a better candidate for improved monitoring of patients' well-being and better patient care than the current sensors used in minimally invasive operations. The application area of our fiber sensor is not limited to the biomedical field but also smart fabrics, cyber-physical and human-robot interactions, and environmental detections due to its ability to perform selective, multimodal measurements.

**Biomimetic Sequence-Templating Approach Towards a Multiscale Modulation of Chromogenic Polymer Material Properties** Yuyao Kuang, Ze-Fan Yao, Sujeung Lim, Catherine Ngo, Megan Rocha, Dmitry Fishman and Herdeline Ann Ardoña; University of California Irvine, United States

Polydiacetylene (PDA) is an established conjugated polymer material useful as a colorimetric indicator of environmental conditions, such as small molecule binding, mechanical force, heat, or solvent, for multiple sensing applications due to the structural dependence of their optical and electronic properties. With its emerging utility for biological applications, there is a critical need to develop PDAs that can be processed in the physiological-relevant environment with predictive structures and properties. Using sequence-tunable peptidic supramolecular interactions to template diacetylene monomer assembly offers a facile synthetic approach and enables a way to rationally influence PDA structure and properties via peptide sequence engineering. This presentation focuses on investigating the structural influences of peptide templating groups on PDA structures and functional properties across length scales by molecularly controlling the properties of peptide moieties through steric effects and hydrophobic interactions. In particular, a library of peptide-PDA conjugates with systematically varied dipeptide segments is established to demonstrate the influence of residue sterics, polarity, and position of substitution on multiscale PDA material properties. We show that steric effects predominantly influence the electronic structure and resulting trends in chain conformation-dependent photophysical properties. On the other hand, distinct trends were observed for bulk properties, such as film conductivity and cellular response to material interfacing. By tuning peptidic molecular volume and polarity, we exhibited a general increase in conductivity with smaller peptide molecular volume and higher hydrophobicity. The properties of peptide-PDA films suggest more interplay between residue size and hydrophobicity at larger length scales. In summary, this work provides new molecular-level insights on how sequence-tunable sterics and polarity can be used as a synthetic handle to rationally modulate multiscale structure-function correlations for peptide-PDAs as functional biomaterials. These findings pave the way for further developing sequence-defined programmable properties and complex behavior for peptide-PDAs, such as the adaptive evolution of their properties in response to living systems interfaced with these functional biomaterials in physiologically relevant environments.

**Biomaterials Strategies Towards Multimodal Neural Probes for Chronic Neural Recording, Chemical Sensing and Delivery** Xinyan T. Cui; University of Pittsburgh, United States

Microelectrode array (MEA) devices, placed in the nervous system to record and modulate neuroactivity have demonstrated success in neuroscience research and neural prosthesis applications. Functionalizing the microelectrode sites on MEAs to enable neurochemical sensing and delivery adds additional dimensions of information, and presents tremendous potential for understanding neural circuits and treating neurological diseases. In this talk, I will introduce the methods by which we enable chemical sensing and delivery from MEAs. By incorporating nanocarbon into the conducting polymer electrode coating, we achieved direct detection of electroactive species such as dopamine, melatonin, and serotonin. By immobilizing enzymes or aptamers on nanostructured electrodes, we achieved multisite detection of glutamate, GABA, and cocaine. By incorporating nanocarriers into conducting polymer coating, we enabled on-demand drug delivery. Multisite and multiple analyte detection or neurotransmitter delivery along with neural recording have been demonstrated with these MEAs. Chronic neural interface performance has been sub-optimum. Quantitative histology, explant analysis, and 2-photon imaging revealed biofouling, neuronal damage, inflammation, and oxidative stress at the site of implants, as well as material degradations. We use several bioengineering strategies to minimize these failure modes. First, materials and devices that mimic the mechanical properties of the neural tissue have been developed and shown to significantly improve device-tissue integration. Secondly, biomimetic coatings and drug delivery have been applied to reduce biofouling and inflammatory responses. These approaches may be combined to achieve long-term and high-fidelity multimodal neural interfacing.

**Magnetolectric Metamaterials and Miniature Bioelectronics** Jacob T. Robinson; Rice University, United States

Magnetic fields show very little absorption or reflection in bone and tissue, making these fields magnetic materials ideal as a transducer for bioelectronic systems. Here I will discuss how we can engineer the properties of magnetolectric materials to show electrical and optical properties not found in nature. With these magnetolectric metamaterials, we can rapidly control nerve impulses in rodent models for nerve injury and control the activity of engineer cells. Furthermore, magnetolectrics enables us to create highly efficient, miniature battery-free bioelectronic networks for cardiac and neural applications. Overall, engineering the material properties of magnetolectrics and magnetolectric metamaterials provides a route to multifunctional miniature bioelectronic networks.

#### 11:00 AM SB05.09.02

**Cell Mechanotransduction Driven by Bio-Organic Optoelectronic Devices** Vanessa Spagnolo<sup>1</sup>, Leonardo maver<sup>1</sup>, Johannes Gladisch<sup>2</sup>, Iwona Bernacka Wojcik<sup>2</sup>, Gabriele Tullii<sup>1</sup>, Eleni Stavrinidou<sup>2</sup> and Maria Rosa Antognazza<sup>1</sup>; <sup>1</sup>Istituto Italiano di Tecnologia, Italy; <sup>2</sup>Linkoping University, Sweden

Biophysical cues, especially mechanosensation, play a fundamental role throughout life, starting from early embryonic development over function and interplay of cells and tissues in the adult body up to regeneration processes. Tissue regeneration, which includes phenomena like cell division, differentiation, migration and expulsion is triggered by extracellular mechanical cues. The body's capability to regenerate decreases with age and therefore impacts our life in sometimes detrimental aspects.

Currently available tools to modulate or control mechanosensation often lack features necessary for *in vitro* and *in vivo* applications, in terms of efficiency, reliability, reversibility and spatial sensitivity. Here we show a novel approach to control mechanosensitive ion channels, through exogenous organic semiconductors. Materials in this class are fully biocompatible, thus offering the perspective for *in vivo* application, they can be easily processed in several forms, such as thin films, microstructured devices or nanoparticles. Most importantly, they are characterized by distinctive opto-electrical properties, providing excellent visible light responsivity, as well as electron and ion conductivity.

In this work we explore the opportunity to use organic semiconductors, and in particular conjugated polymers, to control the activation of mechano-sensitive ion channels, in a reliable and effective manner. We critically discuss results obtained with different tools, including polymer thin films and microstructured devices. In more detail, we present first examples, to the best of our knowledge, of devices based on conjugated polymers to activate PIEZO channels in mammal cells.

Our results may contribute to develop innovative smart materials for tissue regeneration and pathologies involving mechanosensation driven by physical cues.

**Monitoring Water Permeation in Flexible Bioelectronic Devices** Massimo Mariello and [Stephanie P. Lacour](#); Ecole Polytechnique Federale de Lausanne, Switzerland

Most bioelectronic interfaces call for long-term operation. Their formfactor requires new packaging strategies to ensure hermeticity, thinness and mechanical compliance. Inspired from display technologies, organic-inorganic multilayers are promising candidates to package thin, flexible and miniaturised bioelectronic devices. Besides the materials challenges associated with the choice of suitable thin films, stacking and deposition methods, quantitative evaluation of their barrier performance is a must. We have developed real-time monitoring methods of permeability or water transmission rate of thin film multilayers leveraging magnesium (Mg) degradation under physiological conditions. Water permeation drives Mg hydrolysis. Using Mg film electrical and electrochemical sensors prepared with thin-film microfabrication, embedded in bioelectronic interfaces, ultra-low detection of water permeation (as low as of  $3.3 \times 10^{-8}$  g/m<sup>2</sup>/day at room temperature) can be achieved. This method should provide useful information on novel encapsulation strategies for miniaturised, long-term bioelectronic implantable systems.

**Noninvasive Optogenetics to Study Brain-Body Circuits** [Ritchie Chen](#); University of California, San Francisco, United States

Viscerosensory signals, such as hunger pangs, pain, and a racing heart, shape our cognitive state and behavior. However, the neural basis that drives these adaptive behaviors remains poorly characterized, largely due to a lack of tools to map, record, and modulate specific cell types within a dynamically moving body. This presentation will highlight recent advances in optogenetics that enable noninvasive photoactivation of electroactive cell types in the body using external, distally placed light sources. I will demonstrate how these methods can be applied to manipulate cardiac physiology and establish causal roles of visceral cardiac signals in influencing anxiety-like behavior in mice.

**Nanoparticles for Wireless Magnetolectric Neural Modulation** [Ye Ji Kim](#), Noah Kent, Florian Koehler, Emmanuel Paniagua, Nicolette Driscoll, Marie Manthey and Polina Anikeeva; Massachusetts Institute of Technology, United States

Magnetic nanomaterials offer a minimally invasive alternative to invasive neuromodulation implants. A variety of magnetic nanomaterials have been developed to transduce physiologically benign magnetic signals (field-frequency product  $H \times f < 5 \times 10^8 \text{ Am}^{-1}\text{s}^{-1}$ ) to signals perceived by biological receptors including heat, mechanical stimulation, chemical release, and electric field. Magnetolectric nanomaterials composed of magnetostrictive (magnetic field to strain) cores and piezoelectric (strain to electric polarization) shells are particularly promising candidates for wireless transgene-free neuromodulation in deep-brain structures. Although strain-mediated magnetolectric (ME) materials have been shown effective for neuromodulation at the millimeter and micrometer scale, achieving efficient ME coupling at the nanoscale remains a challenge. Here we report a strategy for enhancing the strain-mediated ME coupling at the nanoscale. We synthesize core-double shell magnetolectric nanodiscs (MENDs) with  $\text{Fe}_3\text{O}_4$  -  $\text{CoFe}_2\text{O}_4$  -  $\text{BaTiO}_3$  architecture. In these nanodiscs, magnetostriction is enhanced through anisotropic shape and interfacial strain between  $\text{Fe}_3\text{O}_4$  and  $\text{CoFe}_2\text{O}_4$ , which collectively enable the generation of 30  $\mu\text{V}$  in  $\text{BaTiO}_3$  piezoelectric shell, which predicted numerically and measured experimentally via an electrochemical three-electrode cell. Although the electric field generated by individual MENDs is far below than the necessary potential change to reach the action potential threshold in neurons, we find that MENDs robustly evoke neural activity *in vitro* in the presence of a magnetic field. To explain this finding we propose a biophysical model of repeated neuronal depolarization based on cable theory and stochastic membrane potential fluctuations. Using the proposed model, we optimize the stimulation parameters *in vitro*, and then translate our approach to neuromodulation *in vivo*. Specifically, we show remote control of behavior in mice following 1.5  $\mu\text{L}$  MEND injections at 1 mg/mL concentration (~100 times lower concentration than previous studies involving nanomagnetic transduction regardless of mechanism). We offer a mechanistic approach for further refinement of magnetolectric neuromodulation at the nanoscale with the goal of empowering neurobiological discovery.

**Engineering a Biohybrid Neural Interface for Synaptic Deep Brain Stimulation** Léo Sifringer<sup>1</sup>, Alex Fratzl<sup>2</sup>, Stephan Ihle<sup>1</sup>, Parth Chansoria<sup>1</sup>, Jens Duru<sup>1</sup>, Blandine F. Clément<sup>1</sup>, Sinead Conolly<sup>1</sup>, Benedikt Maurer<sup>1</sup>, Christina M. Tringides<sup>1</sup>, Leah Mönkemöller<sup>1</sup>, Giulia Amos<sup>1</sup>, Sean Weaver<sup>1</sup>, Sophie Girardin<sup>1</sup>, Katarina Vulčić<sup>1</sup>, Simon Steffens<sup>1</sup>, Anna Beltraminelli<sup>1</sup>, Eylul Ceylan<sup>1</sup>, Srinivas Madduri<sup>3</sup>, Marcy Zenobi-Wong<sup>1</sup>, Botond Roska<sup>2</sup>, Janos Vörös<sup>1</sup> and [Tobias Ruff](#)<sup>1</sup>; <sup>1</sup>ETH Zürich, Switzerland; <sup>2</sup>IOB Basel, Switzerland; <sup>3</sup>University Geneva, Switzerland

Restoring functional vision in blind patients lacking a healthy optic nerve requires bypassing retinal circuits. This can be achieved by high resolution stimulation of the visual thalamus, which is located deep inside the brain and serves as the main input to cortical circuits underlying vision. However, available deep brain stimulation electrodes suffer from low stimulation resolution, limited biocompatibility and limited coverage of the targeted tissue. To overcome those limitations, we propose a novel living biohybrid neural interface with the goal of restoring functional vision in the blind without a healthy optic nerve. Our interface uses living on-chip grown retinal neurons as relays to convert electrical signals from a stretchable microelectrode array into synaptic stimulation of a neural target tissue.

Our interface is based on a stretchable micropatterned microelectrode<sup>[1,2]</sup> array onto which we align axon guiding microfluidic structures that enable unidirectional guidance and merging of axons to form an artificial optic nerve. We increase the biocompatibility of our device by replacing the Polydimethylsiloxane (PDMS) based nerve forming channel with a collagen or gelatin methacryloyl (GelMA)<sup>[3]</sup> tube that is only 300  $\mu\text{m}$  in diameter and directly integrated onto the PDMS device.

We demonstrate the seeding of retinal spheroids into our biohybrid devices using a modified fluid force microscope. The retinal ganglion cells form an artificial optic nerve up to 3mm long that can transit from the device into the PDMS-bound hydrogel tube to reinnervate a matrigel-based target structure in vitro. We show that we can stimulate individual retinal spheroids using our stretchable microelectrode array. We also present in vitro data on how spikes propagate within the biohybrid implant to modulate thalamic target activity using glass and CMOS<sup>[4]</sup> multielectrode arrays. Finally, we present first progress towards in vivo implantation.

#### 3:30 PM \*SB05.10.04

**Biohybrid Interfaces with Light-Sensitive Dynamic Polymers for Neuroelectronic Applications** [Francesca Santoro](#); Forschungszentrum Jülich/RWTH Aachen University, Germany

Bioelectronic platforms more and more aim to integrate into tissues and organs in a seamless way to monitor and eventually restore lost functionalities. This is particularly relevant for brain implants where the functional electrical connections can be restored by the use of functional electrodes to stimulate injured area due to pathologies such as neurodegenerative diseases. In this scenario, polymers have found a major use in the last decade to design and engineer organic biointerfaces<sup>1</sup> between electronics and brain cells also with their integration into soft flexible probes. However, existing platforms still lack: 1) 2.5-3D features to locally better anchor to the target area, 2) undergoing on demand mechanical plasticity which is greatly required because of micromovements and tissue reshaping over time and 3) materials which exhibit also electrical plasticity and not only conventional passive behavior to better enhance the ion-electronic transduction process which is at the core of the neuronal communication in the brain. Here, we will present how conjugated polymers can be engineered with azopolymers (opto-sensitive polymers which switch from cis to trans conformation upon certain light exposure) to feature diverse optoelectro-mechanical properties from nano to macroscale lever in organic bioelectronic platforms. In particular, we will discuss how azo-based materials can be patterned into 2.5-3D designs to locally couple to cells and thus dynamically tune the cell electrode interface over time<sup>2</sup>. Furthermore, these films can be further engineered with PEDOT:PSS to create dynamic organic electrochemical transistors (OECT, Figure 1) which also exhibit opto-electronic short and long term plasticity, enabling the use of such platforms as neurohybrid<sup>3</sup> devices. This new class of on demand organic opto-electronic devices<sup>4</sup> paves the way for bioelectronic implantable platforms to be more biomimetic as they can adapt to the 3D environment of the neuronal tissue and its continuous reshaping, also featuring neuromorphic electrical behavior.

**Hair-Compatible Sponge Electrodes Integrated on VR Headset for Electroencephalography** [Hongbian Li](#), Hyonyoung Shin, Minsu Zhang, Jose del R. Millán and Nanshu Lu; The University of Texas at Austin, United States

Electroencephalography (EEG) combined with virtual reality (VR) represents a promising method for the measurement of brain activity in an immersive and interactive environment, which can provide insights into cognitive and neural processes. However, current VR-EEG headsets mainly rely on rigid comb electrodes, which are uncomfortable after prolonged wear. To address this limitation, we created soft, porous, and hair-compatible sponge electrodes based on conductive poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS)/melamine (PMA), and integrated them onto a VR headset through a customized flexible circuit for multichannel EEG during VR task performing. Our PMA sponge electrodes can deform to make contact with the scalp skin through hairs under the pressure naturally applied by the strap of the VR headset. As a result, our VR-EEG headset is capable of recording alpha rhythms during eye-closure at both hairless and hairy sites. Furthermore, we developed a VR task to evoke the contingent negative variation (CNV) potential and achieved a classification accuracy of  $0.66 \pm 0.07$ . Our sponge-electrode-integrated VR headset is user-friendly and easy to set up, marking a step toward future reliable, comfortable, and reusable VR-EEG technology.

**A Flexible and Switch-Matrix-Addressable Active Electrode Array Based on Complementary Organic Electrochemical Transistor and p-n Diode Technology** Ilke Uguz<sup>1</sup>, David Ohayon<sup>2</sup>, Sophie Griggs<sup>3</sup>, Sahika Inal<sup>2</sup> and Kenneth L. Shepard<sup>1</sup>; <sup>1</sup>Columbia University, United States; <sup>2</sup>King Abdullah University of Science and Technology, Saudi Arabia; <sup>3</sup>University of Oxford, United Kingdom

Due to their effective ionic-to-electronic signal conversion and mechanical flexibility, organic neural implants hold considerable promise for biocompatible neural interfaces. Current approaches are, however, primarily limited to passive electrodes due to a lack of circuit components to realize complex active circuits at the front-end. Here, we introduce a p-n organic electrochemical diode (OED) using complementary p- and n-type conducting polymer films embedded in a 15- $\mu\text{m}$ -diameter vertical stack. Leveraging the efficient motion of encapsulated cations inside this polymer stack and the opposite doping mechanisms of the constituent polymers, we demonstrate high current rectification ratios and fast switching speeds. We integrate p-n OEDs with organic electrochemical transistors (OECT) in the front-end pixel of a recording array. This configuration facilitates the access of OECT output currents within a large network operating in the same electrolyte, while minimizing crosstalk and interference from neighboring elements. We further demonstrate it to generate time-division-multiplexed amplifier arrays. When fabricated in a shank format, this technology enables the multiplexing of amplified local field potentials directly in the active recording pixel in a minimally invasive form factor.

**4:30 PM SB05.10.07**

**Investigating the Effect of Photopharmacological Interventions on Cortical Seizures using Organic Perforated Multielectrode Arrays** Sofia Drakopoulou, Linta Sohail, Jeroen Spanoghe, Dina K.C., Robrecht Raedt and Georgios D. Spyropoulos; Gent University, Belgium

Epilepsy is a chronic neurological disorder characterized by recurrent seizures, affecting millions of people worldwide. Current treatment methods have limitations such as side effects and incomplete seizure control. One potential approach to address these challenges is by targeting the adenosine type 1 receptor, which is abundantly present in the body, for epilepsy suppression. However, it is important to note that this approach may introduce multiple undesired side effects such as dizziness, sleep disturbances, mood, cognitive, memory changes etc. Optopharmacology is an emerging approach for the treatment of focal epileptic seizures by activating and deactivating photoswitchable/photocaged molecules with light. It is a particularly interesting treatment solution which could result in powerful suppression of focal seizures with a limited number of side effects. In this work, we study the neural dynamics of epileptic networks (in rodent model) and the effect of timely photo-release of a caged adenosine type 1 receptor agonist (caged CPA; N6-cyclopentyladenosine) hereon. To achieve that, we had to develop: i) animal protocols with evoked epileptic seizures, ii) illumination protocols proper for photorelease of the novel caged CPA molecule, iii) efficient microelectrode arrays, to trace the corresponding electrophysiology, that can simultaneously offer large spatial epidural coverage and high signal to noise ratio without sacrificing resolution or hindering illumination and drug appliance. In more detail, we performed craniotomies on several subjects to place semitransparent microelectrode array based on organic electronics on dura and trace electrophysiology. To provoke focal random epileptic seizures 4 - Aminopyridine (4-AP) was microinjected in different areas of the rat brain through specifically designed perforation paths. Upon microinjection of caged CPA epileptic activity continued but when the brain was exposed to pulses of 405nm light for uncaging of cCPA, local epileptic activity was strongly attenuated. The results of this study provide a better understanding of propagation of 4AP induced seizures and confinement dynamics upon spatially resolved optopharmacological interventions. These findings are significant because they will positively impact the development of optopharmacological molecules and protocols, microelectrode arrays and therapeutic systems.

**4:45 PM SB05.10.08**

**Surface Modification with Biocompatible Polymer Conductors for Stable and Compliant Electrode Interfaces for Communicating with Neurons** Rachel Blau<sup>1</sup>, Abdulhameed Abdal<sup>2</sup>, Wade Shipley<sup>1</sup>, Yi Qie<sup>1</sup>, Allison Lim<sup>1</sup>, Samantha Russman<sup>2</sup>, Alexander X. Chen<sup>1</sup>, Guillermo Esparza<sup>1</sup>, Shadi Dayeh<sup>2</sup> and Darren J. Lipomi<sup>1</sup>; <sup>1</sup>University of California; San Diego, United States; <sup>2</sup>University of California San Diego, United States

Neural interfaces for recording or stimulating cells and tissues require long-term stability, mechanical compliance, low impedance, and high charge injection capacity. However, the mechanical mismatch between stiff metal electrodes (e.g., gold, platinum, and iridium oxide) and soft biological tissue poses a significant challenge, hindering optimal performance. To address this, conductive polymers have been used as an additional interface layer, with poly(3,4 ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) being a widely utilized material. While PEDOT:PSS offers good charge injection capacity and lowers impedance, its long-term stability when implanted in the body remains a bottleneck due to delamination, pH changes, charge injection, and immune responses.

In this work, we propose a chemical approach to enhance the adhesion between gold electrodes and PEDOT:PSS by covalently attaching the polymer to the gold surface, i.e., generating polymer brushes. We designed and synthesized polymer brushes made of block copolymer scaffold using a surface-initiated living radical polymerization (grafting-from). Our polymer brushes comprise a poly(styrenesulfonate) (PSS) block and a soft poly(polyethylene glycol methyl ether methacrylate) (PPEGMEMA) segment. This scaffold serves as a platform for polymerizing PEDOT, creating an adhesive and compliant interface with the brain tissue.

We successfully implemented this approach on a flexible microarrayed neural probe and evaluated its electrical charge transport and long-term stability for brain activity recording. The covalently attached polymer brushes significantly enhanced the adhesion between gold and PEDOT:PSS coating, addressing the challenges associated with delamination over time. The resulting interface exhibited improved long-term stability, and reduced impedance compared to traditional PEDOT:PSS-coated gold electrodes.

Our findings offer insights into the development of more reliable and efficient neuroprosthetic devices. By enhancing the stability of PEDOT:PSS coatings, we pave the way for improved neural interfaces with long-term functionality in neuroscientific research and clinical applications.

**5:00 PM SB05.10.09**

**Photosynthetic Microorganisms in Coffee-Based Photoelectrochemical Systems** Rossella Labarile<sup>1</sup>, Paolo Stufano<sup>1</sup>, Matteo Grattieri<sup>2,1</sup>, Maria Varsalona<sup>2,1</sup> and Massimo Trotta<sup>1</sup>; <sup>1</sup>Consiglio Nazionale delle Ricerche, Italy; <sup>2</sup>Università degli Studi di Bari Aldo Moro, Italy

Evidence collected in the last years indicates that the application of redox mediators in bioelectrochemical systems enhanced the electron transfer from microorganisms to anodes and from cathodes to microorganisms [1]. Some artificial redox mediators are expensive chemicals and are putatively toxic to the environment, so downstream removal techniques or biodegradable electron shuttles are highly desirable.

Coffee is one of the most consumed beverages in the world. As a direct consequence of the global coffee consumption, the wastes and byproducts generated along the entire value chain (from the agricultural production, through industrial transformation, until the brewing and the final user consumption) can enter in a circular development model for a sustainable society [2].

The use of photosynthetic bacteria for the valorization of waste produced by agricultural systems represents an eco-friendly, cost-effective, and socially acceptable agri-waste management technology [3]. Here, the versatile metabolism of photosynthetic purple non sulfur bacteria was exploited to develop bio-hybrid photoelectrochemical systems. The performance of poorly electroactive bacteria, such as *Rhodobacter sphaeroides* and *capsulatus* [4] were improved using green coffee extracts as effective mediators for extracellular electron transfer. Moreover, the preliminary results obtained by coupling such

system with bio-based carbon composite electrodes recently developed, pose the foundation for a new class of circular coffee-based photoelectrochemical systems.

**Engineering Extracellular Electron Transfer in *Escherichia Coli* for Microbial Electrochemical Devices** Mohammed Mouhib<sup>1</sup>, Melania Reggente<sup>1</sup>, Lin Li<sup>1,2</sup>, Nils Schuergers<sup>1,3</sup> and Ardemis Boghossian<sup>1</sup>; <sup>1</sup>École Polytechnique Fédérale de Lausanne, Switzerland; <sup>2</sup>Chongqing University, China; <sup>3</sup>Universität Freiburg, Germany

Microbes hold great potential for green electrochemical synthesis as well as bio-electricity generation from organic waste. The key to the successful development of microbial electrochemical devices lies in the ability of the microbes to transport electrons across their outer membranes. These devices thus often rely on the use of microbes known as exoelectrogens, which include bacteria that have evolved metabolic pathways that enable extracellular electron transfer (EET) to solid substrates for cellular respiration. While exoelectrogens demonstrate facilitated electron transfer with the electrodes of these devices, natural exoelectrogens are often restricted to utilizing a narrow range of substrates that limits their versatility for processing different organic wastes and electrosynthesizing a rich diversity of high-value chemicals. By contrast, non-exoelectrogenic microbes such as *Escherichia coli* that lack efficient EET pathways are host to rich metabolic reaction networks that can be more readily tailored for various applications using synthetic biology.

In this work, we biologically engineer *E. coli* for enhanced EET. To this end, we expressed different combinations of proteins from the natural exoelectrogen *S. oneidensis* MR-1, as well as *E. coli* native proteins to optimize EET of the bioengineered strain [1]. We further introduced biosynthesis pathways for redox mediators to facilitate EET [2]. The bioengineered strains show significant improvements in electron transfer rates, as confirmed through colorimetric reduction assays of soluble electron acceptors and electrochemical characterizations following electrode reduction. The improved EET demonstrated in this work paves the way for increasing the efficiency of existing *E. coli*-based electrochemical devices while opening the doors to new applications that benefit from the broad chemical repertoire of these microbes.

**Soft Device for Simultaneous Measurements of Contractility and Electrophysiology of Neuromuscular Tissue** Poppy J. Oldroyd<sup>1</sup>, Sophie Oldroyd<sup>1</sup>, Rajesh Makwana<sup>2</sup>, Gareth Sanger<sup>2</sup>, David Bulmer<sup>1</sup>, George G. Malliaras<sup>1</sup> and Roisin Owens<sup>1</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>Queen Mary University of London, United Kingdom

Biological tissues serve as rich sources of electrical and mechanical signals that offer valuable insights into their function, disease conditions, and metabolic activity. However, certain neuromuscular tissues, such as those in the gastrointestinal (GI) tract, can undergo significant conformational changes when physiologically active. These tissues have received limited research attention due to challenges faced by rigid probes in conforming to their dynamic surface, which can experience strain levels of up to 40%. Conventional inextensible devices cannot capture the relationship between electrophysiological and mechanical responses of these tissues. This hinders the acquisition of crucial neuromechanical information in the gastrointestinal system, essential for understanding GI homeostasis and the connections between the enteric and central nervous systems.

To address these challenges, this study introduces bimodal electrodes made from poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) and polydimethylsiloxane (PDMS) that enable simultaneous monitoring of electrical and mechanical responses of gut tissue. PEDOT:PSS demonstrates long-term stability and outperforms metal electrodes that delaminate, crack, and degrade over time. PDMS, used as a substrate and insulation material, shows promise due to its superior intrinsic strain properties surpassing popular polymers like polyimide and parylene C.

In contrast to traditional electrode fabrication methods, this work utilizes shadow masks and solution-processable spin coating techniques, resulting in a faster and simpler fabrication process. To optimize the spin coating of PEDOT:PSS on PDMS, Capstone FS-300 was added for stability and film homogeneity. Polyethylene glycol (PEG) was incorporated to maintain electrical conductivity during stretch, enabling mechanical monitoring. The PEG concentration can be adjusted to tune the device's electrical sensitivity to strain changes. A low PEG concentration improves sensitivity to smaller strains for measuring spontaneous contractions, while a higher concentration makes the device strain insensitive for pure electrophysiology data. The PDMS-PEDOT:PSS-PDMS devices exhibit reduced delamination and cracking during accelerated aging compared to metal-based and parylene C devices. The device was validated on *ex vivo* mouse and human gastrointestinal tissues. The device successfully monitored muscle electrical activity and motility. During induced propulsive movements through the mouse small intestine, the device recorded electrophysiological voltage amplitude changes ranging from 2.1 to 3.5 times, corresponding to the strength of the contraction. These voltage changes were temporally correlated with resistance variations resulting from mechanical propulsion. The signals observed from the human stomach were similar in nature to those observed when monitoring the mouse small intestine, highlighting the variety of *ex vivo* applications of the devices and ability to detect signals in relatively thick (human) and thin (mouse) tissues. Furthermore, the ability to wrap the electrode system around a small diameter tissue as well as affixing it to a flat surface demonstrates the adaptability of device.

In conclusion, the presented bimodal tissue monitoring device integrates soft, flexible, and stretchable electrodes using thin PDMS and PEDOT:PSS layers doped with PEG and Capstone. Its electrical sensitivity to strain can be finely tuned for specific applications by adjusting the dopants in the PEDOT:PSS. The device's flexibility and stretchability make it suitable for monitoring gastrointestinal function, including motility and electrical activity, as demonstrated on mouse small intestine and human stomach tissue. It has the potential to provide clinical insights into complex disorders like irritable

bowel syndrome and gastroparesis.

#### 8:15 AM SB05.11.02

**Modular Skeletal Muscle Biohybrid Robots: Creation & Multi-Unit Assembly of Functional Muscle Building Blocks** [Aiste Balciunaite](#)<sup>1</sup>, Oncay Yasa<sup>1</sup>, Miriam Filippi<sup>1</sup>, Niklas König<sup>2</sup> and Robert K. Katschmann<sup>1</sup>; <sup>1</sup>ETH Zürich, Switzerland; <sup>2</sup>Xolo GmbH, Germany

The emerging field of biohybrid robotics aims to create the next generation of soft and sustainable robots by using engineered biological muscle tissues, integrated with soft materials, as actuators. Alongside robotics, such biohybrid muscles will also find biomedical applications in prostheses and drug development and screening. Current skeletal muscle tissue-based robots are powered by bulk-grown 3D configurations of muscle tissue (e.g., blocks or ring-like tissues). The size of these constructs is restricted to the sub-cm scale due to biofabrication constraints and limited nutrient perfusion. Further, lack of internal topography within bulk constructs results in poor control of myofiber formation and thus low contraction force. Therefore, to generate larger biohybrid constructs capable of complex motion while avoiding the issues of bulk muscle tissue manufacture, we have developed a bottom-up fabrication approach based on the assembly of muscle building blocks into designs that exploit the characteristics of the single actuators to form a multi-unit configuration. We created the muscle building blocks by integrating thin layers of muscle-cell laden hydrogels onto hydrogel-based exoskeletons characterized by material properties and microtopographic patterns that enhance muscle tissue development (i.e., microgrooves). Our thin cell-laden hydrogel layers allowed nutrient diffusion throughout the layer, and we incorporated microtopography with a layer-by-layer approach.

We used a novel linear volumetric printing technique, named xolography, to form the hydrogel exoskeletons (< 1 mm x 5 mm x 8 mm). Adapting xolography for aqueous hydrogel printing allowed us to take advantage of the quick speed, high resolution, and achievable geometric complexity of the technique. We printed exoskeletons with different mechanical properties by combining polyethylene glycol diacrylates with gelatin methacryloyl, e.g. 15% PEGDA700 and 5% GelMA (P700/GelMA, Young's Modulus 140 kPa) and 15% PEGDA575 and 5% GelMA (P575/GelMA, Young's Modulus 270 kPa). The exoskeletons featured microgrooves of 100 – 300 µm in width to guide formation of uniaxially oriented myofibers. To stably integrate the exoskeletal and the cellular hydrogels, we developed a Matrigel, collagen, and gelatin methacrylate-based cellular hydrogel that, when seeded with myoblasts, allowed for both contractile myofiber formation and effective cross-linking with the exoskeletal hydrogel, as shown via confocal and brightfield imaging and histological analysis.

Directionality analysis of confocal microscopy images of samples stained to visualize myofibers (F-Actin) showed uniaxial alignment in the channel direction with a standard deviation of 10°-20°. The structural deformation of these constructs caused by the contraction via electrical stimulation of their muscle tissue component depended on the exoskeleton composition. Constructs based on P700/GelMA contracted 4% in the direction of myofiber contraction, while constructs based on P575/GelMA contracted <1%. Finally, to form modular multi-unit biohybrid robots with predictable motion abilities, we assembled the muscle building blocks by cross-linking the residual unreacted acrylate groups in the PEGDA/GelMA exoskeletons under UV irradiation.

In conclusion, we developed a method that builds biohybrid robots by the assembly of muscle building blocks with tunable mechanical properties and actuation performance. We have reduced the complexity and increased the predictability of biohybrid muscle fabrication, thus unlocking the potential of engineered muscle tissue as an actuating technology.

#### 8:30 AM SB05.11.03

**Integration of Laser-Induced Graphene Strain Gauges and Stimulation Electrodes into 3D Muscle on a Chip Devices** [Anastasia Svetlova](#), Abdulrahman Al-Shami, Ali Soleimani, Hui Tung J. Law, Riya Verma, Stephanie Do, Samuel Kohan, Raymond A. Peck, Maral Mousavi, Gerald E. Loeb and Megan L. McCain; University of Southern California, United States

The emerging technique of direct laser carbonization of polymers to convert them into conductive graphene foam has opened new possibilities for prototyping and fabrication of electronic devices. For example, polyimide (PI) undergoes a photothermal conversion into a 3-dimensional (3D) carbon foam called laser-induced graphene (LIG). This technically simple procedure can be implemented for the photolithography-free fabrication of electronic devices in the absence of a cleanroom, with faster turnover of prototypes, and at a lower cost. The technique has similar spatial resolution to inkjet printing but is more straightforward in implementation.

Muscle on a Chip models have been developed to gain insight into disease mechanisms from the molecular to the tissue scale and test new therapies. Systems that engineer muscle tissue in 3D bundles are especially beneficial for inducing more physiologically relevant tissue architecture. 3D muscle bundles are commonly fabricated by injecting a mixture of muscle cells and hydrogel into an elongated chamber with two flexible anchors. The muscle cells compact into an aligned 3D bundle that mimics native muscle tissue. The flexible anchors are embedded into the tissue during compaction and deflect with muscle contractions. However, the conventionally used method to evaluate muscle contractions by optically monitoring the anchors has low throughput, and limited options for continuous monitoring. To overcome these bottlenecks in Muscle on a Chip systems, we integrated LIG electrodes in our devices. Based on the same engraving technique, we fabricated electrodes for the electrical stimulation and the contractility measurement.

To fabricate LIG on PI films (LIG-PI), we used an Epilog Mini laser engraver equipped with a CO<sub>2</sub> 10.6 µm wavelength laser with maximum power of 30 W. By engraving patterns as an array of raster dots or overlapping vector "lines", and varying laser power and speed, we obtained LIG layers with sheet resistance from 120±17 Ω/sq to 32±4 Ω/sq.

This electrode demonstrated a charge injection capacity in the range of 0.2 mC/cm<sup>2</sup> for cathodic and 0.1 mC/cm<sup>2</sup> for anodic current pulse. Stability of the material after thousands of stimulation pulses was confirmed by measuring Ferricyanide-ferrocyanide oxidation/reduction currents in cyclic voltammetry and calculating the electrochemically active surface area.

We transferred LIG foam into polydimethylsiloxane (PDMS) films by pouring liquid PDMS on LIG-PI, curing it until solid, and peeling off the PI film. This created a stretchable PDMS film embedded with LIG foam (LIG-PDMS), the conductivity of which responded to the stress applied to the layer. We demonstrated that LIG-PI and LIG-PDMS were not toxic by culturing HL-1 cardiomyocyte-like cells on the materials for 1 week.

To fabricate the strain gauge, we engraved LIG in a serpentine line pattern on PI films and transferred it onto PDMS. We further shaped this layer by laser cutting excess PDMS to create flexible anchors for the 3D tissue device, which should change resistivity upon deflection caused by the contracting muscle. To fabricate muscle chambers, we replica molded top and bottom pieces of PDMS from templates 3D printed in a Digital Light Processing printer. After 7 days of culture required for tissue compaction, LIG-PI stimulation electrodes were used to induce contractions of a primary muscle bundle at 2 Hz (twitch) and 20 Hz (tetanus).

We plan to use the developed device to evaluate physiological responses of two tissue models: healthy and diseased cardiomyocytes derived from human induced pluripotent stem cells, and primary skeletal muscle cells with continuous electrical stimulation and monitoring of muscle maturation.

#### 8:45 AM SB05.11.04

**Development of a Biohybrid Tendon Interface for Muscle-Powered Robots** [Nicolas Castro](#); Massachusetts Institute of Technology, United States

**Introduction:** Unlike abiotic materials like metal and plastic, biotic materials can communicate with their surroundings, adapt to stimuli, and self-repair

damage. Incorporating these materials into engineered systems could foster smarter, more adaptable machines. We have shown that engineered skeletal muscle stretched around a flexible elastomer 'skeleton' can generate force and drive locomotion. Since these locomotive robots are powered by 'living' actuators, they can strengthen with exercise and heal from damage, capabilities not possible with abiotic systems [1]. However, the interface between biotic (muscle) and abiotic (skeleton) components in our robot is driven by friction, leading to slippage and inefficient force transmission. In the body, muscle is covalently tethered to the skeleton via tendons, which efficiently transmit force. Thus, we have developed a synthetic tendon to act as a biohybrid interface, enabling the design of more modular, efficient, and adaptive biohybrid machines.

**Methods:** We developed an adhesive tendon in collaboration with Professor Xuanhe Zhao's lab at MIT. It is composed of a poly(acrylic acid) hydrogel functionalized for tissue adhesion with N-Hydroxysuccinimide ester groups. To characterize the interface between synthetic tendon and muscle, we performed tensile tests on differentiated and undifferentiated muscle samples (n=3) bound to the synthetic tendon. Muscle samples were manufactured from C2C12 mouse myoblasts. Cell populations were seeded into a fibrin and matrigel matrix, then cast into polydimethylsiloxane molds. Tensile tests were performed by layering muscle between two pieces of tendon, and pulling the assembly apart until interface failure was observed. To understand the effect of the synthetic tendon on cell viability, a colorimetric MTS assay was performed, along with a pH exposure test. Absorbance readings were taken at 490nm from control and experimental C2C12 myoblast cultures that had been incubated with synthetic tendon overnight (n=3). pH readings were probed at 0 and 30 minutes of control and experimental samples of DMEM culture medium that had also been exposed to the synthetic tendon (n=3).

**Results and Discussion:** Our experiments demonstrated that differentiated muscle had a greater mean force-at-break value (~680mN) than undifferentiated muscle (~520mN) at their interfaces, although this difference was not statistically significant. Both values are magnitudes greater than the mean contractile force generated by our muscle actuators (~300uN) [1], indicating that the interfacial strength far exceeds our target metric and that the muscle-tendon assembly should remain intact over multiple cycles of use. We also observed no statistically significant difference in cell viability from absorbance readings or media pH in response to tendon exposure, indicating biocompatibility. Furthermore, current preliminary tests evaluating the tendon-skeleton interface indicate a robust connection as well, asserting that the whole biohybrid assembly should be resilient to repeated use. We are also now quantifying the improvement in force transmission efficiency enabled by the interface, increasing the performance of our muscle bioactuators.

**Conclusion:** We have developed a hydrogel tendon that serves as a robust biocompatible musculoskeletal interface. The unconstrained nature of this innovation will enable the design of novel robotic architectures capable of functional applications like walking, swimming, pumping, and gripping that were previously not possible to manufacture. We also anticipate our biohybrid interface will advance the fundamental understanding of how passive tension generated by tendons guides muscle fiber alignment during growth and in response to injury. Our work sets the stage for fabricating next generation biohybrid robots that can dynamically adapt to the unpredictability of the real-world.

**Electrically Conductive Nano-Biomaterials and Wirelessly Powered Cell Stimulator for Engineering and Controlling Biohybrid Soft Robots** Su Ryon Shin; Harvard Medical School, United States

Engineered living-synthetic systems possess functions to dynamically control their shape and movements in biological environments that are pertinent to various biomedical applications, such as building biorobots and artificial muscles. To create functional bio-hybrid systems, in vivo-like living natural components such as 2D and 3D muscle tissue constructs, and their contractile function are required to be integrated into artificial platforms. Among various biomaterials, electrically conductive nanoparticles-incorporated hydrogels, which can improve the nanofibrous morphology and electrical and mechanical properties of conventional hydrogels while maintaining the hydrogels' beneficial properties, such as high porosity, biocompatibility, and biodegradability, are required to develop scaffolds mimicking biological and physical properties of native extracellular matrices (ECMs). These nanofibrous and electrically conductive scaffolds showed excellent myofiber maturation and organization along with cell-cell junction formation, providing self-actuating motions. Also, these nano-biomaterials can be engineered by various microfabrication techniques (i.e., bioprinting) to create 3D complex architectures, such as accordion-inspired hydrogel-based scaffolds which replicated the native myofiber architecture together with its function in terms of robustness and enhanced contractibility after culturing with cardiomyocytes. Recently, the maneuvering of bio-hybrid soft robots has been controlled by various strategies, such as by electrical and optical stimulations. We have developed advanced technologies to control the biohybrid soft robots by integrating flexible microelectrodes into soft and deformable engineered scaffolds to stimulate muscle actuators locally. Harnessing wireless power transfer technology without requiring batteries and wires, we developed untethered biohybrid soft robots that could swim; whereby, the steering of this swimming motion could be remotely controlled by transmitting electrical power into a cell simulator wirelessly. To this end, wirelessly powered, stretchable, and lightweight cell stimulators were successfully integrated into self-actuating soft muscle bodies without impeding the robot's underwater swimming ability. Wirelessly modulated electrical frequencies enabled us to control the speed and direction of the biohybrid soft robots. This innovative approach should provide a platform for building untethered biohybrid systems for various biomedical applications.

**Living Diatom Microalgae as Robust Bioanodes for Biophotovoltaic Devices** Cesar Vicente-Garcia<sup>1</sup>, Gabriella Buscemi<sup>1</sup>, Danilo Vona<sup>1</sup>, Roberta Ragni<sup>1</sup>, Matteo Grattieri<sup>1</sup>, Francesco Milano<sup>2</sup> and Gianluca Maria Farinola<sup>1</sup>; <sup>1</sup>University of Bari, Italy; <sup>2</sup>CNR-ISPRA, c/o Campus Ecotekne, Italy

Biophotovoltaic devices are a promising source of renewable energy, given they can generate electrical current from the photosynthetic activity of microalgae, cyanobacteria, or their isolated proteins. Different strategies such as direct electron transfer or, more commonly, the use of soluble mediators allow to directly harvest electrons from the cells of photosynthetic organisms and feed them to a closed circuit to generate current. Green microalgae have been extensively studied for the extraction of photocurrent, yielding promising outputs, mainly thanks to their ease of culture and fast growth.

Alternatively, only a few examples are present in literature about the use of Diatom Microalgae for photocurrent extraction. Besides providing significant photocurrent intensities, diatom microalgae exhibit particular resistance to different kinds of stressors such as desiccation, temperature and mechanical pressure, which comes as an advantage when it comes to processing them into living bioandoes. Their sensibility to different contaminants makes them good candidates for the development of electrochemical biosensing devices. Moreover, diatoms hold the unique characteristic of bearing nanostructured biosilica microscopic shells (frustules), that can be functionalized with active molecules or polymers, opening the door to enhancing electron flow through conductive polymers, or to light absorption modulation for example via introduction of external antennae. This work aims to study the photocurrent extraction from different species of diatom microalgae deposited onto ITO, used as working electrode in a photovoltaic cell, evaluate their interaction with the electrode both in the presence and absence of a soluble mediator, and their resistance to the electrochemical process itself. Cyclic voltammetry and chronoamperometry measurements have been performed; optical and fluorescence microscopies, and metabolic assays have been used to study the microalgae's state under the different conditions studied. We have standardized a method that allows to produce bioanodes resistant to desiccation from several different species of diatoms, that provide significant levels of power output, and are more resistant to repeated cycles of desiccation/photocurrent than a model green alga.

#### 10:45 AM SB05.12.03

**Polymer-Modified 3D Electrode Interfaces for Efficient Charge Extraction from Photosynthetic Microorganisms** [Rachel Egan](#)<sup>1</sup>, Jonas Honacker<sup>2</sup>, Joshua Lawrence<sup>1</sup>, Linying Shang<sup>1</sup>, Laura Wey<sup>3</sup>, Bartek Witek<sup>1</sup>, Nicolas Plumeré<sup>2</sup>, Erwin Reisner<sup>1</sup> and Jenny Zhang<sup>1</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>Technical University of Munich, Germany; <sup>3</sup>University of Turku, Finland

Cyanobacteria are abundant photosynthetic microorganisms that can be interfaced with electrodes in semi-artificial photosynthetic systems for solar-electricity or solar-fuel generation. [1] This approach relies on the ability of the living organisms to exchange electrons efficiently with the electrode. Redox-active and conductive polymers may be introduced at the cell-electrode interface to improve charge transfer efficiency by providing a direct route for electrons to reach the electrode thus overcoming sluggish diffusional kinetics. At present, the polymer properties that are key for efficient wiring of cyanobacteria to electrodes are poorly understood.

In this study, we systematically tested and compared the capacity of a common osmium-based redox polymer (P<sub>Os</sub>) and the conductive polymer poly(3,4-ethylenedioxythiophene) (PEDOT) to act as a wiring tool for *Synechocystis* sp. PCC 6803 on hierarchically-structured inverse opal indium tin oxide (IO-ITO) electrodes. By using stepped chronoamperometry and normalising photocurrents against cell loading, we were able to identify the conditions under which each polymer served only as an immobilisation matrix, enhancing the photocurrent by means of increasing the cell loading rather than by mediation. The contribution of various parameters including polymer type (redox vs conductive), deposition method (dropcasting vs electropolymerisation), deposition geometry (layered vs mixed), polymer morphology and polymer loading towards optimal photocurrent outputs were deconvoluted. Increasing the polymer loading in both cases led to an enhanced mediation effect up until a to a certain point when photocurrents were reduced presumably by a shading effect. This problem was overcome by changing the electrode geometry to micropillar ITO electrodes in which the light path can penetrate through the structure unimpeded. We also investigated the interaction of the polymer with a *Synechocystis* mutant lacking extracellular polymeric substances (EPS). The PEDOT-modified electrodes produced higher photocurrents overall vs the P<sub>Os</sub>-modified electrodes (20-fold vs 5-fold enhancement respectively) relative to unmodified electrodes at a low light intensity of 1 mW cm<sup>-2</sup>. However, the larger photocurrents extracted using PEDOT come at a thermodynamic cost, as the onset potential for mediation is 200 mV higher for PEDOT than for P<sub>Os</sub>. Overall, this study identifies polymer properties that are essential for successful cyanobacteria-electrode wiring and informs future interface design strategies for photosynthetic organisms on complex 3D structures.

**Nanomaterial and Biological Engineering of Living Electronics** [Ardemis Boghossian](#); EPFL SB ISIC LNB, Switzerland

The vast expansion of available synthetic biology tools has led to explosive developments in the field of materials science. The increased accessibility of these tools has pushed the frontier of materials science into the field of engineering biological and even living materials. By coupling the tunability of nanomaterials with the prospect of re-programming living devices, one can re-purpose biology to fulfil needs that are otherwise intractable using traditional engineering approaches.

Optical technologies in particular stand to benefit from the untapped potential in coupling the optical properties of nanomaterials with the specificity and scalability of biological materials. This presentation highlights applications in sensing and energy technologies that exploit the synergistic coupling of nanobio-hybrid materials. This talk will focus on the development of living electronics, such as photovoltaics based on photosynthetic organisms with augmented capabilities.

**Photosynthetic Microorganisms for Optoelectronics** [Gianluca Maria Farinola](#); Università degli Studi di Bari Aldo Moro, Italy

Photosynthetic microorganisms and their molecular components for light absorption and photoconversion, optimized over billions of years of evolution, represent attractive tools for harvesting and conversion of solar light in sustainable and cost-effective transducers. The new era of biohybrid devices relies on the exploitation of isolated structures from these microorganisms, or the entire living cells, as the active components for photoconversion in optoelectronic devices and photoelectrochemical cells [1].

The bacterial reaction center (RC) extracted from the purple non-sulphur bacterium *Rhodobacter (R.) sphaeroides* has been initially modified by covalent functionalization with organic molecules specifically designated to act as artificial antennas to increase its light absorption capability [2].

The same RC has been also integrated into photoactive transistors [3], using molecular or polymeric semiconductor thin films deposited onto metal electrodes as interfaces [4]. Among them polydopamine (PDA), a biocompatible polymer produced *via* self-oxidative polymerization of the dopamine

monomer, gave very interesting results for the stabilization of *R. sphaeroides* RCs. RC has been immobilized both in PDA thin films on the electrode surfaces or in PDA nanoparticles, without altering the enzymatic photoactivity, and producing photocurrents in photoelectrochemical cells [5]. PDA has been modified with diamines, leading to more transparent nanostructures incorporating RC molecules, which outperform RC/PDA structures in light transmission and photoconversion [6].

Finally, we have been investigated different approaches for interfacing intact photosynthetic microorganisms with electrodes, enabling photoconversion of whole living cells of *R. sphaeroides* and *R. capsulatus*, using PDA as the interface material either as a coating on the cells' surface, or as a film entrapping the cells on the electrode surface [7].

Furthermore, eukaryotic diatoms have been also selected for their efficiency in harvesting and converting sunlight into chemical energy and the feasibility of silica shell functionalization. Electrochemical characterizations have been performed to understand the electronic transfer between diatoms and electrodes, using different redox mediators.

## 2:00 PM SB05.13.02

**Polydopamine-Coated Photoautotrophic Bacteria For Improved Extracellular Electron Transfer in Living Photovoltaics** [Melania Reggente](#)<sup>1</sup>, Charlotte Roullier<sup>1</sup>, Mohammed Mouhib<sup>1</sup>, Rossella Labarile<sup>2</sup>, Massimo Trotta<sup>2</sup>, Fabian Fischer<sup>3</sup> and Ardemis Boghossian<sup>1</sup>; <sup>1</sup>École Polytechnique Fédérale de Lausanne, Switzerland; <sup>2</sup>CNR-IPCF Consiglio Nazionale delle Ricerche, Switzerland; <sup>3</sup>HES-SO Valais-Wallis, Switzerland

Living photovoltaics represent a growing class of microbial electrochemical devices based on whole cell–electrode interactions able to convert solar energy into electricity. The bottleneck in current microbial electrochemical technologies is the limited electron transfer between the microbe and the electrode surface. This study focuses on the development of a polydopamine (PDA) coating on the outer-membrane of the photosynthetic organism *Synechocystis* sp. PCC6803. This encapsulation provides a conductive shell to enhance electrode adhesion and improve microbial charge extraction. Cell encapsulation was obtained through an oxygenic dopamine (DA) polymerization in slightly alkaline conditions and the effect of two pH levels (7.5 and 8.2) were examined. PDA-coated cells were characterized and optimized using scanning and transmission electron microscopy (SEM and TEM, respectively) as well as confocal microscopy, UV-Vis and Raman spectroscopies. The microbial exoelectrogenicity was assessed through chronoamperometric measurements. PDA-coated microbes showed three-fold enhanced electron transfer with retained viability and photosynthetic activity.

**Engineered Living Electronic Interface** [Claudia Tortiglione](#)<sup>1</sup>, Giuseppina Tommasini<sup>2,1</sup>, Mariarosaria De Simone<sup>1</sup>, Silvia Santillo<sup>1</sup>, Marika Ienharelli<sup>1</sup>, Gwennaël Dufil<sup>3</sup>, Daniele Mantione<sup>4</sup>, Natalia Dell'Aversano<sup>1</sup>, Eleni Stavrinidou<sup>3</sup> and Angela Tino<sup>1</sup>; <sup>1</sup>Istituto di Scienze Applicate e Sistemi Intelligenti, Consiglio Nazionale delle Ricerche, Italy; <sup>2</sup>Instituto de Nanociencia y Materiales de Aragón (INMA), Spain; <sup>3</sup>Linköping University, Sweden; <sup>4</sup>University of the Basque Country UPV/EHU, Spain

Cells can be considered as nanomaterial factories able to build structures of amazing complexity starting from a few molecular building blocks. The introduction into the cell of an exogenous chemical input may result in the fabrication of hybrid materials with unique functionalities, that can be exploited for diverse applications (from biomedicine to bioelectronics). We exploited this potential in a simple tissue-like organism, the freshwater polyp *Hydra vulgaris*, shown able to produce electronically conductive interface starting from thiophene based compounds. By simply incubating living polyps in a solution containing organic semiconductor oligomers the spontaneous polymerization into microstructures presenting electronic conductivity and electrochemical capacitance was observed[1]. In addition, for the first time their neuromodulatory function was demonstrated by behavioral and electrophysiological approaches. Here we provide an overview of recent results obtained by challenging Hydra with different chemical inputs and envisage the possibility of manufacturing living electronics, acting as highly performant electrodes to monitor and control important processes, from development to regeneration. These interfaces, seamlessly integrated into the cells and naturally evolving with the polyp life cycle, overcoming the issues of tissue-interface mismatch, adverse cell response, and low biocompatibility, suggest the possibility of augmenting electronic functionality in animals and the fabrication of a new class of engineered living materials.

**Controlling the Properties of Macroscopic Living Materials by Genetically Altering Their Matrix** [Esther Jimenez](#), Carlson Nguyen and Caroline Ajo-Franklin; Rice University, United States

Living cells assemble into hierarchical structures, forming complex materials with remarkable properties. Inspired by nature, the emerging field of Engineered Living Materials (ELMs) aims to predictively design cells to grow into materials with tailored properties. Contributing to this goal, our lab has recently reported the first Bottom-Up *De novo* Engineered Living Materials (BUD-ELMs) using the bacterium *Caulobacter crescentus*. BUD-ELMs are comprised of a secreted protein matrix consisting of surface-layer protein and an elastin-like polypeptide (ELP) domain that assembles cells into centimeter-scale materials and defines their mechanical and physical characteristics. However, a fundamental knowledge gap we have yet to address is

understanding how genetic modifications affect bulk material characteristics. Thus, our goal is to elucidate sequence-structure-property relationships of BUD-ELMs to achieve predictive design for targeted mechanical properties. We hypothesized that the mechanical properties of the purified ELPs, which are known to be tunable as a factor of sequence length, would be mimicked in BUD-ELMs. Therefore, to test this hypothesis, we engineered strains expressing ELPs of different lengths, grew the strains to form BUD-ELMs, and characterized each material's viscoelastic behavior by rheology measurements. Our frequency sweep results show that shortening the ELP increases the storage and loss moduli, showing stiffer resulting material, while lengthening the ELP does not affect the moduli. Interestingly, flow sweeps show strong shear-thinning under low shear rates, implying a fragile microstructure network among all the resulting materials from each strain. Additionally, to elucidate the relationship between each material's mechanical properties and microstructure, we employed confocal microscopy. The results show clear differences in each variant's matrix structure. The shorter ELP variant produces spiderweb-like strands over the cells, while the longer ELP sequence forms thinner fiber-like strands between cells. Based on this data, we attribute the changes in this material's mechanical properties to the interconnected network formed by the matrix of the shorter ELP. In comparison, the thin fiber-like strand formation formed by the longer ELP does not impact its rheological characteristics. Furthermore, the different structures produced by each material result in distinct yield stresses. Thus, this exploration into the genetic tunability of BUD-ELMs leads us toward establishing sequence-structure-property relationships for ELMs with programmable mechanical and structural properties for applications such as 3D printing and tissue engineering.

### 3:30 PM SB05.13.06

**Motile Microorganisms in Intelligent Biohybrid Microrobots: Enhancing Propulsion, Control and Therapeutic Capabilities with Microalgae and Bacteria** [Birgul Akolpoglu](#)<sup>1,2</sup>, Saadet F. Baltaci Demir<sup>1,3</sup> and Metin Sitti<sup>1,2,3</sup>, <sup>1</sup>Max Planck Institute for Intelligent Systems, Germany; <sup>2</sup>ETH Zürich, Switzerland; <sup>3</sup>University of Stuttgart, Germany

Biohybrid microrobots incorporate motile microorganisms and artificial components to construct self-powered devices capable of sensing, control, targeting, and delivery at small scales. The integration of such motile microorganisms including microalgae, bacteria, spermatozoa or macrophages as the biological component, combined with artificial components such as polymer coatings, liposomes, and micro- and nanoparticles, enhances the functionalities of biohybrid designs. The careful selection of both biological and artificial units is essential in the design of biohybrid microrobots, as the biological component plays a pivotal role in propulsion, control, and sensing, while the artificial component influences crucial aspects such as biocompatibility, biodegradability, and therapeutic capabilities. However, existing design strategies for biohybrid microrobots encounter challenges concerning low production efficiencies, limited multifunctionality and control over swarm navigation. To overcome these limitations, we propose and conceptualize a range of biohybrid microrobotic designs achieved through facile, robust, and high-throughput fabrication methods, capable of simultaneously executing multiple functions with intelligent complexity.

Specifically, we present two distinct types of biohybrid systems: microalgae- and bacteria-driven microrobots. In the case of microalgae-driven biohybrids, *Chlamydomonas reinhardtii*, a single-cell green alga, serves as the biological model microorganism. By employing a noncovalent assembly approach, a thin, soft uniform coating layer is constructed using a polymer-nanoparticle matrix, resulting in a production efficiency of approximately 90%. This soft surface coating effectively preserves the microalgae's viability and phototactic ability while accommodating the incorporation of drug molecules and enabling active magnetic steerability. The magnetic steering capability of microalgae-driven microrobots is demonstrated in various microenvironments through adjustments in viscosity and confinement, emulating real-world settings that mirror the complexities of the human body. Furthermore, as a proof-of-concept, we showcase the controlled, on-demand drug delivery to tumor cells by conjugating nanoparticles embedded in the thin coating with chemotherapeutic agent doxorubicin, facilitated by a photocleavable linker.

On the other hand, bacteria-driven biohybrids are realized through the development of a magnetically controlled system that enables targeted localization and multistimuli-responsive drug release within three-dimensional (3D) biological matrices. *Escherichia coli* bacteria are integrated with magnetic nanoparticles and nanoliposomes via biotin-streptavidin complex, resulting in a high biohybrid construction yield. These bacterial biohybrids retain their original motility and exhibit enhanced capabilities for navigation through complex biological matrices, including 3D biological gels and tumor spheroids. Under the influence of external magnetic fields, they can effectively localize within specific regions and colonize tumor spheroids, enabling precise and on-demand release of therapeutic molecules upon near-infrared and pH stimuli.

The proposed biohybrid microrobotic designs presented in these studies hold significant promise for future medical applications by addressing current limitations and employing advanced fabrication techniques. These designs offer improved production efficiencies, enhanced control over locomotion, and various medical functionalities.

### 3:45 PM SB05.13.07

**Catalytic Materials Enabled by a Programmable Assembly of Synthetic Polymers and Engineered Bacterial Spores** [Masamu Kawada](#), Hyuna Jo, Alexis Medina and Seunghyun Sim; University of California, Irvine, United States

Natural biological materials are formed by self-assembly processes and catalyze a myriad of reactions. Inspired by such materials, we developed a programmable molecular assembly of designed synthetic polymers with engineered bacterial spores. This self-assembly process is driven by dynamic covalent bond formation on spore surface glycan and yields macroscopic materials that are structurally stable, self-healing, and recyclable. Molecular programming of polymer species shapes the physical properties of these materials while metabolically dormant spores allow for prolonged ambient storage. Incorporation of spores with genetically encoded functionalities enables operationally simple and repeated enzymatic catalysis. Our work lays an important foundation for scalable and programmable synthesis of robust materials for sustainable biocatalysis.

### 4:00 PM SB05.13.08

**Synergy Between Bacteria and Conjugated Polyelectrolytes to Form Functional Biomaterials** [Samantha McCuskey](#)<sup>1</sup>, Glenn Quek<sup>1</sup>, Ricardo Javier Vazquez<sup>1</sup>, Binu Kundukad<sup>2</sup> and Guillermo Bazan<sup>1</sup>, <sup>1</sup>National University of Singapore, Singapore; <sup>2</sup>Nanyang Technological University, Singapore

Combining conjugated polyelectrolytes with electroactive bacteria leads to the formation of living functional materials that improve the performance of bioelectrochemical technologies for biosensing, electricity generation, and electrosynthesis. However, the organization of these hydrogel composites and their effect on microbe physiology remain unexplored. In this study, mixing of a p-type conjugated polyelectrolyte (CPE-K) with *Shewanella oneidensis* MR-1 leads to a three-dimensional organization that generates ~30-fold greater biocurrent density than control biofilms in electrochemical cells. Further, respiration of the bacteria through the polymer promotes conductive network formation with a lower charge transfer resistance than neat CPE-K by itself. Total RNA-sequencing analysis revealed differential gene expression between cells in the polymer composite versus standard biofilm. Genes related to bacteriophages (biofilm development) and energy metabolism were upregulated in the composite compared to control biofilms. Correlating, extracellular polymeric substance (EPS) quantity and lactate coulombic efficiency increased in the composite. Cyclic voltammetry, fluorescent staining, and rheological measurements before and after enzymatic treatment in the living composite show the importance of the extracellular matrix for cohesion. EPS components added to neat CPE-K do not achieve the same properties. Taken all together, the demonstrated abiotic/biotic synergy between microbe and polymer

provides new strategies for designing multifunctional living composite materials.

SESSION SB05.14: Implantable and Wearable Devices

**Wearable *In Situ* Sweat Sensors for Health—On-Skin Electrochemical Real-Time Sensors** [Le Yang](#)<sup>1,2</sup>; <sup>1</sup>Institute of Materials Research and Engineering A\*STAR, Singapore; <sup>2</sup>National University of Singapore, Singapore

In an increasingly health-aware population and a move towards remote diagnostics, remote healthcare monitoring, cloud-based med-tech, etc, we tap on the ubiquitous and unlimited reservoir of on-skin biomarkers, including sweat metabolites, in developing a wearable, non-invasive, continuous and real-time sensor – a printed, multiplexed biosensor. Our integrated devices are designed and developed with scalability and translation in mind – ensuring printability (for scalable manufacturing), ease of fabrication routes, and solid-state and miniaturised prototype.[1-5] We also aim for better validation and correlation studies of non-invasive biomarkers to ensure useful relevance of such non-gold standard devices. Carbon-based electrodes are promising candidates for developing cheap, miniaturized, and disposable biosensors for effective wearable applications. From developing our own printable carbon-based ink, to screen-printing the electrodes, to functionalising each electrode into a specific biosensor, and finally to multiplexing and integration and incorporating of cheap paper-based sweat channels - we show how these devices can potentially add value to home-based/DIY biomarker monitoring. We look at a variation of our flexible electrode, a graphite/carbon fiber (G/CF) hybrid resembling a super-efficient 3D highway network where ample expressways (CF) run through numerous small factories (locally distributed graphite flakes) for rapid goods pick-up and transportation (electron transfer).[6] Lastly, we zoom in on the top-most layer of the device, the Kirigami paper sweat channel, critical in enabling real-time fresh-sweat reading.[7]

**Materials for Cut-And-Seam Fabrication of Soft Functional Interfaces** [Cindy K. Harnett](#)<sup>1</sup> and Samantha Musante<sup>2</sup>; <sup>1</sup>University of Louisville, United States; <sup>2</sup>Trinity College, United States

Interfaces between inorganic and biological systems need to be mechanically compatible with soft surfaces that grow, stretch, and distort over time. This requirement has driven the development of soft photonic and electronic circuits. However, the evolving shape of these circuits poses a problem when connecting circuits together: how can we match up distorted contacts that may be impossible to align? The problem comes up not only when repairing, modifying, or temporarily connecting to a stretchable circuit that's already attached to a biological system, but also when connecting circuit pieces into custom 3D structures to cover one-of-a-kind biological shapes. The usual solution to the distortion problem is to create a stiffened connector region that prevents the circuit from deforming, which is good for alignment but doesn't conform to biological surfaces as closely as a soft region does. The 3D structure problem may be solved by laying out a new electronic circuit for each individual interface, but this makes it difficult to use woven meshes and other regular structures as bases for soft functional interfaces.

This presentation describes our approach to connect signals across thin seams between soft materials without precise alignment at the connections. Our method relies on mm- and smaller scale electrical components inserted into thin adhesive tapes, producing materials with anisotropic electrical conductivity.

The alignment error tolerances we target are 2 mm in the direction perpendicular to the circuit edge, 2 cm parallel to the circuit edge, and a 70 degree angular tolerance. The reason for the large angular tolerance is that 3D cut-and-seam structures are often made from anisotropic woven or knit materials, often have curved seams, and are subject to external constraints such as packing cuts into a sheet to conserve material. These factors mean there is no guarantee that wires, optical fibers, and other anisotropic features will meet at the same angle along every seam, or even within a single seam.

The cut-and-seam fabrication method will also be discussed here as an interface for highly porous mesh-based biosensor circuits. Mesh circuits' applications in tissue engineering and biosensing are promising because meshes permit vapor transport, can be perfused with nutrients, and provide paths for cells to extend through during growth. However, the task of collecting signals from individual wires in a mesh is laborious, and mesh materials are often made from fibers that can't be soldered because of a too-low operating temperature range (for example, metallized polymer threads) or because harsh chemicals are required for solder wetting (for example, stainless steel wires and threads). The seaming materials and methods in this work are designed to make contact to those conductors, forming a distribution network for power and data in the soft sensor interface.

In this presentation, we investigate the above alignment tolerances in circuits made from thin films and fibers, focusing on methods such as capacitance, temperature, strain, and light intensity measurements that function when encapsulated by parylene, silicone and other conformal biocompatible coatings.

#### 8:45 AM SB05.14.03

**Microneedle Array Optical Sensing for Wearable Real-Time Hydration Monitoring** [Lawrence Renna](#)<sup>1</sup>, Kyle Brubaker<sup>1</sup>, Eric Kroon<sup>1</sup>, Megan Sax van der Weyden<sup>2</sup>, Shane Caswell<sup>2</sup>, Joel Martin<sup>2</sup> and Andrew Koch<sup>3</sup>; <sup>1</sup>Intelligent Optical Systems, Inc., United States; <sup>2</sup>Sports Medicine Assessment Research & Testing (SMART) Laboratory; George Mason University, United States; <sup>3</sup>Naval Air Warfare Center Aircraft Division (NAWCAD), United States

The escalating occurrence of physiological episodes leading to flight termination, combined with concerns over dehydration arising from prolonged missions, inadequate relief equipment, and environmental factors, has underscored the necessity for a real-time aviator hydration monitoring system to mitigate cognitive deficits and optimize in-flight performance. Dehydration-induced fatigue prominently impairs physical performance, particularly under heat stress, while also compromising various aspects of fitness such as aerobic capacity, strength, power, and balance. Even a 2% body weight loss due to dehydration can significantly impair cognitive abilities related to attention, executive function, and motor coordination, with more severe dehydration exacerbating cognitive impairment in tasks involving attention, psychomotor function, and short-term memory. To address these challenges, we have developed a wearable, real-time hydration monitor tailored specifically for military personnel, incorporating a novel technology that monitors subdermal chemistry, specifically the interstitial fluid derived from plasma, which is in equilibrium with plasma composition. The wearable device directly tracks a distinct set of biomarkers—sodium ions, proton activity (pH), and water activity—in the interstitial fluid, effectively overcoming the limitations and inaccuracies encountered by existing consumer-oriented products that solely measure surface sweat properties.

The integrated system incorporates a sensor-integrated hydrogel microneedle array (MNA) capable of detecting intradermal hydration biomarkers. The MNAs are equipped with embedded luminescent indicators designed to be sensitive to the target biomarkers. Leveraging the microneedles as conduits, light is efficiently delivered to and from the subdermal sensor, unaffected by variations in skin tone. The sensors are built on luminescence lifetime measurements, a robust optical process ensuring reliable and continuous signal readings even in dynamic and rapidly changing environments. Specifically, our approach involves employing a Dual Luminescence/Lifetime Referencing (DLR) methodology, utilizing two different luminophores with distinct lifetimes or a single material with multiple excited states that possess different lifetimes, that are sensitive to different biomarkers.

To validate our system, a human-subject hydration study was conducted (n=8). They underwent alternating periods of pedaling a stationary bicycle and sitting without water intake over a span of approximately 5 hours, while wearing the hydration monitor continuously. Urine specific gravity (USG) measurements were obtained at hourly intervals. Through the utilization of a random forest regressor model trained on the hydration monitor data, linearly interpolated USG values were predicted. Pairwise correlation analysis was performed to assess the predictive accuracy. The obtained results demonstrated a statistically significant rejection of the null hypothesis ( $p = 0.038$ ), indicating that the predicted and actual USG values were not drawn from different distributions. Furthermore, both the Pearson Correlation and Spearman Correlation tests yielded highly significant p-values ( $p < 0.0001$ ), affirming a strong positive correlation between the actual and predicted USG values.

In conclusion, the development of our wearable real-time hydration monitor, leveraging a microneedle array optical sensing approach, holds substantial promise in addressing the risks associated with dehydration among aviators. This innovative solution provides a reliable means of monitoring hydration status, facilitating proactive interventions to optimize performance and enhance the well-being of military aircrews.

#### 9:00 AM SB05.14.05

**Atomically Thin Boundary Between Wearable and Implantable Bioelectronic Interfaces** [Dmitry Kireev](#); University of Massachusetts Amherst, United States

Modern biosensors reveal a notable trend toward mobile and personalized health monitoring. Monitoring health-related electrophysiological signals, such as brain activity, heart activity, body hydration, or temperature, is essential for better comprehension of human physiology. Continuous long-term monitoring of those signals from individuals of different health conditions is essential to understanding systematic health risk factors and building preventative care solutions, which is paramount for intricate conditions like cardiovascular. However, modern wearable and implantable technologies require substantial improvement in terms of their ability to interact with the tissue without causing harmful consequences. In this work, we report on a substantial advancement of graphene electronic tattoos and use them for bioelectronic applications on the wearable and implantable fronts.

In a groundbreaking advancement in healthcare technology, we have harnessed the power of graphene to create wearable and implantable bioelectronic devices that revolutionize health monitoring and treatment. Using atomically thin and electrically conductive graphene electronic tattoos (GETs), we developed imperceptible monitoring technologies for measuring blood pressure with Grade-A accuracy. Unlike other wearables, GETs are lightweight and skin-conformable, eliminating discomfort during long-term measurements.

Recently, we also translated this technology into implantable sensors, demonstrating the sensing and stimulation of the mammalian heart, including treatment of arrhythmia with graphene pacemakers. The arrays show superior electrochemical properties, and the transparency of the graphene structures allows for simultaneous optical mapping of cardiac action potentials and optogenetic stimulation. Additionally, we advanced in creating tissue-integratable bioelectronic systems resembling biological neurons using soft, flexible, and biocompatible artificial synaptic transistors based on graphene and Nafion, boasting superior energy efficiency. These breakthroughs open up new possibilities for wearable and implantable graphene bioelectronics to transform healthcare and improve patient outcomes.

#### 9:15 AM \*SB05.14.06

**Intrinsically-Stretchable Cardiac Interfacing Devices for Heart Failure and Ventricular Tachycardia** [Dae-Hyeong Kim](#)<sup>1,2</sup>; <sup>1</sup>Institute for Basic Science, Korea (the Republic of); <sup>2</sup>Seoul National University, Korea (the Republic of)

Recent advances in flexible and stretchable electronics have attracted great attention due to its potential applications to personalized bio-integrated healthcare devices. The mechanical mismatch between conventional rigid electronic devices and soft human tissues oftentimes causes various issues, such as a low signal-to-noise ratio of biosensors, inflammations on the tissue interfacing with the bioelectronics, skin irritations in the case of long-term wearing of the device, and ineffective electrical stimulations in feedback therapies. Such issues can be amplified in the case of interfacing with dynamically moving organs including the heart, and lead to unsatisfactory monitoring efficiency and therapeutic efficacy. Intrinsically-stretchable bioelectronic devices have a low system modulus and intrinsic softness, and thereby have a potential to solve these issues. Nanomaterials and their composites with the elastomeric matrix are a particularly promising material candidate for realizing this soft bioelectronics concept. In this talk, the unique strategies in the synthesis of nanomaterials, processing as stretchable functional nanocomposites, their seamless integration with dynamically-moving cardiac muscles are presented. These efforts have combined recent breakthroughs in nanomaterials and soft electronics, and are expected to address unmet clinical challenges.

**Plant Electrophysiology with Conformable Organic Electronics** [Abdul Manan Dar](#)<sup>1</sup>, Adam Armada-Moreira<sup>1</sup>, Zifang Zhao<sup>2</sup>, Dion Khodagholy<sup>2</sup> and Eleni Stavrinidou<sup>1</sup>; <sup>1</sup>Linköping University, Sweden; <sup>2</sup>Columbia University, United States

Plant electrical signals are mediators of long-distance signaling and correlate with plant movements and responses to stress. Presently, these signals are studied with macro single surface electrodes that cannot resolve signal propagation patterns and integration, thus impeding their decoding and link to function. Unlike conventional extracellular electrodes, multielectrode (MEA) technology records the distribution patterns of electrical activity in cellular networks using a non-invasive, dense array of electrodes embedded in a substrate. The MEA technology is extensively used in brain and cardiac tissue research to decode the brain connectivity and potential propagation patterns in cardiac myocytes respectively. However, for plant electrophysiology the MEA technology remains fairly unexplored. Here we developed a conformable multielectrode array based on organic electronics for large-scale high-resolution plant electrophysiology. The MEA is developed with standard photolithography fabrication techniques, with parylene C as substrate and encapsulation layer resulting in total device thickness as low as 5 micrometers. The MEA is therefore highly conformable to the plant tissue leading to high Signal to Noise Ratio (SNR). With the conformable MEA we performed spatiotemporal mapping of the electrical activity of the carnivorous plant *Dionaea muscipula* a.k.a Venus Flytrap (VFT). VFT consists of a bilobed traps having three trigger hairs in each lobe which serve as mechanosensors. When the mechanosensitive hair is deflected, the mechanical stimulus is translated into an action potential (AP), by sensory cells at the base of the hair. Two action potentials (or two touches) in a short period (less than 30 secs) are required to induce closure of the trap. We found that the AP actively propagates through the tissue with constant speed and without strong directionality. We also found that spontaneously generated APs can originate from unstimulated hairs and that they correlate with trap movement. Finally, we demonstrate that the VFT circuitry can be activated by cells other than the sensory hairs. Our work reveals key properties of the AP and establishes the capacity of organic bioelectronics for resolving plants electrical signaling contributing to the mechanistic understanding of plants long-distance responses.

**10:45 AM SB05.15.03**

**Soft Optical Implant for Measuring Water Potential in Plants** [Vesna Bacheva](#), [Eric Wu](#), Piyush Jain, Sabyasachi Sen, Alice Gevorgyan, Margaret Frank and Abraham Stroock; Cornell University, United States

Spending their lives rooted in one place, plants exhibit remarkable adaptability in their metabolism and development in response to the changing environment [1]. One crucial aspect for their survival is the control of water uptake and the maintenance of water status (water potential) [2], which is influenced by environmental factors such as soil moisture, air temperature, and humidity. Evidence suggests that the changing water potential of plants not only results from these factors but also serves as a long-distance signaling mechanism that enables plants to communicate these changes effectively [3-5]. Therefore, measuring water potential would improve our understanding of whole-plant signaling and responses to environmental stresses, allowing us to develop effective strategies for plant health and productivity in a changing climate. However, currently, there is lack of tools for measuring water potential that are suitable for field studies and for a variety of plant species.

Here, we present the development of a soft implant for measuring water potential in plants. The implant contains water-sensitive nanoparticles that exhibit a fluorescence spectrum dependent on the water potential [6]. The nanoparticles can resolve water potentials across the physiologically relevant range (-3 to 0 MPa) while exhibiting minimal sensitivity to other physical factors like temperature and pH. We use fiber optics to illuminate the implant and capture the fluorescence spectrum to determine the water potential. With its small footprint, the implant can be easily embedded into various plant species. To assess the biocompatibility of the implant, we are examining histological sections of the local tissue at the insertion site. In recent years, several polymer-based materials have been developed for packaging of implantable sensors in mammals. Since the effect of these materials has not been studied in plants yet, we are also exploring different polymer- and plant-based materials to enhance the long-term stability of the implant. Additionally, we are considering the integration of a second optical fiber for simultaneous monitoring of sugar concentration, thereby enabling assessment of the osmotic potential.

We believe that the ability to accurately measure the total water and osmotic potential *in planta* will enable unprecedented access to the dynamics of water in plants and shed light on the propagation of long-distance hydraulic signaling. Moreover, the implant can be used beyond the context of plants by measuring water potentials in various environments such as soil, food, cosmetics, medicines, and cement.

**Bioelectronic Platform for Enhancing Plant Growth** [Alexandra H. Sandén](#)<sup>1,2</sup>, Vasileios Oikonomou<sup>1,2</sup>, Torgny Näsholm<sup>3</sup> and Eleni Stavrinidou<sup>1,2,3</sup>; <sup>1</sup>Linköping University, Sweden; <sup>2</sup>Linköping university, Sweden; <sup>3</sup>Swedish University of Agricultural Sciences, Sweden

To cover the food demands of the growing population in the changing climate we need to increase crop yield in a sustainable manner. Hydroponics cultivation minimizes water and fertilizer use while it can be integrated in the urban environment. However, so far the substrates used in hydroponics mainly offer support to the root system. Here, we developed a bioelectronic platform that stimulates the growth of plants in a hydroponics culture. We demonstrate that Barley, one of the most important crops, grows well within the bioelectronic platform. When stimulated, the biomass of the Barley increases by 40%, and the effect is evident in both root and leaf development during the growth period after the stimulation treatment. Results also show that stimulated plants reduce and assimilate NO<sub>3</sub><sup>-</sup> more efficiently than controls, a finding that can have implications on minimizing fertilizers use. Our work opens the pathway for enhancing plant growth in a hydroponics setting using bioelectronics which may result in more sustainable food production.

**Biomimetic Reactive Oxygen Species (ROS) Scavenging System for Stability Enhancement of Thylakoid Membrane-Based Photosynthetic Biosolar Cells** [JaeHyoung Yun](#), JongHyun Kim and WonHyoun Ryu; Yonsei University, Korea (the Republic of)

Since photosynthesis of plants has a high quantum yield close to 100%, many studies have been conducted to utilize the photosynthesis for bio-energy harvesting using algal cells, chloroplasts, thylakoid membranes (TMs), and isolated photosystems (PS I, II). The extracted photosynthetic organelles are preferred among these for their direct contact with the electrode and easier transfer of photosynthetic electrons (PEs). However, under high light intensity, reactive oxygen species (ROS) are generated during photosynthesis, causing damage to lipid membranes or proteins. Therefore, for long-term stability, a closed system capable of scavenging ROS like chloroplasts is required. In this study, we propose a biomimetic ROS scavenging system for stability

enhancement of bio-solar cells. We used catalase to scavenge ROS, which causes the damage to extracted photosynthetic organelles and apparatuses. As a popular extracted photosynthetic organelle, TMs were used for bioenergy harvesting, and an artificial independent closed environment that did not interfere with PEs transport was constructed using alginate as extracellular matrix and the Nafion membrane. First, dye release test and catalase assay either in the presence or absence of Nafion membrane were performed to measure the leakage of catalase. The tests confirmed that the release of dye and catalase from the film coated with the Nafion membrane was negligible. However, the Nafion solution used for coating contains aliphatic alcohol that can damage lipid membranes or proteins. To analysis the effect of alcohol on TMs, photocurrents from TMs for different ethanol concentrations used in Nafion membrane were measured. TMs treated with 5% ethanol concentration produced about 82% of photocurrents from the non-treated TMs. Therefore, it was concluded that a sufficiently diluted Nafion solution did not significantly affect the production of TM photocurrent. Based on this, a 10-fold diluted Nafion solution was used for the coating of TM/alginate mixture film containing catalase. Furthermore, the film fabrication conditions were optimized through the photocurrent results according to the ratio among TMs, alginate, and catalase. Finally, in order to confirm the stability improvement of a photosynthetic bio-solar cell by catalase encapsulated system, the photocurrent from the system was observed for 5 hours under AM 1.5G (1 sun = 100 mW/cm<sup>2</sup>) illumination at intervals of 1,000 s. Afterwards, the stability improvement was evaluated by comparing the initial photocurrent and the photocurrent after 5 hours illumination. As a result, it was confirmed that about 4.3 times improved stability was achieved by the biomimetic ROS scavenging system.

**Smart Wearable Healthcare Devices for On-Demand Theranostic Applications** [Sei Kwang Hahn](#), SangHoon Hong and TaeYeon Kim; Pohang University of Science and Technology, Korea (the Republic of)

A variety of diagnostic and therapeutic devices are routinely used in the clinic. While these devices have a familiar look as wall-plugged in hard packages or placed at patients' bedsides, there has recently been a rapid expansion of new ideas on wearable healthcare devices for greatly improved patients' compliance. Here, we developed smart contact lenses and smart wearable devices for both continuous diabetic monitoring and diabetic retinopathy therapy. Smart contact lens could measure tear glucose levels as a non-invasive alternative to the conventional blood glucose tests and deliver drugs from gold coated reservoirs for the treatment of diabetic retinopathy. On the basis of these results, we also developed a smart wearable device for highly sensitive glucose monitoring in sweat for clinically feasible diabetic diagnosis. A blue-tooth system could send data wirelessly allowing patients to check their diabetic diagnosis results on the mobile phones. Furthermore, we developed cell-integrated poly(ethylene glycol) hydrogels for in vivo optogenetic sensing and therapy. The real-time optical readout of encapsulated heat-shock-protein-coupled fluorescent reporter cells made it possible to measure the nanotoxicity of cadmium-based quantum dots in vivo. Using optogenetic cells producing glucagon-like peptide-1, we performed light-controlled therapy and obtained improved glucose homeostasis in diabetic model mice. Taken together, this presentation will provide the current state-of-the-art smart wearable devices for further clinical applications.

**Cephalopod-Inspired Bioelectronic Control of Cellular Differentiation** [David Berlin](#), Aleeza Farrukh, Georgii Bogdanov and Alon Gorodetsky; University of California, Irvine, United States

Cephalopods (e.g., squids, octopuses, and cuttlefish) have recently become recognized as a promising source of natural conductive biopolymers (1,2). Within this context, our laboratory has studied the proton conducting properties of unique cephalopod structural proteins called reflectins, and we have leveraged these proteins for applications in protonic transistors, photochemically dopable devices, and photochromic color-changing platforms (1,2). Moreover, we have demonstrated that reflectin films are inherently biocompatible, as exemplified by their ability to support the growth and proliferation of both human and murine neural stem/progenitor cells (3,4). Recently, we have extended these efforts to the development of cephalopod-inspired bioelectronic devices that afford the voltage-controlled regulation of cellular differentiation in real-time (5). Our combined findings suggest that reflectins are promising materials for applications in cell- and tissue-interfaced bioelectronic platforms.

**Soft, Skin-Safe Electronic Device Interfaces for Continuous Health Monitoring** [Seonggwang Yoo](#) and John A. Rogers; Northwestern University, United States

#### Abstract

Soft electronic device interface directly with the skin surface allows essential physiological health monitoring. These devices, featuring soft and miniaturized architecture, wireless communication capabilities, and an independent power system, significantly reduce patient burden by eliminating wired connections and bulky hardware of traditional hospital-grade systems. Previous efforts by soft, thin structures with high biocompatibility addressed the many skin damage problems but still present challenges, especially when in direct contact with the delicate skin of ill infants with small anatomical bodies and low-risk perception ability. Here, we report materials and structural design strategies to enhance skin safety during clinical use, especially for infants, without hampering the unique characteristics of the device architectures and the electronic performance. Pre-curved and holey design conforms to the anatomical body and rapidly and effectively releases interface adhesion, significantly reducing skin irritation. Furthermore, an ultrathin, flexible bladder containing small amounts of liquid with a low boiling point provides an active thermal safety system to these soft, skin electronic devices. In a thermal malfunction, the heat evaporates the liquid inside the bladder, forming an effective thermal barrier and automatically delaminating the device from the skin. Our material and structural design approach aims to ensure the safe and reliable use of soft electronic devices for infant health monitoring, promoting overall well-being and comfort during usage.

**Amphiphilic Light-Driven Push-Pull Azobenzenes (ppABs) as Cell Membrane-Targeted Nanoactuators** [Valentina Sesti](#)<sup>1,2</sup>, [Matteo Moschetta](#)<sup>2</sup>, [Arianna Magni](#)<sup>2</sup>, [Paola Moretti](#)<sup>1,2</sup>, [Giuseppe Maria Paternò](#)<sup>1,2</sup>, [Matteo Tommasini](#)<sup>1</sup>, [Guglielmo Lanzani](#)<sup>2,1</sup> and [Chiara Bertarelli](#)<sup>1,2</sup>; <sup>1</sup>Politecnico di Milano, Italy; <sup>2</sup>Istituto Italiano di Tecnologia, Italy

Cationic membrane-targeted azobenzenes have been recently proposed as light-induced nanoactuators for neuronal photostimulation.<sup>1,2</sup> In previous works, we developed an azobenzene as a promising nanoscale tool for cell photostimulation, namely Ziapin2. Our approach resides in non-specific binding, and Ziapin2 has an amphiphilic character allowing it to partition spontaneously within the cell membrane. The cationic terminal groups interact with the phospholipid polar heads of the membrane while the hydrophobic part of the molecule stabilizes inside the lipidic region. We demonstrated that this azobenzene is an effective light-driven intramembrane actuator, able to modulate neuronal firing both in vitro and in vivo.<sup>1</sup> These previous results open to the next generation of light-driven photoswitches aimed at enhancing the performances and improving the partition stability. In this work, new amphiphilic push-pull azobenzenes (ppABs) were designed and synthesized, which feature a strong electron donor group in the *para*-position on one phenyl ring and a strong electron acceptor group in the *para*-position on the opposite phenyl ring. This push-pull substitution of the phenyl rings delocalizes electrons of the azobenzene and shifts the absorption wavelengths towards red, which is a valuable feature for biological application, allowing for a better light penetration in tissues. Interestingly, light-activated electrophysiology of cells loaded with ppABs shows a depolarization of the membrane followed by a small hyperpolarization, and this is owed to the significant variation of the dipole moment.<sup>3</sup> Within this series of homologous ppABs, we also identified the key role of the cationic heads in the partitioning and potential modulation of the cell membrane.

**Integrated Design and Synthesis of Soft Matrices with High Permittivity** [Dylan M. Barber](#) and [Jennifer A. Lewis](#); Harvard University, United States

Emerging applications, such as dielectric elastomer actuators (DEAs), haptics, and bioelectronics, would benefit from soft matrices that simultaneously exhibit high permittivity (relative permittivity  $\epsilon_r \geq 10$ ) and low elastic moduli ( $E \leq 1$  MPa). For example, the energy density of DEAs depends on  $\epsilon_r^2$ , while their actuation strain scales with  $\epsilon_r$ . However, most soft elastomers and gels that serve as compliant dielectric layers exhibit low permittivity ( $\epsilon_r \leq 10$ ). Consequently, the operation of DEAs requires kilovolt-scale potentials to achieve targeted actuation strains and energy densities. The incorporation of high- $\epsilon_r$  fillers affords little improvement, since liquid fillers (e.g., liquid metals) decrease breakdown strength, while solid fillers (i.e., strontium titanate particles) increase modulus. In this talk, we will describe recent advances to design and synthesize intrinsically polarizable elastomers and gels based on a library of small molecules with a large dipole moment and a low melting point – each of which exhibits exceptional permittivity ( $\epsilon_r \geq 250$ ) in the low frequency limit. Their synthesis is both facile (3-5 synthetic steps) and scalable (up to 250 g) from inexpensive starting materials. Using this library, we have created elastomers and gels with  $\epsilon_r \geq 100$  and  $E < 1$  MPa, which may find potential application in high-strain and energy-dense DEA, haptic, and bioelectronic-based devices.

**4:00 PM SB05.17.03**

**Non-Invasive Actuation of Chemical Reactions Through Mechanochemistry and Gas Vesicle Proteins** [Yuxing Yao](#), [Molly McFadden](#), [Mikhail Shapiro](#) and [Maxwell Robb](#); California Institute of Technology, United States

Recent advances in molecular engineering and biomedical ultrasound provide means to apply physical effects, including mechanical stress, deep inside tissues, but limited capability to enact specific chemical processes for applications including drug delivery and non-invasive control of cellular functions. In this work, we show that mechanochemistry, chemical processes initiated by mechanical stress, can be activated with biocompatible focused ultrasound assisted by acoustically-active proteins. Previously, activation of mechanochemistry relies on ultrasound with parameters that are likely to damage tissues. Through acoustic cavitation seeded by genetically encoded, air-filled protein nanostructures called gas vesicles, polymers undergo bond cleavage at the designed, weakest position in backbones and thus release small molecular payloads, including fluorophores and therapeutic drugs by chemical cascade. The efficiency of mechanochemical activation is comparable to what has been achieved with bulk sonication, though with weaker ultrasound parameters. Focused ultrasound further enables the activation of mechanochemistry with spatial resolution in millimeter range as well as the programmable payload release kinetics. Furthermore, we demonstrate the stimulation of mechanochemistry in tissue-mimicking gels, suggesting its potential applications in remotely controlled drug release inside body. Our platform represents a novel modality for controlling chemical reactivity non-invasively in biological systems and unlocks the translational potential of polymer mechanochemistry for therapeutic and bioimaging applications.

**4:15 PM SB05.17.04**

**Nanoparticle-Virus Chimeras as a Novel Strategy for Nanoparticle Delivery** [Keisuke Nagao](#), Katherine Lei, Peyton Worthington, Emmanuel Paniagua, Robert J. Macfarlane and Polina Anikeeva; Massachusetts Institute of Technology, United States

The systemic delivery of nanoparticles (NPs) has garnered significant attention from researchers due to its clinical promise. Various strategies have been developed thus far, including the utilization of the enhanced permeability and retention (EPR) effect to target tumors or the modification of NPs with antibodies to target specific proteins. However, delivering NPs to the brain through the blood-brain barrier (BBB) remains a challenge. Additionally, the importance of the communication between the central nervous system (CNS) and the peripheral nervous system (PNS) has been increasingly recognized, leading to a high demand for delivery systems that can flexibly change their target between the CNS and PNS. Translation of delivery strategies between species offers another challenge, especially in the context of bridging the divide between fundamental research in rodents and clinical research in larger models such as non-human primates (NHPs). Therefore, there is a pressing need for a novel strategy for systemic delivery of nanomaterials that is both translational and capable of flexibly selecting targets.

For decades the field of gene therapy has applied engineered viruses to deliver therapeutic transgenes to particular organs or cells of interest. Adeno-associated viruses (AAVs) are the most ubiquitous gene-therapy tools, particularly in neuroscience, owing to their advantageous characteristics: AAVs are non-pathogenic, easily reproducible, and have numerous accessible serotypes, each with distinct tropism. State-of-the-art serotypes, such as AAV.CAP-B10 and AAV.MaCPNS2, have demonstrated the ability to deliver genes to the brain or PNS in mice following intravenous (IV) injection, while simultaneously suppressing gene expression in the liver. These serotypes have also shown promise for gene delivery in NHPs.

In this study, we hypothesized that AAVs could be employed to guide magnetic nanoparticles (MNPs) to particular organs through IV injection. This approach allows for easy modification of the target by swapping AAV serotypes, for instance, from the brain to the PNS. Furthermore, the target species can also be altered based on the serotypes of AAVs. This concept, termed viral guidance of MNPs, has the potential to serve as a versatile targeting strategy.

We covalently conjugated MNPs and AAVs (MNP-AAV chimeras) through click chemistry. The structure of these chimeras was controlled by adjusting the reaction conditions. In vitro tests were conducted to investigate the efficiency of AAVs in guiding MNPs using MNP-AAV chimeras formed from several different serotypes. As a result, MNP-AAV chimeras retained the tropism of original AAV serotype used, indicating that the delivery target is serotype-dependent and can be easily modified by changing the AAV serotype used for conjugation.

We also investigated an opposite application of MNP-AAV chimeras, namely, the magnetic guidance of AAVs. Since AAVs were conjugated to MNPs, we could manipulate the chimeras using an external magnetic field to exert a magnetic force on the MNPs. HEK293 cells were incubated with MNP-AAV chimeras in a presence of a magnetic field. Following a 24-hour incubation period, the HEK cells expressed high levels of fluorescent protein, which was encoded by the AAVs in the chimeras, near the center of the magnetic field. This result suggests that magnetic guidance of AAVs is feasible, and that AAVs in chimera form (conjugated to MNPs) are capable of transducing cells. The specificity of gene delivery targeting with AAV was previously determined by a combination of two factors: serotype (capsid) and regulatory elements (promoter, enhancer, Cre-lox system, etc.). Now, our chimeras enable spatial restriction of transduction, which adds another layer of control to gene delivery. To the best of our knowledge, this is the first report of magnetically controlled transduction with AAVs.

**Exploring Cell Behavior Through Blanket and Patterned Reprogramming of Nanotopography** [Mona H. Abostate](#)<sup>1</sup>, Nikolaos Liaros<sup>1</sup>, Matthew J. Hourwitz<sup>1</sup>, Wolfgang Losert<sup>2,3</sup> and John Fourkas<sup>1,3,4</sup>; <sup>1</sup>Department of Chemistry and Biochemistry University of Maryland, United States; <sup>2</sup>Department of Physics, University of Maryland, College Park, MD, USA, United States; <sup>3</sup>Institute for Physical Science & Technology, University of Maryland, College Park, MD, USA, United States; <sup>4</sup>Maryland Quantum Materials Center, University of Maryland, College Park, MD, USA, United States

Cellular responses to external stimuli arise from a complex integration of various biochemical and biophysical signals that can occur concurrently, and that exhibit distinct spatial and temporal patterns. Of these signals, nanotopography, which is present in the extracellular matrix, holds special significance in influencing and controlling cell behavior. Nanotopography has the ability to initiate and direct waves of actin polymerization in a phenomenon called esotaxis, which is closely linked to the inherent excitability of cells. For instance, nanoridges can induce a transition from the 2D spreading waves observed on flat substrates to 1D waves.

We have molded large-area master patterns created using conventional lithography, and then replicated these masters using soft lithography. Replicas created using poly (Disperse Red 1 methacrylate, pDR1m), an azobenzene-containing polymer, can be reconfigured with light. The azobenzene moieties undergo photoisomerization from the *trans* isomer to the *cis* isomer, inducing macroscopic alterations in the polymer structure that depend on the polarization of the light.

With this technology, a single nanoridge master can be used to generate a wide range of patterns with different surface features. Photomodification of pDR1m nanoridges was achieved through two different methods: blanket exposure and patterned exposure. The newly patterned surfaces can be replicated in a material that is not photosensitive through a straightforward molding procedure.

We have examined the response of cells to surfaces featuring buckled nanoridges created through. The presence of buckling has a significant influence on esotaxis, ultimately impacting cell migration. Because this effect is cell-type-specific, and depends on the degree of buckling, it is possible to create surfaces that impact different types of cells in different manners.

SESSION SB05.18: Virtual Session: Biohybrid and Soft Functional Interfaces

**Stretchable Silent Speech Glove using Myopotentials and Machine Learning** [Yuta Kurotaki](#)<sup>1,2</sup> and Hiroki Ota<sup>1</sup>; <sup>1</sup>Yokohama National University, Japan; <sup>2</sup>Pepabo Research and Development Institute, GMO Pepabo, Inc., Japan

The field of Silent Speech Interface (SSI) exists as an interface for sending information without speaking. Personal and confidential information can be heard by others when spoken, but if speech can be recognized without voice, confidential information can be transmitted safely. In addition, silent speech can send information to machines and people without disturbing the environment. There are many methods for predicting what is uttered from silent

speech, one of which is the use of muscle potentials around the mouth. Recently, it has been shown that muscle potentials can be measured by placing sensors around the mouth, but the integration of a mechanism that uses soft materials to recognize speech using electrodes, muscle potential amplification circuits, and machine learning models has not yet been realized. Although it is possible to place circuits and elements as well as sensors around the mouth, the area around the mouth is limited, and attaching sensors would interfere with mouth movements. The myopotential amplification circuit requires many elements to be placed on the circuit, which would result in a loss of aesthetics in terms of appearance.

To solve these problems, we developed a myopotential measurement device that can be attached to the human hand using soft materials, liquid metal, transparent FPCs (Flexible Printed Circuits), and a microcomputer. The device can be placed near the mouth and electrodes placed around the mouth to collect myopotential information, which can then be used in a machine learning model to classify speech only when speech recognition is performed without speech. By enabling sensing by placing electrodes on the mouth only when the device is being used, there is no need to worry about information being read at times other than when the device is being used, and since there is no need to always wear sensors or circuitry around the mouth, speech will not be read at unintended times. It does not interfere with the movement of the face or mouth, eliminating aesthetic concerns.

In this study, electrodes based on soft materials were created to realize a device that is worn on the hand and repeatedly measures myoelectric potentials around the mouth. The electrodes were wired to circuits on transparent polyimide film using a liquid metal mixture of Galinstan and nickel powder and bonded with a hard-soft pattern of silicone rubber and epoxy. The electrodes and substrate, which fit the human hand, can capture information around the mouth without breaking, even when the hand is moved, or the fingers are bent. In addition, a speech classification model was created using machine learning based on the acquired data of myoelectric potentials in silent speech around the mouth. We propose a new form of silent speech interface that allows many people to send information to machines and people in more situations and with the same privacy as in their conventional lives.

#### 10:45 AM SB05.18.02

**Permeable Electronic Skins for Health Monitoring** Yan Wang<sup>1,2</sup>; <sup>1</sup>Guangdong Technion-Israel Institute of Technology, China; <sup>2</sup>Technion-Israel Institute of Technology, Israel

One limitation of commercialized wearables, such as smartwatches and bands, is that they cannot form conformable contact with human skin due to their rigid form factor, thereby limiting their monitoring capabilities. Soft bioelectronics, on the other hand, are touted as an ideal platform for personalized health care owing to unique characteristics, such as thinness, lightweight, good biocompatibility, excellent mechanical robustness, and great skin conformability. Permeable skin-mountable electronics that are capable of long-term applications have emerged as promising tools for early disease prevention, screening, diagnosis, and treatment<sup>1,2</sup>. Dr. Wang's research interests mainly focus on the development of wearable electronics for biomedical health monitoring, including stretchable conductors, sensors, and soft energy devices. In today's talk, she will introduce high-performance skin bioelectronics developed by ultrasoft nanomesh systems, which can realize the accurate measurement of minus skin deformations and finger touch without disturbing natural skin motions and sensations, as well as long-term applications for health monitoring<sup>3-5</sup>.

#### 11:00 AM SB05.18.03

**Thin-Film Encapsulations for Compliant Implantable Bioelectronics: Advanced Materials and Characterisation Methods Based on Bioresorbable Magnesium Permeability-Sensing Structures** Massimo Mariello<sup>1,2</sup>, Yves Leterrier<sup>2</sup> and Stephanie P. Lacour<sup>2</sup>; <sup>1</sup>University of Oxford, United Kingdom; <sup>2</sup>Ecole Polytechnique Federale de Lausanne, Switzerland

The next-generation bioelectronic implants will be microfabricated, soft and compliant; they need to be protected from the body environment through encapsulations that must guarantee simultaneously hermeticity, biocompatibility, mechanical compliance, compatibility with microfabrication processes, and long-term reliability. This still represents an unsolved challenge: standard biocompatible barrier technologies based on rigid Ti/silicone capsules do not answer such needs. Advanced hermetic barriers should instead rely on thin-film encapsulations (TFE), based on organic or inorganic films. However, water permeation and mechanical defects are prime drivers for TFE failure, especially for *in vivo* and flexible implantable systems, so a universal solution is still missing. Conventional strategies rely on multilayer architectures, consisting of alternating dyads made of organic and inorganic layers. The accurate evaluation of their barrier performances is challenging because standard measuring systems display too high sensitivity limits (~ 10-5 g/m<sup>2</sup>/day) which cannot detect the ultra-low permeation capabilities of the coatings, and are not suitable for flexible microsystem formfactors. We present here for the first time a comprehensive accelerated-aging method to quantify ultra-low permeability of TFE engineered for bioelectronic micro-devices. The method relies on bioresorbable magnesium (Mg) thin films. Corrosion of Mg induced by water diffusion through the barrier coating is real-time monitored in several testing conditions, including exposure to wet air, soaking in a phosphate buffer saline (PBS) solution that mimics the body biofluids (*in vitro*), and in biological tissues (*in vivo*). The electrical properties of Mg are then monitored and analysed. High temperatures for *in vitro* tests are chosen to perform accelerated aging whereas specific novel analytical/computational models are used to extract from the measurements the water transmission rates (WTR) of the barriers. The advantages of this approach are that Mg does not need a fully inert atmosphere and it can be easily integrated in the microfabrication processes of implantable bioelectronic devices. Therefore, the proposed characterization strategy answers a long-term need to assess reliably and universally thin-film hermeticity *in situ*, and for any types of conformal TFE for bioelectronic systems.

#### 11:15 AM SB05.18.05

**Modulation of Curli Production on Redox Challenged PEDOT:PSS Surfaces** Sanhita Ray<sup>1,2</sup>, Susanne Löffler<sup>1,2</sup> and Agneta Richter Dahlfors<sup>1,2</sup>; <sup>1</sup>Karolinska Institutet, Sweden; <sup>2</sup>AIMES, Sweden

Biofouling is a major problem caused by bacteria colonizing abiotic surfaces, such as medical devices. Biofilms are formed as the bacterial metabolism

adapts to an attached growth state. We have previously found that electrically charged surfaces with high charge storage capacity like PEDOT-based conducting polymers can be used to modulate the amount of gross biomass attaching by altering the surfaces redox state(1). Here, we are delivering an in-depth analysis on the process of biofilm formation on redox-challenged PEDOT: PSS surfaces. We are using GFP tagged *Salmonella* bacteria and a marker for the *Salmonella* extracellular matrix components curli and cellulose (EbbaBioliight 680) to decipher the relationship between the amount of bacterial cells and extracellular matrix produced by bacteria in *Salmonella* wt bacteria as well as mutants deficient in curli ( $\Delta$ csgA) or curli as well as cellulose ( $\Delta$ csgD)(2). We are using a semi-quantitative spectroscopy method to determine relative amounts of bacterial cells and extracellular matrix (ECM) on a large surface area and are performing detailed microscopic analysis to understand biofilm distribution and structure. When the redox challenge was carried out in a fast-charging whole-cell setup, higher amounts of cells and ECM were found on oxidized PEDOT:PSS surfaces compared to their reduced counterpart. When electrodes were separated and charging was carried out with respect to a Pt electrode, the charging process was slower and incomplete. This resulted in almost similar cell numbers for the two cases but showed much higher amounts of ECM on reduced surfaces. A curli mutant, grown under the same conditions produced biofilms that didn't respond to the redox challenge. The microscopic structure of the biofilm showed uniform cell and ECM distribution on all oxidized surfaces but showed high-density local clusters of around 100-200  $\mu$ m diameter on all unchallenged and reduced surfaces.

This leads us to believe that redox modulation of biofilm formation mainly depends on curli production. We forward a theory where an oxidized PEDOT:PSS surface works as an alternate terminal electron acceptor for interfacial biofilm, which might be able to boost ATP production and curli formation. We reason that the negative charge of PEDOT:PSS on unchallenged and reduced surfaces leads to a spotty attachment of the bacteria and to the formation of microcolonies, instead of evenly distributed films.

#### 11:30 AM SB05.18.06

**Toward Enhancing Critical Care Monitoring: Continuous Assessment of Blood Lactate and Potassium with Fiber Optic Sensors Integrated into Intravascular Catheters** Lawrence Renna<sup>1,2</sup>, Narciso Guzman<sup>1</sup>, Emily Vuu<sup>1</sup>, George Harea<sup>2</sup>, Gerardo Ico<sup>1</sup>, Teryn Roberts<sup>2</sup> and Andriy Batchinsky<sup>2</sup>; <sup>1</sup>Intelligent Optical Systems, Inc., United States; <sup>2</sup>Autonomous Reanimation and Evacuation Research Program, The Geneva Foundation, United States

The determination of disease severity and prediction of outcomes in emergency medicine heavily rely on blood lactate (Lac) and potassium ( $K^+$ ) levels. Traditionally, these biomarkers are assessed through repeated invasive blood sampling and subsequent analysis using laboratory blood gas analyzers. However, recent studies have emphasized the dynamic nature of these biomarkers, highlighting the need for continuous monitoring. In trauma cases, elevated blood Lac levels and poor Lac clearance have been associated with higher mortality rates, demonstrating potential for effectively triaging conditions such as lung cancer, lacunar infarction, sepsis, and cardiac failure. Likewise, high  $K^+$  levels, known as hyperkalemia, are linked to life-threatening conditions including arrhythmias and mortality following severe trauma, kidney disease, hemolysis, and acid-base imbalances. In hemorrhaging patients, hyperkalemia can be induced by tissue ischemia, blood transfusion, and acidosis, significantly heightening the risk of death. Consequently, there is an urgent demand for continuous monitoring of blood Lac and  $K^+$  levels in critical care settings. This study aims to develop and evaluate the performance of specialized fiber optic sensors that enable real-time monitoring of Lac and  $K^+$ , thereby providing healthcare providers with timely guidance in rapidly changing situations.

The sensors in this study employ a measurement method known as dual lifetime/luminophore referencing (DLR), which ensures high accuracy and mitigates sensitivity to the amplitude of the optical signal. In contrast to previous fiber optic sensors that are single point sensors located at the tip of the fiber and are susceptible to intermittent contact with tissue, a phenomenon referred to as the "wall-effect," the current sensors utilize a tunable distributed sensing approach. This is accomplished by incorporating redundant "mini-sensors" along a specific section of the optical fiber. Furthermore, optimization of sensor fabrication was conducted to enhance sensitivity specifically for physiologic concentrations. The Lac sensor utilized in this research consists of multiple layers, including a luminescent transducer layer for measuring partial pressure of oxygen, a catalytic enzymatic hydrogel layer, and a diffusion barrier layer to overcome substrate-dependent inhibition. The  $K^+$  sensor is designed as a hydrogel that incorporates a luminescent ionophore for  $K^+$  detection, and a separate reference luminophore. Finally, sensor-integrated catheter prototypes were tested in an ex vivo flow circuit with fresh porcine blood. The sensor-integrated catheter prototypes showed strong pairwise correlation between the optical sensor measurements and blood gas analysis (Spearman correlation  $R^2 = 0.981$  and  $0.970$ , p-value:  $<0.0001$  and  $<0.0001$  for Lac and  $K^+$ , respectively).

In summary, our study has successfully shown that the DLR-based fiber optic sensors for continuous Lac and  $K^+$  monitoring, when integrated into intravascular catheters and evaluated under ex vivo circulation conditions using donor blood, offer a viable alternative to repetitive blood gas analysis. These sensors hold great promise in enhancing clinical decision-making and are now poised for further validation in translational studies focusing on trauma and critical care scenarios under in vivo conditions.

**Single-Protein Electronics: Effect of Surface Mutagenesis and Multiheme Redox Cofactors** [Ismael D Diez Perez](#)<sup>1</sup>, Albert C. Aragonés<sup>2</sup>, Kavita Garg<sup>1</sup>, Marta Ruiz<sup>2</sup>, Guilherme Vilhena<sup>3</sup>, Linda Angela Zotti<sup>3</sup>, Julea Butt<sup>4</sup>, Zdenek Futera<sup>5</sup>, Xiaojing Wu<sup>6</sup> and Jochen Blumberger<sup>6</sup>; <sup>1</sup>Kings College London, United Kingdom; <sup>2</sup>Universitat de Barcelona, Spain; <sup>3</sup>Universidad Autónoma de Madrid, Spain; <sup>4</sup>University of East Anglia, United Kingdom; <sup>5</sup>University of South Bohemia, Czechia; <sup>6</sup>University College London, United Kingdom

*Bioelectronics* is a rapidly evolving field moving towards designing nanoscale electronic platforms that allow *in vivo* sensing, fuel cell powering and chemical biosynthesis. Such devices typically require interfacing a complex biomolecular moiety as the active component to an electronic platform for signal transduction and/or electron source wiring. Inevitably, a true systematic design goes through a bottom-up understanding of the structurally related electrical signatures of such hybrid biomolecular circuits, which will ultimately lead us to tailor its electrical properties and exploit them as high performance bioelectronic devices with a wide variety of applications in organic electronics, sensing, biomanufacturing, *etc.*

In this contribution, we will present our latest efforts on understanding and control charge transport in a single-protein junction. Our approach relies on trapping individual redox proteins in a tunneling junction under electrochemical control to characterize their main electrical signatures. The method can capture very fine details of the charge transport mechanisms across proteins in an aqueous environment [1,2]. Our studies start with a benchmark redox protein model such as a bacterial blue Cu-Azurin. We will show first the main observed electrical signatures of these systems that make them particularly efficient in transporting charge. We then bioengineer the outer protein surface using point-site mutagenesis as a mean to get a more detailed picture of possible electron pathways through the protein backbone [2,3]. Our results suggest that the protein might not use distinct physical electron pathways across its structure, but transport mechanism can be switched upon quenching of particular motions in the protein structure via surface mutations. We then compare the above redox protein model to a natural multiheme molecular wire. Multiheme proteins have been recently discovered as the building blocks in highly conducting pili and transmembrane structures of certain species of the so called electrical bacteria [4]. Such large supramolecular ensembles of multiheme protein complexes support long-range charge transport in record distances over micrometres [5]. We have trapped individual small tetraheme proteins (STC) in our tunnelling gap and measured conductance. STC constitutes a well-known repeating arrangement of *heme* cofactors along larger multiheme complex structures. Our first results suggest a single STC unit can transport electrons via efficient electron tunnelling process along the ~4 nm long protein axis with very shallow electron decay constant. We believe these results contribute to the observed long-range charge transport behaviour observed in these multiheme-based molecular wires.

Summing up, the above work shows the potential of electrochemically controlled nanoscale protein junctions to both elucidating charge transport mechanisms in biological systems as well as in enabling a bottom-up design of electrode/protein interfaces for the future generations of bioelectronic devices.

**9:35 AM \*SB06.01.02**

**Implantable Materials for Chronic Disease Monitoring** [Hanie Yousefi](#)<sup>1</sup>, Xudong Ji<sup>1</sup>, Jagotamoy Das<sup>1</sup>, Yi Li<sup>1</sup>, Jonathan Rivnay<sup>1</sup> and Shana Kelley<sup>1,2</sup>; <sup>1</sup>Northwestern University, United States; <sup>2</sup>Chan Zuckerberg Biohub, United States

Chronic diseases such as heart failure (HF) are increasingly prevalent conditions that are difficult to manage. Patients often experience significant deterioration between clinic visits, and by the time they become symptomatic, their condition cannot be managed outside of the hospital. Inflammation has recently been identified to take roles on promoting and inducing HF but there are no insights on the mechanisms of disease progression. The ability to perform continuous monitoring of protein biomarkers on a body-implanted device will transform our capacity to diagnose disease, preserve wellness, and propose potential treatments. Using Flexible and Implantable sub-millimeter polymeric substrates, we propose a new solution for remote, continuous monitoring of chronic disease clinical biomarkers (BNP, Troponin I, IL6, TNF $\alpha$  as proof of concept) to manage patients' health. We recently developed the first-of-its-kind reagent-less molecular sensor for in situ detection of a wide range of targets, such as viral particles and proteins. However, continuous monitoring of chronic disease requires installing a miniature device inside the human body and continuously monitoring the patient for an extended period. The small device provides efficient reaction rates with a sub-millisecond resolution, which has not been achieved using the current common diagnostics paradigm. By moving from materials used in traditional electrochemistry to using unconventional recent developments in the fields of material science, we introduce a new generation of sensing platforms that are biocompatible, affordable, reliable, and environmentally friendly to deliver the promised goals of chronic disease management. Using an HF rat model and accessing interstitial fluid via contact with the device's implantable part, we will be able to monitor disease progression, inflammation, and biomarker levels. This technology will provide a new generation of devices for the continuous monitoring of vital biomarkers in HF rat models.

**10:05 AM BREAK**

**10:30 AM \*SB06.01.03**

**Molecular Junction with a Single Biomolecule: Self-Restoring Device and Phosphorylation Assay** [Tomoaki Nishino](#); Tokyo Institute of Technology, Japan

Single-molecule junctions, where a single molecule is trapped in a nanogap between metal electrodes, play pivotal roles in nanoscience and nanotechnology. Measuring biomolecules in the single-molecule junctions offers a unique means to develop single-molecule devices with sophisticated

functionalities, to realize novel biomedical and pharmaceutical applications, and so on.

Regarding the device development, the structural, physical, and chemical properties of DNA at the nanoscale have attracted attention to the prospect of using DNA as a building block in single-molecule devices, which leads to extensive investigations into electron transport through a single DNA molecule. Although significant advances have been made in understanding the transport phenomena through a single DNA molecule, the previous studies mainly focused on the transport phenomena in static DNA structure at thermodynamic equilibria. Against this, we expect that electron transport through DNA under the deliberate control of its structure paves the way for DNA electronic devices with functional controllability in a dynamic manner. To prove this, we investigated the electron transport through the single-molecule junction of DNA that orthogonally clamps a metal nanogap. This DNA single-molecule junction differs from conventional ones in the DNA configuration; the present and conventional junctions contain a DNA molecule oriented in perpendicular and parallel directions to the axis of the nanogap, respectively. The STM measurement of the unzipping dynamics revealed that the present DNA junction enables spontaneous restoration of the molecular junction after its electrical failure and thereby improves the reproducibility of the junction formation. Our study demonstrated that a DNA dynamic structural change could be applied to a single-molecule junction by using the perpendicular configuration.

Single-molecule detection of biologically relevant substances has attracted rapidly growing interest. One successful example of single-molecule technology is the detection of DNA achieved using nanogaps between metal electrodes or nanopore devices. Given their primary role in diverse biological functions, proteins have been regarded as the next challenging target in single-molecule studies. In particular, the detection of post-translational modifications (PTMs) of proteins at the single-molecule level is in high demand, since PTMs constitute an essential regulatory mechanism involved in almost all cellular events. Single-molecule studies would revolutionize medical diagnoses through PTM detection primarily because of their high sensitivity and concomitant high-throughput assays. However, the detection of PTMs at the single-protein level is not trivial, since the chemical structure of an amino acid residue is only slightly altered upon modification. Stringent selectivity or specificity for a PTM of interest is consequently vital for single-molecule detection. In this study, we focused on phosphorylation, which is a biologically important PTM, and demonstrated specific single-molecule detection of peptide phosphorylation by electrical conductance measurements. First, we found that a single orthophosphate anion exhibits a conductance value significantly higher than the peptides and their amino acid residues. This unique electronic property of the phosphate serves as a specific marker, enabling the detection of phosphorylation on a single peptide molecule. Based on this unique electrical signature of phosphate, an *in situ* single-molecule assay of enzymatic phosphorylation was achieved with 95% accuracy and 91% specificity for signal discrimination between phosphorylated and non-phosphorylated peptides. The present study demonstrates novel and specific single-molecule detection of PTMs, which will help elucidate their biological functions and facilitate the development of novel medical diagnostics.

#### 11:00 AM \*SB06.01.04

**Beyond the Diffraction Limit—Optomechanics in Biomolecular Contacts** Albert C. Aragonès; University of Barcelona, Spain

Molecular trapping approaches<sup>[1]</sup> that rely on the electrical detection of single-molecule (SM) junctions<sup>[2,3]</sup> often face a significant challenge of short lifetimes, typically ranging from tens to hundreds of milliseconds,<sup>[4]</sup> primarily due to thermally activated junction breaking.<sup>[5]</sup> The limited detection timescales hinder comprehensive fundamental studies, making the extension of detection times a crucial challenge in SM detection. Our plasmon-supported break-junction (PBJ) technique<sup>[6]</sup> addresses this issue by significantly increasing the lifetime of SM junctions while preserving the native structure of the target molecule. Remarkably, the optical stabilizing force exerted by the nearfield gradient in PBJ enhances the stability of SM junctions, eliminating the need for chemical modifications of the target molecule or the electrode.

In the first part, we will explore how the nearfield manipulation influences capture and release mechanisms.<sup>[7]</sup> As the field strength increases, the rate constant of capture kinetics rises while the release kinetics decrease, favouring the capture state over the release state. Consequently, the SM capture state becomes more likely and more stable than the release state above a specific nearfield strength threshold.

In the second part, we will delve into how the PBJ trapping technique can be further enhanced for biomolecular contacts<sup>[8]</sup> through the manipulation of two physical features: (i) the optical resonance of the target molecule and (ii) the energy of the localized surface plasmon resonance in the nanogap. By leveraging these factors, we can extend the effectiveness of PBJ trapping in capturing and biomolecules.

**DNA Guided Self-Assembly of Organic Materials** James Canary, Ruojie Sha, Thanuka Udumulla and Chufan Yang; New York University, United States

We have developed a highly versatile system for the organization of 2-dimensional (2D) materials on the nanoscale. This system is predicated on the use of DNA-based information as an organizing principle, and on our ability to design DNA to encapsulate and orient other molecular and nanoscopic species in a diverse and effective fashion. We apply branched DNA molecules, not simple linear DNA, to the formation of connected networks of materials in a predictable fashion [1]. We are able to build robust DNA 2D assemblies. Each of these assemblies can be filled as desired, with any molecules, macromolecules or nanoparticles that can be derivatized to interact, bond or bind with the DNA.

In earlier work, chemistry was developed to enable covalent attachment of organic groups to the 2'-O-ribose position of RNA nucleotides. Such an attachment strategy minimizes distortion in DNA duplexes by directing appended groups to minimize unfavorable steric interactions with A-form helical structures. A variety of synthetic approaches were examined, involving modifications at different points in DNA oligonucleotide synthesis. Much of the

chemistry was tested in the context of appended oligomers of nylon and poly(ethyleneglycol).

Monodisperse oligomers of electroactive organic polymers were synthesized and appended to DNA oligonucleotides. An octamer of polyaniline, which shows rich electrochemical behavior, was incorporated into a rhombohedral DNA lattice. The resulting crystal showed excellent optical response consistent with cycling between its redox forms [2]. It was later studied in a smaller assembly showing reconfigurable excitonic interactions [3]. A heptamer molecule related to poly(phenylenevinylene) was included in a DNA crystal and found to show strong polarization properties [4].

This presentation will describe unpublished work on the synthesis and assembly of DNA-GNR chimeras within DNA nanostructures.

**DNA Encoded Self-Assembly of Molecular Semiconductors for Light-Harvesting** Jeffrey Gorman, Stephanie M. Hart, Torsten John, Maria A. Castellanos, Adam Willard, Gabriela Schalu-Cohen and Mark Bathe; MIT, United States

Plants transport and convert solar energy into radical-pairs at the 'reaction center' to generate fuel. Nature achieves this with a homogeneous set of pigments, where the host protein environment facilitates tailored couplings between many pigments each with their own function. In contrast, exquisite control over artificial semiconductors for exciton circuits and solar cells remains lacking. Our ability to synthetically generate molecular networks with prescribed nanoscale structure is lacking. To address this gap towards well-designed molecular optoelectronics, we report the development of DNA scaffolds hosting chromophores,<sup>1</sup> to enhance excited state evolution for solar light harvesting.

Here we study the exciton evolution between strongly coupled perylene diimide (PDI) dye pairs scaffolded in DNA. PDIs are exemplar molecular aggregates as they produce a range of photoinduced excited states, depending on their spatial organization.<sup>2</sup> To study how we can map a specific excited-state pathway to a PDI-DNA structure, we exploited the molecular precision of DNA base-pairing and nanoscale rigidity of DNA origami to generate a library of optoelectronic constructs. We make hundreds of nucleic acid-chromophore conjugates and self-assemble them into prescribed shapes. Using ultrafast spectroscopy, we identified designs that gave rise to different photoinduced species, including excimers and charge-transfer states. Next, we use computational modelling to pinpoint geometrical features that can be linked to a specific excited-state pathway. Our synthetic DNA platform offers the ability to rapidly survey the structure-property of molecular aggregates and identify optimized structures that can be useful for applications in excitonic devices, including solar conversion and quantum information.

**Metal-Mediated Molecular Electronics in DNA Nanosystems** Simon Vecchioni<sup>1</sup>, Brandon Lu<sup>1</sup>, William Livernois<sup>2</sup>, Chufan Yang<sup>1</sup>, Yoel P. Ohayon<sup>1</sup>, Karol Woloszyn<sup>1</sup>, Chengde Mao<sup>3</sup>, Lara Perren<sup>1</sup>, James Canary<sup>1</sup>, Anant Anantram<sup>2</sup> and Ruojie Sha<sup>1</sup>; <sup>1</sup>New York University, United States; <sup>2</sup>University of Washington, United States; <sup>3</sup>Purdue University, United States

DNA as a vehicle for molecular programming relies on the predictability and information storage capability of the canonical Watson-Crick base pairs, A:T and G:C. With only four Watson-Crick nucleobases and the poor electronic conduction in A:T pairs, it has become clear that there are strong limitations on the diversity and ensuing complexity of DNA-based electronic systems. To address this limitation, we present an expanded DNA alphabet based on metal-mediated DNA (mmDNA) base pairing in which we substitute hydrogen bonds between pyrimidine nucleobases with templated metal ion coordination.

We employ a self-assembling 3D DNA crystal system, the tensegrity triangle, to determine the biomolecular structures of 30+ metal ion (Ag<sup>+</sup>, Hg<sup>2+</sup>, Au<sup>+</sup>, and Cd<sup>2+</sup>)-mediated DNA (mmDNA) base pairs, and we further use this comprehensive structural library to elucidate fundamental design rules for an expanded DNA metal coding system. Energy gap calculations elucidate an electronic fingerprint for the base pair classes in our library, and show additional levels in the lowest unoccupied molecular orbitals (LUMO) of mmDNA structures, rendering them attractive molecular electronic candidates. Our results are consistent with previous studies in which mmDNA base pairs have been shown to have superlative electronic and magnetic properties, and we suggest a transmission mechanism to describe this behavior.

We further manipulate our self-assembled DNA crystals using pH to capture by x-ray diffraction a series of reversible, pH-driven chemical reactions involving silver, mercury and gold ions, with implications for bandgap tuning. Importantly, we identify titration points at which mmDNA pairs exist in a heterobimetallic state, where a single DNA base pair binds to both Ag<sup>+</sup> and Hg<sup>2+</sup> in tandem. The precision self-assembly of heterobimetallic DNA chemistry at the sub-nanometer scale will drive atomistic design frameworks for more elaborate mmDNA-based nanodevices and nanotechnologies. We anticipate the integration of this expanded mmDNA alphabet as a means of programming specific interactions into DNA nanostructures to enable the exploitation of their electronic, magnetic, and catalytic properties for future nanotechnology applications.

#### 3:45 PM SB06.02.05

**Selectivity and Real-Time Potassium Ion Sensor Based on dsDNA Sequences Aptamer in ZnO Thin-Film Transistors with Floating Structure** Yen Shuo Chen<sup>1</sup>, Chun Chi Chen<sup>2</sup>, Hsin-Chiang You<sup>3</sup> and Fu-Hsiang Ko<sup>1</sup>; <sup>1</sup>National Yang Ming Chiao Tung University, Taiwan; <sup>2</sup>Taiwan Semiconductor Research Institute, Taiwan; <sup>3</sup>National Chin-Yi University of Technology, Taiwan

The level of potassium ions in clinical diagnosis is most associated with chronic kidney disease (CKD) and the pathophysiology of insulin secretion. The normal concentration in human blood of potassium ions is 2.5 to 5.5 mEq/L. In the past, the assay was mostly done by Blood Potassium Content Assay Kit, which provided that the potassium ions in the serum interact with sodium tetraphenylborate to form water-insoluble, which is time-consuming. Therefore, a rapid and immediate of detecting potassium ions is helpful for this issue. Recently, thin film transistors (TFTs) such as zinc oxide (ZnO) for biosensors have become the focus of increased research interest due to their high transparency and non-toxicity, and several reports have discussed the impact of floating gate structures on the sensing and reproducibility aspects of biosensors in solution.

In this study, unique double-stranded deoxyribonucleic acid (dsDNA) was used in combination with different concentrations of K ions detected through ZnO-based biosensors with a floating-gate structure. The TFTs were successfully operated as a switching device at a low operating voltage of 5 V. Here, ZnO TFTs with floating gate structures were used to sense dsDNA bound to metal ions in solution by non-contact sensing, and more than 50 detection times were achieved by removing solutions and low-temperature annealing, which is useful for biosensing. The dsDNA at 100  $\mu\text{M}$  was dissolved in DI water and TE buffer to form a solution. The ratio of DI water to Tris-EDTA (TE) buffer was 1:10, and the molecular weight of the dsDNA (GGTTGGTGTGGTTGG) was 359.8. The KCl concentrations were 0.01 M (0.8 mEq/L), 0.03 M (2.5 mEq/L), and 0.1 M (5.5 mEq/L), respectively. To understand the relationship between the number of combinations of different concentrations of potassium ions and the potential of the DNA sequence, the number of zeta potentials for each concentration was measured. The zeta potential of dsDNA was -23.63 mV. The stability of 0.01 M KCl solution was tested with -15.01 and -14.41 mV, respectively. The zeta potential was measured within an inaccuracy of 0.6 mV because a few ions flowing into the solution were unaffected. A positive charge is generated when the DNA sequence binds to potassium ions showing a glove-like shape and can completely wrap around  $\text{K}^+$ . When the DNA sequence was bound to  $\text{K}^+$  in the 0.01 M KCl solution, the zeta potential was -15.01 mV. The zeta potential was -2 mV when the concentration of the KCl solution was 0.03 M; the zeta potential was 52.53 mV when the concentration was 0.1 M. These results showed that the KCL elevated by 6.75 mV per 0.01 M concentration.

To investigate ZnO-TFT-based potassium ion detectors, the performance of the ZnO TFT was assessed by analyzing the field-effect mobility ( $\mu\text{FE}$ ), threshold voltage ( $V_{\text{TH}}$ ), and threshold voltage shift ( $\Delta V_{\text{TH}}$ ) for carrier transport. In the initial state, the TFTs exhibited typically electrical performance. Specifically,  $I_{\text{on}}/I_{\text{off}}$  was  $2.3 \times 10^4$  A, the threshold voltage ( $V_{\text{TH}}$ ) was -2 V, and the field-effect mobility ( $\mu\text{FE}$ ) was  $0.006 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . A unique ssDNA sequence combined with 0.01, 0.03, and 0.1 M KCl. The TFTs exhibited selective and sensitive electrical performance:  $I_{\text{on}}/I_{\text{off}} = 3.8 \times 10^4$  A,  $V_{\text{TH}} = 2.5$  V, and  $= 0.0052 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ;  $I_{\text{on}}/I_{\text{off}} = 2.9 \times 10^4$  A,  $V_{\text{TH}} = 2$  V, and  $= 0.0059 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ ; and  $I_{\text{on}}/I_{\text{off}} = 3.6 \times 10^4$  A,  $= -0.5$  V, and  $= 0.0068 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ . The ZnO-based TFT showed that KCL was elevated by 0.5 V per 0.01 M of concentration of  $\text{K}^+$ . As the concentration rises, dsDNA binds to more  $\text{K}^+$ , suggesting that the detected positively and negatively charged objects affect the turn-on voltage of ZnO TFTs. The increase in  $\Delta V_{\text{TH}}$  also indicated increased binding of dsDNA to  $\text{K}^+$  with potassium concentrations ranging from 0.01 M to 0.1 M and showed a linear correlation (0.99706). This ZnO-based TFT with DNA sequences aptamer could be used as a biosensor.

SESSION SB06.03: Biomolecular Electronics—The Fundamentals, Experiments and Computational Approaches I

#### 9:00 AM OPENING REMARKS

##### 9:05 AM \*SB06.03.01

**Long Range Conductivity in Non-Redox Active Proteins** [Stuart M. Lindsay](#)<sup>1</sup>, Dmitry Matyushov<sup>1</sup>, Aleksei Aksimentiev<sup>2</sup> and Siddharth Krishnan<sup>2</sup>;  
<sup>1</sup>Arizona State University, United States; <sup>2</sup>University of Illinois at Urbana-Champaign, United States

It is widely assumed that efficient charge transfer in proteins requires the presence of redox cofactors, but we have found long-range (nS over > 10 nm) conductance in many proteins that do not contain redox cofactors. This is important because it means that fluctuations of many proteins can be followed electrically, as their conductance changes with conformation. For example, we have been able to follow the fluctuations in a DNA polymerase as it actively processes a template.

The conductivity of a hopping conductor is proportional to the quantity  $nD$ , where  $n$  is the carrier density and  $D$  is the diffusion constant for carriers. Since proteins do not possess a Fermi sea, charge injection ( $n > 0$ ) is required for conductivity. This is in line with our observations that the protein needs to be coupled to the electrodes via ligands or specific chemical bonds for conductivity to be observed, though adventitious reactive groups on the protein can serve the same purpose.

A diffusion constant  $D > 2 \times 10^{-4} \text{ cm}^2/\text{s}$  is required to account for the most highly conductive protein wires (OmcS cytochrome wires) and this, in turn, requires a reorganization energy on the order of  $kT$ , a small fraction of the value derived from the Stokes shift in classical Marcus theory. Molecular dynamics simulations of a series of linear proteins (whose electronic properties have been measured) show that the Marcus picture is not valid, the free energy parabolas associated with charge transfer between aromatic residues being broader than predicted from the Stokes shift. As a consequence, the reaction barriers are typically  $\sim 40$  meV, almost equal to  $3/2 kT$ . The calculated diffusion constant is  $2 \times 10^{-4} \text{ cm}^2/\text{s}$ , accounting for the observed decay length. A model for charge injection determines  $n$  with one adjustable parameter that is bounded by electrochemical data, and the resulting conductivity is in agreement with experimental data.

##### 9:35 AM SB06.03.02

**Combinations of Analytical and Machine Learning Methods in a Single Simulations Framework for Modelling of BioFETs** [Vihar P. Georgiev](#)<sup>1</sup>, Naveen Kumar<sup>1</sup> and Cesar Pascual Garcia<sup>2</sup>; <sup>1</sup>University of Glasgow, United Kingdom; <sup>2</sup>Luxembourg Institute of Science and Technology, Luxembourg

In this paper, we present the simulation results of a BioFET using a novel simulation methodology implemented in a computational framework called the Biomolecule-Oxide Simulator (BOxSim). Our novel simulation methodology is based on Gouy-Chapman-Stern and the modified Site-binding models in combination with a machine learning methodology.

Moreover, our “BOxSim” framework is the computational simulation framework that works on the hierarchical inclusion of interdependent functions to operate multiple models simultaneously. BOxSim is flexible simulation environment which considers the problems of reactive sites from oxide surfaces or non-specific bindings along with the noise present in the experimental signal to calibrate and extract the required device output characteristics. It can help in generating the sensor response which can be experimentally calibrated to confirm the surface density of the specific and non-specific binding as a yield of the process while filtering the noise with the help of the developed methodology. BOxSim is designed in a way that can interact with the commercial tool (e.g., Synopsys TCAD) and our inhouse-simulator called Nano-electronic Simulation Software (NESS) to simulate the main device characteristics for designing either Ion-sensitive FET (ISFET) or Chem/Bio-FET based on the application. Industry-standard compact (BSIM) models can also be used to interact with the BOxSim which takes the generated surface potential from the BOxSim simulator and transfers it into a circuit simulator to evaluate various ISFET circuit designs.

To show the capabilities of our BOxSim framework, as input we have considered several oxides, amino acids (AA) and short peptides which generate distinct signatures for arch AA or peptide. We have investigated the impact of various high-k dielectric materials as the gate oxide on important Figures of Merit (FoM) such as current in the channel of the device, surface potential ( $\psi_s$ ), sensitivity and intrinsic buffer capacitance. More importantly, the variation

of differential capacitance ( $C_T$ ) with the second gradient of drain current ( $d^2I_e/dpH^2$ ) and surface potential ( $d^2\Psi_s/dpH^2$ ) are used to uniquely identify the signatures of different amino acids or peptides. The surface potential of oxides is dependent on the affinity constants and the zero-cross-over point represents the zwitterion state. Similarly, we have simulated the detection process of different AA such as Glutamic Acid (E) and Lysine (K) immobilized with carboxyl (C-Imm.) or amine (N-Imm.) terminal. The affinity constants, isoelectric point, and density of amino acids can be extracted from the  $d^2\Psi_s/dpH^2$  variation with the bulk pH. Other than amino acids, we have shown the distinct features of short a peptide Phenylalanine-Proline (FP) immobilized with carboxyl-terminal and the addition of Glutamic Acid to the sequence. The sensor output can be observed as the variation of drain current with the pH for the immobilized peptide sequence on the sensing surface. We have also confirmed the reliability of the designed model by calibrating the simulated results with the experimental data for different physical conditions. The proposed method can be helpful in defining an efficient method for label-free protein sequencing.

**Electron Transport Through Proteins beyond the Conventional Tunneling Limit** David Cahen and Sudipta Bera; Weizmann Institute of Science, Israel

A key conundrum of bio-molecular electronics is the quite efficient electron transport (ETp) through solid-state junctions wider than a few nm, often without temperature activation. Such a behavior challenges known transport mechanisms, given that proteins, lacking extended conjugation, are low charge carrier density molecules and the experimental ETp results are surprising. A wide range of electron transport (ETp) studies has been done, mostly on protein films of comparable thickness, one that is within the limit of quantum mechanical tunneling (2, or for conjugated systems ~5 nm). Typically, for polymer junctions, current decays exponentially with junction width, limiting detection beyond a certain thickness and this should hold also with biopolymers, such as proteins. We find now (Bera et al, submitted) that we can detect and measure protein conduction of from 9 - 60 nm thick junctions of self-assembled *bacteriorhodopsin* multilayers to test the limit of ETp as a function of junction thickness, in a large ( $\sim 10^{-3}$  cm<sup>2</sup>) area configuration. Junction quality was confirmed by impedance spectroscopy and voltage breakdown. Such junctions show near or complete activation-less transport with the most-efficient length-normalized electron transport reported so far (0.06-0.53 nm<sup>-1</sup>).

The small to negligible (<200K) temperature dependence, among other things, excludes hopping as a plausible mechanism. While a modified Landauer model could be a possibility, *the large transport distance (60 nm) makes coherent quantum mechanical tunneling physically implausible*. The results may be understood by assuming that ETp is limited by injection at (via tunneling through) one of the contacts, followed by a much more efficient charge propagation across the proteins. Additionally, electrostatics of the protein film, whose dielectric constant we measured by impedance, will further limit the number of charge carriers in the protein film. Such a view also defines the question to tackle now, namely how electrons can pass through such wide protein layers at a rate that is measurable by our electronics and, apparently, more efficient than the rate of injection through the contacts.

**Charge Transport Through Self-Assembled Monolayers—The Roles of Conformation and Chelation** Samuel E. Root, George M. Whitesides, Yuan Li and Lee Belding; Harvard University, United States

To elucidate charge transport mechanisms through complex biomolecules--involving conformationally flexible, supramolecular systems--and isolate effects arising from different molecular scale features, it is useful to investigate simple, well-defined model systems. The "EGaIn junction," which uses a liquid metal electrode to measure charge transport through self-assembled monolayers (SAM), paired with a physical-organic approach to systematically modify the molecules within the SAM, provides a powerful platform for approaching this problem. I will discuss two recent works using this approach to understand (1) the role of molecular conformation (and specifically conformational disorder) on tunneling and rectification of current, and (2) charge transport through SAMs terminated by a chelating group and the influence of the binding of different metal ions.

**1) Conformation.** This work demonstrates that molecular conformation of molecules making up self-assembled monolayers (SAMs) influences the rates of charge tunneling (CT) through them, in molecular junctions of the form AuTS/S(CH<sub>2</sub>)<sub>2</sub>CONR<sub>1</sub>R<sub>2</sub>/Ga<sub>2</sub>O<sub>3</sub>/EGaIn, where R<sub>1</sub> and R<sub>2</sub> were alkyl chains of different length. The lengths of chains R<sub>1</sub> and R<sub>2</sub> were selected to influence the conformational structure of the molecules in the monolayer. The conformations of the molecules influence the thickness of the monolayer and their rectification ratios at  $\pm 1.0$  V. When R<sub>1</sub> = H, the molecules are well ordered and exist predominantly in trans-extended conformations. When R<sub>1</sub> is an alkyl group (e.g., R<sub>1</sub>  $\neq$  H) however, their conformations can no longer be all-trans-extended, and the molecules adopt more gauche dihedral angles. This change in type of conformation decreases conformational order and influences rates of tunneling. When R<sub>1</sub> = R<sub>2</sub>, the rates of CT decrease (up to 6.3x), relative to rates of CT observed through SAMs having the same total chain lengths, or thicknesses, when R<sub>1</sub> = H. When R<sub>1</sub>  $\neq$  H  $\neq$  R<sub>2</sub>, there is a weaker correlation (relative to when R<sub>1</sub> = H or R<sub>2</sub>) between current density and chain length or monolayer thickness, and in some cases the rates of CT through SAMs made from molecules with different R<sub>2</sub> groups are different, even when the thickness of the SAM (as determined by XPS) is the same.

**2) Chelation.** This paper describes a surface analysis technique that uses the "EGaIn junction" to measure tunneling current densities (J(V), amps/cm<sup>2</sup>) through self-assembled monolayers (SAMs) terminated in a chelating group and incorporating different transition metal ions. Comparisons of J(V) measurements (performed ex-situ, in air) between bare chelating groups and chelates—formed through incubation of the SAM within a solution of bivalent metal ions—are used to characterize the composition of the SAM and infer the dissociation constant (K<sub>d</sub>, mol/L), as well as kinetic rate constants (k<sub>off</sub>, L/mol s; k<sub>on</sub>, 1/s) of the reversible chelate-metal reaction. To demonstrate the concept, SAMs incorporating a chelating terminal group were incubated within ethanol solutions of metal salts (CuCl<sub>2</sub>, NiCl<sub>2</sub>, and AgClO<sub>4</sub>). After rinsing and drying the surface, measurements of tunneling current as a function of incubation time and concentration in solution are analyzed with a simple model to infer k<sub>off</sub>, k<sub>on</sub>, and K<sub>d</sub>. X-ray photoelectron spectroscopy (XPS) provides an independent measure of surface composition to confirm inferences from J(V) measurements, as well as to characterize the stoichiometry and oxidation states of the bound metal ions. The titration experiments establish that: (i) bound metal ions are stable to the rinsing step as long as the rinsing time,  $\tau_{\text{rinse}}$  is at least  $10 \times$  lower than  $1/k_{\text{off}}$ ; (ii) the bound metal ions increase the current density at the negative bias and reduce the rectification observed with free bpy terminal groups; (iii) the values of K<sub>d</sub> measured using tunneling currents are comparable to those measured using XPS, but larger than those measured in solution.

**Tunneling-to-Hopping Transition in Multiheme Cytochrome Bioelectronic Junctions** Jochen Blumberger<sup>1</sup>, Xiaojing Wu<sup>1</sup> and Zdenek Futera<sup>2</sup>;

<sup>1</sup>University College London, United Kingdom; <sup>2</sup>University of South Bohemia, Czechia

Multiheme cytochromes (MHCs) have attracted much interest for use in nanobioelectronic junctions due to their high electronic conductances.

Recent measurements on dry MHC junctions suggested that a coherent tunneling mechanism is operative over surprisingly long distances (>3 nm), which challenges our understanding of coherent transport phenomena. In my talk I will present large-scale electronic structure calculations of gold-MHC-gold junctions that have allowed us to obtain the current-voltage characteristic of these proteins in well defined adsorption geometries and orientations [1,2]. We show that the high electronic conductances of MHC proteins is due to (i) a low exponential distance decay constant for coherent conduction ( $\beta = 0.2 \text{ \AA}^{-1}$ ) and (ii) a large density of protein electronic states which prolongs the coherent tunneling regime to distances that exceed those in molecular wires made of small molecules. We also find that incoherent hopping conduction is uncompetitive in the experimental setup due to the large energy level offset at the protein-electrode interface. Removing this offset, e.g., by gating, we predict that the transport mechanism crosses over from coherent tunneling to incoherent hopping at a protein size of  $\sim 7 \text{ nm}$ , thus enabling electron transport on the micrometer scale with a shallow polynomial ( $\sim 1/r$ ) distance decay.

**Modeling Spin Transport in Multi-Heme Cytochromes** William Livernois and Anant Anantram; University of Washington, United States

Multi-heme cytochromes have attracted attention due to their conductive properties [1] and, more recently, their spin-selective properties [2]. The small tetraheme cytochrome (STC), a c-type cytochrome prominently found in *Shewanella oneidensis*, has been experimentally validated to act as a spin filter [3], highlighting its potential integration into the burgeoning field of nano-scale spintronic devices. A spin-dependent transport model was used to model this system, building upon prior work that has proven effective in analyzing similar biomaterials and cytochromes [4]. The improved model incorporates non-collinear effects such as spin-orbit coupling using generalized open shell density functional theory (DFT) in order to analyze the electronic structure of the cytochrome and spin-dependent transport properties. Preliminary findings indicate that collinear effects, arising from electron exchange and spin state, predominantly influence the transport pathway while spin-orbit effects only cause minor shifts in orbital energies.

To complement our electronic structure and transport studies, we have undertaken a detailed analysis of the role of the peptide backbone, employing hybrid Quantum Mechanics/Molecular Mechanics (QM/MM) modeling methods. The modeling results indicate that the peptide backbone functions primarily as a structural scaffold facilitating heme-to-heme electron transport, rather than directly contributing to electron conduction. Additionally, recognizing the importance of solvation effects in biological systems, we have investigated the impact of solvation on the cytochrome's properties. The solvent, modeled using an implicit model and counterions, was found to modulate the coupling between heme sites and the overall conductivity of the cytochrome.

The research was supported by National Science Foundation NSF Grant Number 2317843, NSF Future of Manufacturing Grant No. 2229131 and the NDSEG fellowship.

**Current Rectification via Photosystem I Monolayers Induced by Their Orientation on Hydrophilic Self-Assembled Monolayers on Titanium Nitride** Hector J. Rojas Rojas<sup>1</sup>, Feng Liu<sup>2</sup>, Jerry A. Fereiro<sup>3</sup>, Domenikos Chryssikos<sup>1</sup>, Dario Leister<sup>2</sup> and Marc Tornow<sup>1</sup>; <sup>1</sup>Technical University of Munich, Germany; <sup>2</sup>Ludwig-Maximilians-Universität München, Germany; <sup>3</sup>Indian Institute of Science Education and Research, India

The photosensitive protein Photosystem I (PSI) is considered one of the most efficient light-harvesting molecular complexes in nature [1]. The electron transport studies carried out on PSI monolayer(s) formed on (quasi-) metallic contacts (highly doped silicon, indium tin oxide, silver, or, in the majority of cases, gold) using reliable soft top contacts show high reproducibility [2-5], along with its peculiar ability to rectify electrical current [2,4,5]. In the present study, we introduce titanium nitride (TiN) as a promising alternative bottom contact material to investigate the electronic transport properties of PSI. TiN is a hard, conductive ceramic well-established in CMOS technology, chemically inert, and biocompatible. Self-assembled monolayers (SAMs) of various hydrophilic group-terminated phosphonic acids covalently bound to the TiN surface were used to attach PSI layers onto its head surface electrostatically. Specifically, we investigated -OH, -COOH, and -NH<sub>2</sub> terminal head groups and tailored mixtures of these. We used atomic force microscopy to confirm the formation of a PSI monolayer of thickness approx. 6 nm, with about 80% surface coverage. DC electrical measurements using eutectic gallium-indium (EGaIn) soft top contacts showed asymmetric I-V curves, with rectification ratio (RR) values varying from 150 to 460. We assign the observed rectification to possible PSI orientation preferences on a particular linker head group. Current rectification in PSI has been previously attributed to an internal electric dipole originating from charged states of the protein residual groups [4,5]. Our data indicate an orientation in which the stromal side of the protein complex is predominantly in contact with the hydrophilic linker surface. We analyze our data within the framework of tunneling through an asymmetric trapezoidal barrier [6].

**Modeling Quantum Charge Transport Through Nucleic Acid Structures: Role of Decoherence** Hashem Mohammad<sup>1</sup> and Anant Anantram<sup>2</sup>; <sup>1</sup>Kuwait University, Kuwait; <sup>2</sup>University of Washington, United States

Understanding the conductance of DNA helps in the development of new sequencing techniques, methods to sense biological processes, disease detection techniques, and future DNA-based nanoelectronics. The challenges in understanding the underlying transport phenomena stem from the facts that: 1) DNA is a floppy molecule that exists in a solvent environment, 2) sequence and conformation affect the energy levels distribution along the strand, and 3) the need to account for the details of the DNA-electrode junction.

Modeling of charge transport through nanoscale nucleic acid structures requires careful attention to the quantum effects. The fluctuating nature of the molecule and the surrounding solvent environment can affect the electron transport process depending on the length scale, going from coherent to decoherent transport, or to an intermediate state of coherent-decoherent transport. One prominent method to model charge transport through nanoscale devices is the Green's function formalism. This formalism uses the Hamiltonian obtained from quantum mechanical simulations such as DFT to calculate the electron transmission properties. From the transmission, we can calculate other physical properties such as conductance and current-voltage characteristics. This formalism allows us to include the effect of attaching metallic contacts to the DNA through self-energy terms, removing the need for explicitly including them in the quantum-based simulations step. Additionally, it can incorporate decoherence due to scattering through self-energy terms as well.

This presentation focuses on the theory and modeling of quantum transport through nucleic acid structures using Green's function method with decoherence probes. We model a DNA connected to two metallic contacts in a contact-DNA-contact setup. For a weakly-coupled system such as DNA, we use the decoherence probes method to account for scattering events. This technique uses phenomenological probes to mimic the interaction of electrons with the environment as they lose phase information and/or gain and lose energy (inelastic scattering). Decoherence broadens the energy levels and allows electrons to traverse the structure at energies that were not originally accessible to the electrons. The broadening of energy levels increases the transmission probability across the DNA. This constitutes the main difference between coherent and decoherent charge transport. Thus, the inclusion of decoherence allows us to obtain conductance values within the range of the experimental values, something that the coherent transport could not achieve.

The decoherence probes are included in the model as self-energies controlled by a spatially dependent parameter that represents the average scattering time for the electron. In the previous work, the decoherence parameter used was energy independent. The drawback of this is that it overestimates the transmission in the HOMO-LUMO gap and washes out distinct transmission features within the HOMO or LUMO bands. Therefore, we present an energy-dependent decoherence model that allows us to better describe the transmission spectra. We demonstrate that this model can generate the expected exponential decay of conductance with the increase in DNA length, and yields conductance values that agree with experiments.

We apply the decoherence probe method to a variety of DNA strands to demonstrate its use. The applications involve (i) detecting a single base mutation in a 15-base-pair long DNA strand, (ii) studying the properties of heterostructures created with DNA strands analogous to solid-state heterojunctions, and (iii) doping of DNA by an intercalating molecule (anthraquinone) between the base pairs, which allows a change in conductance depending on the redox state of the intercalator.

**How Do Electric Bacteria Breathe Without Oxygen or Soluble Electron Acceptors? Protein Nanowires: Structures, Functions, and Ultrafast Electron Transfer Mechanisms** Nikhil S. Malvankar; Yale University, United States

Deep in the ocean or underground, where there is no oxygen, *Geobacter* "breathe" by projecting tiny hair-like protein filaments called "nanowires" into the soil, to dispose of excess electrons resulting from the conversion of nutrients to energy, cleaning up radioactive sites. Although it is long known that *Geobacter* use filaments for electron transfer (*Nature* 2002, 2005), it was not clear what they are actually made of and why they are conductive.

Our studies have revealed a surprise: the nanowires have a core of hemes lining up to create a continuous path along which electrons travel (*Cell* 19, *Nature Chem.Bio.* '20, *Nature Micro* '23) and can be engineered with atomic precision using recombinant DNA technology, making for remarkably versatile electronic components.

We have further found that *Geobacter* pili remain hidden inside the cell and serve as a piston to secrete nanowire-forming cytochromes (*Nature* 2021) rather than functioning as a nanowire themselves as previously thought (*Current Opinion* 2020).

These studies solve a longstanding mystery to explain our previous findings that these bacteria transport electrons via nanowires (*Nature Nano*. 2014) over 100-times their size to electron acceptors (*Nature Nano*. 2011) and partner cells (*Science* 2010) and store electrons when acceptors are absent akin to how humans use their lungs (*ChemPhysChem* 2012).

Our contact-free measurements of intrinsic electron conductivity in individual protein nanowires reveals how energetics and proximity of proton acceptors modulate conductivity by 100-fold (*PNAS* 2021, *Biochem. Journal* 2021). We have also developed synthetic protein nanowires with tunable conductivity and programmable self-assembly using non-natural click chemistry functionality (*Nature Comm.* 2022).

In this talk I will present our efforts to identify the physical and molecular mechanism of high conductivity of microbial cytochrome nanowires. Our conducting-probe AFM measurements show one of the highest electronic conductivity ever reported in proteins (> 100 S/cm) (*Nature Chem.Bio.* '20). Femtosecond transient absorption spectroscopy and quantum dynamics simulations reveal ultrafast (<200 fs) electron transfer between nanowire hemes upon photoexcitation, enhancing carrier density and mobility. Photoconductive atomic force microscopy shows up to 100-fold increase in photocurrent in purified individual nanowires. Photocurrents respond rapidly (<100 ms) to the excitation and persist reversibly for hours (*Nature Comm.* '22). Furthermore, nanowires and biofilms show non-classical temperature dependence of conductivity with cooling accelerating electron transport by 300-fold.

Our efforts to computationally model the heme redox potential and conductivity of nanowires yielded up to a billion-fold lower conductivity than experiments (*JPCB* '21, *JPCB* '22), illustrating that the existing computational models based on electron hopping assumption fail to capture electron transfer in biological nanowires. This raises the possibility that biological nanowires employ a fundamentally different, currently unknown mechanism. Thus, existing models predict the same conductivity for all nanowires with computed timescales for heme-to-heme electron transfers (100 ns), million-fold lower than that measured using transient absorption in excited-state (*Nature Comm.*) and conductivity in ground-state for fully hydrated (*Nature & Cell*) or air-

dried nanowires (*Science Adv.*).

Notably, multiple computational studies have predicted that invoking quantum effects could account for the high conductivity of these nanowires (*Nanotechnology*'20, *IEEE*'21, *ACS Nano*'23). I will present our efforts to experimentally assess these computational predictions using multiple probes such as light, temperature, electric and magnetic fields. I will also discuss how our studies are helping to understand, predict and control extracellular electron transfer by nanowires used by diverse environmental microbes to capture, convert and store energy.

### 3:45 PM SB06.04.05

**Combination of Droplet Oscillation and Dielectrophoresis to Increase the Sensitivity of Biosensors** Marten Musiol<sup>1</sup>, Marte Thorns<sup>1</sup>, Benita Hafemann<sup>1</sup>, Fenja Schröder<sup>1</sup>, Felix Hirschberg<sup>1</sup>, Annalena Eckert<sup>1</sup>, Rebekka Biedendieck<sup>1</sup>, Hans-Hermann Johannes<sup>1,2</sup>, Dieter Jahn<sup>1</sup> and Wolfgang Kowalsky<sup>1,2</sup>; <sup>1</sup>Technische Universität Braunschweig, Germany; <sup>2</sup>Leibniz Universität Hannover, Germany

Biosensors have become a research field of high interest over the last few years. Especially the detection of bacteria is one of the main issues for biosensors. To prevent human health risks and detect even a small quantity of bacteria e.g. in water sources, reliable and accurate detection of bacteria must be guaranteed even for small concentration of bacteria. To increase the sensitivity of such biosensors it is of high importance to increase the number of bacteria on the sensing area. In this work dielectrophoresis (DEP) is utilized to improve bacteria collection at the sensing area.

DEP accelerates dielectric particles suspended in a liquid towards regions of either high or low electric field gradient by applying an alternating inhomogeneous electric field. The force associated with DEP is called dielectrophoretic force (DEP force). This force operates in a radius of micrometers. The transport of particles to the operating area of the DEP force is improved by droplet oscillation. This method provides liquid turbulences inside the particle solution. Thereby, more bacterial cells are collected on the sensing area.

The droplet oscillations are generated by two oscillation electrodes. Those electrodes are implemented beneath the DEP setup with a distance of micrometers. Between the DEP and oscillation electrodes a droplet of a polar liquid is located. By applying a voltage to one of the droplet oscillation electrodes the polar molecules of the liquid align with the electric field. The alignment of the molecules leads to a decrease of surface tension in the area of the electric field. As a response the liquid starts to flow towards the region of low surface tension. To get a consistent flow inside the droplet the applied voltage switches between the two oscillation electrodes.

This research focuses on optimizing the reciprocal influence of the DEP field and the electric field for the droplet oscillation. In order to enhance the experimental setup, the simulation software COMSOL Multiphysics® was used. In this simulation parameters like the frequencies of the electric fields or electrode geometries were taken into account. The results of the simulations should allow us to construct a setup combining droplet oscillation and DEP, that is capable of improving the sensitivity of biosensors.

Key words: droplet oscillation, dielectrophoresis, liquid turbulences, biosensors, bacteria

### 4:00 PM \*SB06.04.06

**Seeing is Believing: Quantitative Imaging of Bacterial Electron Export Correlated with Protein Structure and Mechanical Properties** Sibel E. Yalcin; Yale University, United States

Protein nanowires enable *Geobacter* to survive without-oxygen like soluble electron acceptors perform important functions such as cleaning up radioactive sites, generating electricity (*Nature Nano*, 2011, or sharing electrons with other bacteria (*Science* 2010). Although it is known for more than two decades that *Geobacter* make nanowires (*Nature* 2002, 2005), it was not clear what they are actually made of and why they are conductive. I will present recent discoveries that resolve two decades of confounding observations in thousands of publications that thought these nanowires as pili filaments (*Current Opinion in Chemical Biology* 2020).

Our studies have revealed a surprise: the protein nanowires have a core of metal-containing molecules called hemes. Combining high-resolution cryo-electron microscopy with multimodal functional imaging, we found that hemes line up to create a continuous path along which electrons travel. Using multimodal functional imaging (*Physical Biology* 2020) and a suite of electrical, biochemical and physiological studies, we find that rather than pili, nanowires are composed of cytochromes OmcS and OmcZ that transport electrons via seamless stacking of hemes over micrometers (*Cell* 2019, *Nature Chem.Bio.* 2020). I will discuss the physiological need for two different nanowires and their potential applications for sensing, synthesis, and energy production.

As this area of research is in its infancy, many of our advancements are made possible by the new nanoscopic imaging techniques we have developed to address major bottlenecks for the field by quantitatively visualizing the electron export via protein nanowires (*Nature Nano*, 2014) and also by living diverse bacteria at single-cell-level. For example, the studies described above (*Nature Chem. Bio*) also established a new atomic force microscopy-based multimodal imaging platform to correlate protein structures with electrical and mechanical properties in response to environmental changes, such as pH and redox potential. Using this platform, we found that the rate of electron transfer in protein nanowires depends on the environment. Thus, we were able to make electron transfer 100-times faster by changing environmental conditions, suggesting a possible path to engineering even more conductive protein nanowires. Furthermore, methodological innovation has been a cornerstone of my lab, as the availability of new methods has enabled us to make unexpected discoveries and challenge thinking in the field. For example, our method for growing biofilms in electric fields, allowed not only the first electrogenetic control of biofilm growth (*Nature Chem. Bio*), but enabled us to make the initial discovery that bacterial biofilms conduct electricity (prior to our work, bacterial biofilms had been thought to be electronically non-conducting).

Our nanoscopic imaging methods are widely applicable to diverse biological systems. For example, we have applied these imaging methods for nanoscopic visualization of water binding to minerals (*Sciences Adv.*). We revealed that, instead of growing layer by layer as previously thought, water growth starts near edges before surface tension takes over to engulf the surface and forms droplets. This methodology is allowing us to directly visualize how bacteria export electrons to minerals.

I will present our recent experimental and computational studies to identify the mechanism of electron transfer that occurs at unprecedented ultrafast (< 200 fs) rates and over centimeter distances, 10,000-times the size of a bacterium, through measurements of DC and THz conductivity as a function of nanowire length, temperature, frequency, pH and heme stacking (*Science Adv.* 2022). I will also present how we are experimentally assessing computational prediction of quantum effects accounting for the high conductivity of these nanowires (*Nanotechnology*'20, *IEEE*'21, *ACS Nano*'23), using multiple probes such as light, temperature, electric and magnetic fields.

### 4:30 PM SB06.04.07

**Quantum Transport with Two Interacting Conduction Channels in Gold-Azurin-Bismuth Solid-State Junctions** Ping'an Li<sup>1</sup>, Sudipta Bera<sup>2</sup>, Shailendra Kumer-Saxena<sup>2</sup>, David Cahen<sup>2</sup> and Yoram Selzer<sup>1</sup>; <sup>1</sup>Tel Aviv University, Israel; <sup>2</sup>Weizmann Institute of Science, Israel

The fundamental question of 'what is the transport path of electrons through proteins?' initially introduced while studying long-range electron transfer

between localized redox centers separated by proteins *in vivo* is also highly relevant to the transport properties of solid-state, dry metal-protein-metal junctions because the characteristic Fermi wavelength,  $\lambda_F$ , of the involved electrons is smaller than the contact footprint of the proteins. Under such conditions, the transport path appears to depend on the coupling of the proteins to the leads. For example, in one of the 'work horses' of biomolecular electronics, Au-*Azurin*(Az)-Au junctions, the electrons characterized by  $\lambda_F \sim 0.5$  nm appear to be transported coherently by off-resonance tunneling if Az is strongly coupled to the leads and by coherent resonance tunneling associated with levels of the redox center, if it is weakly coupled to the leads. Transport in the latter case is especially puzzling because the modest coupling values invoked for its quantification are sufficiently small to allow the tunneling charges to reside in the resonance levels a sufficient time for structural relaxation (reorganization), which should then entail non-coherent transport by a hopping, i.e., activated hops with tunneling between them.

Here, we report of conductance measurements of molecular ensemble nanopore junctions of Au-Az-bismuth(Bi), with well-defined geometry and containing  $\sim 2000$  proteins in each pore. We argue that since electrons in Bi have  $\lambda_F$  longer than the protein footprint, transport takes place in these junctions by two interacting conducting channels, characterized by different time scales. The slow and fast channels are associated with the redox center and the protein matrix, respectively, and consequently transport takes place in the first channel by a sequential (non-coherent) process and by coherent non-resonant tunneling in the second channel. The resulting overall observed conductance behavior suggests that the two channels are capacitively coupled and that the broad level responsible for the off-resonance tunneling changes its energy in response to the charge occupation of the weakly coupled (redox) channel. This in turn also suggests that transport in these junctions is dominated by the off-resonance (fast) channel, while the slow (redox) channel contribute directly to conductance only negligibly and instead affects transport by intramolecular gating.

**Single-Molecule Electrical Detection Methods for Public Health Applications: Towards Sustainable Biosensing** [Ajoke Williams](#) and Juan M. Artes Vivancos; University of Massachusetts Lowell, United States

In the face of escalating climate change, which significantly impacts both the global economy and public health, changes in environmental conditions can favor the spread of pathogens and the development of new mutants.[1] Early detection and control of pathogen spread are pivotal in enhancing health outcomes on a broader scale. Among the diverse pathways of pathogen screening, nanotechnology has made remarkable advancements in the last decade. It has also extended its applications to biomolecules, giving rise to BioMolecular Electronics.[2] Notably, the Scanning Tunneling Microscopic (STM)-assisted break junction method (STM-BJ)[3] has led to biophysical studies of individual molecules at the single-molecule level. It stands out as a promising approach for single-molecule biomolecular detection. This concept emerges as a compelling solution for the real-time identification of individual biological molecules. Our research leverages the potential of the STM-BJ method to showcase the electrical detection of RNA cancer biomarkers, distinguishing KRAS mutants G12V and G12C from the wild type.[4] Furthermore, our investigation highlights the remarkable sensitivity and specificity of this technique in identifying RNA coronavirus biomarkers, even at the sub-variant level.[5] This tool can also be applied for the electrical measurement of biomolecular interactions at the single-molecule level.[6] Beyond these pioneering advancements, our focus extends now to the sustainability and life cycle analysis of biosensors. Our future research will focus on minimizing the environmental impact of biosensors by utilizing sustainable materials and processes.[7]

**Soft Actuator-Assisted Minimally Invasive Peripheral Nerve Interfaces** [Chaoqun Dong](#), Alejandro Carnicer Lombarte and George G. Malliaras; University of Cambridge, United Kingdom

Peripheral nerve interfacing has emerged as a highly promising therapeutic technology in various applications, including prosthetic limbs, chronic pain modulation, and the treatment of visceral organ disorders. However, current electrode designs present challenges related to complex handling and implantation-associated irreversible neural damage. This abstract proposes an alternative approach by introducing novel actuatable electrodes that might address these limitations. Our research leverages recent advancements in thin film bioelectronics and soft robotics to develop thin, flexible, and importantly, shape-morphing nerve cuff electrodes. The microfabricated device allows for programming the shape of the electrodes, enabling it to enclose the nerve while maintaining the flexibility to loosen or tighten as needed. This feature ensures a close-fitting conformal interface between the electrode and the nerve, meanwhile enabling straightforward and minimally invasive device explantation steps. Our work presents a promising pathway towards the development of bioelectronic devices that can be manipulated by surgeons to enhance the minimally invasive nature of neurosurgery while achieving optimal electrode-nerve interactions.

### 10:45 AM SB07.01.02

**Thermo-Responsive Conductive Gels for Injectable Bioelectronics** [Vidhika S. Damani](#)<sup>1</sup>, Xinran Xie<sup>2</sup>, Khushboo Suman<sup>1</sup>, Rachel Daso<sup>2</sup>, Giana Alepa<sup>1</sup>, Julian Alberto<sup>1</sup>, Casey Lorch<sup>1</sup>, Ai Nin Yang<sup>1</sup>, Yuhang Wu<sup>1</sup>, Norman Wagner<sup>1</sup>, Jonathan Rivnay<sup>2</sup> and Laure V. Kayser<sup>1,†</sup>; <sup>1</sup>University of Delaware, United States; <sup>2</sup>Northwestern University, United States

Conductive hydrogels have gained traction to interface biological systems with electronics for use in sensing and monitoring, tissue engineering, cell adhesion, and implantable electronics. Most bioelectronic implants depend on inorganic nanoparticles such as carbon nanotubes, metals and graphene for conductivity, but these materials lack mechanical compatibility with biological tissue causing scarring and short-term stability. Hydrogels based on water-dispersible conducting polymers such as PEDOT:PSS have been developed to overcome this challenge, due to their lower Young's modulus. However, these gels must either be pre-formed before inserting into the body or, if injected as a fluid, require the presence of external trigger methods and small molecules, such as chemical crosslinkers or endogenous metabolites for crosslinking *in vivo*. Therefore, there is a need for minimally invasive injectable conductive liquids which can gel rapidly in the body irrespective of the type of tissue, are biocompatible, and do not rely on externally applied triggers. To that end, we have developed a thermo-responsive conducting polymer which forms a stable dispersion in water and gels in 41 seconds at 37 °C. We employ the reversible hydrophilic-hydrophobic transition of poly(N-isopropylacrylamide) close to body temperature, which, when combined with the mixed ionic-electronic conduction of PEDOT:PSS yields a fully reversible and conductive gel with a modulus of 20 Pa. In addition, the mechanical and electronic properties can be tuned by changing the concentration of the dispersion in water. The material has shown biocompatibility with L929 cells both by indirect and direct contact assays. This is the world's first fully reversible conductive gel and has potential for use in cardiac patches, scaffolds for tissue engineering and wound healing and for better contact between electrodes and cells for biosensing.

### 11:00 AM SB07.01.03

**Conductive Polymer Enabled Biostable Liquid Metal Electrodes for Neural Interface** [Huanan Zhang](#); University of Utah, United States

Gallium (Ga)-based liquid metal materials have emerged as a promising material platform for soft bioelectronics. Unfortunately, Ga has limited biostability and electrochemical performance under physiological conditions, which can hinder the implementation of its use in bioelectronic devices. Here, an effective conductive polymer deposition strategy on the liquid metal surface to improve the biostability and electrochemical performance of Ga-based liquid metals for use under physiological conditions is demonstrated. The conductive polymer [poly(3,4-ethylene dioxythiophene):tetrafluoroborate]-modified liquid metal surface significantly outperforms the liquid metal-based electrode in mechanical, biological, and electrochemical studies. *In vivo*

action potential recordings in behaving nonhuman primate and invertebrate models demonstrate the feasibility of using liquid metal electrodes for high-performance neural recording applications. This is the first demonstration of single-unit neural recording using Ga-based liquid metal bioelectronic devices to date. The results determine that the electrochemical deposition of conductive polymer over liquid metal can improve the material properties of liquid metal electrodes for use under physiological conditions and open numerous design opportunities for next-generation liquid metal-based neural electrodes

#### 11:15 AM SB07.01.04

**Identification of Mitral Valve Disease from Cardiac Potentials in Canine Patients with High-Density, E-Textile, Conducting Polymer BSPM Arrays** Ruben Ruiz-Mateos Serrano<sup>1</sup>, Santiago Velasco Bosom<sup>1</sup>, Antonio Dominguez-Alfaro<sup>2,1</sup>, Matias L. Picchio<sup>2</sup>, Daniele Mantione<sup>2</sup>, David Mecerreyes<sup>2</sup> and George G. Malliaras<sup>1</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>University of the Basque Country UPV/EHU, Spain

Valvular heart diseases (VHD) are a major contributor to cardiovascular mortality worldwide, affecting ~75 million people every year. The detection of VHD is currently achieved by means of non-invasive mechanical activity imaging modalities such as magnetic resonance imaging (MRI), computed tomography (CT) or echocardiography. These techniques require expensive equipment and technical user expertise which hinder their employment in general practice clinics. As a consequence, VHD can be only diagnosed at larger medical centres where these machines and the personnel required to operate them are available. In addition, these imaging modalities cannot be employed for the long-term monitoring of acute conditions outside healthcare centres, which forces patients with these conditions to remain in hospital for long periods of time.

Electrocardiography (ECG) is a well-established and inexpensive method for the identification of electrical heart conditions, or rhythms, which is readily available in most local clinics. Despite the fact that ECG is designed to detect electrical activity, it has been shown to be able to capture some of the symptoms caused by VHD. Furthermore, the implementation of deep learning (DL) algorithms which analyse conventional 12-lead ECG data has recently demonstrated the ability of ECG to fully characterise and classify between different types of VHD.

Even though DL algorithms are able to identify VHD, the maximum accuracy they can achieve is limited to ~80%. Furthermore, these complex classifiers require vast amounts of fitting data, long training times and offer little clinical insights into what features of ECG are involved in the identification of VHD. One of the primary factors which restricts the performance of these classifiers is the limited amount of spatial data the 12-lead ECG offers. The sampling of multiple cardiac sites across the torso by means of high-density electrodes in the form of body surface potential maps (BSPM) offers the opportunity to train classical machine learning algorithms on temporal and spatial ECG features, thus increasing both the explainability and the maximum achievable accuracy of VHD classifiers.

In this work, a novel high-density electrode array fabrication technique on e-textiles with conducting polymer coatings is presented through the implementation of a tailored vest for canine models. The data obtained from this vest is presented and specific temporal and spatial features are employed to train a classical machine learning algorithm able to identify mitral valve disease in a canine patient cohort. The results from the classifier are presented in a human-readable format and performance and training metrics are compared and shown to surpass those of state-of-the-art models in the literature. The results hereby obtained pave the way towards the use of BSPM as an affordable and scalable screening technique for VHD.

SESSION SB07.02: Multifunctional Bioelectronics  
Session Chairs: Achilleas Savva and Georgios Spyropoulos  
Monday Afternoon, November 27, 2023  
Hynes, Level 1, Room 110

#### 1:30 PM \*SB07.02.01

**Multifunctional Fiber-Based Interfaces with Central and Peripheral Circuits** Polina Anikeeva; Massachusetts Institute of Technology, United States

To probe the complexity of neuronal signaling between the central and peripheral nervous systems our group designs multifunctional, multimaterial fibers based on soft polymers, composites, and hydrogels. Previously limited to passive electrical, optical, and microfluidic features, these fibers have been augmented with active solid-state devices to record and deliver signals to organs as diverse as the brain and the gastrointestinal tract in freely-behaving rodents. Integration of solid-state components further enabled wireless operation of these fibers. In addition to probing electrophysiological activity, we have recently explored optical recording of neurochemistry using multifunctional fibers in conjunction with fluorescent activity indicators. Photometric recordings revealed the effects of drugs of abuse on neural circuits, and for the first time, permitted recording of signaling of non-neuronal tumor cells in vivo, empowering studies of tumor growth and informing brain-cancer therapies.

#### 2:00 PM SB07.02.02

**High-Density Soft Bioelectronic Fibers** Muhammad Khatib and Zhenan Bao; Stanford University, Israel

Bioelectronic fiber devices hold tremendous potential for both research and clinical applications due to their compactness, ease of implantation, and ability to incorporate advanced functionalities such as sensing/recording, stimulation/modulation, and imaging. However, existing devices are hindered by issues such as bulkiness, rigidity, limited functionality, and low density of active components. These limitations stem from the challenges associated with integrating multiple components on one-dimensional (1D) devices, as they are not compatible with conventional microfabrication methods like photolithography, primarily due to their thin, curved, and elongated structures. In this work, we present a fabrication approach called spiral transformation that overcomes these obstacles by converting 2D thin films containing pertinent microfabricated devices into 1D fibers. This approach allows for the creation of bioelectronic fibers that offer a high density (300 channels on a 250-micron fiber) and variety of components while enabling precise control over their longitudinal, angular, and radial positioning. We have successfully demonstrated the utility of these fibers for motility and serotonin sensing and tissue stimulation within the dynamic and soft gastrointestinal (GI) system. Notably, our soft fibers have shown minimal interference to GI tissue structure and natural movements. Taken together, the developed bioelectronic fibers showcase significant promise for next-generation clinical monitoring and modulation applications, particularly in minimally invasive deployments within the GI tract and other curved and confined regions of the body.

#### 2:15 PM SB07.02.03

**Multifunctional Microelectronic Fibers Enable Wireless Modulation of Gut-Brain Axis** Atharva Sahasrabudhe<sup>1</sup>, Laura Rupprecht<sup>2</sup>, Sirma Orguc<sup>1</sup>, Diego Bohorquez<sup>2</sup> and Polina Anikeeva<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Duke University, United States

The peripheral organs of the body are in a constant bidirectional cross-talk with the brain, that generates a cognitive map of body's physiological state

which is vital for survival. This is exemplified by the gut-brain communication; wherein hormonally and neurally mediated signals emerging from the abdominal viscera transduce metabolic information to the brain for maintaining energy homeostasis. Although these internally arising brain-to-body sensory cues are consciously imperceptible, recently they have been shown to influence higher level neurocognitive processes such as motivation and affect. These findings create opportunities for co-opting organ-to-brain neural circuits to develop new paradigms for autonomic neuromodulation therapies. However, probing and understanding critical brain-body circuits presents a neurotechnology challenge due to contrasting design criteria imposed on the implantable devices by drastic anatomical differences between the skull-encased brain tissue and mobile, delicate peripheral organs in behaving animal models.

In this talk I will describe our efforts in addressing this challenge. Seeking inspiration from nerve fibers, we design a soft, flexible polymer fiber-based organ-brain neurotechnology. In order to match the inherent signaling complexity of the nervous system we envisaged probes that integrate multiple functionalities while still retaining a miniature device foot print to facilitate chronic bio-integration. To create such a multifunctional and multi-organ neurotechnology we combine the scalability and rapid customization of fiber drawing with functional sophistication of solid-state microdevices. With this approach we successfully produce hundreds of meters of flexible polymer filamentary probes integrating microscale light emitting devices, thermal sensors, microelectrodes, and microfluidic channels. The ability to process thermoplastic elastomers with the same route enables deterministic tunability of device mechanics and allows probes for targeting deep-brain structures and/or various regions of the murine intestine. We custom design a light-weight and modular wireless control circuit, NeuroStack, that offers bidirectional wireless control and real-time programmability of in-fiber microdevices along with an intuitive user interface. The brain fibers offer gene delivery for cell-type specific optogenetic neuromodulation, single-neuron recordings, thermometry, and tetherless control of mesolimbic reward pathway. The soft gut fibers grant access to anatomically challenging and delicate intestinal lumen, allowing intraluminal optofluidic control of sensory epithelial cells that guide feeding behaviors. Using this technology, we uncover that optogenetic stimulation of vagal afferents from the intestinal lumen is sufficient to drive reward behavior in untethered mice.

We anticipate that these illustrative applications will foreshadow widespread use of wireless multifunctional microelectronic fibers to study the roles of specific cells in bidirectional communication between the peripheral organs and the brain. This will not only empower the field of interoception, but also pave the way for mechanistically guided improved autonomic neuromodulation therapies.

### 2:30 PM SB07.02.04

**In Vivo Bioengineering of Conductive Microfibers: From In Vivo Biosynthesis to Advanced Characterization** [Claudia Tortiglione](#)<sup>1</sup>, Marika Iencharelli<sup>1</sup>, Giuseppina Tommasini<sup>2</sup>, Valentina Di Meo<sup>1</sup>, Gennaro Sanità<sup>1</sup>, Alessio Crescitelli<sup>1</sup>, Emanuela Esposito<sup>1</sup>, Maria Antonietta Ferrara<sup>1</sup>, Giuseppe Coppola<sup>1</sup>, Francesca Di Maria<sup>3</sup>, Mattia Zangoli<sup>3</sup>, Maria Moros<sup>2</sup> and Angela Tino<sup>1</sup>; <sup>1</sup>Istituto di Scienze Applicate e Sistemi Intelligenti, CNR, Italy; <sup>2</sup>Instituto de Nanociencia y Materiales de Aragón (INMA), Spain; <sup>3</sup>Istituto per la Sintesi Organica e Fotoreattività, CNR, Italy

The unmatched capability of living cells to fabricate complex structure starting from simple building blocks offers new paradigms to seamlessly integrate new electronic structures into the living matter, creating new hybrid devices. We have previously shown the capability of the living tissue-like organism, the freshwater polyp *Hydra vulgaris*, to produce fluorescent and conductive interface embedded into the animal tissues, starting from thiophene-based compounds, demonstrating the feasibility to use these organisms as biofactories of novel biocompatible and conformable bioelectronic interfaces [1-2]. Here we show that the potential of biofiber production is broadly valid in other biological systems, and showed that it can be promoted by different human and murine cell lines and by other invertebrate *in vivo* models (such as the sea anemone *Nematostella vectensis*). The cell type influences the fiber shape, amount and optical properties. In order to understand the mechanism underlying the fiber biogenesis, on one side we performed a systematic chemical engineering approach to identify the structure/groups involved in the spontaneous fiber assembling. On the other, we performed several physical and chemical treatments to identify the cell machinery components involved in the biosynthetic process. Finally, by mean of advanced characterization methods (ultrastructural, spectroscopical and imaging techniques) we shed light on the mechanism of biofiber production and the fine structure, paving the way to new bioengineering concepts to fabricate novel living conductive materials.

### 2:45 PM BREAK

SESSION SB07.03: Bioelectronic Prototypes  
Session Chairs: Maria Asplund and Alexandra Paterson  
Monday Afternoon, November 27, 2023  
Hynes, Level 1, Room 110

### 3:15 PM \*SB07.03.01

**Prototyping Neuroelectronic Device Concepts in Low-Cost Invertebrate Model Organisms** [Eric D. Glowacki](#)<sup>1</sup>, Petra Ondrackova<sup>1</sup>, Mary J. Donahue<sup>2</sup> and Malin Silvera Ejneby<sup>2</sup>; <sup>1</sup>Brno University of Technology, Czechia; <sup>2</sup>Linköping University, Sweden

Next-generation bioelectronics hardware evolves through interdisciplinary collaborations between materials and device engineers and neuroscientists, with certain barriers existing between design/fabrication, in vitro, and finally in vivo testing. It is rare for research teams handling device development to have in-house capability for electrophysiology in animals. I will describe our recent work on using simple invertebrate models for in vivo testing of novel recording and stimulation hardware: namely leeches (*Hirudo medicinalis*) and locusts (*Locusta migratoria*). Several showcase examples will be discussed. The leech nerve cord provides a suitable testing platform for prototyping nerve cuff devices for recording and stimulation. Stimulation can be validated using highly reproducible muscle electrophysiology or force transduction measurements. The locust, with its segmented body and well-defined skeletal muscle, is a convenient model for testing neurostimulation techniques, including noninvasive electrical stimulation which can be validated by precise activation of limb movements. The overall goal of this work is to present a toolbox of low-cost and ethically favorable approaches to test new device concepts before they are deployed on mammals.

**3:45 PM SB07.03.02**

**High-Density, Large-Scale Recording and Stimulating Neural Probes with Integrated ASIC** Yuhang Ma, Yingying Fan, Weinan Wang, Pavlo Zolotavin, Hanlin Zhu, Taiyun Chi and Chong Xie; Rice University, United States

Ultraflexible probes enable stable neural recording and stimulation by building a glial scar-free neuronal interface using biocompatible materials with small cross-sectional areas. However, these probes don't have an equivalent number of electrodes within the same invasive footprint as the rigid probes have. This limitation stems from photolithography, which is currently used for fabricating ultraflexible probes, is not capable of yielding a similar high electrode density. Here, to maximize the number of accessible neurons per implantation, we present the method of using electron-beam lithography (EBL) to pattern densely-packed electrodes on the polyimide encapsulations. We design and fabricate a 128-channel probe that presents the highest electrode density per cross-sectional area in flexible probes. The ability of oversampling can isolate highly clustered single units locally and across the brain regions, for example, the motor cortex and the hippocampus, for up to 3 months in freely behaving mice and 2 months in rats. Using 4 modules, more than 270 single units are recorded simultaneously with 1/3 of them decoded from the visual receptive field. We also propose an approach to design and fabricate a large-scale flexible EBL array with 5,376 simultaneously recording electrodes which equalize the total channel count of the state-of-the-art active probes. The first design will have 12 penetrating shanks, each of which has 448 recording electrodes at a density of 100 sites per millimeter of depth. To record, amplify and digitize all the channels simultaneously, we use gold ball bonding to connect with a customized application-specific integrated circuit (ASIC). This combination of large channel count flexible EBL-probe and ASIC will provide neuroscience studies in animal models with chronic, stable electrophysiology data at a large scale.

**4:00 PM SB07.03.03**

**An Experimental Platform to Study Axonal Guidance and Function** Katarina Vulić, Giulia Amos, Sean Weaver, Tobias Ruff and Janos Vörös; ETH Zurich, Switzerland

Studying neurons and axons *in vivo* poses a significant challenge due to the complex nature of the nervous system. The living environment makes it difficult to observe and manipulate individual axons effectively. In response to these limitations, researchers turn to *in vitro* models to gain insights into axon function and development from the bottom up. Our approach involves culturing neurons within polydimethylsiloxane (PDMS) microstructures on multielectrode arrays (MEAs) [1], [2], providing a controlled environment for studying axonal growth and activity. By utilizing these easily controllable and tunable systems, we aim to uncover the spatial limitations of axonal growth and determine the optimal spatial constraints for promoting healthy and robust axonal growth.

In this work, we study axonal growth dynamics using rat primary neurons cultured in custom-designed PDMS microfluidic devices containing nanochannels [3] of minimal size 100 nm. To generate the nanoscale features, a thin 350 nm layer of silicon dioxide (SiO<sub>2</sub>) was deposited on a silicon wafer followed by a thin layer of photoresist that was then patterned using E-beam before the structures were etched in the SiO<sub>2</sub> using reactive ion etching. After stripping the remaining photoresist, the two subsequent layers were patterned in SU8 using conventional photolithography. The resulting microstructure design allows for separation of cell soma from axons and thus studying axons in detail. By varying the nano-/microchannel size, we show the spatial limitations for axonal growth and observe changes in axonal guidance depending on the channel width. We note that there is almost no penetration in the channels below 400 nm in width. Furthermore, we analyze the formation and structuring of axonal bundles, their dependence on cell density, and on the type of spatial constraint. We observe more frequent formation of bundles in cases where we topologically force the narrowing. The opposite is seen in the channels that are orders of magnitude larger than the average axon size, where they tend to spread along the available space. We also see that bundling is present in the nodes with lower cell density. We also see that axons grow the longest in the channels of 10-12 μm width range. Finally, we assess neuronal activity by culturing neurons in PDMS microstructures on MEAs. The temporal precision of action potentials recorded by MEAs in combination with spatial precision of axonal growth within the PDMS, enabled to analyze action potential fidelity, e.g. its velocity, shape and amplitude depending on the number of cells, the width of the formed axonal bundle and the age of an *in vitro* culture.

Looking forward, we aim to improve the system further by modifying substrate stiffness to make it more physiologically relevant, by adding hydrogels into the microstructures. The potential to expand our findings on human induced pluripotent stem cell (hiPSC) derived neurons and the diseased cells, offers yet another application. Additionally, a promising direction is the investigation of axon fasciculation [4] by alternating the angle at which axons approach one another with PDMS. With its wide range of capabilities, this highly tunable system holds promise for unlocking new insights and advancing our understanding of axon function and pathology.

**Laminin Adsorption and Adhesion of Neurons and Glial Cells on Carbon Implanted Titania Nanotube Scaffolds for Neural Implant Applications** Jan Frenzel<sup>1,2</sup>, Astrid Kupferer<sup>1,2</sup> and Stefan G. Mayr<sup>1,2</sup>; <sup>1</sup>Leibniz Institute of Surface Engineering, Germany; <sup>2</sup>Universität Leipzig, Germany

As the world's population ages, the incidence of neurodegenerative disorders such as Parkinson's disease inevitably increases. Currently, brain-machine interfaces are used to study these diseases *ex vivo*, while neural electrodes are employed to treat them symptomatically *in vivo*. However, numerous obstacles arise at the interface between the brain and the brain-machine interface. Long-term adhesion is often weak, and rejection reactions such as glial scarring occur. We demonstrate that ion-implanted titania nanotube scaffolds are a promising candidate to overcome these problems, as they combine high biocompatibility with appropriate electrical conductivity.

In our systematic study, we show how implantation-induced tube shrinkage and altered electrical conductivity of titania nanotube scaffolds influence protein adsorption kinetics. Interestingly, laminin adsorption is affected by changes in surface free energy upon implantation. An increase in the pH-dependent ζ-potential of the surfaces leads to changes of the laminin binding.

In addition, viability, toxicity and morphology of U87MG glial cells and differentiated SH-SY5Y neurons is analyzed after one and four days, respectively, and correlated with surface characteristics. Environmental electron microscope images reveal that cells on all scaffolds stretch out and expand even after one day. This first evidence of biocompatibility is confirmed by a high cell viability. Significant differences of cell viability are explained by changes of protein adsorption induced by ion implantation. Additionally, the increase in conductivity does not affect neuronal viability after four days but inhibits glial cell proliferation.

Based on these findings, there is great potential for novel neural electrode materials with tailored morphology and unique conductivity that suppress glial scar formation.

We gratefully acknowledge funding from the Saxon State Ministry for Higher Education, Research and the Arts, project MUDIplex, grant number 100331694.

#### 4:30 PM SB07.03.05

**Monolithic Silicon Devices for Multisite, Multiscale and Translational Photostimulation** Pengju Li and Bozhi Tian; University of Chicago, United States

Electrode-based electrical stimulation is foundational for numerous clinical bioelectronic devices, including deep brain stimulators and cardiac pacemakers. However, achieving multisite or random access stimulation, vital for high-fidelity and efficient biological regulation, remains challenging even in high-density electrode arrays due to spatial access constraints. While optogenetics offers high-spatiotemporal multisite stimulation capabilities, its clinical adoption presents hurdles. In this work, we introduce a multisite photostimulation technique for cardiac systems via a non-genetic platform utilizing semiconductor-based biomodulation interfaces. We investigate the precision, accuracy, and resolution of the photostimulation by analyzing spatiotemporal photoelectrochemical currents in four leadless silicon-based monolithic photoelectrochemical devices. Our study validates the multisite stimulation capacity of these systems through optical overdrive pacing applied to cultured cardiomyocytes targeting multiple regions and length scales, isolated rat hearts in a Langendorff setup, and in vivo rat heart ischemia models. To demonstrate cardiac control under clinical conditions, we also perform the first optical pacing of a pig heart in vivo. To further solidify the clinical potentials, we fabricated minimally invasive device delivery and fiber-optics platform and successfully performed pig heart stimulation without opening the chest. Our findings underscore the potential of this leadless, lightweight photostimulation platform, possibly revolutionizing cardiac pacemaking in treatments like cardiac resynchronization therapy where lead-placement complications often arise.

#### 4:45 PM SB07.03.06

**Organic Semiconducting Nanoparticles for Neural Interfacing: Integrating Mechanical, Chemical and Optoelectronic Stimuli for Wireless Neuromodulation** Rafael Crovador<sup>1,2</sup>, Jessie Posar<sup>3,4</sup>, Paul Dastoor<sup>2</sup>, Alan Brichta<sup>1</sup>, Rebecca Lim<sup>1</sup> and Matthew Griffith<sup>2,3</sup>; <sup>1</sup>University of Newcastle, Australia; <sup>2</sup>The University of Newcastle, Australia; <sup>3</sup>The University of Sydney, Australia; <sup>4</sup>University of Wollongong, Australia; <sup>5</sup>University of South Australia, Australia

Electronic devices capable of stimulating neurons have revolutionized the treatment of several neurological conditions by providing a direct interface with the nervous system. These devices hold great potential for treating disorders such as Parkinson's disease, epilepsy, spinal cord injuries, and even blindness.<sup>[1]</sup> However, the use of traditional electronic materials such as metals and silicon in such devices have significant limitations due to poor biocompatibility,<sup>[2]</sup> mechanical mismatch with tissue, low spatial selectivity, and the requirement for external power supplies. Soft and flexible organic semiconducting materials represent a new frontier in electronic materials that are capable of overcoming these challenges.<sup>[3]</sup> The solution processability of organic semiconductors also enable several additional attractive features, including low-cost manufacturing of devices on flexible substrates using industrial scale printing techniques, addition of neurotransmitter molecules to the electroactive solutions to chemically assist neuromodulation, adjustable surface topography to induce mechanical cues for neuron attachment and growth, and optically triggered charge generation for wireless electrical neuromodulation.

In this study, we present our recent endeavours to tackle these challenges of mechanical, chemical and electronic stimulation of neuronal cells simultaneously in a single bioelectrode. We achieve this by forming soft carbon-based organic conductors into aqueous nanoparticle dispersions using established solution-based mini-emulsion chemistry methods.<sup>[4]</sup> We subsequently integrate the organic nanoparticle dispersions with neurotrophic factors prior to the device fabrication process. These pharmaceutical components subsequently enhance cell adhesion and neural network outgrowth upon release from solid films cast from the electroactive nanoparticle dispersions.

Bioelectronic nanoparticle-based devices were fabricated from n-type material *Poly(9,9-dioctylfluorene-alt-bithiophene)* (F8T2), which were shown to exhibit high biocompatibility with primary neuron cultures from mice via anatomical (live-dead assay) and functional (neuronal cell stain) protocols. Kelvin Probe Force Microscopy measurements demonstrated the creation of photo-capacitive charge under direct light stimulus, potentially capable of depolarising the neuronal cell membrane and generating action potentials (*wireless electronic neuromodulation*). By adjusting the surface roughness of devices by tailoring the nanoparticle size during synthesis, we verified by AFM analysis an optimal nano-topography that promotes neuronal cell growth (*mechanical neuromodulation*). Finally, by extensive neuronal morphology analysis we demonstrated the direct effect of sustained and locally delivered neurotrophic factors (*chemical neuromodulation*) on cell survival and neuronal outgrowth through neurite elongation.

**Transient Bioelectronic Medicines** John A. Rogers; Northwestern University, United States

Advanced electronic/optoelectronic technologies designed to allow stable, intimate integration with living organisms will accelerate progress in biomedical research; they will also serve as the foundations for new approaches in monitoring and treating diseases. Specifically, capabilities for injecting miniaturized electronic systems and other components into soft tissues or for softly laminating them onto the surfaces of vital organs will open up unique and important opportunities in tracking and manipulating biological processes. This presentation describes the core concepts in materials science, circuit design and

manufacturing that underpin these types of technologies, with a focus on bioresorbable, or 'transient', devices designed to disappear into the body on timescales matched to natural processes. Examples include bioelectronic 'medicines' for neuroregeneration, pain mitigation and temporary cardiac pacing.

#### 9:30 AM SB07.04.02

**E-Sutures: Electrical and Ionic Conductive Sutures for Medicine and Bioelectronics** Onni Rauhalu, Jennifer Gelinis and Dion Khodagholy; Columbia University, United States

Metals have long served as the foundational electrode and wiring materials for implantable bioelectronics due to their high conductivity and processability to achieve the small size necessary for *in vivo* electrophysiological signal acquisition and stimulation. However, metal-based wires are susceptible to mechanical damage due to material rigidity, and in bulky, high-density systems, they may contribute to patient discomfort. The ideal bioelectronic wire is thus soft, highly conductive, mechanically and chemically resilient and biocompatible. Most importantly, such a wire should also leverage modern polymer chemistry to enable multi-modal interventions, namely mixed-conductors that facilitate delivery of positive and negative charges. In this work, we use PEDOT:PSS to turn silk sutures into flexible, mixed-conducting and biocompatible wires (e-sutures) that can be used for suturing, acquiring electrophysiological signals, delivering electrical stimulation and finally, delivering drug molecules as ion pump channels.

We fabricate e-sutures by coating silk sutures with PEDOT:PSS to produce a mixed conducting suture and then create an insulation layer (jacket) on the fiber using subsequent coatings of PDMS and parylene-C to preserve the conductive properties in an ionic environment. We demonstrate the high conductivity and stability of e-sutures as well as their ability to form robust mechanical connections with metallic circuit components to facilitate integration to a complete bioelectronic device. Further, the conductive nature of e-sutures *in vivo* is demonstrated by recording electrocardiogram (ECG) from mouse pups, elicitation and recording of intramuscular electromyogram (EMG) in rats as well as local field potential (LFP) from the surface of a rat brain using e-sutures as electrodes. Finally, we demonstrate that e-sutures can serve as an ion pump channel and deliver positively charged molecules from a hydration reservoir to the target tissue without generating volumetric pressure in the delivery target. In summary, the work highlights the capability of PEDOT:PSS coated silk fibers to serve as a soft, biocompatible alternative to metallic wires and electrodes in a research and clinical setting while providing the additional capability of drug-delivery through ion pumping.

#### 9:45 AM SB07.04.03

**Implantable Iontophoretic Devices for Cancer Therapy** Xudong Tao, Tobias Naegele and George G. Malliaras; University of Cambridge, United Kingdom

Chemotherapy has a fundamental limitation for the treatment of brain tumours – poor penetration through the blood-brain barrier, leading to sub-therapeutic concentrations in brain tumours. This study focuses on an implantable electrophoretic drug delivery device (left behind in the tumour after biopsy), which uses an electric field to improve drug transport. The technology is called iontophoresis – a 'dry' delivery that only delivers the charged drug ions into the tumour region by electric fields and avoids pressure-related problems. This study explores a novel iontophoretic device which significantly improves the efficiency of drug delivery.

#### 10:30 AM \*SB07.05.01

**Translational Neuroelectronics** Dion Khodagholy; Columbia University, United States

Our understanding of the brain's pathophysiology relies on discoveries in neuroscience and neurology fueled by sophisticated bioelectronics enabling visualization and manipulation of neural circuits at multiple spatial and temporal resolutions. In parallel, to facilitate clinical translation of advanced materials, devices, and technologies, all components of bioelectronic devices have to be considered. Organic electronics offer a unique approach to device design, due to their mixed ionic/electronic conduction, mechanical flexibility, enhanced biocompatibility, and capability for drug delivery. We design, develop, and characterize conformable, stretchable organic electronic devices based on conducting polymer-based electrodes, particulate electronic composites, high-performance transistors, conformable integrated circuits, and ion-based data communication.

These devices established new experimental paradigms that allowed monitoring of the emergence of neural circuits during development in rodents and elucidated patterns of neural network maturation in the developing brain. Furthermore, the biocompatibility of the devices also allowed intra-operative recording from patients undergoing epilepsy and deep brain stimulation surgeries, highlighting the translational capacity of this class of neural interface devices.

In parallel, we are developing the fully-implantable, conformable implantable integrated circuits based on high-speed internal ionic gated organic electrochemical transistors that can perform the entire chain of signal acquisition, processing, and transmission without the need of hard Si-based devices. This multidisciplinary approach will enable the development of new devices based on organic electronics, with broad applicability to the understanding of physiologic and pathologic network activity, control of brain-machine interfaces, and therapeutic closed-loop devices.

#### 11:00 AM \*SB07.05.02

**Graphene-Based Active Neural Sensors for Brain Monitoring and Mapping** Eduard Masvidal-Codina<sup>1</sup>, Ramon Garcia-Cortadella<sup>1,2</sup>, Xavi Illa<sup>3</sup>, Rob Wykes<sup>4</sup>, Anton Sirota<sup>2</sup>, Anton Guimerà-Brunet<sup>3</sup> and Jose A. Garrido<sup>1,5</sup>; <sup>1</sup>Catalan Institute of Nanoscience and Nanotechnology, (ICN2), CSIC and BIST, Spain; <sup>2</sup>Bernstein Center for Computational Neuroscience Munich (SyNergy), LMU, Germany; <sup>3</sup>Instituto de Microelectrónica de Barcelona IMB-CNM (CSIC), Esfera UAB, Spain; <sup>4</sup>Institute of Neurology, UCL, Queen Square, United Kingdom; <sup>5</sup>ICREA, Spain

Large effort is being dedicated to the integration of novel materials into neural interface devices that offer certain advantages in terms of recording and/or stimulation of neural activity. In the particular case of the recording capabilities, they need to be such to allow the detection of brain activity over large areas and with a high spatial resolution. Because its two-dimensional nature, graphene exhibits a rather unique combination of physicochemical properties which make it attractive for the development of active sensors for neural technologies.

This contribution will focus on the recording capabilities of active sensor technology based on single-layer graphene, highlighting its potential for the development of the next-generation neural prostheses and brain-computer interfaces. Recently, solution-gated field-effect transistors (SGFET) based on

graphene are being explored with increasing interest as novel transducers for neural signals. The electrochemical stability of graphene and its facile integration with flexible substrates were among the initial triggers that attracted the interest of the community to develop flexible neural probes for brain interfacing. In addition, other properties such as the high carrier mobility and the field effect associated to single-layer graphene allows for the implementation of an active sensor configuration that will be shown in this contribution to offer significant advantages with respect to the classical passive metallic electrodes. Further, this presentation will discuss how SGFET-type sensors allow us the implementation of multiplexing strategies, time-domain and frequency-domain multiplexing, that reduce the footprint of connectivity, permitting an aggressive scaling up in the number of recording sites. Very interestingly, we will demonstrate that SGFETs also have a distinctive capability to expand the temporal resolution of classical electrocorticography technologies, allowing the recording of the relatively unexplored infra-slow brain activity and, thus, potentially enabling the study of novel biomarkers for monitoring neurological disorders.

This work has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N. 881603 (GrapheneCore3)

#### 11:30 AM SB07.05.03

**Spatially Controlled Microcortical Stimulation using High-Density PEDOT:PSS Surface Electrodes** Ilike Uguz and Kenneth L. Shepard; Columbia University, United States

Most neuromodulation approaches rely on extracellular electrical stimulation with penetrating electrodes at the cost of cortical damage. Surface electrodes, in contrast, are much less invasive but are challenged by the lack of proximity to axonal processes leading to poor resolution. Here, we demonstrate that high density (40  $\mu\text{m}$  pitch), high capacitance ( $> 1$  nF), single neuronal resolution PEDOT:PSS electrodes can be programmed to shape the charge injection front selectively at depths approaching 300  $\mu\text{m}$  with a lateral resolution better than 100  $\mu\text{m}$ . These electrodes, patterned on thin film parylene substrate, can be subdurally implanted and adhere to the pial surface in chronic settings. By leveraging surface arrays that are optically transparent with PEDOT:PSS local interconnects and integrated with depth electrodes, we are able to combine surface stimulation and recording with calcium imaging and depth recording to demonstrate these spatial limits of bidirectional communication with pyramidal neurons in mouse visual cortex both laterally and at depth from the surface.

#### 11:45 AM SB07.05.04

**Foldable Three Dimensional Neural Electrode Arrays for Simultaneous Brain Interfacing of Cortical Surface and Intracortical Multilayers** Ju Young Lee, Young Uk Cho and Ki Jun Yu; Yonsei University, Korea (the Republic of)

The brain is a complex three-dimensional network composed of billions of interconnected neurons that respond to important activities such as cognitive function, memory, or even communication by transmitting neural signals. The development of neural interfaces that can precisely measure the complex activities of neurons are helping to understand for identifying unpredicted neuronal diseases and brain functions. Therefore, to understand the functionality of the brain via these diverse activities, it is essential to measure the brain activity with three-dimensional structure.

Current diagnostic methods for brain disorders involve functional magnetic resonance imaging (fMRI) that detect the changes of related cerebral blood flow and positron emission tomography (PET) that detect emits positrons distribution in the body through receptor or metabolic imaging. These imaging techniques can capture the changes in brain signals in three-dimensions by combining continuous two-dimensional sectional imaging frames. However, despite their excellent spatial resolution, these methods suffer from poor temporal resolution because of the limitations of captured series of two-dimensional frames. To overcome these time-resolution limitation, for the proper neuropathological analysis, electrophysiological approach serves as a major strength as it provides an excellent temporal readout resolution compared to upper imaging method.

The electrophysiological approach to the measuring the neural propagation is broadly classified into three methods, 1) Electrocochography (ECoG), 2) Michigan probe, 3) Utah array. However, these traditional methods have limitation of two-dimensional measurements. Frist, ECoG arrays for brain surface recording provide high-resolution signals over a large area but cannot map the intracortical area. In contrast, Michigan probe and Utah arrays for intracortical or deep brain recording do not provide clues about the propagation of expressed signals from inside the brain to the surface. Several attempts have been made to measure neural signals in three-dimensional form to overcome this limitation, but these efforts have encountered challenges due to the separate devices for simultaneous measurement of surface and intracortical area that leading to recording mismatch, or due to the use of rigid shanks for device implantation that leading to immune response with mechanical mismatches between the brain recording surface and the device.

Here, we introduce the foldable, flexible three-dimensional neural mapping electrode that achieved by extending the three-dimensional structure of the neural interface in way to accurately analyse complex neural signalling. The device establishes a single integrated platform with four flexible penetrating shanks and surface electrodes by combining advantages of the ECoG arrays and neural probe with Utah array shape for multisite recording. This system can simultaneously measure both surface signals of the brain and neural activity occurring in the intracortical area. To provide sufficient insertion of the device, the penetrating shanks were coated with a biocompatible/bioresorbable stiffener. To demonstrate the performance of the device, inserting the device into the somatosensory cortex of mice and stimulating whisker of the mice. The device can measure both the local field potential (LFP) and single neuron spike in simultaneously from the surface and intracortical area of the brain. Consequently, this platform will pave the way for neuroscience studies and biomedical practices by providing unprecedented electrophysiological signals in three-dimensional form.

SESSION SB07.06: Minimally Invasive Neuroengineering

Hynes, Level 1, Room 110

#### 1:30 PM \*SB07.06.01

**Ultrasound Microsystems for Minimally-Invasive Neuromodulation via Low-Intensity Focused Ultrasound** Tiago Costa; Delft University of Technology, Netherlands

Minimally-invasive neuromodulation using low-intensity focused ultrasound (LIFU) holds great promise for treating various neurological disorders. It has been demonstrated to modulate neural activity, promoting both excitatory and inhibitory effects. This capability allows for restoring aberrant neural circuitry or suppressing hyperactive regions, thereby alleviating symptoms associated with conditions such as Parkinson's disease, epilepsy, chronic pain, and depression.

One of the key advantages of LIFU neuromodulation is its combination of high spatial resolution, minimal invasiveness, and extensive coverage of the nervous system. Unlike traditional electrical, magnetic, or optical neuromodulation techniques, which can achieve high-spatial resolution at the expense of

high invasiveness and reduced brain coverage, ultrasound waves benefit from low wavelengths, scattering, and absorption in brain tissue and hence, can be focused virtually anywhere in the brain, with high-spatial-resolution and without requiring brain surgery. This reduces the risk of infection, tissue damage, and other complications associated with invasive procedures, making it a safer option for patients, and also allows for accessing a broader range of neural circuits with high precision.

Despite the abovementioned promise, there is still a knowledge and technological gap in LIFU neuromodulation to maximize its potential. LIFU neuromodulation is achieved by means of an ultrasound transducer. These transducers generate low-intensity focused ultrasound waves that can penetrate deep into tissues while maintaining spatial specificity. By adjusting the parameters of the ultrasound waves, specific regions of the brain or peripheral nerves can be targeted with precision. However, similar to their use in medical diagnostic imaging, conventional ultrasound transducers used in LIFU neuromodulation have hand-held form factors and require off-the-shelf equipment. These bulky setups lead to two severe limitations: in pre-clinical research, the mismatch of size between bulky transducers and in-vitro/in vivo models (mice, rats) impose severe limitations in understanding the effects of ultrasound on the nervous system and how to better apply LIFU neuromodulation for different disease models; secondly, in clinical applications, the use of LIFU neuromodulation can only be applied in a bed-side scenario, where the patient either would visit the clinic once or twice per week to receive a treatment or would operate a LIFU neuromodulation system at home.

This talk will describe the recent research in the field of ultrasound microsystems towards developing the next generation of LIFU neuromodulation systems that can be seamlessly integrated into in vitro/in vivo experimental setups in pre-clinical settings and used as wearable and minimally-invasive devices for clinical treatments. This description will answer two questions: how to massively integrate all the necessary LIFU neuromodulation functionality into a single-miniaturized and battery-powered microsystem? How can ultrasound microsystems be designed to be mechanically flexible to better adjust to the body's natural curvature?

To answer these questions, the talk will focus on novel ultrasound microfabrication and microsystem integration methods and next-generation ultrasound electronics. Furthermore, the talk will also show a few examples of ongoing projects featuring *in vitro* and *in vivo* validation, showcasing the potential of LIFU microsystems for minimally invasive and precise neuromodulation for treating neurological diseases.

## 2:00 PM \*SB07.06.02

**Learning in Spiking Neural Networks with a Calcium-Based Hebbian Learning Rule** Willian Soares Girão and [Elisabetta Chicca](#); University of Groningen, Netherlands

The effectiveness of neural interfaces depends on the ability of electronic systems to speak the same language of the biological counterpart. Furthermore, the mechanisms underlying learning in biological systems should be better understood to harness the adaptability of the brain when interfacing it to artificial systems. In particular, understanding how biological neural networks are shaped via local plasticity mechanisms can lead to energy-efficient and self-adaptive brain-like information processing systems which can enhance neural interfaces with unprecedented adaptability.

In this work, we present a Hebbian local learning rule, the Bistable Calcium-based Local Learning (BCaLL) rule, that models synaptic modification as a function of pre- and post-synaptic calcium traces tracking neuronal activity, based on a large body of work that has established the role of calcium transients in modulating plasticity. The calcium trace variable, modeled via a first-order differential equation, integrates neuronal activity over time such that both the time since the last spike and mean firing rate information can be encoded in this trace. The learning rule we propose reads out the calcium traces from the neurons it connects and computes whether its weight should be increased or decreased. We show that BCaLL is able to reproduce both spike-time dependent plasticity (STDP) and spike rate plasticity outcomes. With it, we are able to demonstrate that temporal correlations added at the spike-pair level can modulate the learning rate in spiking neural networks, without modifying the rule's parameters or the mean rate activity of neurons in the network.

We showcase this property by simulating and comparing recurrent Spiking Neural Networks (SNNs) with and without excitatory neurons' subthreshold membrane oscillations. We demonstrate that in the networks where the neurons oscillate, the learning rate of attractors is increased due to an increase in their synchronicity. This is particularly interesting for simulating and studying learning in models of brain structures like the Inferior Olivary Nucleus, where previous work has shown that the lack of electronic coupling, which plays an important role in synchronizing the activity of neurons within the nucleus, leads to impaired learning of motor tasks. This modulated learning rate via synchronization we show can provide a starting point in understanding such learning dynamics.

By applying BCaLL to feedforward SNNs, we describe the mechanisms necessary to train such networks for classification problems and how these mechanisms resolve the coding-level problem that arises from learning with binary synapses. Thanks to our simulations, we find that allowing the networks' transient activity during the switching of input patterns to interact increases classification performance, contrary to what previous work has reported, by reducing overlaps in the learned class representations. This could be a benefit of tracking spiking activity via traces: while some models might rely on the neuron's membrane voltage to compute weight updates, utilizing traces allows us to decouple from the membrane dynamics the extent to which correlated activity in time can be measured.

Elucidating how computation in such systems can benefit from encoding information in traces is not only important for better modeling the complex biochemical machinery existing in biological neural networks but also for the design of analog application-specific integrated circuits (ASIC) implementing these algorithms. This integration step is crucial for the embedding of such algorithm into neural interfaces.

## 2:30 PM SB07.06.03

**Origami-Inspired Smart Implants for New-Age Neurology** [Prasanth Velvaluri](#)<sup>1</sup>, Huan Liu<sup>2</sup>, Lars Thormählen<sup>1</sup>, Hanna Lewitz<sup>1</sup>, Olav Jansen<sup>3</sup>, Richard D. James<sup>2</sup>, Dirk Meyners<sup>1</sup>, Nian Sun<sup>4</sup> and Eckhard Quandt<sup>1</sup>; <sup>1</sup>Kiel University, Germany; <sup>2</sup>University of Minnesota, United States; <sup>3</sup>University Hospital Schleswig-Holstein, Germany; <sup>4</sup>Northeastern University, Germany

Intracranial aneurysms are balloon-like disfigurements along the brain blood vessels. If not treated such aneurysms can rupture and cause brain hemorrhage. Many different implants are available in the market for intracranial aneurysm treatment. Though the available implants fabricated from wire braiding and laser cutting are successful, specific gaps must be filled to allow for low treatment complications. One such gap is that all the available implants have simple geometries and do not allow any personalization. Such individualization of implants is essential to provide safer treatments to patients with complex aneurysms. Second, all available implants have passive operation and currently, there are no "smart aneurysm implants" that could potentially monitor the treatment over time. Such a smart implant could detect if the intended blood flow reduction is not achieved after its placement and could potentially alert to early intervention. Smart implants require integrated antennas for data and energy transfer as well as sensors for the measurement of blood flow.

Magnetolectric (ME) antennas consisting of magnetostrictive and piezoelectric layers have shown that they can be scaled down by orders of magnitude in size compared to conventional electromagnetic antennas [1]. This is because the ME antennas operate at their acoustic resonance rather than at their electromagnetic resonance. Such compact miniaturized ME antennas on the implant surface provide an optimal way to transmit the data wirelessly for a smart implant operation. However, there are certain difficulties to integrating such antennas into conventional implants as their fabrication technology of wire braiding and laser cutting does not allow monolithic integration of ME composites. Second, the conventional implant design does not allow such sensitive components to survive the harsh crimping process, which is pre-requirement for a minimally invasive treatment.

On the other hand, the origami-based design approach provides an attractive alternative for implant design. It consists of a 2D pattern with regions of rigid panels and flexible hinges. The folding pattern for origami can be generated from a flat 2D sheet and converted into a complex 3D shape on folding. Such structures have great potential as medical implants as they provide two major advantages (1) they allow the folding of large implants into a compact area to

be loaded into a catheter and (2) certain regions in the origami pattern are almost stress-free during folding, making them ideal sites for loading sensitive elements such as sensors and antennas. The main challenge lies in fabricating these microscale devices without compromising the quality and performance. Recent developments in microsystem technology offer a method to fabricate freestanding nitinol (NiTi) shape memory thin films. The fabricated implants are flexible, biocompatible, and have high design freedom, e.g., allowing films with multiple thicknesses [2]. Thus, providing a solution for origami-based implant fabrication. The wafer-based approach allows the monolithic integration of functional layers for biosensing and smart implant functioning. Thus, allowing for the incorporation of ME antennas on the NiTi implant surface.

The current work focuses on fabricating an ME antenna on top of a NiTi substrate using microsystem technologies, as a first step in realizing origami-based smart implants. In this work, we discuss the various challenges and possible solutions for integrating an ME antenna on top of a NiTi substrate.

Furthermore, we consider the choice of magnetostrictive and piezoelectric materials that are essential for the required antenna operation at a frequency that is permissible for human use. We intend to demonstrate the potential of an origami-based design approach for fabricating brain implants.

#### 2:45 PM SB07.06.04

**Atomic Layer Infiltration for the Enhanced Longevity of Thin-Film Polymer Implant Encapsulation** Martin Niemiec and Kyunjin Kim; University of Connecticut, United States

Bioelectronic interface technology has advanced significantly since its inception, as implantable devices develop smaller form factors and better integration with the human body. Advanced implants have thousands of channels interfacing with hundreds of neurons, and often feature wireless transmission of power and data enabled by miniaturized active electronic components and multiplexing techniques. However, while the technical capabilities of implantable bioelectronics continue to increase at an astounding rate, their ability to remain functional after long periods of implanted time has not seen significant improvement, especially in the field of flexible polymer-based thin film devices. Due to their inherently poor barrier properties, polymer implants require additional hermetic encapsulation to become viable therapeutic instruments for several decades of constant use. In this regard, metal oxide, nitride, and carbide materials deposited by atomic layer deposition (ALD) represent some of the best-performing barrier materials in terms of low permeability to water and ionic species, yet they are mechanically incompatible with flexible electronic substrates: bending and stretching of the flexible substrate invariably results in cracking or delamination of the rigid barrier coating, reducing its protective capability to near zero. Here, we explore a method of increasing the mechanical compatibility of inorganic barrier coatings with flexible substrates by means of a modified ALD technique alternately known as atomic layer infiltration (ALI), vapor phase infiltration (VPI), or sequential infiltration synthesis (SIS), which results in a gradual transition between the mechanical properties of the substrate and coating, reducing the susceptibility of the interface to such catastrophic failure modes. During ALI, precursors are allowed to remain in the reaction chamber for longer times at higher pressures than ALD. This allows precursors to diffuse into the substrate and reaction products to form at depth, resulting in a gradient from pure substrate to pure coating material. This technique has been used to create flexible, nearly impermeable coatings for organic electronics applications, but to our knowledge has not been demonstrated in implantable bioelectronics. We demonstrate water vapor barrier performance of the ALI encapsulation strategy on the order of  $10^{-4}$  g/m<sup>2</sup>/day, as well as high mechanical compliance (*i.e.*, critical bending radius below 500µm without delamination). In addition, we fabricate test devices featuring interdigitated electrodes on flexible substrates and encapsulate them via 3-dimensional ALI using a custom stand within a domed reaction chamber, then study the effects of ALI encapsulation on device lifespan in physiological conditions by means of accelerated aging tests in phosphate buffered saline (PBS). We investigate the accelerated aging results of current bioelectronic implant encapsulation strategies and compare them with our own results. Our uncoated polyimide devices failed after 80-100 days at 37°C, while coated devices have exceeded 230 days of 37°C-equivalent aging and continue to remain below failure thresholds. Optimization of the encapsulation via material selection (*e.g.*, polyimide vs. parylene substrates, Al<sub>2</sub>O<sub>3</sub> vs. TiO<sub>2</sub> ALI) and multilayered structure is explored. In-depth failure mode analysis of the tested thin film devices is performed, analyzing cracking, delamination, moisture permeation, and connector failures using optical and scanning electron microscopy and permeation analyzer; critical failures modes upon specific loading are discussed.

#### 3:00 PM BREAK

##### SESSION SB07.07: Neural Interfaces II

Tuesday Afternoon, November 28, 2023

Hynes, Level 1, Room 110

#### 3:30 PM \*SB07.07.01

**A Subdural Bioelectronic Implant to Obtain Recordings of Spinal Cord Activity and to Deliver Electroceutical Therapy Following Spinal Cord Injury in Rats** Darren Svirsakis<sup>1</sup>, Bruce Harland<sup>1</sup>, Brad Raos<sup>1</sup>, Brittany Hazelgrove<sup>1</sup>, Simon O'Carroll<sup>1</sup>, Lukas Matter<sup>2</sup> and Maria Asplund<sup>2</sup>; <sup>1</sup>University of Auckland, New Zealand; <sup>2</sup>Chalmers, Sweden

Bioelectronic devices have found use at the interface with neural tissue to investigate and treat nervous system disorders. We have developed and characterized a very thin flexible polyimide-based bioelectronic implant that is inserted along the thoracic spinal cord in rats directly in contact with the dorsal surface of the spinal cord. This has no negative impact on hind-limb functionality nor any change in the volume or shape of the spinal cord. We routinely maintain the bioelectronic implant in rats for a period of 3 months.

We have obtained the first subdural recordings of spinal cord activity in freely moving animals. Recordings contain action potentials from fibre tracks in the cord. Following spike extraction propagation velocities were analyzed. Propagation was predominately in the afferent direction, with a smaller proportion of spikes propagating in the efferent direction.

A clinically relevant spinal contusion injury can be achieved with the implant in place. The bioelectronic implant contains stimulating electrodes with relatively larger areas than the recording electrodes that are capable of delivering precise, strong electric field therapies (electroceuticals) directly to the injured spinal cord tissue. The effects of these therapies are currently being investigated, early data is demonstrating a different recovery profile compared to control animals who do not receive the treatment. Over the course of the 12-week experiment, the animals receiving electroceutical therapy show improved hind limb function determined in open field assessment and an enhanced recovery of touch sensitivity as determined by the Von Frey test.

This device has great potential to monitor electrical signaling in the spinal cord after an injury, and in the future, this implant will facilitate the identification of biomarkers in spinal cord injury and recovery. We are exploring further development of this implant to deliver localized treatments to the spinal cord towards regeneration of damaged tissues to recover lost function. Localized therapies are being developed not only in the form of electroceutical treatment through precise electrical field stimulation, but also through the local and sustained delivery of neurotrophic factors.

**4:00 PM SB07.07.02**

**Soft and Stretchable Neural Electrodes Based on Gold Nanowire Composites** Laura Seufert, Mohammed Elmahmoudy, Mary J. Donahue, Yuyang Li, Samuel Lienemann, Simon Farnebo and Klas Tybrandt; Linköping University, Sweden

Two-way communication between electronics and neural tissue is key for advancing diagnosis and therapies for neurological diseases and disorders. Establishing such neural interfaces is a major challenge, as the tissue response to implants can have a detrimental effect on the signal quality and functionality of the implant. Matching of the mechanical properties of the electronic implant to the soft interfaced tissue can reduce the tissue response and improve the long-term performance of the device. This requires soft and stretchable conductors, which typically are composed of elastomer/hydrogels and conductive fillers. However, the tough materials requirements on biomedical implants, including material chemistry, mechanical and electromechanical properties, and long-term stability, disqualifies most of the developed stretchable electronic materials for such applications. Here I will present our efforts in developing inert soft neural electrodes based on stretchable gold nanowire composites, covering aspects ranging from synthesis and processing to devices and applications.

**4:15 PM SB07.07.03**

**Ultraconformable Cuff Implants for Long-Term Bidirectional Interfacing of Peripheral Nerves at Sub-Nerve Resolutions** Alejandro Carnicer Lombarte, Alexander J. Boys, Amparo Guemes, Johannes Gurke, Santiago Velasco Bosom, Sam Hilton, Damiano Barone and George G. Malliaras; University of Cambridge, United Kingdom

The peripheral nervous system is crucial for the communication between the brain and the rest of the body. Implantable devices interfacing with this part of the nervous system hold great potential for the development of treatments for a wide range of clinical conditions, whether by recording electrical activity carried by nerves, or influencing it through electrical stimulation. However, current nerve interfacing technologies lack the necessary resolution to selectively record and stimulate from nerves at the sufficient resolution and stability to enable their therapeutic use.

Here, we present a nerve cuff implant with an ultraconformable design that achieves high-quality and stable interfacing with nerves in chronic implantation scenarios. The cuffs are comprised of a parylene-C body 4 μm in thickness, rendering them highly flexible and able to conform to the surface of nerves. Combined with low impedance PEDOT:PSS microelectrodes, we show that these features allow the ultraflexible cuffs to record neural signals from awake animals for 21 days while exhibiting minimal fibrotic scarring. We furthermore show that high-resolution interfacing capabilities of the cuffs can be used to record action potentials with fascicle-specific resolution and extract from these physiologically-relevant features such as conduction velocity and direction of propagation. We evaluate the potential of this technology in two nerve systems in freely-moving rodent animal models: movement and sensory perception in the arm, and monitoring and control of bladder function.

The developed implantable devices represent a platform enabling new forms of fine nerve signal sensing and modulation, with applications in physiology research and closed-loop therapeutics.

**4:30 PM SB07.07.04**

**Towards Longer Working Times for Implanted Electrodes through Integration of Perpetual Antioxidants at Device Interfaces** Vicki L. Colvin; Brown University, United States

Medical devices implanted in the human body are increasingly common in the management and treatment of disease. An important and growing subset of these devices termed here 'active' implants, require electrical contact with tissues. For these devices the foreign body response to an electrode can preclude chronic function and limit many applications. The local delivery of an antioxidant able to protect tissue for months or even years is one possible solution. Nanoparticle ceria is a perpetual antioxidant due to its large cerium(III) content and the possibility of recovering cerium(III) from cerium(IV) after use.[1] For this work its antioxidant capacity was augmented by the use of molecular tethers that stabilized the reactive Ce(III) state. The efficacy of these materials was evaluated in a three-dimensional in vitro model by seeding primary cortical cells around microwires to reveal independent innate neuroinflammation. We demonstrated the use of ceria nanoparticles for reducing oxidative stress, increasing neuronal density, and reducing functional connectivity in wire implanted samples. These results indicate that antioxidant ceria nanoparticles may be efficacious drug treatment for protecting neural function at the device-tissue interface. We optimized ceria nanoparticles for small diameter, biocompatibility, and colloidal stability using reactive polymer coatings. To evaluate their utility in combating inflammation, we developed a 3D in vitro model of the device-tissue interface. This system can disentangle the different contributions of the innate immune system to neuroinflammatory device responses. Ceria nanoparticles reduced the oxidative stress, increased neuronal density, and reduced functional connectivity in wire-implanted samples [2]. The development and characterization of a novel 3D in vitro model of the device-tissue interface revealed a significant innate immune response to neural implants. This study has broad implications for the role of the innate immune system and potential treatment strategies for the chronic foreign body response to neural implants. The mitigation of oxidative stress, neuronal density, and functional connectivity with antioxidant ceria nanoparticles offers significant supporting evidence to indicate that many symptoms of the tissue reaction are related to redox dysregulation. Successful treatment of the device-tissue interface with long-acting antioxidant ceria nanoparticles shows potential for a local long-term antioxidant treatment strategy for clinical applications that need the long-term use of implanted neural devices.

**Improving Cytocompatibility of Commercial PEDOT:PSS for Bioelectronic Applications** Aaron Lee<sup>1</sup>, Joshua Killilea<sup>1</sup>, Estelle Cuttaz<sup>1</sup>, Christopher Chapman<sup>2</sup>, Josef Goding<sup>1</sup> and Rylie Green<sup>1</sup>; <sup>1</sup>Imperial College London, United Kingdom; <sup>2</sup>Queen Mary University of London, United Kingdom

Conducting polymers have emerged as a strong candidate material for bioelectronic applications owing to their mixed ionic-electronic conduction which allows them to efficiently transfer charge in aqueous environments. Commercial formulations of water-dispersible poly(3,4-ethylenedioxythiophene):poly(styrene sulfonate) (PEDOT:PSS) have facilitated development of flexible conductors, sensors, organic electronics and electrode interfaces. While PSS is an efficient counterion and dopant for PEDOT, its presence in excess to enable water-based processing can result in variable processability and electrochemical performance. While chemical crosslinking approaches can be used to address the stability of PEDOT:PSS in aqueous environments, it can hinder further processing. Importantly for bioelectronic applications, the release of excess PSS in aqueous environments from commercially based PEDOT:PSS materials can result in cytotoxicity. To ameliorate these effects, the use of physical separation was explored to remove the excess dopant. PEDOT:PSS dispersions were produced in N,N'-dimethylacetamide and separated by centrifugation. Analysis of the supernatant by NMR indicated the presence of PSS and the remaining polymer was blended with a polyurethane to produce a conductive elastomer. The electrochemical performance of the conductive elastomer and its resultant cytotoxicity profile were assessed as a function of PSS removal. Reducing the amount of PSS prior to preparation of the final conductive elastomer material was demonstrated to markedly improve the cytocompatibility of the material while retaining a degree of electrochemical functionality. These findings represent a key step in facilitating the translation of PEDOT:PSS-based materials to clinical

applications.

**An Extended-Gate Field-Effect Transistor as a Highly Sensitive Biosensor to Detect Bacteria** Lea Könemund<sup>1,2</sup>, Aaron Bongartz<sup>1</sup>, Fenja Schröder<sup>1</sup>, Svenja Herdan<sup>1</sup>, Laurie Neumann<sup>1</sup>, Rebekka Biedendieck<sup>1</sup>, Dieter Jahn<sup>1</sup>, Hans-Hermann Johannes<sup>1,2</sup> and Wolfgang Kowalsky<sup>1,2</sup>; <sup>1</sup>TU Braunschweig, Germany; <sup>2</sup>Cluster of Excellence PhoenixD (Photonics, Optics, and Engineering—Innovation Across Disciplines), Germany

The detection of bacteria requires full-fledged qualified employees to prepare individual samples for corresponding machine-based analysis. This process is highly time-consuming and cost-intensive. Therefore, there is a great demand for more rapid, portable, and cost-effective sensors for the detection of bacteria.

For this, well-established electrical measurement methods might be transferred to the investigation of biological systems. Our approach is the development of an extended-gate field-effect transistor (EGFET) as a biosensor. The EGFET is composed of a standard metal-oxide semiconductor field-effect transistor (MOSFET) and a physically separated but electrically connected sensor unit produced as a thin-film device.<sup>1</sup> The connection is realized by extending the MOSFET's gate electrode into the sensor unit. The potential of the gate-electrode is regulated by the electrical impact of the sensor unit on the MOSFET which further gates the measurable current between its drain and source electrode. The main constituent of the sensor unit is a suspension containing the bacteria of interest, which connects the extended-gate with a control-gate electrode. Both electrodes are functionalized with A<sub>2</sub>BC-type porphyrins to link the bacterial cells to the electrode surfaces to shift the electrical potential of the extended-gate electrode on the gate-solution interface.<sup>2</sup> Different optical and electrochemical methods verified clearly the successful formation of the functional layer. Further, the successful linkage of bacteria on the functionalized electrode were analyzed by fluorescence lifetime imaging microscopy (FLIM).<sup>3</sup> The transfer characteristic of the EGFET also clearly indicated the impact of trapped bacterial cells due to lower potential values on the extended-gate electrode.<sup>1</sup> However, our latest results indicate a non-homogeneous coverage of the electrodes by the bacteria.<sup>3</sup>

Further investigations focus on the increase of trapped bacteria to improve the sensitivity of the biosensor. Here, one of our approaches is the integration of dielectrophoresis (DEP) to the electrodes of the sensor unit. DEP is a highly flexible and multifunctional method to immobilize, separate, and concentrate biological particles such as whole cells but also dissolved molecules in a liquid. In addition, an optimized measurement setup or different functional layers based on e.g. boron-dipyrromethene (BODIPY) might also improve the sensitivity. The synthesis of BODIPYs compared to the A<sub>2</sub>BC-type porphyrins are less complex which fulfills the requirement of a lean device.

**Kirigami-Based Stretchable Interconnects for Robust, Soft Neural Interfaces** Laurine Kolly, Florent-Valéry Coen and Stephanie P. Lacour; École Polytechnique Fédérale de Lausanne, Switzerland

Recording or modulating neural activity using implanted electrode arrays has enabled advancements in the restoration of sensory-motor pathways and brain-computer interfaces. Long-term reliability of these interfaces (>6 months) is paramount to their deployment in neuroprosthetic medicine. Furthermore, hermetic encapsulation of conductive components within electrode arrays is required for long-term protection against the moisture and ions from the physiological environment to avoid electrical failure over time.

We have developed a kirigami-based technology to engineer elasticity within thin films of metal and thermoplastic polymer. The periodic cuts (kirigami) patterned and replicated across a thin stack of Polyimide/Platinum/Polyimide of 1/0.1/1 μm thicknesses program stretchability within interconnect tracks as narrow as 52 μm width. The Polyimide layer is patterned with a 1 μm width offset to that of the Platinum layer, such that the metallization is fully encapsulated, top, bottom, and sideways with Polyimide, thereby providing a built-in long-term hermetic barrier.

We assessed the robustness of the kirigami-based interconnects through a set of *in vitro* accelerated aging tests and repeated mechanical loading tests. We monitored the evolution of leakage current between two interdigitated tracks (IDE) biased at 5 V and soaked in phosphate-buffered saline (PBS) at 67 °C for 20 days. The elastic regime and plastic onset of the interconnects were measured during incremental uniaxial tensile stretching cycles. The electro-mechanical fatigue was assessed through uniaxially stretching linear interconnects for 1 million cycles at 10% strain, within the elastic regime.

The results of the accelerated aging showed that the leakage current remained below 0.2 μA after 20 days. These findings indicate that the interconnects maintain a high level of hermeticity, equivalent to >25 MΩ after 160 days at 37 °C, in accordance with Arrhenius law. The electro-mechanical characterization demonstrated that the Polyimide-encapsulated kirigami interconnects can deform reversibly up to 15% of applied strain. Moreover, cyclic stretching for 1 million cycles at 10% strain resulted in a slight increase of 5% in relative resistance, indicating minimal mechanical fatigue.

The *in vitro* characterization demonstrated that the kirigami micro-patterning strategy used to fabricate stretchable interconnects can achieve a high level of hermeticity and exhibit low mechanical fatigue. Ongoing research efforts are focused on integrating materials with superior moisture barrier properties, such as silicon carbide, and further tuning the kirigami geometry to achieve a higher range of stretchability. These advancements aim to design functionally stable and longer-lasting neural interfaces that can withstand the mechanical challenges associated with chronic applications.

#### 8:00 PM SB07.08.03

**Flexible and Transparent Microelectrode Array for Simultaneous 2-Photon Imaging and Electrical Recordings** Vikrant Kumar<sup>1</sup>, Connor

McCullough<sup>2</sup>, Emily Gibson<sup>2</sup>, Diego Restrepo<sup>2</sup> and Ioannis Kymissis<sup>1</sup>; <sup>1</sup>Columbia University, United States; <sup>2</sup>University of Colorado, United States

Combining two modalities, optical imaging and electrical recordings of neural cells, can shed light on a more profound understanding of neural circuits. Microelectrode arrays with high optical transparency in the near-infrared (NIR) and high electrical conductivity are required to enable simultaneous 2-photon imaging and electrical recording. A transparent microelectrode array allows us to perform imaging and electrical recording at the exact location for improved correlation between the two modalities, with imaging having a better spatial resolution and electrical recording having a better temporal resolution. We present an ITO-based transparent microelectrode array's design, fabrication, and testing. The microelectrode array has 16 recording sites, with each electrode size of 20  $\mu\text{m}$  x 20  $\mu\text{m}$ . The microelectrode array uses 3  $\mu\text{m}$  parylene-C as a substrate and encapsulation layer maintaining excellent flexibility. Bending tests for different radii are performed to characterize the array's flexibility. The 2-photon imaging through the electrode array shows optical transparency at the desired wavelength of 920 nm. Electrochemical impedance spectroscopy (EIS) is done to characterize the electrical characteristics of the microelectrode array. Finally, the simultaneous 2-photon imaging and electrical recording through the array on a head-fixed animal is underway for the final testing of the microelectrode array. The microelectrode array is connected to a custom PCB using heat seal connectors for further connection to the data acquisition system.

#### 8:00 PM SB07.08.04

**Nanomesh microelectrode Arrays on 10 $\mu\text{m}$ -Thick PDMS for Ultrasoft Neuroelectronics** Jaehyeon Ryu<sup>1,2</sup>; <sup>1</sup>Dartmouth College, United States; <sup>2</sup>Northeastern University, United States

Ultrasoft neuroelectronics are highly interesting because they enable conformal and compliant interfacing with the soft, curvilinear surface of the neural tissue. However, current ultrasoft neural interfaces are usually limited by their electrode performance and scalability for neuroelectronic applications. Here, we present multi-functional nanomesh as an approach to achieve ultrasoft microelectrode arrays (MEAs) with excellent scalability. By stacking mechanical supporting polymer, metal, and low impedance coating, here we demonstrate an Au/PEDOT:PSS bilayer-nanomesh-based MEAs on ultrathin Polydimethylsiloxane (PDMS) substrate. We have successfully fabricated 32-channel, bilayer-nanomesh-based MEAs on PDMS with total device thickness down to only 10  $\mu\text{m}$ . The 32-channel bilayer-nanomesh arrays have demonstrated over 90% yield on average. We also achieved low impedance of 60 kilohms at 1 kHz with site area down to 400  $\mu\text{m}^2$ , comparable to the size of a single neuron. The performance of this bilayer-nanomesh MEAs has been characterized through bench testing. This MEA achieves excellent and stable electrochemical performance and also demonstrates good optical transparency over a broad wavelength spectrum. Other achievements of this research are hydrophilic surface modification on the MEA surface along its stability and great sterilization compatibility with ethylene oxide (EtO) sterilization which highlights the practical utilization of this novel device for advanced neural interfacing. This multi-functional bilayer-nanomesh approach provides a promising pathway toward ultrasoft neural interfaces with excellent electrochemical performance and large throughput for applications ranging from neuroscience to biomedical devices.

#### 8:00 PM SB07.08.05

**Optimization of Parylene Coatings for Implantable Neural Devices** Saman Ebrahimbasabi, Layla Khalifehzadeh and Hamed Arami; Arizona State University, United States

Parylene C is a widely utilized biocompatible thin-film polymer coating for implantable devices, specifically neural implants, due to its ability to cover uniformly complex shapes, protect the implants against corrosive body fluids such as CSF (cerebrospinal fluid), electrical insulation, chemical stability, and durability. However, weak adhesion to the various types of device substrates remains a significant challenge for this promising coating material. Here, we will present the impact of substrate material selection, silanization (as adhesion promoter), different deposition parameters (such as silane concentration) and post-deposition annealing on overall characteristics of the coating layer (such as thickness and adhesion strengths). First, silicon wafers were coated with different thicknesses of Parylene C using SCS coating machine, followed by annealing in Ar atmosphere at temperatures of 150, 200, and 250°C. Additionally, the effect of thickness (1 and 3  $\mu\text{m}$ ), and silane A-174 concentration (0.5, 1, and 1.5%) on adhesion strength were investigated. To assess long-term adhesion of Parylene, samples were submerged in an in-vitro accelerated aging bath consisting of PBS at 87°C for 7 days, and the properties were compared before and after the aging, to estimate the coating's stability in body environment after implantation. Coating thickness and molecular structure were investigated using Ellipsometry and FT-IR, respectively. Adhesion strength was determined using ASTM D3359 tape test. Our initial results indicated that 1  $\mu\text{m}$  Parylene coating with 1.5 vol% silane as adhesion promoter, and annealed at 150°C can potentially result in optimal adhesion for silicon substrates. We are pursuing follow up studies on silicon and other types of substrates (such as polyimide, which is a common flexible substrate for a variety of brain and neural implants) to further validate these observations. We envision that our results are critical to address unmet challenges for prolonging the lifetime of the implantable neural devices.

#### 8:00 PM SB07.08.06

**Frequency-Dependent Mechanism of Magnetic Nanoparticle Re-Laxation** Mingu Song, Dowoo Kim and Heon-Jin Choi; Yonsei University, Korea (the Republic of)

Magnetic nanoparticles (MNPs) play a central role in magnetogenetics as energy transducers, delivering the external energy in focus to neighboring cell membranes. Especially, magnetothermal heat conversion is held by two major relaxation mechanism: Néel relaxation (spin) and Brownian relaxation (rotative). As of now, efforts have been ongoing to accurately reflect stochastic nano system with refining mathematical model as more sophisticated. Here, our idea is "there is no gold model". We carefully argue that particle dynamics between forward field alignment and backward thermal randomization is clearly different. By coining the very field-dependent alignment mechanism as "laxation", we differentiate alignment and relaxation, also integrate suitable expressions that have been examined so far. Then we compute and visualize theoretical boundaries of Néel & Brownian movement. This approach allows us to decode the frequency sensitivity of heat conversion of magnetic nanoparticles based on relaxation mechanism. Relatively small, less anisotropic particles tend to spin-relax; thus, they efficiently convert high frequency field (~MHz). On the other hand, big, anisotropic particles are inclined to rotative-relax so that they could react only low frequency field (~few kHz). Moreover, we illuminate the enigmatic mixed mechanism, optimistic waveform, field amplitude dependency, and shape factors of MNPs. We support our arguments through experiments. Finally, we propose a simple fabrication method for transition of relaxation mechanism to regulate activation frequency. This frequency tuning may provide a range of possibilities for magnetogenetics, such as multi-channel activation of noninvasive deep brain stimulation (NIDBS).

**3D-Microelectrode Arrays (MEAs) for In Vitro Applications** Inola Kopic<sup>1</sup>, Hu Peng<sup>1</sup>, Sebastian Schmidt<sup>1</sup>, Annika Weisse<sup>2</sup>, Richard Miru George<sup>2</sup>, Gil Westmeyer<sup>1</sup>, Christian Mayr<sup>2</sup> and Bernhard Wolfrum<sup>1</sup>; <sup>1</sup>Technische Universität München, Germany; <sup>2</sup>Technische Universität Dresden, Germany

##### **Abstract:**

In the realm of 3D cell cultures and organoids, capturing electrical activity across multiple planes is essential for a comprehensive understanding of their behavior. Conventional microelectrode arrays (MEAs) with surface recordings fall short in addressing this requirement. The limitations of clean-room methods restrict electrode design possibilities and can impede effective cell-electrode coupling. To tackle this challenge, we present a novel approach that

leverages rapid prototyping processes to enhance electrode fabrication. Our laser-patterned MEA incorporates printed 3D-electrode structures, enabling precise recording and stimulation within cell tissues. This advancement improves signal quality through enhanced cell-electrode coupling and provides greater flexibility in electrode placement. We believe this innovative approach will significantly contribute to improvements in 3D cell cultures and organoids, opening new avenues for understanding complex biological systems and developing targeted therapeutic interventions.

**Introduction:**

Standard planar MEAs can only record electrophysiological signals in 2D, making them unsuitable for capturing the complexity of emerging 3D cell cultures or organoids [1]. To overcome this limitation, we design and fabricate 3D MEAs using additive manufacturing techniques [2]. These 3D MEAs hold promise for studying neuronal functions and diseases using neuronally differentiated human-induced pluripotent stem cells (hiPSC) in vitro.

**Results and Discussion:**

Here, we present the microfabrication of our 3D MEAs. In the first step, silver ink pillars are printed on suitable substrates, followed by sputtering with gold to create a biocompatible electrode interface. Individual electrodes and feedlines are then generated through laser ablation, with feedline structures patterned within minutes, representing a significant improvement over conventional lift-off techniques. The chips are fully passivated with a parylene C layer deposited via vapor deposition. Laser ablation at different angles is used to open the tips of the pillars precisely, and partial etching is employed to create tubular structures. In the final step, individual pillars undergo stepwise electroplating with gold and PEDOT:PSS to prevent silver contamination during long-term cell culture. Our fabrication method offers a fast and easily adjustable approach compared to traditional clean-room techniques. Using the inkjet printing process with laser ablation and electroplating, the height of each pillar can be accurately determined. This enables the realization of multiple pillars with various heights on a single chip. Moreover, the design of the MEA aligns the electrodes in a manner that simplifies their insertion into organoids or 3D cell models. With this highly flexible approach, we aim to record cellular signals from various planes within the targeted tissue.

**Conclusion:**

This work demonstrates a process for fabricating MEAs with integrated 3D electrodes, providing a platform that facilitates recording and stimulation within 3D cell aggregates or organoid models.

**Brain-Machine Interfaces—Taking the Next Step Towards Translational Devices** [Santiago Velasco Bosom](#) and George G. Malliaras; University of Cambridge, United Kingdom

Aphasia is defined as the impairment of speech as a result of acquired brain injury, rapidly hindering communication skills in the patient. Current therapeutical approaches are complex and rely on compensatory strategies to regain the lost communicating abilities.

Based on the concept proved by Khodagoly et al, multielectrode arrays (MEA) using electrodes as small as  $10 \times 10 \mu\text{m}^2$  are sufficient to capture both local field potential and putative single neuron activity when used for electrocorticography, causing minimal tissue damage. To date, MEAs have predominately been used for investigating human neural network mechanisms and better understanding of brain disorders. Nonetheless, better interpreting these mechanisms carries the potential to open an entire new medical field to use brain signal recordings for healthcare applications and personalized medicine.

In this work, we present the first translational Neurogrid (ultraconformal ECoG multielectrode array) that will be used for the chronic study of cortical neural signals and its decodification into conversation. By complying with European medical regulation in the development of the device, we aim to increase the duration of the implantation in awake human studies, to better understand the potential of this technology with respect to long-term human-machine interfaces. Integrating state-of-the-art machine learning algorithms to the brain signals recorded by the Neurogrid, we aim to decode neural activity in patients suffering from aphasia and translate it into speech.

The combination of these powerful technologies can pave the way for brain-machine interfaces to become powerful clinical tools that increase the wellbeing of patients with neurological disorders. However, to champion the way of this technology into a final clinical product, it should still undergo multiple intermediate steps to prove its safety and reliability.

**8:00 PM SB07.08.09**

**Flexible Printed Circuit Board (fPCB) Neural Probes for Monitoring Neural Signals** [Daerl Park](#)<sup>1</sup>, Hyeonyeong Jeong<sup>1</sup> and Jungsik Choi<sup>2</sup>; <sup>1</sup>Yonsei University, Korea (the Republic of); <sup>2</sup>Nformare, Korea (the Republic of)

Neural activity monitoring in the central nervous system often utilizes silicon-based micro electro mechanical systems (MEMS) probes. Despite their strength in monitoring and stimulating capabilities, these probes are fragile due to the brittle nature of silicon materials limiting their application in various fields. Here, we introduce flexible printed circuit board (fPCB) neural probes that have robust mechanical and electrical properties. The probes fabricated via a roll-to-roll process on films with thickness of  $3.5 \mu\text{m}$  and  $10 \mu\text{m}$  line width of electrodes exhibit an impedance of approximately  $1.5 \text{M}\Omega$ , reducing to about  $120 \text{K}\Omega$  after typical platinum colloidal coating. This impedance range is suitable for multiunit recordings, enabling simultaneous monitoring of a large population of neurons in the brain. The probes are mechanically very flexible and thus shows no fracture or mechanical/electrical failure under repeated bending test of up to 500 times, and also in the course of handling and monitoring. Furthermore, it is thermally stable that can endure the properties up to 175 degree Celsius and also chemically stable under acidic/alkaline condition that make possible to modify the electrodes easily under harsh conditions such as CVD (chemical vapor deposition) or electro-deposition. In fact, any mechanical failures, or degradation of monitoring capabilities has not been observed in the courses of modification. It indicates that the fPCB probes can be used as a “DO IT YOURSELF” type chronic, tailorable neural probes for chronic neural signal monitoring.

Keywords: flexible neural probe, modification, monitoring of neural systems, chronic

**8:00 PM SB07.08.10**

**Fully 3D Printed Bio-Electronic Devices for Nerve Regeneration** [Ju-Yong Lee](#)<sup>1</sup>, Jooik Jeon<sup>2</sup>, Joo-Hyeon Park<sup>1</sup>, Yea-Seul Park<sup>1</sup>, Se-Hun Kang<sup>1</sup>, Min-Sung Chae<sup>1</sup>, Kang-Sik Lee<sup>3</sup>, Jung Keun Hyun<sup>2</sup> and Seung-Kyun Kang<sup>1,4,5</sup>; <sup>1</sup>Seoul National University, Korea (the Republic of); <sup>2</sup>Dankook University, Korea (the Democratic People's Republic of); <sup>3</sup>Asan Medical Center, Korea (the Republic of); <sup>4</sup>Soft Foundry Nano Systems Institute (NSI), Seoul National University, Korea (the Republic of); <sup>5</sup>Research Institute of Advanced Materials (RIAM), Seoul National University, Korea (the Republic of)

Advancements in miniaturization, wireless technology, and flexible electronic components have led to the development of diverse bio-interfaced

electronics for medical devices. Extensive research has focused on implantable electronic components that can be precisely positioned within the body to record or stimulate specific areas. A significant challenge in this field is achieving a seamless interface between the inserted electronic component and the complex surface or irregular structure of the body. To overcome this challenge, customization of the electrode part and the main body of the device is necessary to adapt to the intricate body surface. Moreover, optimizing space utilization is essential to enable smooth packaging of components in limited spaces, requiring a compact form factor. Therefore, the utilization of additive manufacturing for configuring data-driven voxelated electronic materials within a three-dimensional space holds great potential for integrating electronic components in customized forms. Additionally, it is crucial to prevent infections or internal damage caused by permanent implantation or removal surgery in implantable electronic components. Ultimately, addressing these concerns necessitates biodegradation after the device's operational lifespan. In this study, a fully printed wireless electroceutical tube was developed, capable of treating injuries by inserting it as a tube into peripheral nerves. This achievement was based on the use of biodegradable voxelated electronic ink. Notably, the integration of biodegradable voxelated semiconductors with conductors and dielectrics enabled the creation of a device that generates wireless-controlled monophasic pulses, demonstrating its significant potential for biomedical applications. The suitability for in vivo application was evaluated in small and large animals, and the validity of the findings was confirmed through biological verification, which involved confirming therapeutic effects and assessing their impact on actual functional recovery.

#### 8:00 PM SB07.08.11

**Using Digital Image Speckle Correlation (DISC) to Identify Micro Emotions** Shirley Xiong<sup>1</sup>, Hyeonji Ahn<sup>2</sup>, Elaina Heghes<sup>3</sup>, Anusha Misra<sup>4</sup>, Elaine Zhang<sup>5</sup>, Jessica Hofflich<sup>6</sup>, Shi Fu<sup>6</sup>, Pawel Polak<sup>6</sup> and Miriam Rafailovich<sup>6</sup>; <sup>1</sup>Ward Melville High School, United States; <sup>2</sup>St. Mark's School, United States; <sup>3</sup>South Side High School, United States; <sup>4</sup>Dana Hills High School, United States; <sup>5</sup>Jericho Senior High School, United States; <sup>6</sup>Stony Brook University, The State University of New York, United States

Facial expressions are one of the most basic and natural forms of communication between humans. Alongside general facial expressions, micro-emotions are spontaneous changes in facial muscles that indicate hidden emotions. Micro-emotions become apparent in response to specific emotion-inducing stimuli, such as pictures and videos. These fleeting expressions are low in intensity and are, therefore, significantly more difficult to identify than visible facial expressions and emotions.<sup>1</sup> This study uses Digital Image Speckle Correlation (DISC) to identify micro-emotions by analyzing subcutaneous facial muscle displacement through a contact-free, non-invasive method.

To verify the validity of DISC for tracking facial muscle movement, a video was taken of identical twins and a control performing the same facial actions of frowning and smiling. The control was a subject with no relation to the twins. While the twins used similar parts of muscles to perform actions, the control used quite different parts of facial muscles to perform the same actions. For instance, when frowning, the identical twin's forehead muscles toward the inside of the face. However, the control's forehead muscles moved downward toward the outside of the face.

Sets of ten images were obtained from the International Affective Picture System (IAPS) and categorized using a valence and arousal scale. Valence denotes the emotional value, while arousal characterizes its level of stimulation. The analysis of the participants' faces shows that high-valence images tend to evoke positive emotions, translating to more pronounced movement in the cheeks and mouth region. When the subject saw an image with positive valence and high arousal, large levels of displacement occurred in those areas. The magnitude of facial displacement in four quadrants of the face was represented through a graph. In the graph, visible spikes span approximately a second. These peaks represent fleeting muscle movements that correlate to micro-emotions, which can be detected through displacement. On the other hand, the negative valence images induced significant amounts of micro-emotions in the upper quadrants, specifically in the forehead and eyebrow areas, commonly associated with reactions to sad emotions.

DISC has the potential to be used to analyze the efficacy of treatments for certain psychological disorders. Major Depressive Disorder (MDD) presents with non-verbal indicators such as the lack of or abundance of specific facial movements and reactions. Hence, changes in facial expressions and movements as identified by DISC can be used to diagnose and understand depression and track the progression and regression of depressive symptoms.<sup>2</sup> For example, esketamine is approved by the FDA to treat MDD that cannot be treated through other antidepressants.

In particular, a case study involving an esketamine patient before and after receiving treatment was utilized to analyze the effects of this treatment on patients. Analysis of the video images indicated differences in the intensity of the patient's reactions before and within an hour after treatment. The time to react to the different images was also measured and could be a measure of the impact on the information processing ability of the patient. These results will be correlated to the known physiological impact of esketamine as a sedative agent<sup>3</sup> and the answers to the self-report questionnaire administered to the patient, such as BDI or HAM-D which are used to assess the severity of depressive symptoms.

**Design and Fabrication of a Flexible Implantable Microelectrode Array for Electrophysiological and Non-Enzymatic Glucose Recording in an Artificial Brain Prosthesis** Che-Hung Chu, Pei-Ling Chen and Pochun Chen; National Taipei University of Technology, Taiwan

For neuroscience research, scalability in regard to the length and dimension of implantable neuro devices was required owing to differences in species and brain regions. For the clinical investigation of neurological disorders, including Alzheimer's disease, Parkinson's disease, and epilepsy, specifically

designed implantable neuro devices for precise focus localization have emerged. Among them, in Alzheimer's disease (AD) studies, the metabolic hypothesis of AD is among the models that have gained much traction because glucose hypometabolism is one of the early markers of AD that precede clinical dementia. While a strong argument can be made that reduced glucose uptake is merely a consequence of neurodegeneration, the metabolic hypothesis asserts that brain glucose metabolism is nonetheless an integral part of AD progression and the precipitation of cognitive deficits. In this study, a flexible microelectrode array device is developed with a polyimide substrate, nanoporous platinum microelectrode array, and a biocompatible Parylene C package. This device has low electrochemical impedance with an improved signal-to-noise ratio and high sensitivity of glucose concentration by non-enzymatic electrochemical detection. The nanoporous Pt microelectrode demonstrated excellent electrochemical performance of 88.2 ( $\mu\text{Acm}^{-2}\text{mM}^{-1}$ ) and 37.02 ( $\mu\text{Acm}^{-2}\text{mM}^{-1}$ ) using a chronoamperometry (i-t) test method in PBS and ACSF, respectively. Additionally, we dedicate to maintaining animal welfare ethics and reducing the consumption of animal experiments by developing an artificial prosthesis with agarose to mimic the brain tissue. We successfully developed a prosthesis with tunable impedance, in which we can simulate different neural diseases by adjusting its conductivity to reduce unnecessary animal experiments. The flexible platinum microelectrode shows its high sensitivity to the variation of glucose concentration in the agarose brain prosthesis.

**Decorating Bioelectronic Surface with Supported Lipid Bilayer to Study Viral Entry and More** Zhongmou Chao<sup>1</sup>, Ekaterina Selivanovitch<sup>1</sup>, Zixuan Lu<sup>2</sup>, Konstantinos Kallitsis<sup>2</sup>, Roisin Owens<sup>2</sup> and Susan Daniel<sup>1</sup>; <sup>1</sup>Cornell University, United States; <sup>2</sup>University of Cambridge, United Kingdom

There are two pathways for the entry of SARS-CoV-2: early (cell surface) entry and late (endosomal) entry. In both pathways it requires the initial binding of SARS-CoV-2 spike proteins with host cell membrane receptor (ACE2), followed by the cleavage of spike protein by either TMPRSS2 (early entry) or cathepsin L (late entry). We have previously demonstrated a supported lipid bilayer (SLB) containing native membrane component can maintain membrane fluidity and thus its biological functionalities, making SLB a desirable platform to recapitulate the conditions in vitro that support virus infection of a host cell. In this work, by forming SLB containing ACE2 receptors on a conductive polymer-based substrate, we have probed the two entry pathways of SARS-CoV-2 using electrical signal. Our results suggest the specific binding between spike protein containing virus pseudo particles and ACE2 receptors will increase membrane electrical resistance, while the fusion events catalyzed either by TMPRSS2 and cathepsin L will further increase membrane resistance. Our work shows the electrical readout of membrane properties based on SLB platform can be a powerful tool in detecting SARS-CoV-2 virus entry without the complications of working with live cells. In addition to viral entry, the versatile SLB based bioelectronic sensors are also applied to investigate the interactions between chemical permeation enhancer (CPD) and lipid bilayers, providing insights in the drug development against otitis media.

**Lactate Biosensor Based on Aerosol Jet Printed Organic Electrochemical Transistors (OECTs) for Real Time Monitoring** Yuchen Shao, Paul Lavryshyn, Jiaxin Fan and Manisha Gupta; University of Alberta, Canada

Diabetic patients have an increasing risk of developing the foot ulcers. Diabetic foot ulcer (DFU), as one of the complications for diabetics, has bothered people for many years. Clinical research has shown that real time monitoring of the lactate concentration helps guide therapy and improve patient outcome [1]. To reduce blood tests for lactate level measurements, non-invasive and low-cost reliable biosensors need to be developed for monitoring.

In this research, we developed a 3D-printed lactate sensor on top of the flexible Kapton substrate. Organic electrochemical transistors (OECTs) are chosen for the biosensors because of its good performance under aqueous environments and signal amplification. Sensors are fabricated using Optomec Aerosol Jet 5X printer with Au as the source and drain electrode, Pt as the gate, poly(3,4-ethylenedioxythiophene) doped with polystyrene sulfonate (PEDOT:PSS) as the channel and polyimide as the insulator layer. Layer by layer strategy is applied for functionalization, tetrathiafulvalene (TTF), chitosan, lactate oxidase (LoX) and bovine serum albumin (BSA) are drop-casted on top of the gate area and then both channel and gate are covered by gelatin to further improve the repeatability of the lactate sensor. Functionalized sensors can be stored in 1X PBS solution for over one month without any deterioration in their sensitivity. The device was measured in both PBS and artificial sweat buffer for comparison and obtained a broad sensitivity range between 10 $\mu\text{M}$  up to at least 50mM, which is far beyond the desired range. Blood lactate meter was using as the reference to calibrate the lactate sensor. The printed lactate sensor includes the ZIF connector which can be inserted onto a PCB board and will be used for further diabetic model test.

SESSION SB07.10: Auditory Neuroengineering  
Session Chairs: Maria Asplund and Georgios Spyropoulos  
Wednesday Morning, November 29, 2023  
Hynes, Level 1, Room 110

#### 10:30 AM \*SB07.10.01

**Integration of Soft Materials in Microfabrication for Auditory Neuroprostheses** Alix Trouillet<sup>1</sup>, Emilie Revol<sup>1</sup>, Florent-Valery Coen<sup>1</sup>, Daniel Lee<sup>2</sup> and Stephanie P. Lacour<sup>1</sup>; <sup>1</sup>Ecole Polytechnique Federale de Lausanne, Switzerland; <sup>2</sup>Harvard University, United States

Implantable neuromodulation systems often rely on macroscopic electrodes to deliver streams of electrical pulses to a small targeted region of the nervous system. Miniaturisation and design of electrode materials can help improving on the spatial selectivity and electrode reliability over time. In the context of auditory neuroprostheses, we are designing, scaling and implementing soft microelectrode arrays to generate resolute sound percept with minimal off-target effects in a pre-clinical model of auditory brainstem implants (ABI).

Using microfabrication, we manufactured a macaque sized multichannel, MRI compatible, soft auditory brainstem implant (150 $\mu\text{m}$  thick silicone carrier, 11 platinum-silicone composite electrodes of 300 $\mu\text{m}$  diameter) that delivers selective electrical stimulation. We engineered customised biodegradable implant holder to ease handling and implantable without compromising the ABI compliance, as well as connectors to reliably interface mechanically and electrically the soft implant with flexible cables and a head-mounted pedestal. The ABI is surgically implanted through a retro-sigmoid craniotomy under endoscopic visualisation at the surface of the cochlear nucleus (<5 mm<sup>2</sup> surface area).

We evaluated the efficacy of the soft ABI by monitoring the animal's performance in a behavioural task. Using burst of electrical pulses (ranging from 50-100 pulses per second at 0.1-2 mA) applied through the ABI electrodes, we confirmed the resolute capability of the implant: the animal was able to

differentiate percept generated from different electrode pairs, with distinct activation threshold for each electrode, indicating good spatial resolution. Systematic characterisation of the materials and processes at each step of the manufacturing of the implant enabled the successful deployment of the soft auditory neuroprosthesis.

#### 11:00 AM \*SB07.10.02

**Waveguide-Based Optical Modules for Cochlear Implant Applications** [Christian Göbeler](#)<sup>1,2</sup>, [Michael Ribeiro Stührenberg](#)<sup>1,2</sup>, [Katharina Kunze](#)<sup>3</sup>, [Daniel Keppeler](#)<sup>1</sup>, [Ulrich T. Schwarz](#)<sup>3</sup> and [Tobias Moser](#)<sup>1,2</sup>; <sup>1</sup>University Medical Center Göttingen, Germany; <sup>2</sup>German Primate Center, Germany; <sup>3</sup>Technical University of Chemnitz, Germany

Cochlear implants (CIs) enable open speech comprehension in otherwise deaf patients. Potential improvements affect the limited spatial resolution of the electric stimulus. Optogenetic activation promises a better spatial resolution due to high-precision activation with micro-scaled light emitters. Here, we discuss the development of passive optical modules with integrated micro-optics and laser diode arrays. Remote red-emitting laser diodes are placed outside the cochlea and coupled to polymer-based waveguides with lens-based systems. The waveguides, which are directing the light towards and into the cochlea need to be highly flexible to enable precise placement in the scala tympani with a bending radius of down to 2.5 mm for the human cochlea. Ridge waveguide laser diodes are used due to their available power of several tens of milliwatts. Multibeam applications are enabled by emitter chips with a multitude of parallel aligned laser ridges with a lateral spacing in the 100  $\mu\text{m}$  range. The astigmatic emission profiles of the ridge laser diodes has to be addressed in the optics design, as well as the integration of a transparent sapphire window into the beam path. We evaluate different optical systems on the path towards a human optical cochlear implant prototype, including macroscopic aspherical lenses, which enable medium-scaled optics with beam path length in the range of 15 mm. Further miniaturization of the beam path length to less than 2 mm can be achieved via a micro-lens-based approach. Here, we discuss the different optical systems in terms of channel scalability and waveguide coupling.

#### 11:30 AM SB07.10.03

**Acousto-Sensitive Ion-Based Transistors and Soft Electronics for Artificial Basilar Membrane** [Linta Sohail](#), [Sofia Drakopoulou](#) and [Georgios D. Spyropoulos](#); University of Ghent, Belgium

Current solutions for hearing impairment lie vastly in cochlear implants (CIs). However, they are limited by bulky, power-demanding external uncomfortable components that hinder sound localization and suboptimal neural interfaces which negatively impact the efficiency of hearing restoration. To overcome these issues, we exploit novel internal ion-gated electrochemical transistors (IGTs) and piezoelectric (PVDF) nanofibers to establish a soft, biocompatible artificial basilar membrane (ABM) for a fully implantable and self-contained CI. We hypothesized that organic electronics can create all the required components; IGT-based acousto-electrical transducers with a high signal-to-noise ratio (SNR), and low-impedance, stable stimulation electrodes. To achieve that, we created efficient and fast acousto-sensitive IGTs ( $gm/\tau > 10^6 \text{ mSs}^{-1}$ ), high capacitance conductive polymer films, overcome stability issues and design smart fabrication routes that allow the development of all components into a single conformable substrate. We tuned materials composition, improved designs, and investigated the geometry and morphology effects on piezoelectric nanofibers. We explored IGT-arrays gated by continuous electrospun PVDF nanofiber (~0.6  $\mu\text{m}$  diameter fiber) films with gradually decreasing areas, to provide a deeper understanding of the device physics and elucidate their exact operating principle under various acoustic stimulations (0.1-10kHz). This work lead to an ABM with 8 intracochlear excitation points that conforms to the intact basilar membrane, generates, and amplifies electrical pulses ( $>10^3$ ) according to incoming acoustic stimuli, to stimulate the spiral ganglion neurons and restore hearing without external components. We examined the performance of the ABM in-vivo by recording the electrically evoked auditory brain recordings (ABRs) in a rat model.

This project will generate safer, smaller, and more conformable acoustic-sensitive devices and stimulation electrodes that will build an ABM that can modulate electrically the neurophysiological activity of the spiral ganglion neurons. Further, the materials and methods that will be used in this project will lay the foundation for cost-effective and improved neurological devices such as micro-EEG systems and brain stem implants.

**Coin-Sized, Fully Integrated and Minimally Invasive Continuous Glucose Monitoring System based on Organic Electrochemical Transistors** [Jing Bai](#), [Xinyu Tian](#) and [Shiming Zhang](#); The University of Hong Kong, Hong Kong

Continuous glucose monitoring (CGM) systems are currently a major focus of research in advanced diabetes management. The rapid development in this field calls for next-generation CGMs with improved sensitivity, reliability, and wearability.

Here, we propose a coin-sized, fully-integrated, wearable CGM system [1] that combines cutting-edge technologies from the intersecting fields of biosensors, minimally invasive tools, and hydrogels.

This CGM system includes: 1) an emerging biochemical amplifier, the organic electrochemical transistor (OECT), to improve sensitivity beyond traditional electrochemical modules; 2) a microneedle array for interstitial-fluid (ISF) sampling with reduced pain during skin penetration; and 3) a tough, adhesive enzymatic-hydrogel-membrane to enhance reliability of glucose sensing on skin. Unlike conventional CGMs, the employed OECT amplifier empowers the OECT-CGM with a high anti-noise ability, an on-demand-tunable sensitivity and current regeneration ability, enabling long-term stable glucose sensing within specific clinical ranges (1~20 mM).

This work paves the way for the development of next-generation CGMs that can simultaneously deliver high and adjustable sensitivity, minimal invasiveness, and improved wearability.

[1]. Submitted.

**Artificial Retina with Three-Dimensional Microelectrodes of Liquid Metals for Vision Restoration** [Won Gi Chung](#)<sup>1</sup>, [Jiuk Jang](#)<sup>1</sup>, [Gang Cui](#)<sup>2</sup>, [Sanghoon](#)

Lee<sup>1</sup> and Jang-ung Park<sup>1,2</sup>; <sup>1</sup>Yonsei University, Korea (the Republic of); <sup>2</sup>Yonsei University College of Medicine, Korea (the Republic of)

Inherited retinal degenerative diseases can lead to both gradual loss or permanent damage of photoreceptor cells, resulting in the impairment of vision, or even blindness. However, as inner retinal neurons can be preserved even when this degeneration of photoreceptor cells, various approaches by stimulating the inner retinal neurons to restore vision have been developed. Electronic retinal prosthesis, which uses photo-responsive devices to electrically stimulate inner retinal neurons, has emerged as a promising approach to restore vision. Over the past decade, this electronic retinal prosthesis has been adapted to clinical trials, although being still limited by low visual acuity. One of the main limitations is the low proximity that results from the unconformities between the retina and the implant. Since the stimulation threshold that elicits retinal responses strongly depends on the electrode-cell distance, it is important to reduce this distance. Also, the imprecise stimulation on the epiretinal surface caused by this low proximity can inevitably excite the axons of retinal ganglion cells (RGCs), generating irregular visual perceptions to patients. In this regard, 3D electrodes show promise for effectively stimulating the nervous system, dramatically reducing this electrode-cell distance by positioning the stimulation site adjacent to the target cell. Also, compared to the electrodes that have flat surfaces, these 3D electrodes enable their stimulation to selective local areas, bypassing neurons that should not be stimulated, thereby providing excellent selectivity and high spatial resolution. However, previous 3D neural electrodes have been formed using rigid solid-state materials, showing a significant mismatch of mechanical properties at their interface with soft biological tissues, which can directly damage the soft retina, or cause inflammatory responses within the retina.

Herein, we present an artificial retina where flexible ultrathin phototransistors are integrated with 3D microelectrodes of liquid metals. These phototransistors directly convert light into electrical stimuli, stimulating the retina through our soft 3D microelectrodes. The flexible ultrathin layer of this artificial retina can be conformably laminated on the innermost surface of the retina, directly stimulating the RGCs using the softly protrudent pillars of 3D liquid-metal electrodes. The developments of this artificial retina include several unique strategies as follows: First, these 3D microelectrodes can enhance the proximity to the target cells and provide effective charge injections to elicit neural responses in the RGCs. These soft stimulation electrodes are directly printed in a pillar shape on the top surfaces of the drain electrodes to overcome the geometrical gap at the interface between the device and the locally nonuniform surface of degenerative retina, enhancing the proximity to the target RGCs. Here, these 3D electrodes can be printed with desired heights to selectively reach target cells. Also, the Pt nanoclusters locally coated only on the tip of these 3D electrodes show advantages to reducing the impedance of the stimulation electrodes, and injecting charges effectively into the retinal neurons. Second, their low Young's modulus owing to their liquid form, can minimize the undesired damage to the interfacing biological tissues. Third, unsupervised machine learning approach can effectively classify the evoked spikes, and the results indicate the potential for the selective stimulation of RGC somas using our 3D microelectrodes. Lastly, in-vivo experiments using a retinal degeneration mouse model demonstrate that the spatiotemporal distribution of neural responses on their retina can be mapped under selective localized illumination areas of light, suggesting the restoration of their vision.

**Flexible Pressure Sensor for Continuous Physiological Monitoring** Hemanth Kalluru Nagarajarao, Maryam Golshahi and Layla Khalifehzadeh; Arizona State University, United States

The field of bioelectronics has witnessed remarkable advancements in recent years, playing a crucial role in biomedical applications such as home-based monitoring of blood pressure and blood glucose levels. To expand the potential of bioelectronics, researchers have focused on developing advanced pressure sensors capable of monitoring various health parameters, including intraocular glaucoma, tendon repair and cardiovascular health. Meeting the growing demand for accurate pressure measurements, a multitude of flexible sensing technologies have been devised. These technologies employ techniques such as capacitive, piezoelectric, and piezoresistive sensors to convert external pressure into measurable signals. The success of these mechanical sensors hinges on their ability to compress under applied pressure. Notably, studies have demonstrated that capacitive pressure sensors outperform other options in faithfully reproducing the desired sensing behavior. Capacitive pressure sensors operate by detecting changes in initial capacitance caused by applied pressure. These sensors consist of a dielectric layer sandwiched between two parallel conductive plates. The sensitivity of these sensors increases with higher capacitance. Increasing capacitance can be achieved by reducing the plate distance or selecting a material with a high dielectric constant. This study aims to assess and compare the sensitivity of capacitors using five distinct viscoelastic polymers. The selection of these materials is guided by several factors, including their general properties such as biocompatibility, thermal stability, and cost-effectiveness. Moreover, their mechanical properties, such as high compressibility, low hysteresis, and high tensile strength, are carefully considered. These characteristics are crucial in determining the suitability of the polymers for capacitive pressure sensors, as they directly impact the sensor's performance and reliability. By leveraging these insights and engineering the materials and designs, the sensitivity and overall performance of capacitive pressure sensors can be significantly improved, paving the way for more precise and reliable biophysical pressure measurements in various biomedical applications.

#### 2:45 PM SB07.11.05

**Flexible Electrochemical Sensors for Detection of Neurotransmitter** Farbod Amirghasemi, Ali Soleimani, Sina Gharahtekan, Mona Abdelmonem, Abdulrahman Al-Shami and Maral Mousavi; University of Southern California, United States

Acetylcholine (ACh) functions simultaneously as a neuromodulator and neuromuscular transmitter in the brain, thus playing critical roles in learning, recognition, motivation, and muscle control. Alterations in ACh concentration in the cerebral cortex were correlated to dementia and Alzheimer's disease, psychiatric disorders, anxiety, and depression. Therefore, developing instruments for selective sensing of ACh is essential to enhance the fundamental biological understanding of the role of this neurotransmitter in disease progression, as well as the rational design and testing of therapeutics that interact with the cholinergic receptors. Here, we are developing a sensor for the in-vivo recording of ACh levels in the brain tissue to address current challenges in ACh detection, including bulky and rigid neural probes and low selectivity in biofluids.

I am utilizing potentiometric sensing, which offers direct selective measurement by eliminating separation and sample processing. Potentiometric sensors offer detection in a physiologically relevant concentration range and are a passive sensing mechanism that does not consume or perturb the analyte. These characteristics make potentiometric sensing a robust analytical technique that has grown in popularity for analyzing inorganic ions, including potassium

(K<sup>+</sup>) and sodium (Na<sup>+</sup>) but has<sup>+</sup>) and sodium (Na<sup>+</sup>), but has remained underutilized for detecting neurotransmitters. We developed a proof-of-concept flexible potentiometric sensor for detecting ACh with less than one-second temporal resolution based on flexible parylene electrodes via utilizing a calixarene-based ionophore for ACh.

Using parylene as the structural material for developing neuroprostheses has been validated and could be compared with technologies based on other materials such as PDMS, polyimide, and silicon. However, we are reporting the first potentiometric parylene-based ACh-selective neural probe. We are utilizing parylene due to providing a pinhole-free, highly flexible, sturdy mechanical strength, and biocompatible platform to construct implantable ACh-detecting sensors consisting of a working electrode (containing an acetylcholine organic sensing membrane) and a reference electrode (having a reference membrane). The parylene C substrate encompasses three 200 nm thick Pt electrodes with a 200  $\mu$ m radius. The electrical potential (emf or electromotive force) between the ACh sensor and reference electrode correlates to the activity of ACh levels in the biofluid, according to the Nernst Equation ( $E = E^\circ + (RT/zF) \log a_i$ ), where  $E^\circ$  shows the standard potential, R the universal gas constant, T temperature, F the Faraday constant, z the charge of the ion, and  $a_i$  the activity of ACh. A theoretical slope of 61.5 mV/decade is expected at body temperature and is defined as the Nernstian slope. The ACh-sensing membrane will be drop-casted onto the circular area of the platinum contact. To optimize the high signal stability, we will modify the surface of platinum with the variation of carbon nanotubes (CNTs) due to CNTs' capability to generate a stable and reliable interfacial potential in potentiometric sensors with an organic sensing membrane.

**Photocapacitive Electrostimulation with Hybrid Silicon/Organic Heterojunction Devices** Vedran Derek<sup>1</sup>, Aleksandar Opančar<sup>1</sup>, Tony Schmidt<sup>2</sup> and Rainer Schindl<sup>2</sup>; <sup>1</sup>University of Zagreb, Croatia; <sup>2</sup>Medical University of Graz, Austria

Wireless electrostimulation by silicon photodiodes[1], as well as with organic photocapacitive devices[2,3] has been reported earlier, by *in-vitro* and *in-vivo* measurements on single cells and tissues. Organic electrolytic photocapacitor (OEPc) devices can be fabricated on micrometre-thin flexible substrates, with the entire active device stack thinner than 100 nm. Even though large optical absorption coefficients of organic materials allow for very thin and conformable devices, their inherently lower photo-conversion efficiencies require relatively large, millimetre-scale devices for effective stimulation. Silicon photodiodes, due to order of magnitude higher photo-conversion efficiencies, can be scaled down to a size of tens of micrometres while still being able to effectively stimulate. However, silicon photodiodes are based on high thermal budget dopant-diffusion and annealing processes, time-consuming and complex steps which in turn increase per unit cost of the devices[4]. We will present novel hybrid inorganic/organic photovoltaic-like devices based on *n*-type silicon as a substrate and a photo-active material and spin-coated and crosslinked PEDOT:PSS as a hole-collecting contact, with the heterojunction region being responsible for the charge separation and PEDOT:PSS additionally enhancing the capacitive properties of the device. Such solution-processed hybrid devices retain high photo-conversion efficiencies of traditional silicon *pn* homojunction photodiodes, yet can be fabricated cheaply and rapidly, enabling quick turnover times for device customization when being used as test beds for *in-vitro* experiments. We will demonstrate enhanced efficiency, spatial resolution and stability in aqueous environments of hybrid devices in comparison to purely organic OEPc's by measurements of the 3D transducing extracellular potential and corresponding E-fields. In addition, we will show *in-vitro* photo-induced modulation of the cell membrane potential of the human embryonic kidney (HEK) cells with heterologously expressed voltage-gated K<sup>+</sup> channels, in comparison with OEPc devices.

#### 10:45 AM SB06/SB07.03

**Biocompatibility of PEDOT:DNA and PPy:DNA for Bioelectronics** Serpil Tekoglu<sup>1</sup>, Sarka Hradilova<sup>2</sup>, Katerina Polakova<sup>2</sup> and Serdar N. Sariciftci<sup>1</sup>; <sup>1</sup>Johannes Kepler University Linz, Austria; <sup>2</sup>Czech Advanced Technology and Research Institute, Czechia

Poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) has showed promising potential for soft and implantable bioelectronics due to mixed ionic-electronic transport<sup>1</sup>. On the other hand, natural biopolymers and their composites with synthetic conductive polymers have attracted researchers for biomedical applications due to their biocompatibility, biodegradability, and low toxicity nature<sup>2</sup>. They can be utilized for a variety of applications, including drug delivery, tissue engineering, and medical implants and grafts<sup>3</sup>. Although biomaterial properties of polypyrrole (PPy) and PEDOT have been extensively studied for implantable electrodes, introducing acidic the surfactants, such as PSS might be cons to this approach. The long-term effects of PSS in the brain have not yet been fully investigated.

The aim of the present study is to investigate cytotoxicity of PEDOT:PSS as well as the new composite materials previously suggested for bioelectronics by our group.<sup>4</sup> Deoxyribonucleic acid (DNA) was extracted from salmon fish residuals and implemented as secondary dopant during the template synthesis of biocomposites. PEDOT:DNA and PPy:DNA were synthesized by following the same procedure.<sup>4</sup> As a follow up study, we performed a comprehensive set of cytotoxicity testing of PEDOT:PSS, PEDOT:DNA and PPy:DNA films using NIH3T3 mouse fibroblast cell line. The thin-films of the materials were deposited on glass and used as specimen which allowed cells to grow and proliferate on the surface. The cross-linker glycidoxypropyltrimethoxysilane (GOPS) was added into the dispersed solution of composites against film delamination. We monitored the morphological changes via fluorescence microscopy. The live/dead cytotoxicity/viability tests were determined by flow cytometry. The results show that the novel composites are promising with high biocompatibility to living cells while preserving the benefits of electrical conduction for future biomedical applications. Overall, the implementation of natural polymers in biocomposites for medicine has the potential to revolutionize the field by providing safer, more effective treatments for a range of medical conditions.

**Towards the Development of an Electrochemical Random Access DNA Memory (e-RADM)** Miguel A. Jimenez-Munoz, Christopher Wood and Christoph Walti; University of Leeds, United Kingdom

Over the last decades, we have produced an unprecedented and exponentially growing amount of information, now approaching the limit that current technology can physically store. Storage demand is in fact likely to exceed the capacity of silicon-based devices within 20 years. Current storage technologies, such as magnetic tapes, have limitations such as large power requirements and cooling systems, as well as only offering limited lifetime that requires periodically transferring data to new devices. As a result, new alternative data storage technologies are required that are space and cost-effective, and able to store large amounts of information in a small contained volume, with minimum power consumption.

As an alternative data storage material, DNA has attracted a lot of attention thanks to several intrinsic properties that make it a desirable data storage medium. First, even very long DNA molecules can be condensed into a small physical space as seen in living organisms, and it can hold 2 bits of information per nucleotide. A single gram of DNA has the potential to store two orders of magnitude more data than the amount of data expected to be produced by 2025. The DNA's extraordinary capacity is also coupled with an excellent inherent stability. But the most important aspect that makes DNA such a viable material is the large number of biotechnological tools that have been developed for the manipulation of this biopolymer.

Current strategies aiming to use DNA as a data storage material rely on sequencing technologies for data recovery. However, on a DNA-based memory, having to fully sequence all DNA strands for retrieving a specific subset of information would imply very high levels of latency and risking integrity of information. As a result, random access strategies are required.

Here, we present the first stages of an electrochemical Random Access DNA memory (e-RADM), which utilizes DNA origami nanostructures and localized strand displacement reactions (SDRs) for data manipulation. Short DNA hairpins containing toeholds complementary to the sequences of adjacent hairpins are attached to the DNA origami such that cascades of SDRs can occur. When a data retrieval query is submitted in the form of a short oligonucleotide, only those hairpins with toeholds complementary to the oligo will open, potentially triggering a cascade reaction. After the cascade reaction, the loops of the hairpins are exposed, containing the information related to the query. The unzipping of these hairpins can be monitored by electrochemical means (Squarewave Voltammetry, SWV), as opened hairpins increase the average distance to the surface, preventing electrons from a redox active molecule attached to the end of the sequence to be transferred to the electrode. The final aim of this work is to develop a fully functional electrochemical device in which functionalized DNA origami structures are immobilized on a gold microelectrode array.

Poly(alkylene furanoate)s (PAF) are the most credible bioderived alternative to oil-based poly(alkylene terephthalate)s, as they show superior thermomechanical and functional properties and are therefore attractive for applications in the packaging, textile, and biomedical fields. This work summarizes some of the most recent and promising developments in the processing and characterization of PAFs with variable alkyl chain length and PAF/poly(lactide (PLA) blends and nanocomposites, highlighting the advantages and challenges of each processing technique and the main thermomechanical and functional properties of the resulting films, fibers, and nanofibrous mats.

Solvent mixing and casting have been used to prepare PLA/PAF films, and their microstructural and thermomechanical properties were evaluated as a function of PAF concentration (5–30 wt%) and type (4–10 carbon atoms in the alkyl subunit). For neat PAFs, an increase in the alkyl chain length promotes a decrease in  $T_g$  and  $T_m$  and an increasing tendency to crystallize. However, the latter is true only for PAFs with an even number of methylene groups in the alkyl subunit, while crystallization is generally hindered for the odd-numbered ones. For PLA/PAF blends, the added PAFs are effective in mitigating one of the most important drawbacks of PLA, i.e., its brittleness, as the strain at break of the resulting blends is up to 30 times higher than that of neat PLA. Adding PAFs to PLA also increases its gas- and UV-shielding properties while keeping good transparency in the visible range, which is very desirable for packaging applications. The permeability and diffusivity to  $N_2$ ,  $O_2$ , and  $CO_2$  further decreases with the addition of reduced graphene oxide (rGO), which also promotes blend compatibilization and microstructural refinement [1-3].

The same PLA/PAF blends were also processed to produce fibers, both through solutions spinning and through melt spinning, and a detailed statistical analysis was performed to establish the optimal drawing conditions for each composition. Also in this case, the addition of a small (5-10 wt%) fraction of PAFs (with either short- or long alkyl subunits) promotes a remarkable increase in the strain at break compared to neat PLA [4] and, in some cases, also a simultaneous enhancement in the mechanical strength and elastic modulus. Following SEM observations, this effect has been attributed to the orientation and possible crystallization of the PAF phase and a plastic-rubber transition of PAF domains in the strain-hardening phase of the stress-strain curve.

Finally, we explored, for the first time, the production of nanofibrous mats made of poly(butylene 2,5-furanoate) (PBF) and poly(pentamethylene 2,5-furanoate) (PPeF), which have very similar chemical structures but remarkably different physical and mechanical properties [5]. A detailed morphological analysis of the resulting non-woven mats, carried out through SEM analysis, allowed the screening of the best processing conditions for PBF and PPeF. The resulting mats are not cytotoxic, promote cell adhesion without any surface treatment, and allow the retainment and controlled release of model drugs (e.g., dexamethasone), thus being promising for biomedical applications, for example as patches for transdermal drug delivery.

**A Green Conformable Thermoformed Printed Circuit Board Sourced from Renewable Materials** [Pietro Cataldi](#); Italian Institute of Technology, Italy

Printed Circuit Boards (PCBs) physically support and connect electronic components to implement complex circuits. The most widespread insulating substrate that also acts as a mechanical support in PCBs is commercially known as FR4 and is a glass fiber-reinforced epoxy resin laminate. FR4 has exceptional dielectric, mechanical, and thermal properties. However, it was designed without considering sustainability and end-of-life aspects, heavily contributing to electronic waste accumulation in the environment. Thus, greener alternatives are needed that can be reprocessed, reused, or biodegraded/composted at the end of their function.

This work introduces diverse PCB substrates based on biobased and/or biodegradable polymers and fibers, a sustainable alternative to the conventional FR4. The substrates have been developed by compression molding, a process compatible with the polymer industry. We demonstrate that conductive silver ink can be additively printed on the substrate's surfaces, as their morphology and wettability are similar to those of FR4. The PCBs have tunable mechanical properties depending on the polymer-fiber combination, ranging from Young moduli of tens of MPa to GPa, and are thus flexible or rigid. Furthermore, they can be thermoformed to curved surfaces at low temperatures while preserving the conductivity of the silver tracks. The green substrates have a dielectric constant comparable to the standard FR4, while they are suitable for micro-drilling, a fundamental process for integrating electronic components into the PCB. The substrate's biodegradability is tested both in seawater and in soil. We implemented a proof-of-principle circuit to control the blinking of LEDs on top of the PCB, comprising resistors, capacitors, LEDs, and a dual in-line package circuit timer. The developed PCB substrate represents a sustainable alternative to standard FR4 and could reduce the overwhelming load of electronic waste in landfills.

#### 11:00 AM SB08.01.03

**Sustainable Photoluminescent Materials Based on Bio-Based Photocurable Functional Inks for Digital Light Processing** [Cristian Mendes-Felipe](#)<sup>1,2</sup>, [Bárbara Cruz](#)<sup>3</sup>, [Daniela M. Correia](#)<sup>3</sup>, [Veronica de Zea-Bermudez](#)<sup>4</sup>, [Marco Sangermano](#)<sup>2</sup> and [Senentxu Lanceros-Mendez](#)<sup>1</sup>; <sup>1</sup>BCMaterials - Basque Center for Materials, Applications and Nanostructures, Spain; <sup>2</sup>Politecnico di Torino, Italy; <sup>3</sup>University of Minho, Portugal; <sup>4</sup>University of Trás-os-Montes e Alto Douro, Portugal

The increasing demand for additive manufacturing, particularly digital light processing (DLP) printing, has raised concerns regarding its environmental impact. Conventional materials used in DLP printing, such as petroleum-based resins, often pose challenges in terms of sustainability, resource depletion, and waste generation. To address these issues, it is required to explore sustainable alternatives derived from natural sources.

Natural polymers have gained significant attention as potential ink materials due to their availability, low cost, biodegradability, and compatibility with various printing techniques. The formulation of natural polymer-based inks involves careful consideration of their rheological properties, stability, and printability, while maintaining biocompatibility and environmental sustainability. This work highlights the key factors influencing ink development, including material selection, ink formulation, and process parameters optimization, to achieve reliable and high-quality 3D printed objects. Thus, different reactive diluents have tested in soybean oil-based ink in order to optimize the ink viscosity with the aim to produce a completely DLP printable formulation. Furthermore, photopolymerization process of obtained materials denotes to be comparable with commercially available resins maintaining high biorenewable carbon content and presenting high quality in printing parts.

Furthermore, the incorporation of fillers into natural polymer-based inks has opened up new possibilities for functionalizing printed objects. By incorporating photoluminescent materials into the ink formulation, printed objects have been fabricated that exhibit luminescent characteristics, making them suitable for applications such as signalling, identification, security features, or decorative elements.

This work delves into the potential of photoluminescent salt fillers based on lanthanide ions as they possess several unique luminescent features of high technological interest: long luminescence lifetimes ( $\mu$ s to ms), fingerprint emission profiles, fine emission bands, and large pseudo-Stokes shifts. Thus, five

photoluminescent salts are used, three of them that emit efficiently in the visible spectral region based on  $\text{Eu}^{3+}$  (red, 612 nm),  $\text{Tb}^{3+}$  (green, 544 nm) or  $\text{Tm}^{3+}$  (blue, 440 nm), and two more emitting in the near infrared spectral region, the  $\text{Yb}^{3+}$  (1000 nm) and the  $\text{Nd}^{3+}$  (808 nm). The impact of filler type and dispersion on the optical properties and overall performance of printed structures will be discussed, showing quantitative signal even at low concentration of 5 wt.%, together with a high quality of printing parts. In addition, the challenges associated with natural polymer-based ink development, such as achieving sufficient mechanical strength due to the negative impact of the addition of fillers into the polymer, optimizing print conditions ascribed to the light absorption of the fillers that difficult the photopolymerization process during printing, and ensuring good photoluminescent properties will be addressed.

Overall, this work sheds light on the advancements in natural polymer-based ink development for additive manufacturing, specifically targeting DLP technology, and emphasizes the potential of integrating photoluminescent fillers to expand the functional capabilities of 3D printed objects. The findings presented in this abstract contribute to the broader understanding of materials development in additive manufacturing.

**Stretchable and Biodegradable Plant-Based Organic Batteries** Aiman Rahmanudin, Mohsen Mohammadi, Nara Kim and [Klas Tybrandt](#); Linköping University, Sweden

Next-generation electronics will interface intimately with the human body. This requires devices with high degrees of conformability and autonomy, where integrated soft and stretchable batteries are an essential component. However, existing stretchable batteries are predominantly based on unsustainable transition metal-based active materials and use non-biodegradable petroleum-based elastomers. Such batteries cause environmental issues like waste generation upon disposal and the use of finite resources during manufacturing. To address this, we present a stretchable and biodegradable organic battery employing sustainable plant-based materials with cellulose as a structural component in the electrode, separator, and current collector, and with redox-active biomaterials for energy storage and a biomass-derived biodegradable elastomer for encapsulation. Our 3D porous scaffold design allows for high mass loadings of redox-active biomolecules, in combination with a low Young's modulus. The full cell showed reversible electrochemical performance under stretching and is biodegradable.

**Lignin-Based Thermosets via Direct Functionalization using an Efficient and Solvent-Free Valorization Method** [Dean C. Webster](#), Alexander Hart and Eric Krall; North Dakota State University, United States

Since lignin is the most abundant aromatic biopolymer, there has been significant interest in identifying ways to convert lignin into useful materials. Degradation of lignin into oligomers and monomers has been a potential approach, however, involves additional processing steps and creates waste. Lignin has abundant hydroxyl groups which can be used for further functionalization to enable crosslinking through a variety of mechanisms. To enable functionalization, lignin—which is a solid material—needs to be converted into a homogeneous mixture for the functionalization reaction. Most commonly, lignin is dissolved in a solvent, functionalized, and then the solvent removed. This process creates waste. We have discovered that lignin is soluble in polyols—such as ethylene glycol, butane diol, glycerol—and the mixture of lignin and polyol can be functionalized together creating a 100% solids crosslinkable liquid resin without creating solvent waste. This approach has been demonstrated with two functionalization chemistries. First, lignin/polyol was functionalized with acetoacetate groups which can be cured using multifunctional amines at ambient conditions. This approach also lends itself to the formation of rigid foams without the use of isocyanates. Lignin/polyol can also be functionalized using methacrylate groups. These can then be cured via free radical initiated crosslinking either thermally or using UV. Due to the aromatic content of the lignin as well as the high functionality of the resins, the thermosets are very hard, with high modulus.

### SESSION SB08.02: Development and Applications of Bio-Based Polymers II

**How to Implement a Recyclable Materials—Considerations for Scaling, Sourcing, Polymerization and Performance of Bio-Derivable Resins** [Nicholas A. Rorrer](#), Robynne Murray, Erik Rognerud and Ryan Clarke; NREL, United States

Thermoset materials have many energy relevant applications due to their excellence performance, versatility, and long material lifetimes. Despite this, at the end of their material life they are often rendered unrecyclable by virtue of the the chemical bond topology, namely highly crosslinked networks. Recently, there has been a growing interest in making these materials from biobased sources and recyclable, both of which are feasible to do. In fact, thermosets represent an ideal market for these materials due to their robust performance and cost premium. Despite the interest and potential, scaling the manufacturing of these materials goes beyond hitting performance specifications; other parameters such as cure time, peak exotherm, and creep must all be considered the entire further interest in material performancne. In this work, we will present upon a bioderivable polyester covalently adaptable networks (PECAN) and its many uses in manufacturing, such as fiber reinforce plastics for wind turbine blades, dual cures for accelerated and decarbonized manufacture, and carbon fiber composites for vehicles applications. The benefit in the experimental work will be coupled with technoeconomic and supply chain analysis demonstrating the potential of these recyclable and bioderivable systems.

#### 2:00 PM SB08.02.02

**Nature-Derived Polymer, Lignin as n- and p-Type Dopants for Tuning the Thermoelectric Properties of Nano-Carbon Materials** [Yoohyeon Choi](#)<sup>1</sup>, Tuan Tran<sup>1</sup>, Doojoon Jang<sup>1</sup>, Jin Young Kim<sup>2</sup>, Hyun Joo Lee<sup>1</sup> and Heesuk Kim<sup>1</sup>; <sup>1</sup>Korea Institute of Science and Technology, Korea (the Republic of); <sup>2</sup>Seoul National University, Korea (the Republic of)

Commercial polymers play a crucial role in controlling the electrical properties of organic electronic materials, particularly through the widely adopted charge-transfer doping. Charge-transfer doping is an essential technique in the industry for modifying the electrical properties by controlling the Fermi level of both host materials and dopants. The dopants involve electron-withdrawing groups (EWGs) that exhibit strong electrophilicity, making them suitable for p-doping. Conversely, n-dopants consist of electron-donating groups (EDGs) that enhance the nucleophilicity of the dopants by increasing the electron concentration. However, the production of these commercial organic dopants from fossil fuels is environmentally problematic, necessitating the development of nature-derived dopants to meet global carbon-neutrality (net zero) policies. As a possible candidate, lignin, an abundant biopolymer found in nature, possesses a phenolic structure that can be modified through various functionalization reactions, similar to commercial polymers.

In this study, we propose a lignin as a dopant for tuning the electrical properties of carbon nanotubes (CNTs) by functionalization. This can be achieved by employing electron-withdrawing groups (EWGs) and electron-donating groups (EDGs) *via* fluorination and amination, respectively, using a simple and eco-friendly synthesizing method, microwave-assisted synthesis. The fluorinated lignin works as a p-dopant and the aminated one acts as an n-dopant. Furthermore, the thermoelectric properties of lignin-doped CNTs and their devices are demonstrated for their applications to flexible energy harvesting systems. The fluorinated lignin exhibits the high Seebeck coefficient and electrical conductivity, increasing the power factor by 117% compared to the pristine CNT films. The aminated lignin shows the Seebeck coefficient of  $-48 \mu\text{V/K}$  with good electrical conductivity of 246 S/cm and the high power factor. It should be mentioned that the n-type characteristics of aminated lignin-doped CNTs are valuable due to the inherent p-type properties of pristine CNTs. We also demonstrated a thermoelectric generator (TEG) only with lignin-doped CNT films of 10 pn pairs in series, exhibiting an output voltage of 7.86 mV and an output power of 247.3 nW at a temperature difference of 15 K. This study promises the realization of nature-derived n- and p-dopants by an easy modification to improve the thermoelectric performance of CNTs, which performs similar to or superior to those of commercial dopants.

### 2:15 PM SB08.02.03

**Computationally Developed Bio-Based Pressure-Sensitive Adhesives for Healthcare Applications** [Manjinder Singh](#)<sup>1,2</sup>, Alessio Alexiadis<sup>2</sup>, Michael J. Adams<sup>2</sup> and Gaurav Manik<sup>1</sup>; <sup>1</sup>Indian Institute of Technology Roorkee, India; <sup>2</sup>University of Birmingham, United Kingdom

The adhesive materials used in healthcare sectors for developing adhesive bandages and transdermal patches have been using petro-based components, which cause contact allergy and allergic contact disease, such as dermatitis and stomatitis. In this investigation, linseed oil has been modified to acrylated epoxidized linseed oil (AELO) and acrylated epoxidized methyl ester (AEME) and further used as a low  $T_g$  component to develop bio-based pressure-sensitive adhesives (PSAs) computationally using molecular dynamics simulations. The bulk polymer adhesive properties such as density, solubility parameter, and glass transition temperature have been estimated and compared with previously reported literature. The values for density and solubility parameters for the control system have been closely related to the experimental as well as simulated values reported earlier. The glass transition temperature was observed to be in close proximity to the Fox equation values as well as the reported literature, verifying the simulation protocols adopted. Further, surface properties were evaluated in order to understand the adhesive behavior and estimate the interfacial strength with the substrate. The human skin has been considered as a substrate for analysis to understand the interfacial behavior of PSAs and suitability in healthcare industries. The surface energy of human skin was found to be in range with the experimental value, verifying the human skin model adopted for this study. The surface energy for all the developed systems has been estimated, and the AELO-based PSA surface energy value was found to be the highest among all the PSAs. Moreover, the interfacial adhesion strength of AELO-based PSA with human skin was found to be superior to that of AEME-based and control PSAs. An in-depth analysis suggests that the addition of polar groups in AELO and AEME was governing factor affecting the surface properties positively. This study paves the way for exploring the potential of AELO and AEME to formulate novel PSAs with desirable properties for the healthcare industries.

**Biomimetic Multifunctional Nanocomposites from Naturally Derived Materials: Exploring the Functionalities of Conductive Melanin and Crystalline Nanocellulose** [Bong Sup Shim](#); Inha University, Korea (the Republic of)

Emulating the sophistication and functionality inherent in natural systems, we have designed multifunctional nanocomposites from naturally derived materials such as conductive melanin-like polydopamine (PDA) and crystalline nanocellulose. Nature employs a bottom-up assembly of nanomaterials to create multiphase structures with hierarchical organization, providing inspiration for our work.

PDA, despite its historical limitation due to low electrical conductivity and limited material functionalities, has been restructured in our laboratory to possess tunable electrochemical conductivities, optical reflectivity, and casting shape stability, while maintaining inherent biocompatibility. This presentation will highlight these innovative modifications, focusing on the unique functional features of PDA in the realm of biosensors and bionic interfaces.

Additionally, our research has expanded to include crystalline nanocellulose, another naturally derived material with promising potential in the creation of multifunctional nanocomposites. Its exceptional strength, biocompatibility, and eco-friendly nature make it a promising candidate for applications alongside conductive melanin.

We will also share insights on our newly developed process for creating electrically conductive PDA, setting the stage for its role in emerging bioelectronic applications such as biotic-abiotic interfaces, edible sensors and actuators, and sustainable electronics. This presentation ultimately bridges the gap between nature-inspired designs and cutting-edge material sciences, pointing to an exciting future in multifunctional biomimetic nanocomposites.

### 3:15 PM SB08.02.05

**Nature's Way: Hierarchical Manufacturing with Biotic Composites** [Sabrina Shen](#) and Markus J. Buehler; Massachusetts Institute of Technology, United States

Industrial material production is responsible for over half of greenhouse gas emissions from industry which, coupled with biodiversity decline and depletion of critical resources, threatens the livelihood of current and future generations of both humans and non-human species. Conversely, the natural world manufactures enormous quantities of materials that can dramatically outperform human engineering while empowering, rather than degrading, the environment, by architecting simple and common building blocks in creative ways, tuning molecular composition, then nanoscale and macroscale geometries to derive highly specialized properties. This work proposes a new paradigm for materials design that achieves goals of sustainability by aligning and integrating models of material production with natural systems, utilizing modern computation and additive manufacturing technology while drawing source and inspiration from nature. We develop a library of 3D-printable functional composites from fully biotic and non-toxic building blocks, and characterize their mechanical, surface, and biodegradation characteristics. We moreover investigate the advantages afforded by additive manufacturing, including fabrication of hierarchical architectures similar to those found in nature. Finally, we explore strategies to further functionalize similar material platforms with computation-guided biocomposite optimization, generative microstructure design, and incorporation of living components for novel hybrid-living materials.

### 3:30 PM SB08.02.06

**Alternatives to Traditional Plastic: PHB-Based Biodegradable Polymer Composite Films and Disposable Tableware** Jiyeon Kim and [Kwan-Soo Lee](#); Los Alamos National Laboratory, United States

Nowadays, plastic materials are taking an important place in our everyday life. Plastic production has soared since it became commercially produced more than 50 years ago. This growth has seen plastic become one of the biggest environmental issues worldwide, with plastic waste polluting land, oceans, air, and even food and human blood. The majority of U.S. plastic waste is landfilled. Of the estimated 40 million tons of municipal plastic waste generated in the U.S. in 2021, at least 85% was sent to landfill sites. Biodegradable polymers have emerged as an alternative. However, certain types of biodegradable polymers, such as PLA, PBAT, Bio-PP, and Bio-PE, require specific environmental conditions or microbial activity to initiate the degradation process. In

natural environments where these conditions are not present, such as in landfills or marine environments, the biodegradable polymers may persist for extended periods without undergoing significant degradation. This leads to the accumulation of non-degraded biodegradable polymers, which can contribute to environmental pollution and waste management challenges. Polyhydroxybutyrate (PHB) is a class of polymers naturally created by living microorganisms or synthetically produced from biorenewable feedstocks. They're biodegradable in the ambient environment, including oceans and soil. However, the PHB has a long-standing problem, due mainly to its inherent brittleness ( $\epsilon = 3-5\%$ ) and poor melt-processability. In this study, we have developed new compositions of PHB-based polymer ( $\geq 90$  wt.%) film/tableware bearing green additives (i.e. FDA approved) to overcome the mechanical instability of PHB and optimize their processability. Furthermore, various formulations developed not only increased the elongation properties of the films but also improved processability by lowering the melt temperature of the plasticware. This result has important implications for disposable plastic applications, as it removes the often-cited inferior mechanical properties of currently available bioplastics.

### 3:45 PM SB08.02.07

**Rhizobium Tropici-Produced Biopolymer: Chemical Characterization and Modeling its Interactions with Clay** Tei Kim<sup>1</sup>, Brinley Dai<sup>2</sup>, Jerry Gao<sup>3</sup>, Tony Guo Feng Tung<sup>4</sup>, Ashritha Kalakuntla<sup>5</sup>, Haaris Alam<sup>6</sup>, Elise Ngo<sup>6</sup>, Isana Alicea<sup>7</sup>, Aaron Sloutski<sup>8</sup>, Yiwei Fang<sup>8</sup>, Marcia Simon<sup>8</sup>, Jay Gao<sup>8</sup>, Miriam Rafailovich<sup>9</sup>, Steve Larson<sup>9</sup> and Fengxiang Han<sup>9</sup>; <sup>1</sup>Stanford Online High School, United States; <sup>2</sup>Experimental High School Attached to Beijing Normal University, China; <sup>3</sup>Beijing No. 80 High School, China; <sup>4</sup>Shanghai High School International Division, China; <sup>5</sup>Ed W. Clark High School, United States; <sup>6</sup>Portola High School, United States; <sup>7</sup>Patchogue Medford High School, United States; <sup>8</sup>Stony Brook University, The State University of New York, United States; <sup>9</sup>US Army Corps of Engineers Research and Development Center, United States

Preventing soil erosion is important in areas vulnerable to flooding, such as watersheds in the Mississippi River Basin. A potential solution is extracellular polymeric substances (EPS), which can increase and maintain the structural stability of soil by increasing resistance to environmental stresses. EPS can improve subterranean root growth, which can stabilize topsoil and help in erosion control. Furthermore, much research in the last decade has focused on explaining EPS-clay/soil interaction in order to improve its applicability. This project aims to investigate the chemical properties of *Rhizobium tropici* bacteria-derived EPS (RT-EPS) and its interactions with clay to model the on-site interactions with soil. EPS produced from the bacteria was used to generate an Ethanol Precipitate Material, RT-EPM, whose chemistry was researched in depth.

First, the chemical composition of RT-EPM was analyzed with thermogravimetric analysis (TGA) and high-performance liquid chromatography (HPLC). TGA results indicated that most of the EPM was organic matter, and HPLC results demonstrated a significant presence of polysaccharides, with glucose being the main component (73%) and a significant presence of galactose (25%). Moreover, the chromatography also showed a dispersity of 1.013, indicating uniformity of the polysaccharides obtained from the RT bacteria.

The interactions between RT-EPM and clay was explored through rheology. To examine the reformability of EPM-clay interactions in aqueous medium, an amplitude sweep, an angular frequency test, and a shear rate test were conducted. Comparing the viscosity values across the three freeze-dry and hydration cycles of the EPM, a negligible change in the mechanical properties was identified, indicating the reversible nature of the dynamic cross-linking. To examine the anchoring properties of the EPM to the soil, the rheological properties of the EPM mixed with various concentrations of clay were tested. An overall increasing soil shear strength as the clay concentration increased was found, demonstrating the anchoring capabilities of the EPM to clay. Rheology displayed the mixture's desirable mechanical properties, which simulate RT-EPM's on-site reinforcement of soil via shear strength enhancement. In conclusion, beside a significant polysaccharide presence, a small fraction of proteins was also found by running respective BSA-assays. It was also determined that the EPM, due to its adhesive properties, once mixed with clay forms interactions that are reversible, significant, and are environmentally-influenced.

Future directions include in-depth research on the protein fraction RT-EPM contains, with a focus on their influence on the interactions with clay. In order to study the EPM-production influence on the interactions with clay, different dialysis cutoff standards will be applied to treat the EPM. Then, HPLC and rheology tests will be run separately for each cutoff (2K and 14K dialysis). C-NMR and H-NMR will also be applied to further shed light on the chemical composition of the EPM and interactions with clay. Zeta potential of the RT-EPM and clay solution will be used to measure the electrochemical potential and the stability of the particle interactions.

The authors would like to thank the US Army Corps of Engineers (ERDC) for their support (W912HZ-20-2-0054) in this research.

**Study of Vitrimization of Thermosetting Liquid Crystal Epoxy Resin via Chemical Reprocessing and Recycling** Kyosun Ku and Hyeonuk Yeo; Kyungpook National University, Korea (the Republic of)

Thermosetting polymers are applied in various industrial fields due to their excellent physical properties, high thermal and mechanical stability. In particular, epoxy materials are attracting attention as next-generation electronic materials due to their bio-friendliness, electronic insulation, and thermal mechanical stability. However, most thermosetting polymers including epoxy resins, still face challenges from insoluble and non-recyclability. In this study, Liquid Crystal Epoxy Resin (LCER) are synthesized which can be reproduced to overcome the limitations of thermosetting polymers. Also, for application as an electronic material, high thermal conductivity are realized. These results suggest the applicability as electronic materials.

### 8:00 PM SB08.03.02

**Interfacial Assembly of Cellulose Nanofibers at Oil/Water Interface via Tailored Electrostatic Attraction to Establish Surfactant-Free Emulsion Stabilization** Jaewon Shin, Bokgi Seo and Jin Woong Kim; Sungkyunkwan University, Korea (the Republic of)

The pervasive utilization of petroleum-based cationic surfactants has led to significant pollution of aquatic environments, emphasizing the urgent need to explore sustainable alternatives. Aligned with this concern, this study introduces a novel bio-friendly natural cellulose nanofiber system for surfactant-free emulsion stabilization. To achieve this, glycidyltrimethylammonium chloride was incorporated into bacterial cellulose fibers to enable cationization and nanofibrillation. The newly developed ammonium-functionalized bacterial cellulose (ABC) exhibited electrostatic adsorption at the oil/water interface, facilitated by the spontaneous negative charge present on interfacial hydrocarbon oil drops. Through theoretical considerations that employed the Young's equation and contact angle measurements of three-phase sessile droplets, we observed that current ABC-based solid interface displayed approximately 10-fold higher adsorption energy compared to hydroxylated solid interface. This unique interfacial adsorption behavior of ABC not only reduced interfacial tension but also promoted the formation of a robust interfacial membrane. Importantly, these interfacial properties are corresponding to the high aspect

ratio of nanofibers, which provide a larger surface area and, consequently, an increased adsorption energy. Furthermore, our rheological studies revealed that the presence of a fibril network formed by the adsorbed ABC nanofibers facilitated the association of droplets and gelling of the continuous phase, thereby improving the durability of emulsion drops against applied shear stress. Collectively, our findings highlight that our innovative surfactant-free emulsion system would pave the way for development of environment-friendly complex fluids.

#### 8:00 PM SB08.03.03

**Scalable R2R Processing of Regenerated Silk Fibroin Film** Jeff Roshko and Fiorenzo Omenetto; Tufts University, United States

Owing to its tunable physical, chemical, and biological properties, regenerated silk fibroin (RSF) has been studied extensively in the film format for potential use in many applications, namely drug delivery, medical/environmental diagnostics, electronics, optics, and tissue engineering. Methods such as spin coating and drop casting are routinely employed to create films from RSF solution in the laboratory for research sample production. However, these techniques do not necessarily translate to larger scales without considerable waste or inconsistency, potentially limiting widespread adoption of useful engineering devices developed from RSF. Meanwhile, techniques developed to produce films industrially such as roll-to-roll (R2R) processing are utilized to manufacture large areas of sensitive coatings and intricate devices, such as microfluidics and flexible solar panels. Herein, we present the development of a scalable means of producing RSF films employing techniques from R2R manufacturing using aqueous processing of RSF. This includes the optimization of RSF-inks that are conducive to solution coating and the comparison of knife-blade sheet-coating at the laboratory scale and slot die R2R coating at multi-meter production scale. This work demonstrates that scalable production is possible for widespread adoption of RSF-based functional devices.

#### 8:00 PM SB08.03.04

**Tensile and Compressive Properties of PLA-Based Polymeric Blends Depending on PBS, PBAT and TPS Content and Testing Temperature** Anna Dmitruk, Joanna M. Ludwiczak, Mateusz Skwarski, Piotr Makula and Pawel Kaczynski; Wroclaw University of Science and Technology, Poland

Environmentally friendly biopolymeric materials can be utilized to replace commonly used plastics, what leads to a noticeable reduction of the pollution level, caused by their processing and exploitation. Nevertheless, in comparison with their non-biodegradable precursors, they suffer from some severe limitations, such as their capability to be untimely decomposed during long-term work, lowered mechanical properties and impaired thermal resistance. Therefore, it is crucial to make efforts to surpass the mentioned constraints by modification of the properties of biodegradable polymers. Among the possible solutions to advance their development a preparation of variously composed biopolymeric blends seems to be a promising route. Poly(lactic acid) (PLA), being widely applied, is one of the most popular biodegradable plastics, characterized with rather high mechanical properties, but with reduced deformability at the same time. To overcome its brittleness, it can be joined together with more ductile additives, namely: polycaprolactone (PCL), poly(propylene carbonate) (PPC), poly(butylene succinate) (PBS), poly(butylene-succinate-co-adipate) (PBSA), poly(butyleneadipate-co-terephthalate) (PBAT), thermoplastic starch (TPS) and polyamide 11(PA11) [1-5]. This work was focused on PLA-based compositions doped with different ratios of PBS, PBAT and TPS to evaluate their mechanical (tensile and compressive) properties in various temperatures (-20°C, 0°C, 20°C, 40°C). Specimens for testing were obtained by preliminary extrusion, subsequent injection molding and final cutting into the intended dimensions. Mechanical properties e.g. tensile strength, elongation at break, Young's modulus, yield strength and compressive strength for the deformation of 0.4 were investigated. No additional modification step, as for example, addition of compatibilizers was necessary to be involved in the manufacturing method, what significantly simplified this process without impairing the properties exhibited by the obtained blends. Each of the tested plasticizing secondary compounds positively influenced the elongation at break of PLA – increasing it especially in the case of PBAT and TPS. Simultaneously, together with the increasing content of a ductile component, other mechanical properties i.e. tensile and compressive strength were decreased. The stability of the mechanical performance of thus fabricated mixtures was assessed taking into account also the test conditions (strain rate and temperature), aiming to understand its dependence on these parameters. To gain a deeper insight into the potential applicability of the hereby proposed materials also some selected processing parameters were investigated, namely: melt flow ratio (MFR), melt volume ratio (MVR), heat deflection temperatures for 1.8 MPa and 8 MPa (HDT A and HDT C) and Vicat softening temperatures for two loadings of 10 N and 50 N (VST A and VST B). Finally, the DSC test results were used to complement the study, providing information on the softening, glass transition, cold crystallization and crystallization temperatures of the developed mixtures. It can be concluded that the elaborated biodegradable blends provide a desired compromise between the mechanical properties, in terms of both tensile and compressive characteristics, and deformability of durable and brittle PLA and ductile PBS, PBAT and TPS additives. Hereby described biomaterials aim to find their use in energy absorption applications, as for the manufacturing of thin-walled, cellular inserts filling sports helmets, acting as energy absorbers and replacing regularly utilized foamed materials in protection of their users during an accident.

**Funding:** This work was supported by the project BOKASK “Development of innovative, replaceable, energy-absorbing structures based on biodegradable plastics for protective helmets” (0223/L-11/2019, LIDER, NCBR).

#### 8:00 PM SB08.03.05

**Evaluation of Mechanical Properties of Wood, Changed by Structural Changes in Alkali Treatment and Liquid Impregnation** Rika Takenaka and Daisuke Ishii; Nagoya Institute of Technology, Japan

One of the increasingly serious environmental problems is plastic waste disposal. In addition to direct solutions such as reducing the amount of plastic used, there are indirect solutions such as using less environmentally hazardous materials as substitutes for plastic materials. Familiar examples include the widespread use of paper bags and straws. In this research, we focused on wood, whose main component is cellulose, as a natural polymeric material with the potential to have the same properties as light and strong plastic. In order to increase its versatility and make it an excellent substitute for plastic, we aimed to investigate novel mechanical properties, such as controlled flexibility, by treating it with alkaline solutions and impregnating it with various liquids.

Commercially available balsa wood was used as the experiment material. Alkaline mixture solutions of NaOH 2.5 mol/L and Na<sub>2</sub>SO<sub>3</sub> 0.4 mol/L were prepared, and the balsa wood was immersed in the prepared alkaline mixture solutions on a hot stirrer set at 212 °F. Duration times of alkali treatment were 0 h (untreated) and 6 h. The alkali-treated balsa wood was washed with pure water and freeze-dried. Structural observation and mechanical strength measurements were performed on these two types of samples.

Scanning electron microscopy (SEM) was used to observe the cross-sectional structure in each cellulose fiber direction. In particular, cross-sectional observation in the vertical fiber direction showed that the cell wall thickness increased in the alkali-treated samples. This is thought that the cellulose fibers unraveled and swelled by dissolving some of the hemicellulose and lignin that bind the cellulose fibers together. It is expected that this structural change affects the novel mechanical properties.

In the compression test, dry samples before liquid impregnation and liquid-impregnated samples of pure water, ethanol, ethylene glycol, and silicone oil of various kinematic viscosities up to equilibrium were prepared. All measurements were performed in the direction parallel to the cellulose fiber. The results showed that strength varied significantly depending on the alkali treatment and the liquid impregnation. The samples without alkali treatment showed no significant difference in strength depending on the type of impregnating liquid. On the other hand, the alkali-treated samples were softer in water and ethylene glycol and harder in ethanol. This led us to believe that the ratio of hydrophilic to hydrophobic groups was a factor in determining whether the

liquid acted as a cushion between the cellulose fibers. With silicone oil, the smaller the viscosity, the stiffer the sample. This is expected to be due to the degree of penetration of the liquid, i.e., the degree to which the molecular chains of the silicone fluid entangle with the loosened cellulose fibers. In the bending test and the falling-ball impact test, two types of samples were prepared, one in a dry state before liquid impregnation and the other in a liquid-impregnated state after absorption of pure water. Measurements were performed in the direction parallel and vertical to the cellulose fiber. As a result, it was found that the tenacity against bending and the tendency of the force to receive impact differed depending on the fiber direction. We believe that this is due to the effect of structural changes identified by SEM.

As described above, it is possible to control the physical properties of wood using a relatively simple method, and it is hoped that this research will contribute to the development of highly functional sustainable materials that can replace plastics in the future.

#### 8:00 PM SB08.03.06

**Lignin-Silica Bio-Composite: A Sustainable Solution for Wastewater Purification** [Nataliia Smyk](#)<sup>1,2</sup>, Oleg Tkachenko<sup>3</sup>, Tetyana Budnyak<sup>3</sup> and Olena Sevastyanova<sup>2</sup>; <sup>1</sup>Taras Shevchenko National University of Kyiv, Ukraine; <sup>2</sup>KTH Royal Institute of Technology, Sweden; <sup>3</sup>Uppsala University, Sweden

The proper purification of wastewater is a pressing environmental concern, given the wide range of pollutants it can contain. In this study, a groundbreaking approach utilizing lignin-silica bio-composite as an effective and sustainable sorbent for removing cationic-type contaminants from wastewater is presented. The research team conducted a comprehensive characterization of the proposed sorbent using SEM, FTIR, XPS, and adsorption methods, ensuring its structural integrity and functionality. This attention to detail instills confidence in the efficacy and reliability of the lignin-silica bio-composite. One of the key strengths of this sorbent is its high sorption capacity. The lignin-silica bio-composite demonstrates an impressive ability to attract and retain heavy metal cations, dyes, and cationic medicines, thereby effectively reducing their presence in wastewater. This feature is particularly noteworthy as it addresses a diverse array of cationic pollutants commonly found in both industrial and domestic wastewater. Furthermore, the sorption kinetics of the lignin-silica bio-composite are commendably rapid. Its efficient adsorption process allows for the removal of contaminants within a short period, ensuring swift and effective treatment of wastewater. This attribute is of utmost importance when considering large-scale implementation and practical application.

At room temperature and near-neutral pH, the sorbent exhibited an adsorption capacity of 0.98 mmol Cu(II) and 1.21 mmol Cr(III) per gram of dry adsorbent. These values were three times higher than those achieved by using lignin or silica alone as starting materials. The kinetics study further demonstrated the efficiency of the composite sorbent. Within a short span of 20 minutes, it was able to effectively extract copper(II) and chromium(III) from the solution. Additionally, the adsorption capacity of the immobilized lignin towards brilliant green dye was found to be relatively high. Furthermore, the capacity of the initial silicas and lignin significantly increased when combined in the bio-composite. This enhancement can be attributed to the "extended" conformation of lignin, which allows for better accessibility of various functional groups when adsorbed onto the charged silica surface. By utilizing lignin, a byproduct of the pulp and paper industry, as a key component of the sorbent, the researchers have showcased a valuable and eco-friendly approach to wastewater treatment. This not only provides an innovative solution but also contributes to the broader goal of promoting a circular economy and reducing waste. The robust characterization methods employed, combined with the sorbent's impressive sorption capacity and rapid kinetics, make it a promising candidate for large-scale wastewater purification. Moreover, its sustainable nature aligns with the increasing need for eco-friendly solutions.

#### 8:00 PM SB08.03.07

**Scalable and Sustainable Valorization of Lignin using Single-Step Aerosol Method** [Sujit Modi](#)<sup>1</sup>, Onochie C. Okonkwo<sup>1</sup>, Sulay Saha<sup>1</sup>, Hao Zhou<sup>1</sup>, Shalinee Kavadiya<sup>2</sup>, Marcus Foston<sup>1</sup> and Pratim Biswas<sup>2</sup>; <sup>1</sup>Washington University in Saint Louis, United States; <sup>2</sup>University of Miami, United States

Growing demand for energy and materials has led to increased greenhouse gas emissions from the use of fossil resources. Lignocellulose biomass, one of the few renewable resources of carbon, has an abundance and geographical distribution to displace fossil resources. However, the under-utilization of by-products (i.e., lignin fraction) remains one of the challenges to the rapid growth of biorefinery. Thus, developing technologies that can valorize lignin to high-value products is crucial. Lignin could be used as a precursor for the synthesis of a diverse range of high-value nanomaterials, including lignin nanoparticles (NPs), carbon NPs, and functionalized carbons. However, conventional synthesis methods of these nanomaterials are limited by multistep and batch processes or large volumes of solvents/activating agents. To overcome these challenges of conventional synthesis methods, the present work explores the synthesis of high-value nanomaterials from lignin using a novel and simple furnace aerosol reactor (FuAR) technique.

First, the FuAR is demonstrated for controlled synthesis of lignin NPs of mean sizes between 50 and 68 nm. The as-synthesized lignin NPs are analyzed for their size and functional groups. The mean size of lignin NPs showed an increasing trend with lignin solution concentration. Based on the changes in functional groups, the maximum temperature in FuAR to obtain lignin NPs without significant chemical degradation was found to be around 300 °C (at a residence time of 5.8 s). Furthermore, the bulk and as-synthesized LNPs were tested for UV protection applications. The observed improvement in UV protection with a decrease in lignin particle size is systematically investigated using the optical absorption parameter [1].

Next, temperature and residence time are expected to have a key impact on products obtained from the pyrolysis of lignin. With the systematic understanding of the role of these parameters, carbon nanoparticles with high surface area (up to 925 m<sup>2</sup>/g) are synthesized in FuAR without the use of activating/templating chemicals. This one-step approach requires significantly less time for synthesis: an order of seconds in comparison to hours for conventional methods. Furthermore, the as-obtained carbon nanoparticles are tested for specific capacitance which showed a linear trend with surface area. The best-performing material (with the highest surface area) exhibited a specific capacitance of 247 F/g at 0.5 A/g with excellent capacity retention of over 98 % after 10,000 cycles [2,3].

Finally, the FuAR is used for in-situ nitrogen functionalization to synthesize nitrogen-functionalized porous carbons. Urea is added to the lignin solution as a precursor for nitrogen functional groups. Furthermore, the as-obtained carbon nanoparticles are tested for CO<sub>2</sub> adsorption and the material with a maximum surface area of 1051 m<sup>2</sup>/g exhibited a CO<sub>2</sub> adsorption capacity of 62 mg/(g of carbon) and excellent cyclability.

Overall, these studies demonstrate the unexplored potential of FuAR for the scalable valorization of lignin as well as the excellent performance of obtained nanomaterials in respective applications, which will help advance displacing the fossils with renewable resources.

**Bacterial Factories for the Production of Functional Lubricants** Stephen F. Bartolucci, Cameron M. Longo, Erica Richael and Joshua A. Maurer; U.S. Army DEVCOM Armaments Center, United States

The use of bacteria to produce novel materials is a rapidly expanding arena across many sectors of industry. These “bacterial factories” can be engineered to produce a wide variety of moderately valuable materials. This has been demonstrated both in academia and industry, with the production of such resources as biofuels, natural products, and pharmaceuticals. The use of bacterial factories offers several advantages to other means of production, namely that production can occur at the point of use, and can be fed waste products as feedstock, which otherwise would have little to no value. These two factors make bacterial factories an attractive method for production of kilogram scale quantities of various supplies. One such material which serves as a useful foray into this field is the production of mucin-like greases. Mucins are naturally-produced lubricating substances, the structures of which can be altered to produce materials with varying properties, including lubricity, viscosity, and thermal stability. We hypothesize that by intelligently designing mucin-like compounds, and hijacking the biosynthetic pathways of *E. coli* to produce these proteins, we can construct bacterial factories which produce water-based, ecofriendly lubricants, which can then be compared in terms of performance to traditional, petroleum-based greases. We demonstrate here, the work thus far in the design, transfection, and expression of these proteins, as well as preliminary results of their glycosylation and functionalization towards a functional lubricant.

**Relationship Between the Structure and Properties of Recycled High-Density Polyethylene Reinforced with Rice Husk Biochar** Hussein S. Alrobei; Prince Sattam Bin Abulaziz, Saudi Arabia

The focus of this investigation is on how recycled High Density Polyethylene (HDPE) is affected by rice husk biochar in terms of its structural, thermal, flammable, and mechanical characteristics. The different ratios of recycled HDPE to rice husk biochar were prepared and the best ratios were discovered for different kinds of features. Tensile, flexural, and impact properties were considered when evaluating mechanical features. In order to expound on this fluctuation in attributes, Scanning Electron Microscopy and Fourier Transform Infrared Spectroscopy were carried out. All of these experiments demonstrated the importance of rice husk biochar as an additive for improving the mechanical properties of recycled HDPE.

**Improving Water Resistance and Film Forming Ability of Cellulose Based Film with Lotus Leaf Extract and Gelatin** Behrokh Shams, Evan K. Wujcik and Douglas Bousfield; University of Maine, United States

Cellulose is extensively employed in food packaging to enhance moisture barrier properties. However, cellulose nanofibrils face challenges such as low flexibility and high water vapor permeability. Utilizing hydrophobic materials, like lotus leaves, is a promising approach to improve water vapor transmission rates. Gelatin can help with film forming and flexibility. In this research, cellulose nanofibrils are combined with a natural hydrophobic extract and gelatin to enhance moisture resistance and film forming process.

**Algae-Powered Sustainability via Hydrothermal Liquefaction: Revolutionizing Epoxy Resins** Keshan Lighty, Phillip Agbo, Abhijeet Mali, Lijun Wang and Lifeng Zhang; North Carolina A&T State University, United States

In the growing field of materials science, our study establishes a revolutionary creative approach in the area of biocomposites for sustainable manufacturing. We present research using the hydrothermal liquefaction process used to produce eco-friendly epoxy resins from algae. The materials science community will be interested in this study since it has the potential to alter how epoxy resin is made in the future.

Traditional epoxy resins come from petroleum sources and are necessary but have a significant environmental impact. Through the use of algae, a plentiful, quickly expanding, and underutilized resource, our work reimagines these resins. We unlock the potential of algae using hydrothermal liquefaction to produce a bio-binder that is not only competitive with conventional components in terms of performance but also a champion of sustainability. The biomass is subsequently transformed into a versatile bio-binder by the state-of-the-art conversion method known as hydrothermal liquefaction, which is prepared to give epoxy resin compositions new life.

The incorporation of bio-binders made from algae not only improves the performance of epoxy resins but also tells a captivating story of ethical material development. Our discovery also changes the paradigm by decreasing reliance on limited fossil fuel resources, which helps lessen the carbon load on our world. The size of the world's epoxy resin market was approximately USD 8.70 billion in 2020, and it is anticipated that it will increase from USD 11.59 billion in 2021 to USD 17.10 billion by 2028. When it comes to these widely utilized composite materials, our capacity to reduce the consumption of fossil fuels while incorporating sustainability will have an enormous impact on society as a whole for the better.

With the help of this scientific development, we are encouraging researchers, thinkers, and proponents of sustainable materials to set off on an exploration that will not only enhance the study of materials but also fundamentally alter the way that Epoxy Resin can be manufactured. This research can make an impact in the areas of painting/coatings, electronics, wind turbines & composites, construction, and adhesive/sealants.

We look to encourage creativity, foster teamwork, and bring in a new era of sustainable materials for a more promising, responsible future. I want to assist society in both self-healing and improving the quality of life through sustainable manufacturing and this research assists with that but this is only the beginning. The goal is to help build a better tomorrow starting today.

**8:00 PM SB08.03.12**

**In-Situ Treatment of Flexible Polylactic Acid (PLA) using Non-Thermal Plasma and Various Electrode Geometries: Towards Developing Advanced Analytical and Machine Learning based Hybrid Methodologies to Study The Wettability Characteristics using Surface Topography, Contact Angle Characteristics and Electrical Impedance Spectroscopy** Derek Xiong<sup>1</sup>, Kaiyu Vang<sup>1</sup>, Prakhyat Gautam<sup>1</sup>, Parshwa Khane<sup>1</sup>, David Ryman<sup>1</sup>, Harshkumar Bhatt<sup>1</sup>, Edbertho Leal-Quiros<sup>2</sup>, Saquib Ahmed<sup>3,3</sup> and Sankha Banerjee<sup>1,4</sup>; <sup>1</sup>California State University, Fresno, United States; <sup>2</sup>University of California, Merced, United States; <sup>3</sup>Buffalo State College, United States; <sup>4</sup>University of California, Davis, United States

Polymer and polymer composite-based 3D printing processes allow users to fabricate multiple prototypes and proofs of concept, making it an excellent method for testing concepts in the early stages of development. However, the layer-by-layer printing procedure can result in issues with surface properties and the strength of the finished printed geometry, making the product an inaccurate representation of the design. The current work involves the in-situ treatment of biocompatible and flexible-PLA, with non-thermal and room-temperature microplasma-based corona discharge to address this problem and try to optimize the surface properties. The work also involves the evaluation of the effects of plasma-treated 3D printed polymer materials as compared to non-

treated samples. This will involve tailoring the polymer properties in the layer-by-layer process to create stronger and more cohesive bonds between each layer through the modification of the surface characteristics of each of the printed layers. Advanced hybrid machine learning models will be developed in combination with analytical methods and empirical data sets to develop strategies for tailoring surface properties of these materials. Additionally, the work involves the characterization of the surface electrical properties using impedance spectroscopy, surface energy and topographical properties using profilometry, and hydrophobic or hydrophilic properties using water contact angle measurements. This will provide valuable insights into the effects of room temperature-based plasma-based surface modification of the printed layers towards enhancement of surface properties of the samples and which electrode will be the most effective.

SESSION SB08.04: Lignocellulosic Technologies

**Nanocellulose as a Sustainable Alternative to Improve the Performance of Resins for Additive Manufacturing** Maria Soledad S. Peresin, Laura Alvarez and Zahra Naghizadeh; Auburn University, United States

In a plea to become more sustainable, the construction industry is increasing the demand for research on partially replacing synthetic resins with renewable and more environmentally friendly resources, such as biomass. Having good properties, epoxy resins have been an excellent candidate in composites for construction applications. However, it is a relatively brittle material, with a poor resistance to crack initiation and growth. Reinforcing epoxy composites with renewable and mechanically strong materials like nanocellulose is progressively considered recently. In this research, different percentage of bleached and unbleached cellulose nanofibers (BCNF/LCNF) were used to reinforce and partially replace epoxy resin in composites containing Epon 828 and Jeffamine d-400 catalyst. The chemical interaction between cellulose nanofiber and epoxy resin was investigated by quartz crystal microbalance with dissipation monitoring (QCM-D). Mechanical and thermal performances of the reinforced resin were studied using tensile test and thermal gravimetric analysis (TGA) method, and the elemental analysis, Fourier transform infrared spectroscopy (FTIR), was employed on the cured reinforced resin in order to understand the composition of the mixtures after nanocellulose addition. The results proved that the nanocellulose addition changes the chemical composition of epoxy resin, and based on the QCM-D data, BCNF showed favorable chemical interactions with the resin. The mechanical tests indicated the promising results and they proved that the BCNF can be used as a biodegradable and sustainable additive and partially replacement for epoxy resin in composite materials. BCNF reinforced epoxy showed better tensile performance compare to LCNF one. For both LCNF and BCNF dispersed epoxy, the maximum enhancement in tensile properties occurred with 1 wt.% nanomaterial added. It should be noted that the moisture stability of the wood composites was not significantly affected by the nanocellulose content, however, the thermal stability decreased slightly.

**Cellulose Nanocrystals-Based Membrane: Enhancing Dimensional Stability and Water Uptake for Alkaline Fuel Cells** Yuan Lu<sup>1</sup> and Soydan Ozcan<sup>2</sup>; <sup>1</sup>LL products, United States; <sup>2</sup>Oak Ridge National Laboratory, United States

The design of anion-conducting polymeric materials has been an active field of research, driven by their application in alkaline fuel cells. These membranes offer advantages such as higher cell efficiencies and cost-effectiveness. However, a major challenge lies in balancing high conductivity with excessive water uptake, which can lead to uncontrolled dimensional swelling or membrane disintegration. In this study, we present a unique approach to address this challenge by utilizing cellulose nanocrystals as the basis for a membrane design. Cellulose nanocrystals, derived from cellulose-rich sources through acid or base hydrolysis, possess exceptional mechanical properties and are known for their high water absorption capabilities while maintaining excellent dimensional stability. By incorporating cellulose nanocrystals with various commercially available polymeric binder systems, we prepared an electrolyte membrane for alkaline fuel cells. We systematically investigated the impact of cellulose nanocrystal content, binder formulations, and temperature on water absorption, swelling, and hydroxide conductivity. Our results demonstrate that the resulting membrane exhibits improved dimensional stability, with less than 10% swelling, and excellent water uptake exceeding 100% compared to membranes solely based on polymer binders. Importantly, the presence of cellulose nanocrystals does not compromise the hydroxide conductivity of the polymer binder system. This approach offers a facile and renewable strategy for preparing solid electrolytes with exceptional dimensional stability and high hydroxide conductivity. It represents a promising avenue for the development of solid electrolytes in alkaline fuel cells, offering a simpler alternative to complex polymer synthesis routes.

#### 10:00 AM SB08.04.08

**Highly Filled Short Banana Fiber-Polypropylene Composites: Fiber Concentration and Interfacial Adhesion Effects on Damping and Mechanical Performance** Caitlyn Clarkson<sup>1</sup>, Sanjita Wasti<sup>1,2</sup>, Amber M. Hubbard<sup>2</sup>, Soydan Ozcan<sup>1,2</sup> and Uday Vaidya<sup>2,1</sup>; <sup>1</sup>Oak Ridge National Laboratory, United States; <sup>2</sup>The University of Tennessee, Knoxville, United States

Natural fiber-hybrid composites are gaining significant interest from automotive applications because these composites meet performance requirements but are often lighter and lower cost than other fiber composites, therein reducing the environmental burden of the vehicle during its use phase. In the case of natural fibers, the inherent hydrophilicity of natural fibers is one of the biggest challenges to overcome as these materials take up moisture at a significantly higher rate and most thermoplastic matrices are hydrophobic, resulting in poor interfacial bonding between the dissimilar fiber and matrix. In this work, composites are prepared by first creating a non-woven fiber mat of polymer fiber and natural fiber in a wet-lay process, drying, and then compression molding to the final desired shape. A water-based sizing agent is added directly to the process to size fibers in situ during wet-lay. The composite properties are evaluated including the tensile strength and impact resistance, damping, heat distortion temperature and water uptake. Finally, demonstration parts will be shown that are compression molded from the wet-laid non-woven process.

**Ultra-Strong and Tough Bacterial Nanocellulose Sheets and Fibers via Rotational Fluid Flow Assisted Shear Alignment** Md Abid Shahrir Rahman Saadi<sup>1</sup>, Yufei Cui<sup>2</sup>, Shyam Bhakta<sup>1</sup>, Matthew Bennet<sup>1</sup>, Pulickel Ajayan<sup>1</sup> and Muhammad M. Rahman<sup>1</sup>; <sup>1</sup>Rice University, United States; <sup>2</sup>Massachusetts Institute of Technology, United States

Bacterial nanocellulose (BC) has emerged as an excellent alternative candidate to non-biodegradable polymers due to the remarkable mechanical properties of its basic nano-fibrillar building blocks. However, full utilization of the mechanical properties in BC structures is yet to be achieved due to the challenge of alignment of the nanofibrils. Herein, we report a facile bottom-up fabrication technique for producing ultra-strong BC sheets by using shear alignment from fluid flow in a rotational culture device, which enables in-situ layer-by-layer deposition of anisotropic cellulose nanofibrils. Specifically, we introduce a custom-designed culture device where the cellulose-producing bacteria are cultured in a cylindrical oxygen-permeable incubator that is continuously spun using a central shaft to produce a directional fluid flow. This flow results in consistent directional motion of the bacteria that significantly improves nanofibril alignment in the bulk BC sheets. The BC sheets produced from the rotation culture device after stretching displayed specific tensile strength (up to  $\sim 1 \text{ GPa/g-cm}^{-3}$ ) and are comparable to the highest tensile strength of BC sheet ever reported yet showing excellent flexibility that allows forming into desired shapes. We show that the BC sheets can be twisted and stretched to make BC micro-fibers of  $\sim 200 \mu\text{m}$  diameter with tensile strength of 1.3 GPa, the highest reported to date among strong natural fibers. We also compare the mechanical, environmental, and cost-effective aspects of the BC fiber with widely used structural fibers such as E-glass and lightweight steel, showing the superiority of BC fiber. This fabrication technique yielding highly aligned, ultra-strong BC sheets and fibers would pave the way toward extensive applications of BC in a range of bio-degradable structural and functional materials.

**10:30 AM SB08.04.10**

**Self-Organized Mycelium-Based Biocomposites for Sustainable Buildings: From Structure to Fracture and Toughening Mechanics** [Precious O. Etinosa](#)<sup>1</sup>, Ali Salifu<sup>2</sup>, Sarah Osafo<sup>1</sup>, John Obayemi<sup>1</sup> and Winston O. Soboyejo<sup>2</sup>; <sup>1</sup>Worcester Polytechnic Institute, United States; <sup>2</sup>Boston College, United States

This work presents the results of a combined experimental and analytical study of the structure and fracture/toughening of bioprocessed mycelium composites. The mycelium composites are reinforced with self-organized cellulose/hemicellulose hemp ducts and varying laterite proportions. In-situ studies of crack growth are used to provide insights into the underlying toughening mechanism that gives rise to resistance-curve behavior. The crack-tip shielding contributions from the observed crack bridging and crack deflection mechanisms are then quantified using fracture mechanics models. The results show that toughening is dominated by crack-bridging at low volume fractions of laterite ( $\leq 20\%$ ), while a combination of crack-bridging and crack deflection is observed to occur at increased laterite volume fractions (20 – 60 %). Finally, toughening is shown to occur predominantly by crack deflection at higher volume fractions ( $\geq 60\%$ ). The implications of the results are discussed for the microstructural design of mycelium and mycelium-laterite composites for potential applications in sustainable buildings.

SESSION SB08.05: Novel Bio-Based Materials

**High Specific Surface Areas and Interconnected Pore Networks of Porous Pectin Particles for Enhancement of Protein Adsorption Capacity** [Tue Tri Nguyen](#) and Takashi Ogi; Hiroshima University, Japan

The aging population is leading to an increasing demand for nutritional supplements, including functional foods. Functional foods aim to provide essential nutrients and proteins to the human body. Porous particles, specifically macroporous particles with pores size larger than 50 nm, have emerged as promising carrier materials for efficient delivery of bioactive compounds. While macroporous particles have been developed from various inorganic and organic materials, their application to natural polymer-derived materials remains unexplored.

This study focuses on the synthesis and characterization of porous pectin particles, utilizing a template-assisted spray drying method combined with a chemical etching process to prevent thermal decomposition of the natural polymer. Calcium carbonate ( $\text{CaCO}_3$ ) was used as templates to investigate the formation of porous structures. The incorporation of  $\text{CaCO}_3$  significantly increased the specific surface area and pore volume, with the porous pectin particles offering interconnected pore networks for penetration and binding. The porous particles had the large specific surface area ( $171.2 \text{ m}^2 \text{ g}^{-1}$ ), and 114 times compared with non-porous particles prepared without  $\text{CaCO}_3$  particles ( $1.5 \text{ m}^2 \text{ g}^{-1}$ ). The study also explored the application of porous pectin particles in protein adsorption using lysozyme as a model protein, providing insights into the adsorption kinetics and isotherm parameters. By comparing the adsorption kinetics of different materials, it was found that increasing  $\text{CaCO}_3$  concentrations led to enhanced specific surface areas and total pore volumes, thereby promoting protein adsorption capacity. All porous pectin particles performed rapid adsorption and high uptake capacity on lysozyme, in which PPT-C has the highest adsorption capacity of 2621 mg lysozyme/g adsorbent for the same amount of adsorbent particles. The adsorption isotherm analysis confirmed the formation of a monolayer following the Langmuir model.

In summary, this report highlights the synthesis of porous pectin particles using a template-assisted spray drying method with  $\text{CaCO}_3$  templates. Since this technique is rapid, continuous, reproducible, and one-step, it is attractive both in laboratories and in the industrial setting. Thus, it shows significant promise for developing materials on a large-scale in the future. The porous pectin particles exhibited increased specific surface areas compared to pure pectin particles. Notably, the porous pectin particles utilizing  $\text{CaCO}_3$  templates displayed excellent lysozyme adsorption capacity, making them promising adsorbents for various applications such as protein and antibodies purification, virus capture, and micro- and nanoplastic recovery from the environment.

**1:45 PM SB08.05.02**

**Unleashing Nature's Potential: Mycelium-Based Innovation in Bio-Composites** [Chiara Dognini](#) and Laura Eleonora Depero; Università degli Studi di Brescia, Italy

Mycelium-based composites are groundbreaking biomaterials that are attracting considerable attention in the European Union and the United States. They have tremendous potential for commercializing sustainable products and offer numerous advantages over traditional materials in industrial sectors like construction, packaging, and textiles. These composites are derived from the vegetative part of fungi, which grows on a substrate, often made from agricultural or other renewable waste materials. They can be utilized in the production of various goods, ranging from furniture to insulation panels and eco-friendly leather, aligning with the principles of the circular economy.

Compared to conventional building materials, mycelium-based composites are more environmentally friendly as their production requires fewer resources and generates less waste and pollution. Moreover, they possess superior technical characteristics and can be molded into different shapes and sizes, opening new design possibilities. These adaptable biomaterials possess physical and mechanical properties that can be customized to meet specific requirements. This unique characteristic holds the potential to make a substantial impact on reducing the construction industry's carbon footprint, which currently

contributes to around 40% of the total CO<sub>2</sub> emissions.

Building materials contribute to various forms of pollution during their life cycle, caused by production, transport, installation, use, and disposal procedures. Addressing the pollution associated with building materials requires sustainable practices throughout the construction industry. Developing solutions without exploiting natural resources whilst safeguarding the environment is crucial for the ecological transition and the future of a green building market.

In recent years, microorganisms have been validated as a promising alternative to highly polluting products, such as foam insulation boards, particle boards, packaging materials, concrete, non-structural furniture elements, textiles, automotive and aerospace materials, and even medical applications. Mycelium-based composites consist of a lightweight material developed by an interwoven three-dimensional filamentous network of hyphae able to bind the feedstock. The use of biomaterials may have seemed like a utopian concept less than a decade ago, but today, they are gaining increased attention due to their customizable properties achieved through specific cultivation procedures.

Key factors that influence the mechanical behavior of mycelium-based composites include the selection of fungal strains, substrates, and cultivation conditions. Despite the exciting opportunity presented by the development of mycelium-based composites to create sustainable and environmentally friendly materials for the manufacturing industry, their widespread adoption has been limited by the lack of efficient manufacturing processes at the industrial level. The presentation discusses and compares various protocols to standardize an efficient manufacturing process for potential industrial scale-up.

**Design of Novel Chitosan Nanoparticles for Antimicrobial Applications** [Magdalena Hudek](#), Karina Kubiak-Ossowska, Karen Johnston, Valerie A. Ferro and Paul A. Mulheran; University of Strathclyde, United Kingdom

Chitin and chitosan (de-acetylated chitin) are biopolymers derived mainly from langoustine shell waste and are considered potential candidates for novel antimicrobial applications. Chitosan is soluble in weakly acidic aqueous solutions and is polycationic, which gives rise to its antimicrobial properties. We have employed computational simulations to study the binding of chitosan to two different substrates to design new composite nanoparticles with antimicrobial properties. The model substrates studied are chitin nanocrystals and silica nanoparticles. Chitin nanocrystals are stable, biocompatible and biodegradable, and silica nanoparticles have been used for medical applications for a long time and are readily available. Using fully atomistic molecular dynamics and enhanced sampling methods, we evaluated the binding energies of chitosan to the substrates and studied the dynamics of the adsorption process. We show that the adsorption of chitosan to the chitin nanocrystal surface is driven by dispersion forces and hydrogen bonding, while the adsorption to the silica surface is driven by electrostatics. Furthermore, we have simulated the development of a biopolymer film with the substrates, providing insight into the loading capacity of the nanoparticles and the availability of the chitosan to interact with its environment. Our work therefore shows how computational simulations can be used to guide the design of novel composite materials for antimicrobial applications.

#### 2:15 PM SB08.05.04

**Data-Driven Representative Models of Bio-Oils for Atomistic Simulations of Biobased Asphalt Rejuvenators** [Daniel J. York](#)<sup>1</sup>, Isaac Vidal-Daza<sup>1,2</sup>, Cristina Segura<sup>3</sup>, Jose Norambuena-Contreras<sup>4</sup> and Francisco Martin-Martinez<sup>1</sup>; <sup>1</sup>Swansea University, United Kingdom; <sup>2</sup>University of Granada, Spain; <sup>3</sup>Universidad de Concepción, Chile; <sup>4</sup>Universidad del Bío Bío, Chile

A large variety of waste can be transformed into bio-oils and biocrude oils via processing techniques such as pyrolysis and hydrothermal liquefaction (HTL), respectively.<sup>1</sup> These techniques provide a waste valorization route with applications such as the production of biofuel precursors, asphalt additives and other carbon-based materials, which can be derived from plastics, lignocellulosic biomass, chitin, etc. However, there are challenges in the fundamental understanding of the structure-property relationships within these bio-based oils, which are exasperated with difficulty in experimental characterisation of these complex bitumen-like materials. To address this lack of understanding, the development of molecular models for density functional theory and molecular dynamics (MD) studies is key and has potential to identify applications for oils produced by the pyrolysis or HTL of plastics and bio-based polymers (i.e. shopping bags, food utensils, packaging) at the end of their life cycle. Computational studies have been carried out to elucidate the mechanisms occurring during production of bio-based oils during hydrothermal liquefaction<sup>2,3</sup> but there are few of these studies investigating the properties and behaviours of the produced bio-based oils with only one comprehensive atomistic model having currently been developed for algae-derived biocrude<sup>4</sup>. This model is based on existing models for crude oil and asphaltene<sup>5,6</sup>, which are based off years of development and research but are tailored to a specific material. In this work, we present a methodology to generate data-driven representative models from pyrolysis gas-chromatography (py-GC-MS) experimental characterization of any complex organic fluid, e.g., bio-oil, biocrude oil, or asphalt samples by generating a selection of statistically representative models that simplify the complexity of the fluid into a limited group of molecules. A variety of different molecular models have generated using a range of different approaches to evaluate the best method for capturing the key chemical features a complex organic fluid that are required for further computational chemistry calculations and large scale molecular dynamic simulations. These atomistic models are key to understanding and implementing waste valorization routes to sustainable, added-value products with potential to accelerate material development from waste. A computational framework has been developed to automate model creation from py-GC-MS data, which could enable future high-throughput MD simulations; ultimately helping to shape future waste-to-materials strategies.

#### 3:00 PM SB08.05.05

**Biomechanics of Biogenic Termite Structures** [Zion Michael](#)<sup>1</sup>, Sang-bin Lee<sup>2</sup>, Thomas Chouvenec<sup>2</sup> and Anamika Prasad<sup>1</sup>; <sup>1</sup>Florida International University, United States; <sup>2</sup>University of Florida, United States

Cellulose-based composites possess notable properties such as high-strength to weight ratio, non-toxicity and biodegradability which make them suitable for applications ranging from aerospace to construction. Due to challenges with manufacturability, synthetic production of cellulose-based composites has failed to achieve comparable outcomes to their natural counterparts. One solution is to look to nature for insights and apply biomimetic principles of design to the development of novel fabrication techniques. Here we focused on the cellulose-based structures created by termites to explore the rules and design

principles.

Subterranean Termites produce a cellulose-based composite called Carton that is used as a construction material during nest formation. Carton is a sponge-like material that consists of biocemented fecal matter, soil, and saliva. Despite relatively weak microconstituents, Carton is light, resistant to weathering, and multi-functional, adapting macroscopic composition and architecture according to function. Although the macroscopic features of nests have been evaluated in existing literature, there are few studies on material structure, and those that exist are limited by specie, variable and test type. Elucidating the compositional properties of cartons at the microscale may yield learning about interfacial interactions between cellulose polymer and its matrix and solvents for solubilizing cellulose.

Samples of carton from *Coptotermes Gestroi* were obtained from 4 yr-old laboratory reared colonies. After termite extraction and drying, carton was cut and sectioned according to distinct morphological characteristics, correlated with functional architectural features. These features are referred to in this study as nursery, high-cellulose and high-soil regions. Duplicates of samples were taken from each region and embedded in resin. The embedded media was sanded then polished to prepare for material characterization.

Here we perform imaging, Raman Spectroscopy, and Nanoindentation to determine the underlying structure-function-compositional characteristics of the carton and use that to elucidate design principles for cellulose-based structural composite design. The above-proposed research area remains largely unexplored, and this study represents the first of its kind for biogenic structures produced by subterranean termites.

### 3:15 PM SB08.05.08

**Peptide Nanowire Coated Jute as Hydrophobic Bio-Based Filter for Oil Water Separation** [Noah Hann-Deschaine](#), Jeiko J. Pujols and Ramesh Adhikari; Colgate University, United States

Solutions to oil-water separation have received a great deal of attention recently in an attempt to address the environmental damage of oil spills. However, many of these separation methods are materially expensive, environmentally hazardous, require elaborate fabrication, or rely on large amounts of energy to function. Herein we provide an effective, low-cost, and environmentally sustainable method for oil-water separation based on the hydrophobicity of self-assembling diphenylalanine nanowires grown on jute fabric. This modified jute fabric exhibits high levels of both hydrophobicity and oleophilicity due to the nanoscale surface roughness created by the growth of the self-assembling peptides on the jute fibers. The treated jute fabric also achieves consistent oil separation efficiencies of 98% via filtration and high levels of efficiency in a novel boat method of separation. Due to the high efficiency and low environmental impact of this method, we believe our diphenylalanine treated jute fabric has a promising potential in the field of oil-water separation.

### 3:30 PM \*SB08.05.09

**Novel Recyclable Bio-Based Materials and Technologies for Sustainable Biocomposite Applications** [Katariina Torvinen](#) and Kirsi Immonen; VTT Technical Research Centre of Finland Ltd, Finland

Due to challenges in global climate change and related regulations of EU Green Deal, there is a growing need in markets to have sustainable and low carbon footprint materials and products, which are recyclable and utilize bio-based additives. In this paper, we will present novel results in terms of biocomposite material development as well as manufacturing point of view. In addition, we will discuss possibilities to upscale solutions in different end-use sectors, e.g. automotive, construction and packaging.

An optimization of composition and structure of thermoplastic biocomposites having improved functionalities (e.g. fire resistance) is crucial. We have studied sustainable solutions using PLA (polylactid acid) and cellulose esters, and show characteristics of those composites regarding of density, strength and structural properties. We will also address 3D-printable cellulose-based composite material solution, which can be recycled several times without to deteriorate mechanical properties of it.

We will introduce an innovative up-scalable web-forming manufacturing method to produce thermoplastic composites with raw materials like long fibers (natural and synthetic ones), bio-based polymers and additives. Thermoformed products are lightweight, strong and sustainable. The target is to enable the full reinforcing potential of long fibres in thermoplastic composites for high performance applications. In this paper, the selected applications will be highlighted and discussed.

**Trojan Horse PET Counts for Facile Chemical Recycling** [Eric Cochran](#), Ting-Han Lee, George Kraus, Dhananjay Dileep, Michael Forrester and Nacu Hernandez; Iowa State University of Science and Technology, United States

In this talk I will review our efforts to develop PET copolymers designed for low-energy chemical recycling. For example, PET copolymers with diethyl 2,5-dihydroxyterephthalate (DHTE) undergo selective hydrolysis at DHTE sites, autocatalyzed by neighboring group participation (NGP). Liberated oligomeric subchains further hydrolyze until only small molecules remain. Copolymers were synthesized via melt polycondensation and then hydrolyzed in 150-200 °C water with. Degradation progress was tracked via measurement of retained solids and quantitative analysis of the aqueous phase. With increasing DHTE loading, the rate constant increased monotonically while the thermal activation barrier decreased. The depolymerization products were ethylene glycol, terephthalic acid, 2,5-dihydroxyterephthalic acid, and bis(2-hydroxyethyl) terephthalate dimer, which could be used to regenerate virgin polymer. Composition-optimized copolymers showed a decrease of nearly 50% in the Arrhenius activation energy, suggesting a 6-order reduction in depolymerization time under ambient conditions compared to that of PET homopolymer. Thermomechanical properties were in general similar to PET, with increased tensile strength and reduced extensibility the most notable differences. This approach is readily extended to other "Trojan Horse" counts that provide internal catalysis for facile hydrolysis, methanolysis, or glycolysis.

### 9:00 AM SB08.06.02

**Additive Manufacturing of Hybrid Cellulose Fibers Reinforced Polymer Nanocomposites** Bivek Bista<sup>1</sup>, [Xianhui Zhao](#)<sup>2</sup>, Lu Wang<sup>1</sup>, Douglas Gardner<sup>1</sup> and Soydan Ozcan<sup>2</sup>; <sup>1</sup>University of Maine, United States; <sup>2</sup>Oak Ridge National Laboratory, United States

Hybrid reinforced polymer composites are materials in which a particular polymer matrix is reinforced with more than one reinforcing materials, or one type of reinforcing material is incorporated into two similar or different polymer matrix mixtures. Hybrid reinforced polymer composites are among multifunctional materials when more than one characteristic benefit (e.g., mechanical strength, conductivity) is needed. In this study, pulp and nanocellulose fibers were used for reinforcing polylactic acid (PLA) because of their relatively low cost, abundance, and biodegradability. The hybrid nanocomposites were produced with nanocellulose loading between 0 and 20 wt% to investigate the effect of fiber loading on the composite tensile performance. The hybrid nanocomposites obtained were characterized using tensile testing, differential scanning calorimetry (DSC), and scanning electron microscopy (SEM). In addition, a demonstration of additive manufacturing (i.e., 3D printing) of hybrid nanocomposites was carried out. Results show that cellulose fibers can provide PLA with a higher tensile performance.

#### 9:15 AM SB08.06.04

##### Using Waste Organic Matter from Landfills to Create Lignocellulosic Filler Materials for Biocomposite Plastic Products Roger B. Tipton<sup>1,2</sup>;

<sup>1</sup>University of North Carolina at Charlotte, United States; <sup>2</sup>Newell Brands, United States

Utilization of waste materials in the production of new materials is a fundamental component of the circular economy. We experimentally evaluated four different levels of upcycled organic trash material as filler material in a polyethylene wastebasket. We found that we could include up to 7% upcycled organic waste material into existing wastebasket designs as a filler before product requirements were out of tolerance. Upcycled trash, at production volumes, can be a usable filler in low concentrations in industrial plastic products which has the potential reduce landfill waste and reduce virgin resin requirements.

#### 9:30 AM SB08.06.05

##### Understanding the Fragmentation and Transformation Behavior of Plastics in Marine Environments under the Weathering Effect via Ultrasonication-Assisted Mimicking Kyungtae Park and Jinkee Hong; Yonsei University, Korea (the Republic of)

As the amount of plastic usage increases, environmentally exposed plastics rapidly accumulate, with a significant portion eventually ending up in the ocean. The fragmentation of plastics has raised considerable concerns regarding microplastics (MPs) as pollutants and potentially toxic substances to ecosystems and human beings. Previous research has highlighted the threat of fragmentation and surface changes caused by eco-corona or weathering, which can result in severe damage to human beings.

Despite the importance of understanding plastic fragmentation, the influence of weathering and the prediction of fragmentation behavior have not been thoroughly investigated. Therefore, it is important to establish an analytical model that can simulate the behavior of environmentally weathered plastics and their transformation. In this study, we focused on the ocean environment, which is considered the ultimate destination for discarded plastics, as our target environment. Our aim is to conduct a comprehensive study on the effects of weathering and the potential threats posed by weathered plastics.

To understand the weathering effect in marine environments, we employed focused ultrasound irradiation. As the cavitation and collapse process repeated during ultrasound irradiation, sonoluminescence emitted ultraviolet (UV) energy to the microplastics. We analyzed the morphological and functional group changes on the surface of particles, comparing manufactured plastic with fragmented nano plastics. Our results showed an oxidation process occurring around the microplastics' surfaces, which we detected through FT-IR and XPS analysis. By comparing the oxidation rate of ultrasound-irradiated microplastics with aged microplastics, we aimed to establish an analytical model for mimicking weathered plastics in marine environments.

While increasing research has highlighted the toxicity of microplastics to the human body, the potential toxicity of naturally fragmented and weathered nano plastics has not been clearly investigated. However, microplastics can transform into nano plastics and undergo changes in surface characteristics due to external physical and biological stresses in the ocean. In this study, we focused on manufactured polyethylene plastic particles and used ultrasound to simulate the natural fragmentation of nano plastic particles caused by weathering in the ocean. We examined the potential threats posed by fragmented nano plastic particles to the human body through immune-cytokine analysis, cytotoxicity tests, and co-culture with human umbilical vein endothelial cells. Our study implemented naturally transformed nano plastics through weathering and evaluated their potential toxicity.

#### 9:45 AM BREAK

#### 10:15 AM SB08.06.07

##### Bioinspired Biomaterial Composite for All-Water-Based High-Performance Adhesives Marco Lo Presti<sup>1</sup>, Nicholas Ostrovsky-Snyder<sup>1</sup>, Giorgio Rizzo<sup>2</sup>, Davide Blasi<sup>2</sup>, Marina Portoghese<sup>2</sup>, Gianluca Maria Farinola<sup>2</sup> and Fiorenzoomenetto<sup>1</sup>; <sup>1</sup>Tufts University, United States; <sup>2</sup>Università degli Studi di Bari Aldo Moro, Italy

Nature has ingeniously developed adaptable adhesive materials by utilizing versatile chemistry centered around two fundamental components: catechols and polypeptides. This chemistry enables adhesive processes even in underwater environments using water-soluble biological substances, presenting a technological challenge that current synthetic adhesives are unable to meet. In this study, we present a bioinspired adhesive composite that aims to integrate the adhesive mechanisms observed in mussels and barnacles. The composite formulation comprises silk, polydopamine, and Fe<sup>3+</sup> ions, all derived from organic and non-toxic sources in a water-based medium. By combining the adhesive properties exhibited by *Mytilus sp.* (mussels) and *Cirripecta sp.* (barnacles), which rely on proteinaceous filaments and proteic cement, respectively, the composite demonstrates remarkable adhesion capabilities in both dry and wet conditions. In lap-shear tests, it outperforms synthetic commercial glues and other adhesives based on natural polymers, rivaling the effectiveness of leading underwater adhesives. It is worth noting that the composite is entirely biologically sourced, eliminating the necessity for synthetic processes. Moreover, the adhesive production method can be extended to utilize proteins beyond silk by fine-tuning the tyrosine:catechol molar ratio to optimize bonding strength. These findings present a cost-effective and sustainable approach that leverages easily accessible raw materials to develop high-performance adhesives suitable for underwater applications.

#### 10:30 AM SB08.06.08

##### Scalable Synthesis of Biodegradable Polyesters Based on Interfacial Polymerization Cecile Chazot and Sara E. Johnson; Northwestern University, United States

Biodegradable polyesters have gained increasing attention as environmentally friendly alternatives to polyolefins, due to their attractive mechanical properties and thermal processability through thermoforming and melt processing. State-of-the-art synthetic routes for aliphatic and aliphatic-aromatic polyesters employ reaction conditions that are not conducive to industrial scale production, such as inert gas environments, high reaction temperatures, long reaction times, and applied vacuum. These complex reaction conditions are a result of oxidation and slow reaction rates due to limited functional group reactivity of the monomers. Here we discuss the development of an open-air, room temperature and scalable synthesis of polyesters based on interfacial polymerization (IP). We investigate the suitability of environmentally friendly solvents and solvent blends in inducing simultaneous fast polycondensation and polymer precipitation in IP and characterize how reaction conditions depend on the backbone chemistry of the synthesized polyesters. This IP route has the potential to enable large-scale production of biodegradable polyesters for applications in consumer products such as packaging and textiles.

10:45 AM SB08.06.09

**Hybrid Poly(lactic Acid) (PLA) Composites: Impact of Varying the Cellulose Material (CM) Source** [Amber M. Hubbard](#), Katherine E. Copenhaver, Caitlyn Clarkson, Meghan Lamm and Soydan Ozcan; Oak Ridge National Laboratory, United States

Thermoplastic composites are of significant interest in a variety of industries ranging from automotive to construction as they present a recyclable, low cost, and lightweight alternative material without sacrificing performance. Additionally, hybrid composites which contain more than one type of reinforcement (e.g., natural fibers and cellulose materials (CM)) have gained increasing attention where target properties are enhanced via composite formulations. Herein, three different fibers (i.e., creafill, flax, and wheat straw) are mixed with three different CM and incorporated into poly(lactic acid) (PLA) via melt compounding. PLA was chosen as the matrix material for all hybrid composites due to its industrial compostability and its demonstrated applicability in 3D printing. The mechanical and thermomechanical properties of the resulting thermoplastic, hybrid composites are reported where the composite strength and modulus exhibit marked increases compared to the non-hybrid composites. In addition, by matching the fiber and CM, the material demonstrates further improvements; the mechanism for property enhancement is explored as a function of CM. Finally, these hybrid composites are formulated and targeted for automotive and tooling applications.

SESSION SB08.07: Sustainable Composites and Recycling II

1:30 PM \*SB08.07.01

**Renewable Fiber-Based Prepregs for Composite Laminates** [Vikram Yadama](#), Avishek Chanda, Muhammad Bakri and Lloyd Smith; Washington State University, United States

Forming bio-based materials into complex three dimensional shapes can be enhanced using a "prepreg" like material. Adapting bio-based materials into material forms that have successfully been used with synthetic composites allows downstream manufacturing of compression molded panels for a variety of higher value applications. This presentation will discuss the development of a natural fiber prepreg for a variety of applications including automotive interior and exterior panels. Wood strands produced from small diameter trees were stitched to make a preform, which was then injected with a liquid thermoplastic resin, Elium<sup>®</sup> (produced by Arkema), using a vacuum assisted resin transfer molding (VARTM) technique. The outcome was a thin and flexible thermoplastic wood prepreg with an average thickness of 0.017-in.

Lumens of wood strands were completely filled with the thermoplastic resin resulting in 38% and 124% higher Young's modulus and strength, respectively, of the saturated wood strands compared to wood strands prior to being infused with resin. A temperature and pressure for the thermoforming process were determined, and these thin and flexible thermoplastic wood-strand prepregs were then laminated by compression molding into panels that are flat or profiled with three-dimensional cross-sections. Compared to wood-strand panels produced using compression resin transfer molding (CRTM) and epoxy resin, Young's modulus and strength of a flat laminate, made of 12 layers of wood prepreg, were 73% and 20% higher, respectively. Prepreg laminates are resistant to moisture uptake and are dimensionally stable as reflected in the water absorption and thickness swelling results. The ability to recycle these thermoplastic composites reinforced with renewable fibers at the end of their service life fits within the circular economy model. These new opportunities and applications for wood strands from small diameter timber would also contribute to sustainable forest management.

2:00 PM SB08.07.02

**Economic and Environmental Viability of Mixed Polyester Chemical Recycling for a Circular and Sustainable Plastic Economy** [Taylor Uekert](#), Jason DesVeaux and Katrina Knauer; National Renewable Energy Laboratory, United States

Biodegradable polyesters offer an attractive solution to the plastic pollution problem, as they can biodegrade in composting facilities and specific natural environments. However, these valuable materials should ideally be kept in circulation rather than permitted to degrade. While biodegradable plastics subjected to mechanical recycling often exhibit sub-optimal properties, chemical recycling techniques could potentially retain quality while keeping these materials in a circular economy. Here, we conduct a comprehensive technoeconomic analysis and life cycle assessment of three chemical recycling methods: methanolysis, glycolysis, and acid hydrolysis. Our analysis focuses on mixed polyester feedstocks containing poly(lactic acid) (PLA), polybutylene adipate terephthalate (PBAT), and polyethylene terephthalate (PET). We demonstrate that methanolysis economically and environmentally outperforms the other chemical recycling strategies as well as virgin manufacturing of the assessed polymers. The costs and life cycle impacts of methanolysis also tend to decrease with increasing biodegradable polyester content, indicating the suitability of this technology for emerging plastic materials. We conclude by highlighting the challenges and opportunities facing chemical recycling of mixed polyesters and its role in a more sustainable, circular, and pollution-free plastics system.

2:15 PM DISCUSSION TIME

2:30 PM SB08.07.04

**Surface Functionalized Approaches of Dry Mycelium Membranes for Enhanced Lead Removal** [Mruganka Parasnis](#), Yu Fu, Erda Deng, Fei Yao, Haiqing Lin and Prathima Nalam; University at Buffalo, The State University of New York, United States

Mycelium hyphae are biomanufactured to grow into 3-dimensional porous networks, which presents a promise for developing sustainable filtration membranes. The hyphal surface is decorated with various biomacromolecules and enzymes that facilitate the remediation of toxic contaminants from the surrounding environments. In this study, we explore various approaches to enhance the filtration efficacy of membranes for lead removal by surface functionalizing dried mycelium hyphae.

Firstly, we aim to present the bioadsorption capacity of untreated, dry mycelium membranes as a function of environmental parameters such as lead concentration, pH, and the duration of Pb[II] exposure to mycelium. A thermodynamic investigation for lead adsorption is conducted to estimate the adsorption capacities and the kinetic rate constants of Pb[II] adsorption onto the mycelium network. Secondly, hyphal surfaces' surface-functionalization using phosphate is explored to remediate lead via pH-dependent biomineralization pathways. Stable lead-based salt crystals formed at the hyphal cell wall (biomineralization), synergistically assisted with the bioadsorption of lead ions, especially at high lead concentrations (1500 ppm), showed 42% enhancement in lead remediation efficiency compared to sole bioadsorption. Moreover, crossflow filtration demonstrated a 90% removal of Pb[II] within 30 minutes of filtration, offering the potential for permeate reuse and metal recovery from the retentate.

Lastly, we achieve the uniform functionalization of the hyphal surface in the mycelium network through electrochemical deposition using low-dimensional

layered MXene structures. This innovative approach amplifies the surface-to-volume functional area and permeability of filtrate via mycelium membrane. The preliminary results show an 83% increase in the kinetic rate of Pb[II] removal for the hybrid membrane compared to the unfunctionalized mycelium membrane. Ongoing studies aim to determine the mechanisms underpinning Pb[II] adsorption within the hybrid membrane. Harnessing the intrinsic chemical functionalities of mycelium hyphae presents a promising approach for advancing mycelium-based biomaterials. This research explores novel, sustainable alternatives to synthetic microporous filter membranes exhibiting comparable or higher remediation efficiencies.

Keywords: mycelium membrane, biomineralization, biosorption, MXene

#### 2:45 PM SB08.07.05

**Functional Polyurethane Foams with Sustainable Micro- and Nanoscale Reinforcing Agents** Zeynep Iyigundogdu; Adana Science and Technology University, Turkey

Incorporating additives and structural fillers into polyurethane foams can provide improved mechanical, thermal, electrical properties to create higher performance components made from such foams and can provide improved noise vibration harshness (NVH) and antimicrobial properties. This study explores the effect of adding micro and nanoscale fillers (nanocellulose, biocarbon, graphite, etc.) from sustainable sources as reinforcing agent on thermal stability and mechanical, physical, and sound absorption and antimicrobial properties of flexible polyurethane foam. The incorporation of sustainable micro-and nanoscale reinforcing agents increased the compression modulus and Young's Modulus significantly compared to the control. The addition of reinforcing agents at low concentration (less than 0.25wt.%) showed improvement in sound absorption of plane waves at low frequency range. Minimum inhibitory concentration values were determined by the lowest concentration of the graphite that inhibits the growth of microorganisms. Adding sustainable micro and nanoscale reinforcing agents from the natural sources or recycling products into polyurethane foam reduced waste to landfill and created a superior foam product. This presentation also exemplifies the benefits of creating a closed-loop plastic industry to improve polymer materials and protect the mother earth

**Sustainable Manufacturing of Acrylonitrile** Liesl Schindler; Trillium Renewable Chemicals, United States

Trillium Renewable Chemicals is scaling a two-step thermochemical process that converts a biobased feedstock (glycerol) into valuable chemicals (acrylonitrile and acetonitrile). Acrylonitrile (ACN) is used to manufacture a wide-range of materials (e.g., acrylonitrile-butadiene-styrene (ABS) plastic, carbon fiber, acrylic fiber, nitrile butadiene rubber (NBR), acrylamide, specialty amines) with a wide range of end uses including aerospace, automotive, apparel, toys, energy, personal care products, pharmaceuticals, consumer electronics, and wastewater treatment. The presentation will focus on the progress toward the ultimate goal: de-risking Trillium's bio-ACN™ technology for commercialization while achieving stretch targets for sustainability through a combination of low carbon raw materials and innovative process intensification concepts as well as meeting unit cost economics at parity or below the incumbent process to produce acrylonitrile.

#### 11:00 AM \*SB08.08.02

**Industry–Academic Partnerships: Valorizing Lignin Through De-Aromatization and COOH Functionalization** Mitra Ganewatta<sup>1</sup>, Qi Wang<sup>1</sup>, Thomas Sisson<sup>1</sup>, Mariola Beresniewicz-Kopcinski<sup>1</sup>, Daniella Martinez<sup>2</sup>, Jay Salinas<sup>2</sup>, Michael Kent<sup>2</sup>, JiHyuan Hwang<sup>3</sup> and Chuanbing Tang<sup>3</sup>; <sup>1</sup>Ingevity Corporation, United States; <sup>2</sup>Sandia National Laboratories, United States; <sup>3</sup>University of South Carolina, United States

Lignin is a valuable biomass feedstock that has the potential to produce advanced chemicals and materials. Lignin comprises 15-30% of lignocellulosic biomass and is mostly burned for its heating value within the paper pulping industry. Generating greater value out of this renewable and abundant material is critical for the establishment of a sustainable bioeconomy. We report an industry-academic partnership established to develop high-performance polymeric products from lignin. A near-room temperature aqueous oxidative process was developed to open the aromatic rings within the lignin structure and resulting in carboxylic acid-functionalized lignins. These lignin polyacid materials were evaluated as commercial agricultural dispersants, micronutrient complexation agents, or water-absorbent materials.

#### 11:30 AM SB08.08.04

**Lignin/PBS Filaments for 3D Fused Deposition Modeling of Medical Orthoses** Adnan Memic; King AbdulAziz University, Saudi Arabia

There is a technological need for materials with improved functionalities to propel new biomedical applications. Some of the outstanding challenges could be solved using three dimensional (3D) printing. However, there is a pressing need for new generation of biomaterials that have unique properties.

Combining nanomaterials with bio-based and synthetic polymers could yield biomaterials with improved properties. We developed filaments using bio-based waste polymer (lignin) and synthetic polymer (polybutylene succinate (PBS)). Next we coated these scaffolds that could provide antioxidant and antifouling properties while improving the rheological and physical properties of the composites filaments and easy of extrusion and 3D printing. Taken together these nanocoated filaments could propel several biomedical applications including aiding design of medical orthoses and bracing materials.

#### 11:45 AM SB08.08.05

**Mussel Byssus as a Green Fiber Manufacturing Platform** David U. Zamora Cisneros, Alejandro D. Rey, Noemie-Manuelle Dorval Courchesne and Matthew J. Harrington; McGill University, Canada

Biological materials and Nature's manufacturing processes offer inspiration to move towards more green manufacturing of structural and functional materials. Functionality in Nature's materials is strongly correlated with structure, such as chirality, orientation, and layering. In this Ph.D. thesis, I will focus on the mussel byssus, a thread fabricated by marine mussels from a pretransition liquid crystal organization within vesicles, which offers rich store principles and mechanisms to create green tough functional materials and composites used to remain attached to surfaces under continuous flowing states. The material organization of the mussel byssus precursor is a smectic liquid layered semisolid with oriented elements between layers.

This work is divided into three sequential stages: (i) thermodynamic-geometric modeling to ascertain the energy landscape and the stable, unstable, and

metastable states of this material under changing thermodynamic driving forces, (ii) colloidal organization including the shape, size, and structural organization to attain for the vesicle-vesicle interactions during the transitional state, and (iii) fiber formation under flow conditions. In this work, I will focus on the progress so far in the area of thermodynamic-geometric model and will shed light on how geometric tools are powerful and useful to detect, control, and optimize equilibrium states of smectic liquid crystals, their organization, and thus, its application for the tuning of material properties.

In particular, we use level set lines of steepest descent, bifurcation methods, lines of curvature and geodesic to provide a multidimensional view of the evolution of stable, unstable states that appear when decreasing the phase transition parameter, here taken as temperature. Overall, it is found that the emergence of smectic order favors the increase of the orientational alignment, yielding in the enhancement of the elasticity modulus of the solid state. Understanding the evolution and behavior of the hierarchical organization will provide a pathway for the development of green engineering principles, storage technologies, biocompatible materials such as tissue scaffolds, and advances in the processing of such materials involving scalable biomedical and technical applications like extrusion molding, and injection molding to address crucial public health and environmental concerns.

**Feasibility of Hot-Melt Extrusion of Simvastatin-Based Amorphous Solid Dispersions with PVP-VA and HPMC-AS** Charina Lampa<sup>1</sup>, Scott Smith<sup>2</sup>, Xiaoling Li<sup>1</sup> and Bhaskara Jasti<sup>1</sup>; <sup>1</sup>University of the Pacific, United States; <sup>2</sup>Gilead Sciences, United States

##### Purpose:

Poor aqueous solubility is among the primary causes of low or variable oral bioavailability in pharmaceutical development, with ~45% of new drugs considered very slightly soluble or practically insoluble. Preparation of amorphous solid dispersions (ASDs) is one approach to address the challenge. An ASD is composed of an amorphous drug stabilized in a polymeric excipient matrix. Amorphous forms have higher free energy and thus, higher aqueous solubility and/or faster dissolution compared to crystalline forms. However, its thermodynamic instability means it has a propensity to degrade or crystallize during processing and storage. Hot-melt extrusion (HME) is an emerging technology for ASDs due to its advantages as a scalable and efficient process. It is also attractive due to its sustainability as it does not require the use of solvents as other manufacturing practices like spray-drying. Key challenges with HME are poor physical stability of the amorphous drug and thermal degradation during processing. Simvastatin (SIM), which belongs to an important class of lipid-lowering drugs, was selected as a model drug. Poly(vinylpyrrolidone) vinyl acetate (PVP-VA), a neutral, aprotic polymer, and hydroxypropyl methylcellulose acetate succinate (HPMC-AS), an anionic, protic polymer were selected as the excipients. The objective of this study is to prepare and characterize HME ASDs with varying SIM/polymer ratios.

##### Methods:

**ASD Preparation.** ASDs of SIM/PVP-VA and SIM/HPMC-AS were prepared at varying ratios of 0/100, 25/75, 50/50, 75/25, 100/0 % w/w SIM/polymer using twin-screw hot melt extrusion. Physical blends of SIM and polymer were prepared by a 1-min trituration, followed by a 10-min blending step. Each blend was fed into the hot-melt extruder with a thin-slit die at 150°C. The extrudate was collected and milled to a powder using a tube mill at 15,000 RPM for 1 min.

**Physical form characterization.** The physical form of SIM in the ASDs was identified using powder X-ray diffraction (PXRD). Samples were scanned in reflection mode over a 2.0000 – 39.9990 °2θ range with a Cu Kα1 radiation source and a detector at 45 kV and 40 mA. Step size was 0.0131 °2θ and scan rate was 0.08 sec/step. Modulated differential scanning calorimetry (mDSC) was used to determine the glass transition temperature T<sub>g</sub>, with a nitrogen purge flow of 50 mL/min and a 3°C/min ramp rate and a modulation cycle of ±1°C every 60 sec.

**Water content.** Thermogravimetric analysis (TGA) was performed on the ASDs, with a nitrogen purge flow of 50 mL/min and a 10°C/min ramp rate from 25°C to 150°C. Weight loss was attributed to water content.

**Chemical purity.** Chemical purity was evaluated using ultra performance liquid chromatography (UPLC). A gradient method using water with 0.1% trifluoroacetic acid (TFA) and acetonitrile with 0.1% TFA was employed for separation, and the chromatogram at 236 nm was used for analysis.

##### Results

This study determined the suitability of preparing SIM/polymer ASDs with HME. All extrudates passed through the extruder with a residence time of 5-10 minutes. Subsequent milling of the ribbons yielded free-flowing powders that can be used for further processing. All ASDs demonstrated the amorphous nature of the drug, indicated by an amorphous halo using PXRD. A single glass transition temperature was observed, indicating a homogenous solid solution. The composite T<sub>g</sub> of the ASDs decreased as the SIM-loading was increased. Weight loss by TGA was relatively low across all ASDs, indicating moisture content ranging from 0.3% to 3.8%. Thermal degradation was minimal, with purity >97% across all ASDs relative to starting SIM purity, although purity seemed slightly higher with PVP-VA.

##### Conclusions

ASDs of simvastatin/PVP-VA and simvastatin/HPMC-AS were successfully prepared by hot melt extrusion. Simvastatin was demonstrated to be in an amorphous form with both polymeric excipients, and exhibited good chemical stability during the hot melt extrusion process.

#### 11:55 AM SB08.08.07

**Naturally Derived Photoluminescent Composite Inks for Advanced Applications** Daniela Correia<sup>1</sup>, Bárbara Cruz<sup>1,1,1</sup>, Rita Polícia<sup>1</sup>, Nelson Pereira<sup>1</sup>, Paulo Nunes<sup>2</sup>, Mariana Fernandes<sup>2</sup>, Carmen R. Tubio<sup>3</sup>, Gabriela Botelho<sup>1</sup>, Verónica de Zea-Bermudez<sup>2,4</sup> and Senentxu Lanceros-Mendez<sup>3,5</sup>; <sup>1</sup>University of Minho, Portugal; <sup>2</sup>University of Trás-os-Montes e Alto Douro, Portugal; <sup>3</sup>Basque Center on Materials, Applications and Nanostructures, Spain; <sup>4</sup>University of Trás-os-Montes e Alto Douro, Portugal; <sup>5</sup>Ikerbasque, Basque Foundation for Science, Spain

Naturally derived polymers have been increasingly explored by different fields of knowledge to be applied in different areas. The high interest devoted to natural polymers mainly relies on their natural abundance, unique properties, and sustainability attributes.

The interesting advantages of this type of polymer allow the development of smart and multifunctional materials with a strong potential for sensors and actuators, biomedicine, and environmental remediation applications [1], among others.

Particularly, photoluminescent materials are of high interest for sensors in anti-counterfeiting systems and actuators [2]. This type of material can be obtained by incorporating different luminescent compounds, such as rare-earth elements, quantum dots, fluorescent compounds, and inorganic phosphors. Lanthanide ions (Ln<sup>3+</sup>), have gained a special interest in recent times due to their fine emission bands, wide diversity of colours, large pseudo-Stokes shifts, long luminescence lifetimes, and difficult replication of the fingerprint emission profiles [3].

The present work presents the development of photoluminescent materials based on the natural polymer sodium alginate (SA), a linear polysaccharide derivative of alginic acid comprised of 1,4-β-d-mannuronic (M) and α-l-guluronic (G) acids [1], incorporating different contents of the compounds sodium tetra(2-thenoyltrifluoroacetate) europate (III) (Na[Eu(tta)<sub>4</sub>]) (5, 10 and 20% wt.) and 1-butyl-3-methylimidazolium tetra(2-thenoyltrifluoroacetate) europate (III) [Bmim][Eu(tta)<sub>4</sub>] (20% wt.) have been developed by a solvent casting method [4].

The influence of both compounds in the morphology of all the developed materials were evaluated by SEM and their physical-chemical properties by FTIR-ATR and DSC analysis. Independently of the luminescent compound, a non-porous material was obtained, however, a surface roughness increase was observed. Both Na[Eu(tta)<sub>4</sub>] and [Bmim][Eu(tta)<sub>4</sub>] induce a thermal stability behavior on SA and an improvement of the mechanical properties.

The highest luminescence was observed for SA/[Bmim][Eu(tta)<sub>4</sub>] films, exhibiting an intense red/orange emission when irradiated with ultraviolet (UV) light at 388 nm, and in this context a strong potential to be applied in anticounterfeiting applications. The developed materials are also suitable to be applied as electromechanical actuators.

**Silk Proteins as Functional Biomaterials for Regenerative Medicine** David L. Kaplan; Tufts University, United States

Biomaterials that provide versatility in terms of control of structure, chemistry, morphology, mechanics, degradation lifetime, and material form factor, while biocompatible, are useful in meeting regenerative medicine goals. Silk, as one of the oldest biomaterials utilized as sutures for centuries, is undergoing a rebirth into new biomaterial formats and applications for regenerative engineering for the medical field. Key to this emergence has been fundamental insight into mechanisms of self-assembly and control or tunability of material features achievable with silk. As a unique, high molecular weight, amphiphilic protein, new modes to modify the native protein using processing methods, chemistries and bioengineering approaches are emerging from the laboratory. Some of these recent strategies will be discussed related to fundamental aspects of controlling biomaterial structure and function, leading to new silk-based biomaterials for regenerative medicine.

**9:00 AM SB09.01.02**

**Unconventional Biomaterials for Regenerative Engineering** Gulden Camci-Unal; University of Massachusetts Lowell, United States

Across different areas of regenerative engineering, there are limitations with controlling cell adhesion, viability, growth, differentiation, biocompatibility. Conversion of simple and abundant items to advanced cell culture substrates addresses some of the limitations in regenerative engineering. Departure from complex fabrication processes to the applications of unusual materials provides another dimension to the engineering of viable multifunctional tissue constructs and regenerative can increase access to regenerative engineering technologies on a global scale. In this work, we used unconventional biomaterials such as eggshells and paper for tissue regeneration.

We fabricated eggshell micro/nanoparticle (ESP) reinforced protein-based scaffolds to produce mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells into osteoblasts. The ESP-reinforced constructs were then implanted in a rat model to determine their biocompatibility and degradation behaviors. In addition, these composite scaffolds were used to regenerate critical sized cranial defects in a rat model. We also used mineralized paper scaffolds with hydrogels through an origami-inspired approach to test their osteoinductivity and potential for tissue repair in *in vitro* and *in vivo* studies.<sup>1-6</sup>

The ESP-reinforced scaffolds enabled the differentiation of stem cells into osteogenic lineage. The constructs showed significant enhancement in mineralization by the cells. The ESP composites demonstrated superior mechanical properties and showed favorable *in vivo* responses by subcutaneous implantation in a rat model. The scaffolds were responsive to cells and did not elicit inflammatory responses *in vivo*. The implants were easily accepted by

the host, allowed for cellular infiltration and migration in 3D, and highly vascularized. Implantation of ESP-reinforced scaffolds into critical sized cranial defects in a rat model resulted in significant bone regeneration in 12 weeks. The resulting bone volume and bone density were as high as the native bone using these composite scaffolds as determined by micro-computed tomography assessment.

We also fabricated origami-inspired paper-based scaffolds for biomineralization. Material properties of the paper-based mineralized scaffolds were highly tunable. The tensile modulus of the scaffolds increased significantly after the mineralization process. Gene expression results for the osteogenic differentiation markers revealed the osteoinductivity of the mineralized paper scaffolds. Subcutaneous implantation of the samples in rats demonstrated biocompatibility, vascularization, and integration *in vivo*.

Unconventional scaffolds that are readily available and adapted from nature demonstrated biomimetic characteristics including porosity, structure, and bioactivity resulting in physiologically relevant constructs. The use of existing naturally derived materials in combination with hydrogels for regenerative engineering provides an inexpensive and sustainable approach that benefits the economy and environment while providing unique solutions to unmet clinical needs. Many of the unconventional biomaterials are overlooked and under-studied for biomedical applications, partly for their simplicity as mundane items.

### 9:15 AM SB09.01.03

**Development of Tissue-Safe, Shape Memory Polymer Scaffolds** Courteney Roberts, Sarah K. Beck, Caitlyn M. Prejean and Melissa Grunlan; Texas A&M University, United States

Thermoresponsive shape memory polymers (SMPs) were developed as self-fitting scaffolds to heal cranial bone defects. Exposure to temperatures above the melt transition temperature ( $T_m$ ) causes scaffolds to undergo shape recovery, driving its expansion to the tissue perimeter for improved osseointegration and healing. SMP scaffolds were originally prepared from semi-crystalline, biodegradable *linear*-poly( $\epsilon$ -caprolactone)-diacrylate (PCL-DA; 10k g mol<sup>-1</sup>). However, a major limitation of scaffolds based on *linear*-PCL-DA is a  $T_m$  of ~55 °C. Such a scaffold could be submerged into saline at this temperature and pressed into a bone defect for self-fitting. However, to extend the working time, post-implantation irrigation with ~55 °C saline would induce thermal damage to the surrounding tissues. Ideally, a SMP self-fitting bone scaffold would have a reduced  $T_m$ , but still be > 37 °C in order to ultimately return to its rigid state for mechanical support. Other devices prepared from SMP scaffolds could also be envisioned if the  $T_m$  was reduced to 37 °C, affording shape recovery (expansion) upon implantation. For instance, this would enable the development of self-expanding gynecological stents. Thus, in this work, a  $T_m$  of ~39 - 45 °C (bone scaffolds) and ~37 °C (stents) was targeted for tissue safety and functionality. We sought to lower the  $T_m$  of PCL by altering the architecture, creating *star*-PCL-tetracylate (*star*-PCL-TA), and by also decreasing molecular weight ( $M_n$ ). This yielded scaffolds with  $T_m$  of ~45 °C (10k g mol<sup>-1</sup>), ~40 °C (7.5k g mol<sup>-1</sup>), and ~29 °C (5k g mol<sup>-1</sup>). Owing to reduced crystallinity, scaffolds based on *star*-PCL-TA degraded faster than *linear*-PCL-DA of the same  $M_n$ , and also exhibited decreased compressive moduli. Scaffold degradation rates increased as the  $M_n$  of *star*-PCL-TA was decreased. Overall, by altering the architecture of the PCL macromer from a *linear* to a *star* architecture and reducing the  $M_n$ , more tissue-safe SMP scaffolds were created. Specifically, scaffolds with  $T_m$  values ideal for self-fitting bone scaffolds and self-expanding stents were obtained.

### 9:30 AM SB09.01.04

**Oncological Engineering: The Development of 3D Printed Metamaterial Implants for Patients with Bone Tumours in End-Of-Life-Care** Ali Mohammed, Borut Lampret and Connor Myant; Imperial College London, United Kingdom

Cancer in bone presents a formidable challenge, particularly for terminally ill patients. Addressing this issue, our research focuses on the development of a pipeline for ultra-high-resolution 3D printed metamaterial-based bone replacements. Unlike traditional implants or conventional 3D printed bone scaffolds, our approach aims to improve patients' quality of life during end-of-life care by offering biocompatible, bioinert implants with sophisticated functionality that closely match the mechanical behaviour of native bone. The challenge arises in meeting the custom requirements of patient specific implants such as size, shape and native mechanical properties, along with the fabrication technology required to 3D print them.

The presentation introduces the fabrication process and material for a Metamaterial implant, where the mechanical properties are not derived from the properties of the base material but from its smartly designed architecture. The chosen technology is vat-polymerisation 3D printing which offers the opportunity to produce complex, multiscale, geometries from a suitable biocompatible material at the required specifications. The final implant will be a computationally derived hierarchical lattice with an intricate multiscale structure. It will need to span several orders of length scale (cm > mm >  $\mu$ m) to create the desired properties. However, commercially available 3D printers face limitations with delivering the required high-resolution and small build size print specifications for such designs. These limitations stem from resolution constraints, curing inconsistencies, and challenges in balancing speed and precision. Therefore, a challenge remains in the development of a printer capable of producing biocompatible photopolymer objects with the desired feature resolution at the required build size.

To overcome the limitations faced by commercial 3D printers at the macro scale, we developed an in-house projection micro-stereolithography ( $\mu$ -SL) 3D printer capable of achieving ultra-high resolutions. This achievement is essential for fabricating implants with intricate designs that exhibit metamaterial properties at resolutions of 1-5  $\mu$ m. Further, we successfully developed a photoresin suitable for 3D printing our desired implants. An integral challenge lies in formulating a biocompatible photoresin that can achieve the desired feature resolution when printing at small build volumes. This was achieved by optimising photoresin chemistry, rheological properties, and light penetration depth. Ultimately, a base formulation suited for ultra-high-resolution 3D printing was produced and iteratively tailored to meet the application requirements. Our study identifies a range of photoreactive monomers and cross-linkers that demonstrate biocompatibility and compatibility with sterilization protocols.

In conclusion, our work focuses on developing an in-house  $\mu$ -SL 3D printer and compatible ultra-high-resolution photoresin to address the micro-to-macro scale challenge in 3D printing. Achieving close to 1 $\mu$ m print resolutions, our printer enables the fabrication of novel implant bone replacements. Leveraging metamaterial design and computational frameworks, we aim to produce biocompatible implants emulating native bone properties, advancing additive manufacturing for patient-specific solutions and improving quality of life for individuals with bone cancer.

### 10:15 AM \*SB09.01.06

**Polymer Strategies in Musculoskeletal Tissue Engineering** Elizabeth Cosgriff-Hernandez; The University of Texas at Austin, United States

Over one million surgical procedures are performed each year to treat bone defects with an associated medical cost over 5 billion dollars. Current procedures are fraught with problems that limit clinical success from fixation challenges in osteoporotic bone to replicating form factor in

craniomaxillofacial reconstruction to infection control in traumatic injuries. Each indication requires a tailored strategy to restore function and guide regeneration. Our laboratory specializes in the development of polymeric biomaterials that meet the design criteria of each regeneration strategy. One particular area of interest is the treatment of fractures using an injectable, bone void filler. Current bone cements do not adequately support bone healing and lead to poor clinical outcomes. Our laboratory has developed a novel emulsion templating methodology to generate injectable, high porosity bone void fillers that cure to rigid foams at body temperature with compressive properties in the range of trabecular bone. We have enhanced the regenerative capacity of these synthetic grafts by mixing the emulsion with autograft particles. Recently, we have utilized this biomaterial platform to develop emulsion inks for 3D printing. Emulsions inks are rapidly cured after deposition by constant UV irradiation to form rigid constructs with interconnected porosity in a method we term Cure-on-Dispense printing. 3D printed constructs benefit from the tunable pore structure of emulsion-templated materials and the fine control over complex geometries of 3D printing that is not possible with traditional manufacturing techniques. A cell-releasing hydrogel was then developed to provide osteogenic potential and enhance the regeneration of these 3D printed scaffolds. Finally, we have utilized advanced electrospinning techniques to create bone wraps that eradicate infection and enhance vascularization. Collectively, this work highlights the versatility of polymer engineering to design tissue engineering scaffolds to meet clinical needs.

##### **Injectable Colloidal Hydrogels of N-Vinylformamide Microgels Dispersed in Covalently Interlinked pH-Responsive Methacrylic Acid-Based Microgels** Brian Saunders; University of Manchester, United Kingdom

Injectable hydrogels offer great potential to augment damaged or degenerated soft tissue. A key criterion for such gels is that their modulus is as close as possible to that of the target tissue. The majority of synthetic hydrogels have used low molecular weight polymer chains which may cause problems if they diffuse away from the injection site and/or increase the local osmotic pressure. We previously introduced a different approach of injecting preformed ultra-high molecular weight pH-responsive microgels (MGs) that interlink to form hydrogels. MGs are crosslinked polymer colloid particles that swell when the pH approaches the particle  $pK_a$ . These colloidal hydrogels are termed doubly crosslinked microgels (DX MGs). The gel moduli of previous DX MGs were much greater than that reported for human nucleus pulposus (NP) tissue of the spinal intervertebral disk. Here, we replace some of the pH-responsive poly(ethylacrylate-co-methacrylic acid) (PEA-MAA) MGs with hydrophilic non-ionic MGs based on poly(*N*-vinylformamide) (NVF). We investigate the morphology and mechanical properties of these new injectable DX MG composite gels and show that the mechanical properties can be tuned by systematically varying the NVF MG content. Using this approach, gel moduli close to that for NP tissue are achieved. These injectable new pH-responsive gels exhibit low cytotoxicity. Our work provides a potential new system for minimally-invasive intervertebral disk augmentation[1].

#### 11:00 AM \*SB09.01.08

##### **Regenerative Engineering Through Biomaterial Design** Brendan A. Harley; University of Illinois-Urbana-Champ, United States

Advances in the field regenerative medicine require biomaterials that instruct, rather than simply permit, a desired cellular response. A major contemporary motivator in biomaterial design is the complex organization of the tissues in our bodies, which are hierarchical, vary in space and time, and can differ person-to-person. However, the future success of regenerative medicine requires more deeply considering aspects of human variation and heterogeneity. For example, considering the role of sex-specific differences in tissue engineering technologies motivates innovative lines of investigation that will become central dogma in the future.

Defects in craniofacial bones of the skull occur congenitally, after high-energy impacts, and during the course of treatment for stroke and cancer. They affect a broad segment of the US population, are large and irregularly shaped, and heal poorly. Contemporary tissue engineering efforts that combine exogenous mesenchymal stem cells (MSCs), morphogens, and biomaterials face challenges due to the cost and time for *in vitro* MSC expansion and MSC-biomaterial culture as well as the need for supraphysiological morphogen doses. We are developing porous biomaterials that can be shaped precisely and quickly like an alloplastic implant but that work in a regenerative fashion like autologous bone. Specifically, I will describe a class of mineralized collagen scaffold that promotes MSC recruitment and osteogenicity in the absence of osteogenic supplements. We have refined these materials to study MSC-macrophage crosstalk and to promote MSC-osteoprogenitors to secrete osteoprotegerin, a soluble glycoprotein and endogenous inhibitor of osteoclast activity. We showed polymeric meshes can be integrated into the scaffold, à la rebar in concrete, to create composites that can be shaped intraoperatively to aid surgical-practicality and accelerate regeneration. I will also describe scaffold processing approaches to create spatially-graded collagen biomaterials that direct MSC differentiation down multiple musculoskeletal lineages in a spatially-selective manner, along with methods to develop continuous hydrogel zones that link dissimilar musculoskeletal tissue zones (e.g., tendon and bone) to provide mechanical and trophic advantages to accelerate regenerative healing. I will conclude by describing recent efforts to address barriers preventing regeneration, notably the role of sex-differences in regenerative activity. These initiatives demonstrate that understanding sex-specific differences in cell activity is essential in the design of biomaterial system to improve regenerative potential as well as to study disease progression and therapy.

#### 11:30 AM SB09.01.09

##### **Injectable and Biodegradable Piezoelectric Hydrogel for Medical Applications** Thanh D. Nguyen and Tra Vinikoor; University of Connecticut, United States

Osteoarthritis (OA), a painful joint disease manifested by cartilage damage, affects 654 million people worldwide every year. Currently, there is no cure for OA; available medicines only alleviate the disease symptoms (e.g. pain and inflammation) while surgical approaches including the use of replacement auto- or allo- graft cartilages suffer from the problems of donor-site morbidity, infection, immune-rejection, and especially, limited tissue supply. Herein, we present a novel injectable and biodegradable piezoelectric hydrogel with ultrasound (US) activation to offer a minimally invasive regenerative engineering approach for OA treatment. The piezoelectric hydrogel can be injected into the joints and self-produce localized electrical cues under US activation to drive cartilage healing. *In vitro* data shows the hydrogel with US activation attracts host cells, enhances cell migration, and induces stem cells to secrete endogenous growth factors like TGF- $\beta$ 1 which facilitates *COL2A1*, *ACAN*, and *SOX9* expression to promote chondrogenesis and extracellular matrix (ECM) deposition. Significantly, the piezoelectric hydrogel enables the healing of hyaline cartilage in rabbits with critical size osteochondral defects. After two months of the piezoelectric hydrogel and US treatment, the animals had more subchondral bone formation, well-organized hyaline cartilage structure, and improved mechanical properties, close to those of healthy native cartilages and superior to the other control/sham groups either without US activation or piezoelectricity. This injectable piezoelectric hydrogel is not only applicable for cartilage healing but potentially other tissue regeneration and could serve as a minimally-invasive material platform for important medical devices such as injectable piezoelectric pressure sensors, actuators, energy-harvesters, and transducers, thus offering a significant impact on medicine.

SESSION SB09.02: Polymeric Biomaterials for Regenerative Engineering II

**Cells and Biomaterials as Building Blocks for Tissue Engineering and Regenerative Medicine** [Kent Leach](#), Jeremy Lowen and David Ramos-Rodriguez; University of California-Davis, United States

Biomaterials are an integral component of tissue engineering and regenerative medicine. The selection and biophysical properties of the materials are instrumental in guiding the behavior of transplanted or invading host cells. I will highlight our recent work in two areas to create building blocks for tissue engineering: 1) manufacturing cellular spheroids with instructive cues to guide cell fate; and 2) production of instructive microgel scaffolds to dictate macrophage phenotype, instruct cell differentiation, and promote tissue formation.

Our group has developed key advances in generating and guiding cell spheroids as building blocks for tissue formation. The bioactivity and function of spheroids is dictated by the selected cell population(s) (both homotypic and heterotypic), culture conditions such as local oxygen tension or inflammatory stimuli, and the association of spheroids with instructive biomaterials. Our group engineered a decellularized extracellular matrix (ECM) secreted by bone marrow-derived mesenchymal stromal cells (MSCs). After characterizing its composition, we demonstrated that MSC spheroids loaded with cell-secreted ECM exhibited markedly increased osteogenic potential and survival in harsh conditions. We have iterated on this ECM to retain endogenous growth factors more effectively. We examined the composition and bioactivity of ECM produced by MSCs differentiated from induced pluripotent stem cells as an alternative cell population that addresses shortcomings of MSCs. Finally, we identified key biophysical properties of hydrogels that regulate cell migration, proangiogenic potential, and tissue formation by MSC spheroids.

Tunable scaffolds that direct cell fate are desirable in many tissue engineering applications such as wound healing, organoid systems, and drug delivery. As our understanding of tissue complexity increases, so does the demand for heterogeneous biomaterials. Microgels are an emerging tool that fulfill this role given their modularity, injectability, and range of fabrication techniques. Unlike bulk hydrogels, microparticle-based scaffolds possess tunable void space which inherently exists between the particles. Such void space permits cells to migrate and proliferate readily without first remodeling their surrounding environment. While the effects of pore size on cell penetration and proliferation have been studied in bulk hydrogels, it has yet to be thoroughly investigated in a microgel platform.

We employed the ability to readily alter porosity in photoannealable microgel scaffolds to influence macrophage polarization, alter cell spreading and aggregation, and influence cell function. We generated microgels with compressive moduli ranging from ~ 10-80 kPa, which demonstrates their ability to match a range of tissue stiffnesses. The compressive modulus and bioactivity of the microgels remained constant after cryopreservation at -20°C, which facilitates high-throughput production, storage, off-the-shelf availability, and expands their potential for clinical translation. Void volume was a key stimulus to instruct macrophage polarization toward a pre-regenerative M2 phenotype.

In another example, we created bilayer constructs of microgels with distinct compressive moduli and pro-osteogenic and chondrogenic peptides. Using light to anneal the gels, we produced constructs that did not delaminate, as is common for many bilayer materials. When cultured in mixed media, we observed upregulation of osteogenic and chondrogenic markers that were primarily restricted to the designated layer. The ease of loading cells, cryopreservability, and short annealing time make this a promising platform for translation to the clinic.

**2:00 PM SB09.02.02**

**A Resurfacing-Regenerative Approach to Repair Osteochondral Defects using a Bioprosthetic Device** [Melissa Grunlan](#), Connor J. Demott, Lauren K. Davis, William B. Saunders and Olivia F. Dings; Texas A&M University, United States

Osteochondral defects (OCDs), areas of localized joint damage to articular cartilage and underlying subchondral bone, often lead to pain, loss of joint function, and osteoarthritis. Clinical repair is focused on biological grafting procedures, which are innately limited by graft availability and donor site morbidity. We have developed a bioprosthetic implant, combining articular cartilage resurfacing and osseous tissue regeneration, as a new method for OCD repair. These implants – “cartilage-capped, regenerative osteochondral plugs (CC-ROPs)” - combine a multi-network hydrogel (cartilage cap) and osseous scaffold (base). The cartilage cap is prepared from a multi-network, electrostatic hydrogel that gives rise to articular cartilage-like mechanical, hydration, and tribological properties. The osseous scaffold base is prepared from a semi-interpenetrating polymer network (semi-IPN) of poly( $\epsilon$ -caprolactone)-diacrylate (PCL-DA) and poly(L-lactic acid) (PLLA). The scaffold is intrinsically osteoinductive and has a trabecular bone-like modulus as well as robust degradation rates to facilitate bone ingrowth. Formed as cylindrical plugs, CC-ROPs are able to be implanted using existing grafting techniques and be fabricated at a wide range of sizes. CC-ROPs were successfully implanted into rabbit OCDs using an osteochondral graft delivery device with a custom tip to help alignment on the small rabbit condyles. At 10 days, MRI images illustrating the cartilage cap remained intact with the osseous scaffold (i.e., no delamination). It was also confirmed that CC-ROPs did not become displaced post implantation. Formation of new tissue around the periphery of the osseous scaffold was illustrated in microCT and histological analyses. At 12 weeks post-implantation, there were likewise no signs of delamination or fracture of the CC-ROP. Furthermore, no migration of the implant was seen (e.g., cartilage cap surface congruent with surrounding cartilage). Extensive bone tissue formation was seen around the edges and throughout the pores of the osseous scaffold. Performance in rabbit OCDs illustrated the ability of CC-ROPs to immediately provide an articulating surface as well as promote regeneration of osseous tissue, exemplifying the potential to improve the treatment of OCDs.

**2:15 PM SB09.02.03**

**A Dynamic Hydrogel Platform to Model Cardiac Tissue Development and Disease** Andrew House and [Murat Guvendiren](#); New Jersey Institute of Technology, United States

Heart disease is currently the leading cause of death in the United States, and is most often caused by myocardial infarction (MI). There is a desire to create novel therapies and treatments. However, due to a lack of fundamental understanding of the heart's inflammatory response to infarction, the development of new therapies is both time consuming and costly. In this work, we report a novel biomaterial platform to mimic dynamic changes in the heart tissue during MI. We believe that our platform enables dynamic control of cardiac cell alignment and matrix stiffness (from healthy to fibrotic tissue) to investigate cardiac tissue development and disease.

In this study, we report a novel dynamic hydrogel platform enabling spatiotemporal control of cellular alignment and matrix stiffness (from healthy to fibrotic tissue stiffness). Our approach involves: (i) fabrication of polydimethylsiloxane (PDMS) based elastomeric film displaying lamellar wrinkling

patterns with user defined and spatiotemporally controlled pattern amplitude and wavelength, and (ii) chemically grafting a hydrogel film allowing light-induced stiffening from healthy to fibrotic stiffness, matching values reported in the literature. In our approach, methacrylated alginate (MeAlg) hydrogel films are first fabricated using Michael-type addition crosslinking using dithiothreitol (DTT) to form hydrogels with healthy stiffness (~15 kPa), during which it is also chemically tethered to the PDMS substrate. When needed, hydrogels can be stiffened in situ when exposed to UV or blue light in the presence of a photo initiator to reach to fibrotic stiffness (~55 kPa). Using this platform, we first investigate the effect of pattern size (amplitude and wavelength) on cardiac cell alignment. We then report the effect of matrix stiffness on cardiac cell function. Human cardiac fibroblasts (hCFs, Normal Human Ventricular Cardiac Fibroblasts, NHCF-V, CC-2904, Lonza, United States), human cardiomyocytes (hCMs, AC16 Human Cardiomyocyte Cell, and human induced pluripotent stem cell-derived cardiomyocytes (iPSC-CMs) (iCell Cardiomyocytes 01434, FUJIFILM Cellular Dynamics, Inc.) were used in this study.

In the first part, we show that the degree of cellular alignment for hCMs and hCFs is controlled by the pattern dimensions, such that higher degree of alignment is obtained for higher pattern amplitudes or smaller wavelengths. Spatial control of lamellar patterns allows us to create distinct regions with tunable patterns or continuous patterns with gradient dimensions. In the second part, we show that hydrogels are capable of being stiffened dynamically during the culture (confirmed by AFM and rheology), and gel integrity can be maintained for up to 21 days of culture. In addition, iPSC-CMs cultured for up to 21 days show distinct changes in their sarcomere expression and beating frequency in response to changes in stiffness and alignment. We plan to conclude with our approach to use this platform to mimic the dynamic changes in the ECM post-MI to develop a drug screening platform.

### 2:30 PM \*SB09.02.04

**Engineered Biomaterials for *In Situ* Tissue Regeneration** [Akhilesh K. Gaharwar](#); Texas A&M University, United States

Engineered biomaterials have emerged as powerful tools for a range of biomedical applications, including tissue engineering, drug delivery, and additive manufacturing (3D bioprinting). These biomaterials possess tunable biophysical properties, specific biochemical cues, and complex architecture, enabling precise control over cellular behavior. In this talk, I will outline three biomaterials-based approaches developed in our lab for biomedical applications. Firstly, I will highlight how engineered biomaterials can harness the body's regenerative potential to control and direct cell functions for in situ tissue regeneration. Our work has resulted in a new class of biomaterials for bone regeneration, osteoarthritis treatment, angiogenesis, hemostasis, and wound healing. The second approach focuses on designing nanoengineered biomaterials for sustained and controlled release of therapeutics. We have developed a range of nano-tool kits for the delivery of small molecules drugs and large proteins, which have high loading efficacy and tunable delivery properties. These approaches can be used for targeted delivery of cancer therapeutics. Lastly, I will demonstrate the design of a new class of bioinks for 3D printing anatomical-size tissue constructs. These tissue structures can be used to develop physiologically relevant tissue models, mimicking disease conditions such as vascular pathophysiology and vascularized glioblastoma models.

**Peptides with Polyproline II Helix Secondary Structure and Their Potential Role in Biomaterials Engineering** [Julie Renner](#); Case Western Reserve University, United States

Bound peptide monolayers are a promising way to control surface properties because peptides are biocompatible, easily tunable, and can be designed to have, or not have, interactions with cells. Our lab is especially interested in establishing new engineering models and assembly techniques to control and understand the behavior of surface-bound peptides for use as biomaterials. Peptides with a polyproline II helix secondary structure (PPII helix peptides) have recently emerged as promising tools for biomaterials due to their unique antifouling properties and ability to form dense monolayers. Using a variety of characterization techniques, we uncover new details about the assembly mechanisms of PPII helix peptides and explore their antifouling capacity. In addition, we explore the interactions of these peptides with human mesenchymal stem cells and 3T3 cells with and without bioactive peptides attached. Collectively, these results reveal greater understanding of the mechanisms behind PPII helix peptide assembly and antifouling and provide insight into their potential use as biomaterials for regenerative engineering.

### 4:00 PM SB09.02.07

**Stiffness Assisted Cell-Matrix Remodeling to Induce Stem Cell Differentiation** [Akhilesh K. Gaharwar](#); Texas A&M University, United States

Engineered matrices provide a valuable platform to understand the impact of biophysical factors on cellular behavior such as migration, proliferation, differentiation, and tissue remodeling, through mechanotransduction. While recent studies have identified some mechanisms of 3D mechanotransduction, there is still a critical knowledge gap in comprehending the interplay between 3D confinement, ECM properties, and cell behavior. Specifically, the role of matrix stiffness in directing cellular fate in 3D microenvironment, independent of viscoelasticity, microstructure, and ligand density remains poorly understood. To address this gap, we designed a nanoparticle crosslinker to reinforce collagen-based hydrogels without altering their chemical composition, microstructure, viscoelasticity, and density of cell-adhesion ligand and utilized it to understand cellular response. This crosslinking mechanism utilizes nanoparticles as crosslink epicenter, resulting in 10-fold increase in mechanical stiffness, without other changes. Human mesenchymal stem cells (hMSCs) encapsulated in 3D responded to mechanical stiffness by displaying circular morphology on soft hydrogels (5kPa) and elongated morphology on stiff hydrogels (30kPa). Stiff hydrogels facilitated the production and remodeling of nascent extracellular matrix (ECM) and activated mechanotransduction cascade. These changes were driven through intracellular PI3AKT signaling, regulation of epigenetic modifiers and activation of YAP/TAZ signaling. Overall, our study introduces a unique biomaterials platform to understand cell-ECM mechanotransduction in 3D.

### 4:15 PM SB09.02.08

**Development of an iPSC Loaded Biomimetic Biomaterial Scaffold for Spinal Cord Repair Applications** [Cian O'Connor](#)<sup>1,2,1</sup>, [Ian Woods](#)<sup>1,2,1</sup>, [Sarah F. McComish](#)<sup>2</sup>, [Maeva A. Caldwell](#)<sup>2</sup>, [Adrian G. Dervan](#)<sup>1,2,1</sup> and [Fergal J. O'Brien](#)<sup>1,2,1</sup>; <sup>1</sup>Royal College of Surgeons in Ireland, Ireland; <sup>2</sup>Trinity College Dublin, The University of Dublin, Ireland

**Introduction:** Following spinal cord injury, a lesion cavity develops preventing axonal regrowth. Biomaterial implants that bridge the cavity and encourage axonal growth while delivering trophic cells to restore lost tissue may have potential for repair. Therefore, by identifying neurotrophic extracellular-matrix proteins to incorporate into biomimetic hyaluronic acid biomaterial scaffolds and by tuning the biomaterial stiffness, we aimed to develop a novel platform for spinal cord repair. Furthermore, we wished to determine if the developed biomimetic biomaterial scaffolds were capable of delivering and modulating the trophic capacity of induced pluripotent stem cell (iPSC)-derived progenitors for spinal cord repair applications.

**Methods:** Spinal cord astrocytes and neurons were cultured on a range of extracellular matrix-proteins to identify the optimal neurotrophic substrate combination. Following the incorporation of the neurotrophic substrate into freeze-dried 3D hyaluronic acid scaffolds of varying stiffnesses, scaffold properties were characterized. Next, spinal cord astrocytes, neurons, dorsal root ganglia (DRG) and iPSC-derived astrocyte progenitors were cultured in the

scaffolds for up to 21 days and the effect of scaffold physicochemical properties was assessed. Thereafter, the impact of scaffold properties on the trophic capacity of iPSC-derived progenitors was assessed *in vitro* and *ex vivo* using neurons, DRG and spinal cord explants.

**Results:** A combination of collagen-IV (CIV) and fibronectin (FN) synergistically enhanced neurite outgrowth by 203% while also promoting astrocyte process extension. Subsequently, hyaluronic acid biomaterial scaffolds functionalized with CIV/FN were successfully manufactured with different stiffnesses ranging from soft/biomimetic to stiff/supraphysiological (0.8-3.5 kPa). Spinal cord astrocytes cultured in soft-CIV/FN functionalized biomaterial scaffolds matching cord stiffness, displayed positive stellate morphologies and increased pro-regenerative IL-10 release. Furthermore, soft scaffolds significantly enhanced neurite outgrowth from neurons and adult mouse DRG explant cultures compared to stiffer scaffolds. Soft-CIV/FN scaffolds also enhanced iPSC-progenitor neurotrophic and functional capacity while encouraging the growth of iPSC-derived spheroids that subsequently formed extensive neuronal/astrocytic cellular tracts, colonizing the biomaterial scaffold. Conditioned media from soft-CIV/FN but not other, iPSC-loaded scaffolds, and applied to growing neurons enhanced neurite outgrowth by over 280%. Super-resolution microscopy also confirmed similar neurite enhancement (170%) in mouse primary spinal cord neurons treated with media from soft-CIV/FN scaffolds only without eliciting negative inflammatory and/or reactive responses from healthy and injured astrocytes. Furthermore, analysis of media from stiffer or non-CIV/FN-containing scaffolds showed increased pro-inflammatory IL-1 $\beta$  release compared to soft CIV/FN scaffolds. Finally, when *ex vivo* DRGs or spinal cord explants were cultured directly on CIV/FN iPSC-loaded biomaterial scaffolds up to 21 days, only soft biomaterials enhanced cellular infiltration, astrocytic process extension and directed axonal outgrowth between DRG and iPSC-spheroids.

**Conclusion:** Overall, this research describes the development and utilization of a novel, biomimetic biomaterial scaffold-based platform for spinal cord repair and demonstrates that biomimetically inspired biomaterials can enhance the growth of cord resident neurons and astrocytes and promote the neurotrophic potential of implanted progenitor cells to act as a novel, therapeutic platform for spinal cord injury repair applications.

**Acknowledgements:** This work is funded by the Anatomical Society, Irish Rugby Football Union Charitable Trust, and the Science Foundation Ireland Advanced Materials for Bioengineering Research (AMBER) centre.

#### 4:30 PM SB09.02.09

**Protein-Derived Jammed Microgels as Inks for Extrusion 3D Printing of Bioactive Scaffolds** Lucas Ribeiro<sup>1,2</sup>, Rita Sobreiro-Almeida<sup>2</sup>, Vítor Gaspar<sup>2</sup>, Emerson Camargo<sup>1</sup> and João Mano<sup>2</sup>; <sup>1</sup>Federal University of São Carlos, Brazil; <sup>2</sup>University of Aveiro, Portugal

Extrusion 3D printing has emerged as a promising technique in tissue engineering, enabling the creation of personalized scaffolds for individual patients. Typically, natural hydrogels are utilized as inks due to their resemblance to the extracellular matrix (ECM), as well as their biodegradability and biocompatibility, making them ideal for tissue engineering applications. One such biomaterial is human platelet lysates (PL) derived from whole blood, which contains a rich assortment of growth factors, cytokines, and proteins that can stimulate cell proliferation and differentiation, and tissue regeneration. However, the use of PL as ink for printing scaffolds is limited by its liquid nature even at high concentrations, preventing the formation of a solid and stable filament upon deposition.

To address this challenge, granular hydrogels of methacrylated PL (PLMA) were developed through chemical coupling. These granular hydrogels consist of jammed microgels that exhibit viscoelastic solid properties at low levels of strain while flowing under high levels of strain. This unique characteristic enables filament formation and facilitates their application as injectable biomaterials. Additionally, a granular ink of methacrylated bovine serum albumin (BSAMA) was prepared for comparison, leveraging the high albumin content of PL. The microgels were generated by extruding bulk hydrogels through a series of nozzles with progressively higher gauges (18G, 21G, and 23G), followed by centrifugation to remove excess liquid phase and obtain granular hydrogels. Both materials displayed irregular microgels and a wide size distribution. Moreover, the process resulted in albumin microgels with a larger average size, leading to increased porosity compared to the PLMA hydrogel.

Rheological analysis revealed that both inks exhibited shear-thinning, yield-strain, and self-healing properties—essential characteristics for materials used in 3D printing. Additionally, a time sweep test utilizing UV light demonstrated a rapid increase in the storage modulus of the hydrogels due to photo-crosslinking, indicating rapid stabilization of the printed scaffolds. The study of filament formation using different nozzles allowed an evaluation of the printing fidelity of BSAMA and PLMA inks. In all cases, the filament diameter closely matched the internal diameter of the needles, and thus the smallest nozzle tested (22G) was selected for printing the scaffolds. Due to its larger microgels, the printing of the BSAMA presented some clogging, requiring higher pressure for constant extrusion compared to the PLMA ink. Nevertheless, stable scaffolds with varying geometries and layer numbers were successfully printed, confirming the efficacy of this strategy in producing protein inks with the necessary printing properties.

Finally, the bioactivity of the granular hydrogels was assessed by seeding human adipose-derived stem cells (hASCs) for a period of 7 days. Metabolic activity increased at each time point, being consistently higher in PLMA hydrogels. This can be attributed to cell proliferation in the spaces between the microgels, with cells adhering around them from the first day, as indicated by the Live/Dead assay. Furthermore, only a small number of dead cells were detected, indicating the non-cytotoxic nature and biocompatibility of the inks. The DAPI/Phalloidin assay confirmed a higher cell count in the PLMA scaffolds from day 1, highlighting the superior bioactivity of this material. In summary, bioactive granular hydrogels of protein sources with microporosity were successfully created, demonstrating their potential for 3D printing stable scaffolds with excellent resolution for use in tissue engineering applications.

**Enhanced Therapeutic and Immunomodulatory Effect of Stem Cell Spheroid with Transition Metal-Based Nanoparticles in Rat Myocardial Infarction Model** Yeong Hwan Kim and Suk Ho Bhang; Sungkyunkwan University, Korea (the Republic of)

Myocardial infarction (MI) which accompanies decrease in myocardium function and destruction of millions of cardiomyocytes is a leading cause of mortality worldwide. In this study, we demonstrated advanced stem cell therapy to treat cardiovascular disease with enhanced therapeutic efficacy of stem cell spheroids by upregulating angiogenesis-related paracrine factors secretion and inducing immunomodulatory ability with transition metal based nanoparticles (TMNs). Stem cell spheroids treated with TMNs (spheroids-TMNs) had widen hypoxia inducible factor (HIF) expression area in core with mild reactive oxygen species (ROS) generation. According to increased HIF expression of spheroids-TMNs, the secretion of angiogenesis-related paracrine factors was enhanced compared to untreated spheroids. Immunomodulatory effect of spheroids-TMNs was verified with Raw cell; suppression of pro-inflammatory responses and promotion of anti-inflammatory responses. Enhanced therapeutic effect and immunomodulatory effect of spheroids-TMNs were verified in vivo rat MI model. An advanced stem cell therapy we provided can be a promising therapeutic strategy for cardiovascular disease treatment.

**Injectable Hydrogel Formulations with Controlled-Release of Curcumin and Vitamin E for Dental Tissue Engineering** Deniz Atila<sup>1</sup>, Ali Deniz Dalgic<sup>2</sup>, Agnieszka Krzeminska<sup>1</sup>, Joanna Pietrasik<sup>1</sup>, Edyta Gendaszewska-Darmach<sup>1</sup>, Fouad Laoutid<sup>3</sup>, Piotr Paneth<sup>1</sup> and Vignesh Kumaravel<sup>1</sup>; <sup>1</sup>Lodz University of Technology, Poland; <sup>2</sup>Istanbul Bilgi University, Turkey; <sup>3</sup>University of Mons, Belgium

Dental infections affect millions of people globally with a burden of \$298 billion annually associated with direct costs to treat oral diseases. Injectable hydrogels incorporated with antimicrobial and antioxidant agents can be used to treat dental pulp infections. Herein, injectable hydrogels of chitosan (CH) and liposomes loaded with curcumin and  $\alpha$ -tocopherol have been developed to provide antimicrobial and antioxidant action for dental pulp regeneration. Hydrogels are prepared with high (HCH), and low (LCH) molecular weight chitosan to investigate the impact of molecular weight on injectability, biodegradability, controlled release, and antimicrobial activity. The diameters of liposomes are mostly uniform, in the range of 152 - 162 nm, making them suitable for controlled release and injectability. Zeta potential values of hydrogels are negative, which could lead to a homogenous distribution of liposomes in the positively charged hydrogels. Approximately 80 % of curcumin and  $\alpha$ -tocopherol are released from liposomes within 21 days in a controlled manner. Therefore, the antimicrobial and antioxidant activity of the hydrogels could be sustained during the healing process. TGA results showed that the thermal stability of the hydrogels decreased with respect to the solution volume and the sonication time while preparing the hydrogels (*i.e.*, the mass loss values of LCH and HCH at 500 °C increased from 79 to 96 % and 90 to 95 %, respectively). DSC findings are consistent with the TGA results for LCH groups, where a shift in T<sub>c</sub> from a higher (347 °C) to a lower (326 °C) temperature is observed in response to the increase in volume and sonication time. Nevertheless, the T<sub>c</sub> values of HCH are not influenced (366 °C). Rheological analysis revealed that the viscosity of hydrogels decreases as the shear rate increases, signifying the shear-thinning behaviour and injectability of the hydrogels. *In vitro* biocompatibility and antimicrobial features are investigated using dental pulp stem cells and gram-negative as well as gram-positive bacteria. Finally, the antimicrobial mechanism of LCH and HCH on *Escherichia coli* and *Staphylococcus aureus* is evaluated theoretically by density functional theory.

#### 8:00 PM SB09.03.02

**Novel Bioink for 3D Bioprinting of Complex Structures with Tunable Stiffness** Mrinal Ganash; University of New Hampshire, United States

The field of tissue engineering is rapidly adopting the principles of additive manufacturing (*i.e.* 3D bioprinting), which provides a means to generate complex functional tissue constructs in a programmable manner within micron-scale precision. However, the low mechanical stiffness and strength of 3D printed hydrogels significantly limits the application of 3D bioprinting in tissue engineering. Here, we propose the use of a novel bioink consisting of Gelatin, Methacrylated methacrylated gelatin (GelMA) and  $\alpha$ -Alginate. Once printed, this bioink is crosslinked by (i) photopolymerization of GelMA by UV radiation, (ii) enzymatic crosslinking of gelatin by microbial transglutaminase (mTG) and (iii) ionic crosslinking of alginate by calcium ions, to form an interconnected polymer network (IPN), which exhibits much improved mechanical properties. Enhanced mechanical properties of the IPN hydrogels are demonstrated by rheology and mechanical testing. Biocompatibility of the bioink and the subsequent crosslinking process was demonstrated by cytotoxicity and proliferation assays. Cell morphologies in the 3D structures were monitored by live/dead assay in conjunction with confocal microscopy. Cell viability was measured by calculating the live cell count/total cell count.

#### 8:00 PM SB09.03.03

**Microfluidics-Assisted Fabrication of Human Natural Killer Cell Encapsulated Increases the Therapeutic Efficacy for Cancer Immunotherapy** Dongjin Lee<sup>1</sup>, Seokmin Kim<sup>2</sup>, Dahong Kim<sup>3</sup>, Sua Park<sup>1</sup> and Tae-Don Kim<sup>2</sup>; <sup>1</sup>Korea Institute of Machinery & Materials, Korea (the Republic of); <sup>2</sup>Korea Research Institute of Bioscience and Biotechnology (KRIBB), Korea (the Republic of); <sup>3</sup>Seoul National University, Korea (the Republic of)

Tumors are a global human health issue, and various anti-cancer therapies such as surgical-, chemo-, radiation-, and immunotherapy have been used to treat it. Among these therapies, the therapeutic strategy using immune cells capable of recognizing and killing tumor cells is of interest as a next-generation anti-cancer therapy. In recent years, many studies on the chimeric antigen receptor (CAR) have focused on T cells. However, it takes a long time to modify donated T cells to proliferate them, and it is too expensive to use. CAR-T therapy is generally limited to blood tumors. Additionally, further clinical trials may be limited because cytokine release syndrome (CRS) or other side effects may occur from the off-target.

Unlike T cells, NK cells can distinguish tumor sites in an antigen-independent manner, and have no memory function or clonal expansion, resulting in fewer side effects like CRS. Since allogeneic cell transfer therapy is possible it offers the advantage of being available as an off-the-shelf product. Through preclinical and clinical studies, the safety and efficacy of allotransplantable NK cells for assorted types of hematological and solid cancers have been indicated, and various clinical trials are currently in progress. However, the disadvantages of NK cells include a low proliferation rate and the inability to be cultured for a long period of time. In addition, maintaining the cytotoxic activity of NK cells is important in cell therapy, but it is difficult to maintain it in general two-dimensional cultures and cell proliferation is not easy in in-vivo systems. Microgels were fabricated to contain immune cells in an emulsion method, and solid cancer disease models were demonstrated through in-vitro experiments. However, the NK cell-laden microgel researches for anticancer immunotherapy has not yet been studies. Furthermore, an in-vivo experiment was performed in which cancer cells were killed through intravenous injection of a NK cell-laden microgels which would be degraded.

Double flow-focusing microfluidics was used to create cell-containing photo-crosslinkable methacrylic gelatin (MGel) monodisperse droplets, while cell-containing microgels with high viability were produced through cross-linking. Microgels have the advantage of being able to easily control the modulus of elasticity by controlling the concentration of biopolymers. It can be applied efficiently to produce monodisperse droplets containing a large number of biomolecules and enable high-throughput examination and injectability. The generated droplets can be transformed into microgels through crosslinking and applied in multiple ways depending on the characteristics of the material. However, no study has reported the use of a uniform microgel containing NK92 cells using a microfluidic chip yet.

MGel is one of the materials because it is highly biocompatible and its physical properties can be controlled by regulating its concentration. GelMa is composed of arginine, glycine, and aspartic acid, which are present in large amounts in the molecule, and is designed to be decomposed by the matrix metalloproteinase. There is also growing interest in three-dimensional (3D) cell culture models to enable more multiple and physiologically appropriate biological assays compared to traditional two-dimensional (2D) monolayer cell cultures.

In this study, we encapsulated NK92 cells in the microgels (3D) using a microfluidic chip, and their activity was compared with that of the 2D cultured NK92 cells. We observed that NK92 cell-laden microgels (3D) increased cell proliferation, mRNA expression levels, cytokine release, and anti-tumor

efficacy, compared to the 2D cultures. We have shown that microgels have no diffusion limit because of their size (approximately 100  $\mu\text{m}$ ). These results suggest that microgels containing NK92 cells can be used to provide a new platform for anticancer immunotherapy.

#### 8:00 PM SB09.03.04

**Development of a Sprayable Multifunctional Hydrogel Wound Dressing** [Mine Altunbek](#)<sup>1</sup>, Mert Gezek<sup>1,1</sup> and Gulden Camci-Unal<sup>1,2</sup>; <sup>1</sup>University of Massachusetts Lowell, United States; <sup>2</sup>University of Massachusetts Medical School, United States

Hydrogel-based wound dressings are widely used for the treatment of wounds due to their advantages. Their high-water content allows for maintaining tissue homeostasis in the wound area. In addition, they provide a favorable three-dimensional (3D) matrix during migration and proliferation of fibroblasts, and re-epithelialization, neovascularization, and wound remodeling processes. The convenient and rapid application to irregular surfaces and deep wounds renders hydrogel dressings useful in wound healing. The chemistry of hydrogel-based wound dressings can be modified to improve their functionality for the treatment of specific types of wounds. In this work, we developed sprayable hydrogel-based wound dressings that are self-oxygenating and have anti-microbial and anti-inflammatory functions. We used naturally-derived biomaterials: gelatin (hydrolyzed collagen) and hyaluronic acid for the development of the sprayable hydrogels. The starting materials were modified with methacrylate groups (GelMA and HAMA) to obtain photocrosslinkable gel precursors. The bioactive GelMA component was evaluated at 5-15% w/v while HAMA was used as the anti-inflammatory component at 1% w/v. Solid calcium peroxide microparticles were incorporated into the hydrogel precursor solution at 0-12 mg/mL concentrations to protect the dressing from microbial invasion. The rapid and easy application of *in situ* photocrosslinkable hydrogels were demonstrated by spraying the composite gel precursor on the surface of the *ex vivo* pig skin model. The physical properties of the composite hydrogel dressings were analyzed by measuring the mechanical strength, swelling, degradation, and porosity characteristics at the macro scale. The antimicrobial properties of the composite hydrogels were evaluated against the growth of two major pathogens that typically grow during wound healing: *Staphylococcus aureus* and *Pseudomonas aeruginosa*. The oxygenation kinetics was measured using an oxygen sensing probe under hypoxic condition (2-5% O<sub>2</sub>). The cytocompatibility of the composite hydrogels were assessed by testing their effects on metabolic activity and viability of the primary human dermal fibroblasts. We successfully demonstrated the practical and convenient application of our sprayable composite hydrogels on *ex vivo* pig skin tissue by an *in situ* crosslinking strategy. The optimum sprayable concentration for GelMA was found to be 10% w/v in the dressing. The gelatin, hyaluronic acid, and peroxide containing composite hydrogels showed high tunability in their physical and biological properties. The peroxide microparticles provided antimicrobial properties in this sprayable wound dressing. The composite hydrogels were able to provide oxygen for up to two weeks in the *in vitro* cell culture. The metabolic stress from human dermal fibroblast cells was relieved by the release of oxygen from the peroxide microparticles.

#### 8:00 PM SB09.03.05

**High-Throughput Mass Spectrometry Imaging of Biomaterials for Regenerative Medicine using Three-Dimensional Biomimetic Models (Spheroids and Organoids)** [Sohee Yoon](#); Korea Research Institute of Standards and Science, Korea (the Republic of)

Three-dimensional spheroids and organoids are the next generation of biomimetic models that can mimic tissues and organs, as well as diseases and cellular microenvironments such as microtumors. This biomimetic model can be used to elucidate the mechanisms of various biomaterial changes or to rapidly screen cellular responses to drug treatments, and is therefore actively being applied in disease treatment and regenerative medicine. Imaging-based assays are important for a holistic understanding of tumor cell formation and behavior based on organ mimics. Cell viability in three-dimensional biomimetic models is primarily characterized by fluorescence-based imaging techniques. While fluorescence analysis can confirm cell viability, it is difficult to quickly identify chemical changes occurring in high-throughput cells simultaneously. Mass spectrometry imaging is a label-free, high-throughput imaging technique that can simultaneously obtain spatial and chemical information about analytes. We applied mass spectrometry imaging techniques to a three-dimensional biomimetic model to investigate changes in the cellular microenvironment and drug penetration upon drug application. To this end, we applied drugs and nanoparticles to three-dimensional colon cancer spheroids and liver organoids to investigate chemical changes in the cellular environment by mass spectrometry imaging. In the case of three-dimensional spheroids, the extent of drug penetration into each proliferating, quiescent, and necrotic layer within the spheroid and the accompanying metabolites were investigated, confirming its potential for expansion as a nanomedicine that can be applied to regenerative medicine. To investigate the environmental changes following nanoparticle-based drug delivery in the liver organoid model, we developed and optimized a high-throughput chemical imaging assay that provides a global view of chemical changes within the organoid.

#### 8:00 PM SB09.03.06

**Disulfiram-Encapsulated PLGA Nanoparticles for Liver Injury Treatment** Wei Xu<sup>1</sup>, Waliul Islam<sup>1</sup>, Hisaaki Hirose<sup>2</sup>, Shiroh Futaki<sup>2</sup>, Yukio Fujiwara<sup>1</sup>, Yoshihiro Komohara<sup>1</sup> and [Takuro Niidome](#)<sup>1</sup>; <sup>1</sup>Kumamoto University, Japan; <sup>2</sup>Kyoto University, Japan

Liver macrophages, Kupffer cells, the most abundant immune cells in the liver, play important roles in innate immunity and contribute to many liver diseases. Disulfiram (DSF), a drug used to treat alcohol abuse, has attracted much attention because it has anti-cancer and anti-inflammatory activities. However, DSF distribute in several cell types, and few studies have examined its utility as a potential treatment for liver injury. In this study, we prepared DSF-encapsulated PLGA nanoparticles (DSF@PLGA NPs) and examined anti-inflammatory effect *in vitro* and *in vivo* experiments. Size of DSF@PLGA NPs was about 250 nm and zeta-potential was negative. The encapsulated DSF was slowly released from the nanoparticles over a couple of weeks. DSF@PLGA NPs had low cytotoxicity, were selectively taken up by the human macrophage cell line THP-1 via macropinocytosis, and inhibited lipopolysaccharide-induced proinflammatory cytokine production by THP-1 cells. Intravenously administered PLGA NPs predominantly localized to the liver, specifically CD68-positive Kupffer cells, and DSF@PLGA NPs significantly ameliorated thioacetamide-induced proinflammatory cytokine production and liver injury. These results indicate that encapsulation in PLGA NPs promotes specific delivery of DSF to Kupffer cells and reduces liver injury and inflammation, suggesting that DSF@PLGA NPs may be a promising treatment for liver disease.

#### 8:00 PM SB09.03.07

**Drug-Loaded Decellularized Tissue for Suppression of Anastomotic Stenosis after Artificial Vascular Grafting** [Kaito Shimizu](#)<sup>1,2</sup>, Yoshiaki Hirano<sup>2,3</sup>, Tetsuji Yamaoka<sup>1,4</sup> and Atsushi Mahara<sup>1</sup>; <sup>1</sup>The National Cerebral, and Cardiovascular Center Research Institute, Japan; <sup>2</sup>The Kansai University, Japan; <sup>3</sup>The Kansai University Medical Polymer-Research Center, Japan; <sup>4</sup>The Komatsu University, Japan

**[Introduction]** The suppression of thrombus formation and anastomotic stenosis is required for long-term patency of small-diameter vascular grafts <sup>[1]</sup>. Surface modification techniques for an anti-thrombus surface are reported <sup>[2]</sup>, while no effective strategy has been developed to prevent anastomotic stenosis. It is well known that anastomotic stenosis causes the hyperproliferation of transformed smooth muscle cells (SMCs) <sup>[3]</sup>. SMC phenotype is altered from contractile to synthetic type, resulting in hyperproliferation. Drug eluted stent is a famous device in the clinical site, and the stent is coated with a biodegradable polymer loaded with rapamycin. The drug is released over a month after application to the arteriosclerosis site. If this concept can be applied to artificial blood grafting, we assumed that stable graft patency would be achieved over the medium to long term by the local releasing of the drug at the anastomotic site. In this study, we focused on cilostazol as the anti-proliferative drug for SMC and developed a cilostazol-loaded acellular tissue (CLZ-Graft). After grafting the vessel, CLZ-Graft was implanted into the periarterial anastomotic site. When the tissue was degraded during the tissue

regeneration, anastomotic stenosis would be suppressed by releasing CLZ. Here, we developed the CLZ-loaded acellular tissue, and inhibition of in vitro SMC growth and in vivo stenosis would be discussed.

**[Experiment]** The decellularized carotid artery was freeze-dried, and the artery was immersed in 100 mg/ml of CLZ/DMSO solution for 1 hour. As the control, the artery immersed with only DMSO were also prepared (FD-Graft). After that, the sample was washed with water to remove the solvent. The cilostazol loading in the CLZ-Graft was evaluated by FT-IR. The total amount of cilostazol in CLZ-Graft was quantified by using collagenase digestion. Enzymatically degraded CLZ-Graft was added to SMCs, and suppression of the SMCs proliferation was evaluated. In in vivo experiments, CLZ-Graft was implanted into the periarterial area of the carotid artery in a stenosis model rat. The vascular stenosis was evaluated after 4 weeks by histostaining.

**[Result and Discussion]** IR spectrum derived from CLZ was detected in CLZ-Graft by FT-IR analysis, and approximately 110 µg of CLZ was loaded in 10 mg of the graft. When the graft was incubated with the collagenase solution, the weight of the CLZ-Graft was reduced to 19 % for 8 hrs, and 82% of the loaded CLZ was gradually released during this time. When the lysate was added to the SMCs, the cell number was decreased, suggesting that the SMCs proliferation was suppressed by the degradation of the CLZ-Graft. In vivo experiment, the carotid artery with abraded lumen was wrapped with the grafts. As the result of this, the lumen area in the case of CLZ-Graft was maintained to 60% after 4 weeks while the area was largely reduced to 35% in the case of FD-Graft. These results suggest that CLZ-Graft would suppress anastomotic stenosis by CLZ release.

**Prevention of Adverse Ventricular Remodeling Post-Myocardial Infarction by Sorbitol-Responsive *In-Situ* Gelling Material** Hue T. Le<sup>1</sup>, Atsushi Mahara<sup>1</sup>, Takeshi Nagasaki<sup>2</sup> and Tetsuji Yamaoka<sup>1,3</sup>; <sup>1</sup>The National Cerebral and Cardiovascular Center Research Institute, Japan; <sup>2</sup>The Osaka Metropolitan University, Japan; <sup>3</sup>The Komatsu University, Japan

**Introduction:** The loss of myocardium after myocardial infarction (MI) leads to a thinned left ventricular (LV) wall and the exacerbated dilation of the LV cavity, eventually leading to heart failure<sup>1</sup>. Intramyocardial hydrogel injection has gained attention as a therapeutic approach in MI treatment. Various materials have been tested in preclinical and clinical studies<sup>2</sup>; however, the difficulties in control of their gelation cause inadequate distribution and retention of the hydrogel within the myocardium. We recently developed a sorbitol-responsive *in-situ* gelling material composed of poly (3-acrylamidophenylboronic acid-co-acrylamide) (BAAm), poly(vinyl alcohol) (PVA), and sorbitol. This mixture exists in a sol state because the phenylboronic acid group of BAAm is bound to the sorbitol. The BAAm and PVA are quickly conjugated by a non-covalent bond to form a gel when the sorbitol is released from the BAAm. We previously reported the proof-of-concept for the sol-gel transition of sorbitol-containing BAAm/PVA (S-BAVA) solution in the heart tissue by diffusing the sorbitol out of the sol. In this study, we investigated the distribution and retention of the injected S-BAVA in the infarct myocardium and its therapeutic effect on post-infarct adverse LV remodeling in a rat model.

**Method:** S-BAVA solution was prepared from 25 mg/ml BAAm, 10 mg/ml PVA, and 10 mg/ml sorbitol. To examine S-BAVA hydrogel formation in vivo, 1 mL of the S-BAVA containing 100 mg/mL of iopamidol was intramyocardially injected in the porcine heart and tracked by computer tomography (CT) 30 min after injection. A rat subacute MI model was prepared by surgically ligating the left anterior descending (LAD) artery. The LV wall motion of MI rats was acquired from an MRI scan. To investigate the distribution and retention of S-BAVA solution in the MI heart, 200µL of rhodamine (rho)-labeled S-BAVA solution was injected into the infarct myocardium and observed by fluorescent microscopy up to 21d after injection. Finally, 200µL of the S-BAVA or calcium-crosslinked alginate (ALG) containing 24 mg/mL alginate and 4 mg/mL CaCl<sub>2</sub> or saline solution was intramyocardially injected into the MI hearts (four to six rats per each group). Fraction shortening (FS), and LV internal diameter (LVID) index were measured by echocardiography, and the LV morphology was assessed by histological staining at 21d after administration. The saline was set as a negative control.

**Result:** The CT images showed the presence of the iopamidol-containing S-BAVA in the porcine myocardium 30min after injection, suggesting the occurrence of its hydrogel formation. The rho-labeled S-BAVA was fully distributed in the infarct myocardium and stably remained up to 21d after injection. The MRI images showed the dyskinetic wall motion and thickness in all rats operated with LAD ligation. A gradual reduction of the LV function indicated by a declining FS was observed in the saline-injected MI rats. Even with the ALG injection, the reduction of FS still occurred although it was less severe than in the cases with saline injection. However, the FS in the S-BAVA group was not reduced for 21d. In addition, the increase of systolic LVID caused by MI was suppressed by the S-BAVA injection whereas the saline or ALG injection did not. The histological assessment showed that the infarction area in the S-BAVA group was lower than that in the ALG and saline groups after 21d of administration.

**Conclusion:** Our results proved that the S-BAVA could be widely distributed and retained for 21d in the myocardium. Intramyocardial injection of the S-BAVA solution effectively suppressed adverse LV remodeling, resulting in maintaining cardiac function up to 21d.

**3D Printed Polymer Scaffolds for Bone Regeneration** Shreya Madhavarapu and Joseph Freeman; Rutgers, The State University of New Jersey, United States

Significant bone loss can occur due to trauma or disease, resulting in large bone defects. Typically, autografts and allografts are used as bone grafts but these are associated with disadvantages like limited availability, and the risk of disease transmission with allografts. In recent time, synthetic bone graft substitutes have come up as alternatives, but they fall short in one or more aspects as well. Tissue engineered bone grafts are viable alternatives. In order for these to be successful, we must first address two important issues - lack of cell infiltration throughout their structure and a lack of vasculature formation. We have developed a 3D printed polylactic acid (PLA) scaffold with distinct cortical and trabecular geometries. These are highly porous structures promoting capillary inflow of blood and bone marrow. They are also mineralized and prevascularized to promote regeneration of both bone and its vasculature. These scaffolds are evaluated in a load-bearing, rabbit critical-sized radial defect model and show promise.

Scaffolds were designed using Solidworks and 3D printed using the Ultimaker 2+/S3 3D printers. They were tested under compression and their mechanical properties were compared to the previous iterations of scaffolds developed in our lab. The new design displayed superior mechanical properties when compared to the previous design. Our previous design displayed Ultimate Compressive Stress and Compressive Modulus which fall within the limits for trabecular bone (0.2-10MPa and 7-200MPa) but fall short of those required for native whole bone i.e. 200 MPa and 1 GPa respectively. With our new design, we have been able to achieve a mean Ultimate Compressive Stress of approximately 40 MPa and a mean Compressive Modulus of approximately 600 MPa. Glycerol-water mixtures were used to mimic the viscosities of blood and bone marrow and study scaffolds' ability to promote capillary inflow. Slow capillary rise of fluids mimicking viscosities of blood and bone marrow was observed in the 3D printed scaffolds. In order to improve their ability to wick up these fluids, polymer surface was pretreated with oxygen plasma prior to mineralization using concentrated simulated body fluid. Presence of mineral resulted in them quickly wicking up fluid followed by a more gradual rise. Scaffolds were prevascularized by allowing vascular endothelial cells to grow within the cortical structure. They were decellularized after 2 weeks leaving behind a pro-angiogenic matrix. Scaffolds with and without autologous bone marrow were implanted in a rabbit critical-sized radial defect model, with allografts serving as controls. X-Ray and CT imaging was used to track bone regeneration over the course of 20 weeks. X-ray images showed progressive bone regeneration from 2 to 10 weeks, originating first from the ulna ridge just below where the radius was removed and from the two ends where the radius meets the implant. The CT images taken at 12 weeks post-op showed significant bone regeneration. At the end of the study, histology will be performed to analyze regenerated bone and vasculature.

We have developed load bearing scaffolds that promote infiltration of bone marrow into and throughout the scaffold, reducing the need to add stem cells prior to implantation *in vivo*. Using endothelial cells to prevascularize our scaffolds, we have created decellularized lumens within our cortical geometry to promote growth of vasculature upon implantation. Our ongoing *in vivo* evaluation has shown that our scaffolds can maintain their structural integrity while promoting bone remodeling and show promise as bone graft alternatives.

#### 8:00 PM SB09.03.11

**Eggshell Reinforced Scaffolds for Bone Repair** Mert Gezek<sup>1,1</sup> and Gulden Camci-Unal<sup>1,2</sup>; <sup>1</sup>University of Massachusetts Lowell, United States; <sup>2</sup>University of Massachusetts Medical School, United States

More than two million bone graft procedures are performed to treat patient defects annually.<sup>1,2</sup> The main drawbacks of some of the existing bone graft materials are their complex fabrication steps, inflexibility, lack of porosity and biofunctionality, and requirement of costly reagents. Bone regeneration can be achieved using mineral-based materials, such as calcium carbonate, which is a major component of eggshells. Global waste of discarded eggshells typically amounts to millions of tons annually from household and commercial cooking. Innovative repurposing of eggshells can impact the economy and environment while providing unique solutions to unmet clinical needs. Due to the superior biophysical properties of calcium carbonate over other calcium-based minerals, the incorporation of chicken eggshell microparticles (ESP) into polymers can enhance osteogenic differentiation and bone regeneration.

In this work, we developed ESP-reinforced polymeric scaffolds to obtain mechanically stable and biologically active three-dimensional (3D) scaffolds that can differentiate stem cells or preosteoblasts into osteoblasts.<sup>1</sup> We generated ESP-reinforced 5-50% (w/v) polymeric scaffolds. The concentrations of the ESP were 5, 15, 30, and 50% (w/v) in the scaffolds. We characterized the mechanical properties, porosity, swelling, and degradation of these biomaterials. The cellular response was then evaluated against the ESP-reinforced scaffolds via, cytotoxicity, growth, and proliferation assays as well as gene expression analyses. Implantation of ESP-reinforced scaffolds was performed *in vivo* using a rat model and histology was carried out to evaluate the inflammatory response. In addition, near full regeneration of critical-sized calvaria defects was achieved using our ESP-reinforced scaffolds *in vivo*.<sup>2</sup> These composite materials demonstrated significant bone formation as well as bone remodeling.

This work demonstrates that eggshell microparticles can be used in a composite 3D polymeric construct for bone regenerative engineering. We successfully fabricated ESP microparticle-reinforced biomaterials and evaluated their suitability for osteogenic cell cultures *in vitro*, and biocompatibility and bone regeneration *in vivo*. Pre-osteoblasts were encapsulated within the ESP-reinforced scaffolds at 5 million cells/mL density which underwent osteogenesis as determined by RT-qPCR for osteocalcin and BMP-7. The ESP-reinforced composite scaffolds were osteoinductive and enabled the differentiation of stem cells without the use of a specialized osteogenic growth medium. The ESP-reinforced constructs were then subcutaneously implanted in Wistar rats and found to be biocompatible without inflammatory response and they were biodegradable. The implants were easily accepted by the host, allowed for cellular migration and infiltration in 3D, and were highly vascularized. To study the regenerative capability of the ESP-reinforced scaffolds, they were implanted into critical-size calvaria defects. The *in vivo* model demonstrated a near full regeneration of the critical-size defects in 12 weeks. The newly formed bone had similar bone density compared to the native bone and it was capable of producing bone marrow. Furthermore, in addition to vascularized bone formation, bone remodeling also took place as determined by immunohistochemistry for TRAP. We anticipate that the ESP-reinforced scaffolds will serve as promising implants for the treatment of bone defects in the body.

#### 8:00 PM SB09.03.12

**Simultaneous Antifouling and Selective Adsorption in a Poly(dimethyl siloxane) (PDMS) Based Microfluidic Device using a Functional Surface Segregating Zwitterionic Copolymer Additive** Ryan O'Hara<sup>1</sup>, Luca Mazzaferro<sup>1</sup>, Aslihan Gokaltun<sup>2,3</sup>, Berk Usta<sup>2,3</sup> and Ayse Asatekin<sup>1</sup>; <sup>1</sup>Tufts University, United States; <sup>2</sup>Harvard Medical School, United States; <sup>3</sup>Massachusetts General Hospital, United States

Nonspecific protein adsorption and small molecule adsorption have been a persistent challenge in the use of poly (dimethyl siloxane) (PDMS)-based microfluidic devices due to PDMS's hydrophobicity. This issue has led to the development of various post-processing techniques to make the surface fouling resistant, such as plasma treatment and surface grafting of hydrophilic polymers. However, these approaches often have limited stability, with the surface becoming hydrophobic again within days. Additionally, for many applications, it is of interest to selectively adsorb only specific analytes while preventing the adsorption of others, specifically for use in protein capture for diagnostics, biochemical assays, and cell capture for organ-on-a-chip models. Achieving both selective adsorption and fouling resistance is particularly challenging. To address these challenges, we have synthesized a surface spontaneously segregating copolymer additive to create a hydrophilic, antifouling zwitterionic surface interspersed with functionalizable groups that can be easily blended into pre-cured PDMS during the traditional manufacturing method of microfluidic devices. Using this approach, we have been able to decrease the nonspecific adsorption of Bovine Serum Albumin (BSA) on PDMS surfaces by at least 95%. We have also shown that we can utilize the functionality of this polymer additive to attach desired functional groups to mediate the adsorption of specific analytes using isocyanate or EDC/NHS coupling chemistry. We expect this novel method for simultaneous fouling prevention and surface functionalization of PDMS surfaces to enable the development of better-performing biomicrofluidic devices.

**Decoupling of Adhesive and Repulsive Domains of Microstructured Stimuli-Responsive Polymer Film for the Refining of Particulates and the Non-Enzymatic Harvesting of Cells** Yongwook Kim<sup>1,2</sup>, Ummay M. Jahan<sup>3,2</sup>, Alexander P. Deltchev<sup>2</sup>, Nickolay Lavrik<sup>4</sup>, Vladimir Reukov<sup>2</sup> and Sergiy Minko<sup>2</sup>; <sup>1</sup>Lawrence Livermore National Laboratory, United States; <sup>2</sup>University of Georgia, United States; <sup>3</sup>North Carolina State University, United States; <sup>4</sup>Oak Ridge National Laboratory, United States

Sorting colloidal particles such as protein complexes, cells, and viruses presents a challenge due to their strong and quasi-irreversible adsorption to interfaces, which hampers their efficient separation. To overcome this limitation, a microstructured stimuli-responsive polymer interface has been developed to generate a controlled local oscillating repulsive mechanical force. This force facilitates the transition between particle adsorption and facilitated desorption, allowing for the separation of colloidal mixtures based on their affinity to the particle-polymer interface. The microstructured films consist of adhesive domains and disjoining thermoresponsive poly(N-isopropylacrylamide) brush domains. This dynamic regime holds significant potential for various applications in research, diagnostics, and large-scale label-free sorting of highly asymmetric mixtures of colloids and cells. Furthermore, this novel polymeric interface can be applied to non-enzymatic cell harvesting. By utilizing microstructured patterns, the areas responsible for solid cell adhesion serve as cell growing scaffolds, while the repulsive areas are employed to collect proliferated cells from the surface. This surface design

effectively addresses the limitations associated with thermoresponsive coatings, such as the need for precise coating thickness, grafting or cross-linking density, and specific substrate materials. This innovative architecture enables efficient cell harvesting and selective sorting of particulates by separating the adhesion and detachment processes.

Part of this research was conducted as a user project at the Center for Nanophase Materials Sciences (CNMS), which is a US Department of Energy, Office of Science User Facility at Oak Ridge National Laboratory.

#### 8:00 PM SB09.03.15

**O-Carboxymethyl Chitosan-Based Nanostructured Surface using Poly(Ethylene Glycol) for Multi-Functionalization of Vascular Catheters** Min Yeong Jeong<sup>1</sup>, Se Kye Park<sup>2</sup>, Kibeom Nam<sup>1</sup> and Dong Yun Lee<sup>1</sup>; <sup>1</sup>Kyungpook National University, Korea (the Republic of); <sup>2</sup>Korea Institute of Industrial Technology, Korea (the Republic of)

Vascular catheters (VCs) are essential medical devices used for diagnostic purposes, drug administration, and surgical interventions. However, using VCs can lead to severe complications, including bloodstream infections, thrombosis, and blood vessel damage, posing a risk to patient safety. To address these critical issues, it is crucial to incorporate antimicrobial, antithrombotic, and low-friction properties into the surface of ICs. One approach for achieving multifunctionality in ICs involves coating them with a hydrogel that embeds antimicrobial and antithrombotic agents. Although catheters with such hydrogel coatings have effectively prevented these issues, they can have unwanted side effects such as cytotoxicity and tolerance. Additionally, the performance of hydrogel-coated ICs tends to degrade over time due to the leaching of functional agents from the coating layer. O-carboxymethyl chitosan (O-CMC) is a promising material for multi-functionalizing VCs due to its exceptional material properties, including biocompatibility, biodegradability, antimicrobial activity, and hemocompatibility. However, the antithrombotic activity of O-CMC remains uncertain due to incomplete thrombosis reduction and limited clinical use cases [5]. Although O-CMC has sufficient hemocompatibility, the antithrombotic activity is questionable due to its incomplete performance of thrombosis reduction and lack of clinical use cases[5]. Furthermore, there is a lack of studies on the multifunctionalization of VCs using chitosan derivatives like O-CMC. Consequently, the verification of multi-functional performance, including antithrombotic activity, remains a challenge in the application of actual VCs. In this study, we introduce a novel strategy to achieve surface multi-functionalization of ICs using O-CMC. To enhance the inherent performance of O-CMC, we fabricated a nanoscale rough surface for the coating layer. This is accomplished by fabricating a nanoscale porous O-CMC coating layer on pre-treated ICs through the selective leaching of water-soluble polyethylene glycol (PEG) from a heterogeneous O-CMC/PEG composite. The resulting coated layer exhibits superhydrophilicity due to increased surface roughness. Notably, the antifouling effect by superhydrophilicity of the coating layer effectively prevented the adhesion of bacteria and platelets, synergizing with the inherent properties of O-CMC. Additionally, the porous O-CMC coating layer exhibits sufficient low-friction properties even with its rough surface. Moreover, we have successfully demonstrated that the practical VC with the proposed coating method exhibits excellent trackability in a curved artificial blood vessel. This proposed coating strategy shows great potential not only for VCs but also for a wide range of polymer-based vascular devices, including vascular filters, grafts, pacemakers, and soft robots.

#### 8:00 PM SB09.03.16

**Cationic Material-Free mRNA Delivery Carrier** Naoki Taguchi<sup>1,2</sup>, Akihisa Otaka<sup>1</sup>, Yoshiaki Hirano<sup>2,3</sup> and Tetsuji Yamaoka<sup>1,3</sup>; <sup>1</sup>The National Cerebral and Cardiovascular Center Research Institute, Japan; <sup>2</sup>The Kansai University, Japan; <sup>3</sup>The Komatsu University, Japan

**[Introduction]** Since mRNA is easily degraded in our body, it requires a delivery carrier to be delivered to target cells. Cationic carriers are often used for mRNA delivery because it electrostatically interacts with the phosphate groups of mRNA. However, cationic feature often causes cytotoxicity and nonspecific protein adsorption in the blood, thus decreasing the therapeutic efficiency. To solve this problem, we focused on zwitterionic arginine methacrylamide (ArgMA), in which the alpha-amino group of arginine is conjugated with methacrylic acid as a carrier component. The guanidyl group of arginine has affinity to nucleic acid<sup>[1]</sup> and retains mRNA despite its zwitterionic and nonionic structure. Furthermore, previous papers have reported several attractive features of ArgMA as a delivery carrier, such as lower cytotoxicity than cationic arginine<sup>[2]</sup> and antifouling properties<sup>[3]</sup>. In this study, ArgMA-containing polymers were synthesized and verified whether the polymer can retain and protect mRNA and induce protein expression.

**[Synthesis and Method]** ArgMA was synthesized according to a previous report<sup>[4]</sup>. Since ArgMA homopolymer was insoluble in water, ArgMA was copolymerized with 2-methacryloyloxyethyl phosphorylcholine (PMR) at the ArgMA composition ranging from 0 to 70 mol%. Free radical polymerization and reversible addition-cleavage chain transfer (RAFT) polymerization were performed using 2,2'-azobis(isobutyronitrile) as initiator and water/ethanol as solvent. PMR was mixed with mRNA, encoding a near-infrared red fluorescent protein (iRFP), with a guanidyl/phosphate group ratio from 0 to 200, and the polyplex formation was confirmed by an agarose gel electrophoresis. The mRNA protection by PMR was evaluated after incubation with 10% fetal bovine serum (FBS) at 37°C for 10 min. The transfection efficiency of fibroblast cells (HEK293) was evaluated using flow cytometry analysis.

**[Results and Discussion]** Agarose gel electrophoresis showed that the more mRNA formed polyplex with PMR synthesized by free radical polymerization ( $M_w \approx 100,000$ ) with an increase in the ArgMA composition, while the polymer without ArgMA failed to form polyplex. This suggests that ArgMA is the major mRNA binding domain of PMR. Next, in the mRNA protection assay, the PMR with an increasing composition of ArgMA inhibited mRNA degradation. However, naked mRNA was completely degraded. Similar results were observed using PMR synthesized by RAFT polymerization ( $M_w$  ranged from 7,400 to 27,000) in the agarose gel electrophoresis and the mRNA protection assay. Finally, transfection experiments were performed using iRFP fluorescence expression as an indicator. HEK293 cells expressed the highest iRFP expression by culturing in the medium containing the polyplex composed of RAFT-PMR containing 30 mol% ArgMA. ArgMA will be a promising motif for designing cationic moiety-free mRNA delivery carriers.

**Lyophilized Porous Gelatin Microgels** Ziqiang Guan; University of New Hampshire, United States

Injectable hydrogels are useful for wound healing and tissue engineering due to their ability to conform to the topography of target tissues and provide a natural hydrated 3D environment for cells. However, most injectable hydrogels are nonporous, resulting in a delayed cellular response. Previously, our group developed an injectable microporous hydrogel made of gelatin microgels, which are cured to form a bulk hydrogel using microbial transglutaminase (mTG). This novel hydrogel allowed efficient migration of surrounding cells into the hydrogel phase as well as rapid spreading and proliferation of encapsulated cells. These characteristics indicate its potential use in wound healing and stem cell delivery. In this research, we demonstrate the development of porous gelatin microgels and their assembly for cell encapsulation. The porous microgels are produced by swelling and lyophilization of nonporous gelatin microgels. The micropore structure of the microgels was confirmed using scanning electron microscopy (SEM). The pores in the microgels enabled more rapid diffusion of a model protein (bovine serum albumin) into the microgels, demonstrating that these porous microgels will facilitate the transfer of nutrients and gas molecules in and out of the hydrogel. When these porous microgels were used for the encapsulation of human dermal fibroblasts (hDFs), hDFs were found to exhibit more widespread morphologies. Taken together, these novel microgels will prove useful for stem cell delivery for tissue repair.

**8:00 PM SB09.03.18**

**Novel Nanoscale 3D Mapping of Mechanical Heterogeneities in Hydrogels for Tissue Engineering** [Fei Wang](#), Kevin Grassie, Fayekah Assanah, Yusuf Khan and Bryan D. Huey; University of Connecticut, United States

We are developing a platform to investigate the forces experienced by cells in tissue engineering hydrogels when exposed to external loading by ultrasound, mimicking clinical procedures for bone tissue regeneration. A high density of embedded fluorescent microbeads, which serve as fiducial markers for deformation tracking, is dispersed within the hydrogel. A series of optical images are first acquired over a range of focal planes, spanning thicknesses of tens of micrometers, to map the bead positions in 3D. Such optical stacks are then repeatedly collected as a function of time before, during, and after uniform acoustic loading. Post processing identifies the displacements of the several thousand beads in the field of view. This allows local distortions within the hydrogel, and even incorporated cells, to be volumetrically mapped. Variations in the magnitude and direction imply mechanical heterogeneities due to local differences in hydrogel cross-linking, density, hydration, and/or cellular mechanical structures and active adhesion. This approach will help to investigate the cellular response to clinically applied, but still not well understood, low-intensity pulsed ultrasound (LIPUS) which has been demonstrated to enhance bone formation and healing. Ultimately this approach may enable 3D Traction Force Microscopy, with broader applications to other 3-dimensionally heterogeneous systems including individual cells, tissue, and block copolymers, and nanocomposites.

**8:00 PM SB09.03.20**

**Biomimetic Scaffolds from Biopolymer Ionogels: Elucidating Processing Parameter Dependence on Cell Proliferation** [Evan McDowell](#), Liberty Yoder and Letti Frenadez; North Carolina A&T, United States

Novel tissue engineering approaches are imperative to address the increasing prevalence of replacing damaged or lost organs due to congenital defects, traumas, or disease. Reliance on traditional transplantation techniques as the primary step of intervention has been hindered, as it is constrained by the scarcity of available organs. Advancements in tissue engineering techniques have interested scientists and clinicians as it holds the potential to create safe and reliable methods for developing functional tissue providing the possibilities to improve patient outcomes, alleviate healthcare burdens, and improve quality of life globally. Recently, research developments in stem cells, biomimetics, biochemistry, and material science have begun to pioneer these new paths for researchers, in some cases allowing them to circumvent traditional methods altogether. Most regenerative medicines/techniques that have emerged are centered around infusing a cell's natural mechanisms with manufactured processes, but realizing a functional biomimetic synthetic tissue is an intricate process. Synthetic tissue must aim to mimic the heterogeneity, complexity, structural integrity, mechanical function, and biocompatibility of indigenous tissue. Additive manufacturing, hydrogel cell cultures, and electrospinning have been used to produce tissue that equates to or enhances the regenerative properties of the human body. Here in this study, we follow established ionic liquid protocols, synthesizing BmimCl from conventional precursors to be used in various dissolutions, forming ionogels. These ionogels are composed of cellulose, silk, or a blend of both, and in combination with our regenerating solution, served as the material for 3D printing the scaffolds. Here we show that via standard additive manufacturing processes, we were able to design and manufacture biomimetic ionogel scaffolds with tailored nanosized features that facilitated enhanced cellular activity and proliferation. Each scaffold was done in triplicate and seeded with MDA-MB-231 cells into individual T-75 flasks. They were cultured in 2 variable conditions in addition to the control: ambient dried ionogel, freshly regenerated ionogel, and no ionogel(control). Each condition was seeded without mixing and after 3 days in standard culture conditions, they were removed for counting. MTT analysis uncovered the viability of the cells increased in the freshly regenerated culture and decreased in the ambient dried condition in comparison to the control. This data supports that these scaffolds, when intact, can provide an advantageous nanostructured milieu, that enhances cell proliferation. Polymer matrix density, porosity, and level of regeneration were tailored to improve cell viability, showing up to a 40% increase, outperforming standard biocompatible plastics used in industry. While this work is in its nascent stages, the early indicators are pointing toward a possible pathway for producing rapid, and reliable tissue cultures that could be used for drug testing, medical research, or eventually in-vitro human models. Although it does not replace traditional transplantation, this approach offers researchers the potential to quickly prototype and test tissue models. It holds the potential to accelerate advancements in tissue engineering, providing valuable tools for scientific investigation and potentially transforming the field.

**Actuating Extracellular Matrices Mechanically Program Anisotropy in Engineered Muscle Tissues** [Brandon Rios](#), Angel Bu and Ritu Raman; Massachusetts Institute of Technology, United States

**Introduction:** Multicellularity is the key to the dynamic functionality of biological tissues. Cells embedded in an extracellular matrix communicate with each other, and with their surrounding scaffold, through a combination of chemical, electrical, and mechanical signaling. A soft actuating substrate that is capable of controlling cell-cell mechanical interaction with high spatiotemporal precision, while also allowing for the generation of forces in the biologically relevant range, would enable probing the impact of external forces on intercellular communication and measuring downstream impact on morphology and function. We have developed a magnetically actuated extracellular matrix capable of modular, programmable, and tunable deformation. We test this platform as a mechanically active substrate for skeletal muscle and show that we can control the directional fusion of myoblasts into aligned fibers. By leveraging computational tools to track substrate deformation in response to muscle contraction, we further demonstrate that mechanically programmed anisotropy in muscle improves synchrony of tissue-wide coordinated twitch. This study sets the stage for deploying actuating extracellular matrices to map and modulate mechanical signaling and control a variety of complex biological processes.

**Materials and Methods:** We manufactured magnetic silicone microparticles by mixing iron nanoparticles within poly (dimethyl siloxane) and embedded these microparticles within a fibrin hydrogel. A custom-built linear actuator enabled moving a magnet under the hydrogel with precisely controllable direction and speed. We seeded optogenetic mouse myoblasts on magnetic fibrin gels and differentiated them to form mature muscle in the presence or absence of mechanical stimulation (30 minutes/day, 10 days). The resultant mechanical motion was recorded with a stereoscope and custom automated tracking software was used to map deformation of the hydrogel in response to magnetic (daily) and optical (only on day 10) stimulation. Tissues were fixed and stained for cell nuclei and myosin expression to quantify muscle fusion index and other indicators of mature tissue formation.

**Results and Discussion:** Global fiber alignment is critical to native muscle architecture, as global actuation can only be achieved by independent fibers twitching simultaneously and in the same direction and is thus of relevance for applications ranging from regenerative medicine to biorobotics. Morphological analysis revealed that both control and stimulated fibers grow significantly in length over time, but no significant difference in fiber length or width was observed between experimental groups. We used Fast Fourier Transform image analysis to assess differences in muscle fiber directionality and showed that mechanically stimulated tissues were more likely to align parallel to the direction of magnet movement (0°). By contrast, fibers in control groups did not demonstrate statistically significant global alignment. Optical stimulation of engineered muscle generated globally coordinated twitch deformation in the mechanically stimulated group, while the control group displayed asynchronous and arrhythmic contraction, indicating improved global fiber alignment had an observable downstream impact on function. These quantitative assays, which showed that enhanced x-direction alignment corresponds to increased synchrony of x-direction twitch, corroborate the observation that actuating extracellular matrices can mechanically program anisotropy of form and function in engineered muscle.

**Conclusion:** Our proof-of-concept study demonstrates how modulating intercellular forces in skeletal muscle during growth and maturation can dynamically program tissue anisotropy. Our platform can be readily adapted to a variety of natural and synthetic soft substrates, as well as a range of cell types, and anticipate that this platform will enable a broad range of fundamental studies of mechanobiology.

**8:00 PM SB09.03.22**

**Laminin-Decorated Gelatin Microporous Injectable Hydrogel for the Encapsulation and Differentiation of Neural Progenitor Cells** Seth Edwards; University of New Hampshire, United States

Nervous tissues have limited capacity to regenerate, and damage to these tissues, due to neural injuries or neurological disorders, is often debilitating to the affected patients. The delivery of neural progenitor cells (NPCs), with biomaterials as a delivery vehicle is a promising strategy to promote neural tissue repair. Neural differentiation of NPCs is facilitated by cell spreading and morphological changes, as well as cell-cell interactions. An effective delivery vehicle for the nervous tissue regeneration should promote such cell-matrix and cell-cell interactions. In this report, we investigated the potential for a microporous injectable hydrogel, formed by annealing of gelatin microgels to promote the differentiation of encapsulated NPCs. In addition, we demonstrate a novel method of improving NPC adhesion in the microgel matrix by a facile covalent incorporation of laminin by microbial transglutaminase (mTG) during the microgel annealing process. We found that cell organization, morphology, and differentiation were dependent on the 3D environment, as examined through live/dead assay, immunofluorescence staining for neural markers, mitochondrial activity, and by investigating functional neuronal network formation through monitoring calcium flux of encapsulated cells in response to neurotransmitter. In summary, our results investigate and demonstrate the potential for microporous injectable hydrogels to serve as a vehicle for the encapsulation and differentiation of NPCs.

**Guanidine-Based Hydrophilic Antimicrobial Polymer as a Textile Coating** Urmi V. Mody and Michael Wolf; University of British Columbia, Canada

With the increase in infection transmission and resistance to antibiotics, using clothing as the first of defense can reduce transmission rates and contain disease spread. We report a guanidine-based cationic hydrophilic antimicrobial polymer (GAMS) that can selectively lyse bacterial cells. Antibacterial activity, hydrophilicity, haemolytic and thermal properties of the crosslinked siloxane-based cationic polymer are tested post-functionalization with guanidine groups at 10%, 30%, 50%, and 70% loading relative to the amine groups on the polymer. It is concluded that guanidine functionalized polymer is selective for bacterial cell lysis with complete elimination of class 2 pathogens (E. coli and MRSA) using a contact killing mechanism. GAMS polymers show high thermal stability. Structural characterization of GAMS polymers is performed using NMR (1H, 13C, COSY, HMBC), FTIR, elemental analysis, TGA, (E. Coli/MRSA). Bacterial colony counting assays are performed to evaluate the efficiency of GAMS compared to hydrophobic antibacterial polymers that have been previously reported.

**8:00 PM SB09.03.24**

**Synthesis of Curcumin-Loaded LNP-Based Sarcopenia Treatment using Microfluidic Reaction System** Jun-Won Kook; Ajou University Medical Center, Korea (the Republic of)

Sarcopenia, characterized by progressive loss of skeletal muscle mass and function, is a prevalent condition associated with aging. Currently, there is a growing interest in developing effective therapeutic strategies to combat sarcopenia and improve the quality of life for affected individuals. In this study, we propose a novel approach for the synthesis of curcumin-loaded lipid nanoparticle (LNP)-based sarcopenia treatment using a microfluidic reaction system.

The microfluidic reaction system offers several advantages over traditional bulk synthesis methods, including precise control over reaction conditions, enhanced mass transfer, and reduced reaction times. These characteristics make it a promising tool for the synthesis of drug-loaded nanoparticles with improved physicochemical properties and therapeutic efficacy.

Curcumin, a naturally occurring polyphenol found in turmeric, has demonstrated potential as a therapeutic agent for sarcopenia due to its anti-inflammatory and antioxidant properties. However, its poor aqueous solubility and low bioavailability limit its clinical application. By encapsulating curcumin within LNPs, we aim to enhance its stability, solubility, and targeted delivery to skeletal muscle tissues.

The microfluidic reaction system enables the efficient production of curcumin-loaded LNPs by facilitating the rapid mixing of lipid precursors and curcumin in a continuous flow. This allows for the formation of uniform nanoparticles with controlled size and composition. Furthermore, the microscale dimensions of the system enable the precise tuning of reaction parameters, such as temperature, flow rates, and residence times, to optimize the encapsulation efficiency and loading capacity of curcumin within the LNPs.

To evaluate the potential of the synthesized curcumin-loaded LNPs as a sarcopenia treatment, *in vitro* and *in vivo* studies will be conducted. The nanoparticles will be characterized for their physicochemical properties, including size, zeta potential, and drug release kinetics. *In vitro* assays will assess the cellular uptake and cytotoxicity of the LNPs using skeletal muscle cells. *In vivo* studies will involve the administration of the curcumin-loaded LNPs to animal models of sarcopenia, followed by the evaluation of muscle mass, strength, and markers of inflammation and oxidative stress.

In conclusion, this study proposes a microfluidic-based approach for the synthesis of curcumin-loaded LNPs as a potential sarcopenia treatment. The use of a microfluidic reaction system offers unique advantages in terms of control, scalability, and reproducibility. If successful, this approach could provide a promising therapeutic strategy for the management of sarcopenia, addressing the unmet need for effective treatments for this age-related condition.

**8:00 PM SB09.03.25**

**Noninvasive and Longitudinal Study of Multi-Contrast 3D Bioprinted Tissue Constructs via Photon Counting Computed Tomography** Carmen J. Gil<sup>1,2</sup>, Connor Evans<sup>3</sup>, Lan Li<sup>3</sup>, Alexander Allphin<sup>4</sup>, Martin Tomov<sup>1</sup>, Liqun Ning<sup>2</sup>, Ming Shen<sup>1</sup>, Jarred M. Kaiser<sup>1</sup>, Luz Restrepo<sup>5</sup>, Victor Putaturo<sup>2</sup>, Gabriella Kabboul<sup>1</sup>, Anjum Alam<sup>2</sup>, Travis Fulton<sup>1</sup>, Remi Veneziano<sup>5</sup>, Nick Willet<sup>1</sup>, Hicham Drissi<sup>1</sup>, Cristian Badea<sup>4</sup>, Holly Bauser-Heaton<sup>1</sup>, Ryan Roeder<sup>3</sup> and Vahid Serpooshan<sup>1,2</sup>; <sup>1</sup>Emory University, United States; <sup>2</sup>Georgia Institute of Technology, United States; <sup>3</sup>University of Notre Dame, United States; <sup>4</sup>Duke University, United States; <sup>5</sup>George Mason University, United States

3D bioprinting has revolutionized the fields of personalized and precision medicine by offering the unique possibility of designing patient-specific tissue engineered constructs and therapies. For cardiovascular disease, patient-specific bioprinted cardiac patch devices have emerged as novel therapeutics, demonstrating promising results in restoring and/or improving cardiac function, reducing the infarct size, and enhanced angiogenesis in animal models of myocardial infarction (MI). However, current 3D bioprinted cardiac patch designs primarily lack the ability of noninvasive, longitudinal, and quantitative monitoring of their function following the implantation *in vivo*. Computed tomography (CT) is widely used in clinical settings to monitor cardiac function and anatomy. A recent advancement in CT imaging, i.e., photon-counting CT (PCCT), has enabled simultaneous imaging of multiple contrast agents at higher spatial resolution while potentially reducing the radiation dose. Through integrating advanced multi-material bioprinting and PCCT imaging, this research aimed at design and creation of novel 3D cardiac patch structures, incorporated with multiple CT imaging probes, which can be monitored noninvasively and longitudinally in both *in vitro* and *in vivo* applications.

In this study, distinct k-edge CT imaging probes were incorporated in different bioinks and used to print patch structures. To determine the feasibility of our approach, release profiles of various imaging probes from the constructs were investigated to optimize the production of bioinks with adequate and stable concentrations of imaging probes. Subsequently, imaging properties of bioprinted contrast agent-laden constructs were evaluated by CT/PCCT both *in vitro* and *in vivo*, in a subcutaneous mouse model. Imaging probes added to distinct bioink formulations included gadolinium (Gd) chelate, iodine (Iod), Gd<sub>2</sub>O<sub>3</sub>, gold nanoparticles (Au NPs), and methacrylated Au (AuMA) NPs. Printed patches with single and multiple imaging probes were able to be discriminated and quantified by PCCT, offering the ability to perform longitudinal and noninvasive monitoring of the implanted patch. In the final patch design, AuMA and Gd<sub>2</sub>O<sub>3</sub> NPs were used to label different components of the patch structure, and Iod was used to visualize and quantify perfusion through the printed vasculature in the patch. Future studies aim to further control the stability and release behavior of imaging probes, incorporate advanced drug delivery tools within the patch (e.g., co-encapsulation of therapeutic molecules and imaging probes), and development of novel imaging probes (e.g., via chemical conjugation of probes to the polymer matrix). In addition, we work on improving the functionality of cardiac patch by incorporating various molecular therapeutics and cardiovascular cells, together with the CT imaging probes. In summary, this study demonstrates the feasibility of designing a novel theranostic platform to treat cardiovascular disease using a new generation of bioprinted patch devices.

#### 8:00 PM SB09.03.26

**Compressive Modulus and Charge Dictate Surface Protein Adsorption on Injectable Cellulosic Hydrogels** *In Vitro* Adam Weisel and Steven Nicoll; The City College of New York, United States

Cellulose is a natural polysaccharide that can be modified to meet many physical, biological, and chemical requirements, making it an attractive candidate for tissue engineering<sup>1</sup>. Specifically, its inherent sustainability and the potential for *in-situ* gelling by functionalization with methacrylate groups, makes this system appealing for stable, minimally invasive implants<sup>2</sup>. Water-soluble cellulosic derivatives, such as methylcellulose (MC), which contains hydrophobic methoxy groups that afford thermogelation properties at body temperature, and carboxymethylcellulose (CMC), which provides polyanionic character analogous to native tissue glycosaminoglycans, allow for further tuning of the hydrogel features. The biological response to these materials is dependent on serum protein adsorption, which has not been examined for such cellulosic hydrogels. Thus, this study investigated the effect of hydrogel compressive modulus and charge on surface protein adsorption *in vitro* by varying MC and CMC fractional composition, macromer concentration, and molecular weight.

MC and CMC were functionalized by esterification of hydroxyl groups with methacrylic anhydride and gels were fabricated via free radical polymerization using ammonium persulfate and ascorbic acid redox initiators<sup>2</sup>. Hydrogel hydrophobicity/charge was varied by mixing combinations of MC and CMC, while the modulus was altered by changing the macromer concentration (3% & 6%, w/v) and molecular weight (90, 250 kDa CMC). Generally, concentration was the largest driver of gel stiffness as indicated by compressive moduli ranging from 5.8±1 kPa to 19.9±3 kPa for the 3% group and 59.3±3 kPa to 90.6±32 kPa for the 6%. Relatedly, stiffer gels exhibited less swelling as measured by the equilibrium weight swelling ratio ( $W_{wet}/W_{dry}$ ), with the 6% gels yielding lower values on average. Within a concentration group, charge played a clear role on swelling. For the 3% gels, the CMC only (negatively charged) gels yielded the highest ratio of 41±9, the MC only (hydrophobic) gels the lowest at 22±0.7, and a 1:1 mix of the two polymers was in between (ratio of 36±7). Interestingly, there was an inverse relationship between serum protein adsorption and gel modulus where every 3% gel formulation promoted more adsorption than its 6% macromer counterpart. Adsorption was also affected by charge, as no more than 63±11 µg/mL of protein was measured on MC gels, whereas the CMC only gel values ranged from 138±24 to 568±155 µg/mL.

Tailoring an injectable device is crucial for successful tissue incorporation. Long-term implants often suffer from sustained foreign body responses that may result in dense fibrous tissue encapsulation, and surface protein adsorption is a precursor to this adverse outcome<sup>3</sup>. Thus, the effects of biomaterial stiffness and charge on adsorption are often investigated and are material specific<sup>4,5</sup>. These findings represent an improved understanding of cellulosic materials and are currently being investigated for correlations to *in vivo* foreign body reaction and potential fibrous encapsulation.

**A Fillable Scaffold Mimicking Extracellular Matrix for Chronic Tunnelling Wound Healing** Xiaoyu Wang<sup>1</sup>, Sigen A<sup>2</sup>, Hongyun Tai<sup>3</sup> and Wenxin Wang<sup>1</sup>; <sup>1</sup>Charles Institution of Dermatology, School of Medicine, University College Dublin, Ireland; <sup>2</sup>School of Medicine, Anhui University of Science and Technology, China; <sup>3</sup>Blafar Ltd, Ireland

Chronic wounds impose significant social and financial costs for patients and healthcare systems. Pathogenic abnormalities and hostile wound environments, such as inflammation, and augmented levels of Matrix metalloproteinases (MMPs) render the healing of chronic wounds a major and long-term challenge. Most commercial wound dressings are aimed to target a single non-healing factor, only a few are tailored to the multiple pathological abnormalities of chronic wounds and even fewer are suitable for tunnelling chronic wounds due to the difficulty in making adequate contact with wound beds. Herein, a novel fillable wound matrix mimicking extracellular matrix was fabricated by crosslinking gelatin and glycosaminoglycan *via* Schiff's base reaction to inhibit the inflammatory response, and inactivate excessive MMPs, ultimately promoting chronic wound healing. The degradation rates, pore size, swelling profile, cytotoxicity, cell proliferation and migration were investigated. Highly promoted cell adhesion and proliferation, and significantly improved migration of fibroblasts demonstrated that this fillable scaffold could provide a scaffold for cellular invasion and promote wound healing. It is easy to apply in difficult-to-access tunnelling wounds, indicating the promising potential in treating chronic tunnelling wounds. Moreover, the validation of sterilisation and virus inactivation laid the foundations for the commercialization of this fillable wound matrix.

**Silicone Cryogel Skeletons for Enhanced Survival and Mechanics of Hydrogel-Based Implantable Cell Therapies** William J. Jeang<sup>1,2</sup>, Matthew A. Bochenek<sup>1,2</sup>, Suman Bose<sup>1,2</sup>, Yichao Zhao<sup>1</sup>, Bryan M. Wong<sup>1</sup>, Jiawei Yang<sup>1,2</sup>, Alexis L. Jiang<sup>3</sup>, Robert Langer<sup>1,2</sup> and Daniel G. Anderson<sup>1,2</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Boston Children's Hospital, United States; <sup>3</sup>Wellesley College, United States

The transplantation of cells engineered to secrete therapeutic proteins presents a promising method to address a range of chronic diseases including diabetes, cancer, and blood disorders. However, clinical translation faces several challenges regarding immune rejection, adequate nutrient supply to therapeutic cells, and the mechanical integrity of delivery constructs. Typically, non-degradable hydrogels are used to encase and protect therapeutic cells from immune rejection while still permitting the exchange of nutrients and therapeutics. However, a critical tradeoff exists wherein improving hydrogel mechanics (e.g., by increased crosslinking or molecular weight) often compromises biocompatibility and diffusion. Consequently, the design of macroscale, retrievable hydrogel devices often must balance the risks of mechanical failure and poor viability of encapsulated cells.

We address this challenge through a composite materials system centered around an oxygen-permeable silicone cryogel, which acts as an internal skeletal support for conventional hydrogel matrices coated by an anti-inflammatory polyelectrolyte for alleviating immunological responses towards foreign objects. We show that integration of the skeletal structure dramatically improves mechanical properties and effectively mitigates fracturing of implanted devices. Notably, our approach forgoes the use of commonly employed external housings, which can impede both the transport of nutrients to cells and the release of therapeutics to the host. By contrast, the skeleton leverages the superior oxygen diffusivity of silicone elastomers and a judiciously designed microstructure to improve the oxygenation of encapsulated cells. Fluorescence microscopy reveals that the skeleton acts as an internal scaffold that guides cellular proliferation and results in favorable changes in cell morphology. Pre-clinical studies demonstrate that these functionalities translate to significantly enhanced protein secretion from genetically engineered, xenogeneic cells in immunocompetent animals over 4 weeks, without the need for immunosuppression.

The resulting technology drives important improvements in the efficacy and practicality of implantable cell therapies. Namely, superior materials mechanics translates to easier device handling and reduces risk of mechanical failure, while the ability to sustain denser cell populations enables miniaturization of therapeutic implants. With the capability to modify encapsulated transgenic cells to secrete different biologics, the presented platform promises to support a broad spectrum of protein replacement therapies.

**Voxelated Bioprinting of Double-Network Hydrogel Scaffolds** Liheng Cai; University of Virginia, United States

Analogous to pixels to two-dimensional pictures, voxels — in the form of either small cubes or spheres — are the basic building blocks of three-dimensional (3D) objects. Here, we present a voxelated bioprinting technology that enables the digital assembly of interpenetrating alginate and polyacrylamide (PAM) double-network (DN) hydrogel droplets. The hydrogel is crosslinked via additive-free bioorthogonal chemistry involving a pair of stoichiometrically matched polymers. We develop theoretical frameworks to describe the crosslinking kinetics and stiffness of the hydrogels, and construct a diagram-of-state to delineate their mechanical properties. Multi-channel print nozzles are developed to allow on-demand mixing of highly viscoelastic bio-inks without significantly impairing cell viability. Further, we showcase the distinctive capability of voxelated bioprinting by creating highly complex 3D structures such as a hollow sphere composed of interconnected yet distinguishable hydrogel particles. Finally, we validate the cytocompatibility and *in vivo* stability of the printed DN scaffolds through cell encapsulation and animal transplantation.

#### 8:00 PM SB09.03.32

**Conductive Biodegradable Elastomeric Scaffolds for Bladder Regeneration** Rebecca Keate<sup>1</sup>, Matthew Bury<sup>2</sup>, Jonathan Rivnay<sup>1</sup>, Arun Sharma<sup>2</sup> and Guillermo Ameer<sup>1</sup>; <sup>1</sup>Northwestern University, United States; <sup>2</sup>Lurie Children's Hospital of Chicago, United States

Electrically conductive polymers are a unique class of materials that have demonstrated promising potential to enhance regeneration in several systems including muscle, skin, and neural tissue. The capability to bolster repair in a variety of tissue systems makes conductive polymers a promising material for advanced tissue engineering applications, such as organ regeneration, that require synergistic repair with various cell lineages. One such organ that could benefit from advanced repair solutions is the bladder, the function of which is impaired in cases such as neurodegenerative disorders, cancer or injury. Conductive polymers have not been used for bladder regeneration, in part due to the difficulties of incorporating conductive polymers in a mechanically robust tissue engineering solution. One reason for this loss of material integrity is the inherent phase mismatch between hydrophobic conductive polymers and the primarily hydrophilic biomaterials they are integrated within. Furthermore, we sought to mitigate these shortcomings by adopting a phase-compatible functionalization approach wherein the hydrophobic conductive polymer is embedded within a similarly hydrophobic biomaterial. Citrate-based materials are one such class of hydrophobic biomaterials with excellent bioactivity, morphological versatility, and degradability. By utilizing an *in situ* polymerization of the conductive polymer poly(3,4-ethylenedioxythiophene) in conjunction with citrate-based elastomers, we are able to preserve the intrinsic benefits of the base material including its powerful antioxidant activity, biocompatibility, and mechanical durability. We further demonstrate the applicability of this material in a bladder augmentation model, comparing our PEDOT-citrate based films to cell-seeded citrate-based counterparts. Analyzing regenerated bladder function through urodynamics studies, we find that PEDOT-incorporated films facilitate repair significantly compared to the cell-seeded films and significantly better than the pristine citrate-based film. Furthermore, this work demonstrates (1) advantages of a phase-compatible functionalization approach from a materials-perspective, (2) application of conductive polymer-based materials in a novel regenerative system, and (3) the capabilities for conductive polymers to promote regeneration as effectively as a cell-seeded material.

SESSION SB09.04: Biomaterials for Regeneration of Tissues

**Ultrasound-Responsive Engineered Tissue Constructs for Remote Manipulation of Cell Signaling** Katherine T. Huynh, Mary K. Lowrey, Sara Evans-Dutson, Kevin Schilling, Danielle S. Brasino, Mithila Handu, Sean Speese and Carolyn Schutt Ibsen; Oregon Health and Science University, United States

The controlled presentation of cell signaling proteins in time and space is critical for coordinating biological processes that regulate tissue regeneration. There is a need to recreate and harness these complex dynamic processes within 3D cell scaffolds to better understand their biological roles and provide new regenerative therapies. Manipulating gene expression of targeted cells at specific times and locations within these scaffolds enables controlled protein presentation within a 3D tissue construct. This is a critical tool to control cell behavior and influence cell interactions, including those involved in tissue vascularization and wound repair. These genetic manipulations are difficult to achieve in 3D using traditional transfection methods due to diffusional barriers created by the scaffold itself. To address this challenge, our team has pioneered the development of ultrasound-responsive cell culture platforms

(SonoScaffolds) for noninvasive and spatiotemporally-controlled genetic manipulation of cells in 3D scaffolds. Here, focused ultrasound interacts with integrated echogenic particles within hydrogel matrices to locally deliver nucleic acids to cells to manipulate protein expression and secretion. Ultrasound has distinct advantages as a triggering stimulus as it can be focused to small volumes with multi-centimeter tissue penetration depth [1-2].

Using this approach, we have successfully demonstrated ultrasound-induced transfection of cells embedded in SonoScaffolds, including localized expression of vascular endothelial growth factor (VEGF). A dual expression VEGF-GFP fusion plasmid was coupled to lipid-based ultrasound-responsive microparticles and incorporated into a cell-seeded collagen hydrogel. Focused ultrasound (1 mm<sup>3</sup> focal zone) was applied noninvasively within the hydrogel matrix. Transfection of matrix-embedded cells was localized to the ultrasound-exposed region. The cells showed a punctate distribution of VEGF-GFP consistent with packaging of VEGF into secretory vesicles. Creating user-defined 3D spatiotemporal patterns of growth factor expression can be leveraged to elucidate how spatial presentation and timing of protein expression affect 3D cell migration and to inform therapeutic strategies for tissue repair.

Pushing the boundaries even further, we are creating ultrasound stimuli-responsive scaffolds with complex 3D architectures by integrating our echogenic gene delivery particles into 3D-bioprintable inks. Transfection was selectively activated by ultrasound within printed constructs, demonstrating the first cell-seeded bioprinted structure designed for ultrasound-controlled gene delivery. We are further extending this technique to 3D-printed spheroids and organoid cultures. Together, this work demonstrates a new class of 3D-programmable cell culture materials that enable remote, spatiotemporally-defined genetic perturbation of embedded cells and multicellular structures. These systems will provide new insights into coordinated cell processes and how growth factor presentation can be leveraged to direct healing in implantable biomaterials, with important applications in tissue construct maturation, vascularization, and tissue regeneration.

#### 8:45 AM SB09.04.03

**Shape Memory Polymer Bioglass Composite Scaffolds to Heal Complex Bone Defects** Brandon M. Nitschke, Alexander E. Konz, Elizabeth A. Butchko, MaryGrace N. Wahby and Melissa Grunlan; Texas A&M University, United States

Craniofacial (CMF) defects are generally treated with autografts, but difficulty achieving a conformal fit with can lead to premature graft resorption. Thus, we have developed shape memory polymer (SMP) scaffolds that can “self-fit” into irregularly shaped CMF defects. These are formed from biodegradable *linear*-poly( $\epsilon$ -caprolactone) diacrylate (*linear*-PCL-DA), with crystalline lamellae serving as switching segments ( $T_m = \sim 55$  deg C) and crosslinks acting as netpoints. After exposure to warm saline ( $\sim 55$  deg C), the scaffold becomes malleable, allowing press-fitting into an irregular defect before cooling to body temperature restores its rigid state. Herein, SMP scaffold composition was systematically tailored to enhance thermal tissue safety, degradation rate, modulus, and bioactivity. *Star*-architectures of constituent polymers and inclusion of bioactive Bioglass (BG) were utilized to achieve these properties. To reduce the self-fitting temperature, SMP scaffolds were formed from *star*-PCL-tetraacrylate (*star*-PCL-TA;  $T_m = \sim 45$  deg C). Furthermore, to accelerate degradation and tune modulus, semi-interpenetrating networks (semi-IPNs) were formed by including *linear*- or *star*-poly(L-lactic acid) (PLLA). 45S5 BG is known to induce hydroxyapatite (HAp) mineralization that subsequently promotes osteogenic differentiation (i.e., osteoinductivity) as well as osseointegration. Scaffolds were prepared from *linear*-PCL-DA or *star*-PCL-DA, as well as each with *linear*- or *star*-PLLA (75:25 wt% ratio). BG was incorporated at varying levels into scaffolds (up to 30 wt%) during fabrication. The BG content was confirmed using thermal gravimetric analysis (TGA). The compressive mechanical properties of the scaffolds were evaluated, as well as the *in vitro* degradation behavior. Notably, composite scaffolds exhibited rapid formation (24 hours) of HAp when exposed to simulated body fluid (SBF) as confirmed by SEM/EDS. Overall, these composite SMP scaffolds are expected to provide enhanced healing of complex bone defects.

#### 9:00 AM \*SB09.04.04

**In Vitro Engineered Tissue Screens for Cardiac Regeneration** Nenad Bursac; Duke University, United States

Cell and gene therapies for heart regeneration represent a promising approach to remuscularize the heart following myocardial injury. These regenerative therapies can benefit from *in vitro* chemical and genetic screens in engineered heart tissues to identify and study novel inducers of cardiomyocyte (CM) proliferation. Our recent screens in neonatal rat and human iPSC-derived CMs have identified activations of the mitogen activated protein kinase (MAPK) pathway and pentose phosphate pathway (PPP) as two promising strategies with pro-proliferative effects in engineered cardiac tissues (ECTs). Specifically, a doxycyclin-inducible, CM-specific expression of constitutively-active mutant of BRAF (BRAF-V600E), a major kinase in the MAPK pathway, was sufficient to induce CM cycling in ECTs, but resulted in functional decline and tissue stiffening. These adverse functional effects were associated with broad transcriptional changes, a shift to glycolytic metabolism, and induction of a pro-migratory CM phenotype. While ERK activation was required for the initial establishment of the caBRAF-induced phenotype, inhibition of ERK after the phenotype had been established was insufficient to restore the loss of tissue function. Transient caBRAF expression in ECTs rapidly induced CM cycling that preceded functional decline, which was reversible only if MAPK activation was brief (<3 days). Notably, the increase in ECT stiffness resulting from sustained caBRAF expression was dispensable for induction of CM cycling, as transient caBRAF expression yielded increased CM cycling without altered stiffness. Furthermore, in an independent *in vitro* CRISPR/Cas9 knockout screen, we identified adenosine deaminase knockout (ADA-KO) as the most effective inducer of CM cycle activity in neonatal rat ECTs and long-term cultured hiPSC-CMs. RNA sequencing of ADA-KO vs. control ECTs and measurements of metabolite abundance and enzyme activity suggested lactate generation and PPP upregulation as potential drivers of CM proliferation. Inhibition of the PPP rate-limiting enzyme glucose-6-phosphate dehydrogenase (G6PD) via the small molecule inhibitor 6-aminonicotinamide prevented ADA-KO induced CM cycling, while increased PPP activity *via* doxycycline-inducible lentiviral G6PD overexpression yielded a significant increase in CM cycling. Overall, our studies demonstrate the utility of *in vitro* engineered cardiac tissues as a testbed for identification of novel CM mitogens with potential for use in cardiac regenerative therapies.

#### 9:30 AM SB09.04.05

**3D Bioprinting of Dense Cellular Structures within Functional Hydrogels with User-Defined Heterogeneity** Alperen Abaci and Murat Guvendiren; New Jersey Institute of Technology, United States

3D bioprinting has a strong potential to address tissue and organ shortage for transplantation. Successful fabrication of a functional tissue requires bioprinting strategies that can replicate the biological and structural features of the native tissue including formation of dense cellular structures. Embedded 3D printing approaches advanced extrusion-based bioprinting technology for fabrication of architecturally and biologically complex structures, yet this technology requires the use of support baths which generally hinders the relevant bioactivity and heterogeneity. In this study, we developed a new method to create dense cellular structures where cell-only bioinks could be deposited into photocurable support hydrogels with tunable stiffness, degradation and bioactivity. Our approach can utilize multiple cell types or functional hydrogels to create highly heterogeneous and complex structures that could potentially be used to fabricate functional tissue models, as well as tissue interfaces, with relevant biochemical and physical complexities.

In this study, we demonstrate bioprinting of dense cellular structures using fibroblasts (NIH 3T3), human umbilical vein endothelial cells (HUVECs), and human mesenchymal stem cells (hMSCs) within support or functional hydrogels. To demonstrate the potential of our approach and importance of matrix functionalization, we investigate the osteogenic differentiation of hMSCs bioprinted within MeHA hydrogels with controlled stiffness and bioactivity. To control stem cell aspect ratio initial concentration of the MeHA hydrogel is varied (5-15%). Bioactivity is varied by tethering RGD and BMP-2. Dense hMSCs structures show great overall cell viability (>80%) and inclusion of RGD and then BMP-2 significantly enhanced osteogenic differentiation. This is confirmed with ALP assay, Alizarin Red staining and osteocalcin immunostaining. Finally, we fabricated dense cellular structures with spatially controlled cellular composition and matrix composition towards creating tissue interfaces.

**Conflict of Interest:** New Jersey Institute of Technology has a financial interest in the bioprinting approach reported in this manuscript and has already filed a patent application for the technology described in this paper (U.S. Application No. 17/588,998).

**Acknowledgements:** We acknowledge the funding from NSF/DMR - CAREER 2044479.

**Materials for Engineering Cartilage Integration** [Helen Lu](#); Columbia University, United States

Musculoskeletal joint motion is facilitated by synchronized interactions between multiple tissue types and the seamless integration of bone with soft tissues such as tendons, ligaments or cartilage. Many of these soft tissues transit into bone through a multi-region interface that minimizes the formation of stress concentrations while enabling load transfer between soft and hard tissues. Given its functional significance, re-establishment of multi-tissue interface is thus critical for promoting the integrative repair of biological as well as tissue engineering cartilage grafts. To this end, interface regeneration and formation of composite tissue units have become a design consideration in tissue engineering. Using the classic osteochondral interface as an example and inspired by current understandings of the native interface structure-function relationship, strategies for interface regeneration and homeostasis will be discussed, with the focus on strategic biomimicry and functional multi-tissue integration.

**Development of a Biomimetic Multi-Layered Functionalised Antimicrobial Biomaterial Scaffold for Healing of Complex Wounds** [Matthew McGrath](#)<sup>1,2</sup>, Juan Carlos Palomeque-Chávez<sup>1,2</sup>, Shane Browne<sup>1</sup> and Fergal J. O'Brien<sup>1,2,3</sup>; <sup>1</sup>Royal College of Surgeons in Ireland, Ireland; <sup>2</sup>Advanced Materials and Bioengineering Research Centre (AMBER), RCSI and TCD, Ireland; <sup>3</sup>Trinity Centre for Biomedical Engineering, TCD, Ireland

Diabetic foot ulcers (DFUs) are chronic non-healing wounds that constitute one of the most devastating complications of diabetes. Dysfunctional angiogenesis plays a key role in DFU, limiting tissue repair leaving wounds open and prone to infection<sup>1</sup>. Biomaterial approaches, and in particular the use of collagen-glycosaminoglycan (CG) scaffolds, have shown promise to promote tissue regeneration and burn wound healing<sup>2</sup>. These biomaterial scaffolds provide a platform for infiltrating cells into the wound environment but do not directly deal with the underlying pathology of diabetic wounds, so further functionalisation is needed for these complex wounds. The aim of this project was to engineer a biomimetic bi-layered biomaterial scaffold designed to replicate the anatomical structure of the native skin with an epidermal antimicrobial collagen/chitosan film to prevent wound infection and a pro-angiogenic, matrix molecule functionalised dermal porous CG scaffold layer to heal complex wounds.

A bi-layered scaffold was developed by combining an antimicrobial collagen/chitosan film (0.5%, 1% / 0.75%) with a type I collagen, chondroitin-6-sulfate slurry by lyophilisation. Mechanical properties, including interlayer adhesion, were optimised through the film's collagen content and crosslinking treatment (non-crosslinked (NXL)/dehydrothermal/carbodiimide EDAC crosslinking). The CG layer was then functionalised with either fibronectin, collagen IV, or laminin-1 to enhance its angiogenic and regenerative potential. The film's antimicrobial potential was tested versus *staphylococcus aureus*, and the ability of the film to support re-epithelialisation was verified through seeding of human epidermal keratinocytes (HaCaTs). The vascularisation potential of the scaffold was investigated through the culture of human umbilical vein endothelial cells (HUVECs), and human dermal fibroblasts (HDFs) on the functionalised CG scaffold layer.

The bi-layered scaffolds had enhanced mechanical properties suitable for implantation following EDAC crosslinking (compressive modulus =  $1.83 \pm 0.0035$  kPa (EDAC),  $0.72 \pm 0.15$  kPa (NXL)) adhesion strength between layers =  $32.3 \pm 4.5$  kPa (EDAC),  $22.5 \pm 8.8$  kPa (NXL)) Biological characterisation showed that all collagen/chitosan films had antimicrobial activity versus *staphylococcus aureus* regardless of crosslinking regime and collagen composition and supported the metabolic activity of human epidermal keratinocytes. However, crosslinked scaffolds showed enhanced infiltration and growth of vascular cells<sup>3</sup>. Functionalisation, of the CG layer with laminin-1 significant increased production of vascular endothelial growth factor (VEGF) by HDFs over 7 days ( $1044 \pm 112$  pg/ml). In addition, HUVECs seeded on these scaffolds formed tubular structures.

This study has led to the development of a novel biomimetic multi-layered functionalised antimicrobial biomaterial scaffold for complex wound healing. The collagen/chitosan film layer demonstrated the ability to inhibit growth and infiltration of *staphylococcus aureus*, the most common bacterial isolate found in infected wounds<sup>4</sup> and supported metabolic activity of epidermal cells, demonstrating significant potential as a protective barrier to cover the wound and as a surface for re-epithelialisation. Functionalisation of the CG scaffold layer with laminin-1 enhanced the pro-angiogenic regenerative potential of the dermal CG scaffold layer, with increased growth factor production and vascular cell tube formation. Taken together, these results demonstrate the promise of this scaffold as a biomaterial-based solution to treat DFUs.

**A Versatile, Bioengineered Skin Reconstruction Device Designed for Austere Environments** Joachim G. Veit, Morgan Weidow and [Monica Serban](#); University of Montana, United States

Austere environments in which access to medical facilities, medical personnel, or even water and electricity is limited or unavailable pose unique

challenges for medical device product design. Currently existing skin substitutes are severely inadequate for the treatment of severe burns, chronic wounds, battlefield injuries, or work-related injuries in resource-limited settings. For such settings, an ideal device should be biocompatible, bioresorbable, promote tissue healing, not require trained medical personnel for deployment and use, and should enable topical drug delivery. As proof of concept for such a device, silk fibroin and an antioxidant hyaluronic acid derivative were chosen as primary constituents. The final formulation was selected to optimize tensile strength while retaining mechanical compliance and protection from reactive oxygen species (ROS). The ultimate tensile strength of the device was 438.0 KPa. Viability of dermal fibroblasts challenged with ROS-generating menadione decreased to 49.7% of control, which was rescued by pre-treatment with the hyaluronic acid derivative to 85.0% of control. The final device formulation was also tested in a standardized, validated, *in vitro* skin irritation test which revealed no tissue damage or statistical difference from control. Improved topical drug delivery was achieved via an integrated silk fibroin microneedle array and selective device processing to generate crosslinked/through pores. The final device including these features showed a 223% increase in small molecule epidermal permeation relative to the control. Scaffold porosity and microneedle integrity before and after application were confirmed by electron microscopy. Next, the device was designed to be self-adherent to enable deployment without the need of traditional fixation methods. Device tissue adhesive strength (12.0 MPa) was evaluated and shown to be comparable to a commercial adhesive surgical drape (12.9 MPa) and superior to an over-the-counter liquid bandage (4.1 MPa). Finally, the device's wound healing potential was assessed in an *in vitro* full-thickness skin wound model which showed promising device integration into the tissue and cellular migration into and above the device. Overall, these results suggest that this prototype, specifically designed for use in austere environments, is mechanically robust, is cytocompatible, protects from ROS damage, is self-adherent without traditional fixation methods, and promotes tissue repair.

### 11:30 AM SB09.04.09

**Development of Antibiotic-Free Antimicrobial Scaffolds for Effective Delivery of Osteogenic & Angiogenic MicroRNAs to Simultaneously Treat and Repair Infected Bone Tissue** [Joanna Sadowska](#)<sup>1</sup>, Katelyn Genoud<sup>1</sup>, Rachael Power<sup>1</sup>, Austyn Matheson<sup>1</sup>, Arlyng González-Vázquez<sup>1</sup>, Lara Costard<sup>1</sup>, Tanguy Hallegouet<sup>2</sup>, Gang Chen<sup>1</sup>, Brenton Cavanagh<sup>1</sup>, Huijun Zhang<sup>3</sup>, Aldo Boccaccini<sup>3</sup> and Fergal O'Brien<sup>1</sup>; <sup>1</sup>Royal College of Surgeons in Ireland, Ireland; <sup>2</sup>University of Strasbourg, France; <sup>3</sup>Friedrich-Alexander University Erlangen-Nuremberg, Germany

**INTRODUCTION:** The treatment of bacterial infection of bone while regenerating bone at the same time is extraordinarily challenging in clinical settings (1). The escalating problem of antimicrobial resistance necessitates the development of novel antibiotic-free strategies to eradicate bacteria. One such approach is the use of metal-doped nanoparticles (2). To address bone regeneration, the approaches include the local delivery of gene therapies, such as microRNA in scaffold systems. A scaffold provides structural support while microRNA induces host cells to produce multiple angiogenic and osteogenic proteins essential for bone healing (3). The present study combines these two promising approaches to develop a multifunctional biomaterial-based platform with angiogenic, osteogenic and antimicrobial properties. The scaffold delivers osteogenic genes (by delivering antagomiR-138, a microRNA targeting ERK pathway) (4) and antibiotic-free antimicrobial nanoparticles (copper-doped bioactive glass, CuBG) (2), leading to a novel platform with superior therapeutic potential and angiogenic, osteogenic and antimicrobial features.

**METHODS:** Freeze-dried collagen-based scaffolds, previously optimized in our lab for bone regeneration (3), were enriched with antagomiR-138 and CuBG nanoparticles and assessed *in vitro* using human mesenchymal stem cells (transfection efficacy, osteogenic and angiogenic gene expression, metabolic activity, DNA content, alkaline phosphatase activity, calcium deposition). The antimicrobial properties of the scaffolds were assessed using gram-positive (*S.aureus*) and gram-negative (*E.coli*). The angiogenic and osteogenic properties of the scaffolds were assessed in two *in vivo* models: a load-bearing 5 mm femoral defect in female Sprague Dawley rats and a chick chorioallantoic membrane model (CAM).

**RESULTS SECTION:** The CuBG and antagomiR-138 particles were effectively incorporated into collagen scaffolds without affecting the mechanical and structural properties of the scaffolds. The CuBG scaffolds reduced the adhesion of *S.aureus* and *E.coli* 5-fold and 2-fold, respectively. The antagomiR138 and-CuBG functionalised scaffolds effectively transfected hMSCs *in vitro*, enhancing the osteogenic (COLL1A2, NOCH4, SMAD5) and angiogenic genes (VEGFA) and calcium production. The *in vivo* assessment showed that antagomiR-138 scaffolds promoted enhanced healing in the femoral defect model by producing endochondral ossification. The antagomiR138-CuBG scaffold promoted vasculogenesis, improving the number of branches and the length of blood vessels in *in vivo* CAM model.

**DISCUSSION:** The study demonstrated the therapeutic potential of a multifunctional, antagomiR138 antimicrobial scaffold system. The system delivered antagomiR138 to hMSCs *in vitro*, enhancing the osteogenic genes and mineralisation. The incorporation of CuBG nanoparticles enhanced antimicrobial mechanisms (production of ROS) in *S.aureus* and *E.coli*, inhibiting the attachment to the scaffold. The antagomiR138 scaffolds improved osteogenesis and vasculogenesis *in vivo* in a femoral defect model and a chick chorioallantoic membrane model, respectively. Our work demonstrates, for the first time, the feasibility of combining non-antibiotic biomaterial based-approaches with gene therapeutics for developing a platform which not only regenerates bone but also fights rising problems of antimicrobial resistance. This approach opens the door to new possibilities in a myriad of indications beyond bone repair.

**A Decellularized Cartilage Biomaterials Approach to Pediatric Airway Reconstruction** Paul Gehret<sup>1,2</sup>, Soheila Ali Akbari Ghavimi<sup>2</sup>, Alexandra Dumas<sup>1,2</sup>, Ryan Borek<sup>2,1</sup>, Ian Jacobs<sup>2,1</sup> and [Riccardo Gottardi](#)<sup>1,2</sup>; <sup>1</sup>University of Pennsylvania, United States; <sup>2</sup>Children's Hospital of Philadelphia, United States

**Introduction:** Severe subglottic stenosis (SGS), the narrowing of the airway just below the vocal folds, develops in 8.3% of ICU neonates and directly leads to debilitating comorbidities [1,2]. Pediatric SGS is the result of prolonged intubation and dramatically lowers the child's long-term quality of life, as they often suffer speech and cognitive delays. In the most severe cases, laryngotracheal reconstruction (LTR) surgery is required to expand the airway and

restore airflow [1,2]. During LTR, autologous costal cartilage is harvested, shaped, and implanted into the child's airway. However, a major obstacle is that young children often lack sufficient costal cartilage to ensure a successful graft surgery, leading to donor site morbidity and high risk for restenosis, necessitating revision surgery<sup>3</sup>. Our objective is to utilize xenogeneic decellularized meniscal cartilage (MEND) to engineer a cartilage implant populated with patients' cells to circumvent the limitations of pediatric autologous cartilage.

**Materials and Methods:** *Meniscus decellularization and channel formation:* Meniscus cross-sections were devitalized with 4 freeze/thaw cycles then subjected to pepsin and acetic followed by treatment with elastase. 6 mm cylinders were created with a biopsy punch from the posterior half of the digested cross-sections to ensure the maximum number of channels. *Decellularized Meniscus Reinvasion:* Sterile decellularized, digested meniscus (MEND) cylinders were placed on top of the membrane insert of a transwell plate and cartilage progenitor cells (CPC) were seeded on top of the MEND cylinders. After 3 days, the MEND cylinders were fixed, sectioned, and stained. *In Vitro Differentiation:* CPC-invaded MEND were cultured in chondrogenic medium for 3 weeks and media was renewed twice/week. The differentiated construct were examined for gene expression, compression testing, and histology. *Rabbit Laryngotracheal Reconstructions:* Acellular, re-cellularized, or differentiated decellularized cartilage was implanted in an anterior cricoid split LTR. After 3 months, the rabbits were euthanized and the construct phenotype, airway expansion, and histomorphometry were assessed. **Results and Discussion:** After enzymatic treatment, H&E images of circumferential sections showed that clearly aligned channels are visible post-treatment. Following a serum gradient (transwell) migration, cartilage progenitor cells (blue DAPI nuclei) penetrated in 3 days through the channels the entire depth of the construct (collagen red auto-fluorescence) reaching a density similar to that of native cartilage. After 3 weeks of differentiation, cells were arranged into lacunae with columnar structures resembling the organization of native cartilage and secreted a substantial amount of glycosaminoglycans (GAGs). Importantly, the constructs increased in both bulk mechanical strength and GAG content. Finally, a 38 rabbit study was conducted and MEND was implanted in a rabbit LTR. MEND successfully expanded the airway over the course of the 3 months and integrated with the existing cartilage as shown by the increase of GAGs within the construct and the neo-chondrification protruding from the cartilage rings. We established how decellularized meniscal cartilage reinvaded with progenitor cells can significantly improve outcomes for pediatric LTR.

**Ethical Statement:** All animal studies were conducted with IACUC approval.

**Magneto-Responsive Silk Microfibers for Neuroregeneration** Jeannine Coburn and Melissa Wojnowski; Worcester Polytechnic Institute, United States

Magneto-responsive fiber-based architectures represent an exciting prospect in the development of hierarchically ordered tissue engineering scaffolds, facilitating non-invasive, in situ spatiotemporal manipulation and organization of regenerative cues via an externally applied magnetic field. [1] While magneto-responsive fiber architectures are typically fabricated from magnetic nanoparticle (MNP)-doped polymeric solutions, risks of MNP leaching and subsequent cytotoxic intracellular accumulation remain unaddressed. To this end, chelation of paramagnetic ferric iron ions ( $\text{Fe}^{3+}$ ) is a promising alternative to MNP-doping. [2] Given its innately fibrous structure, notable capacity for heavy metal chelation, and FDA-approval as a biocompatible, biodegradable, naturally derived biomaterial [3, 4], silk fibroin extracted from *Bombyx mori* silkworm cocoons offers a unique, unexplored opportunity to fabricate MNP-free magneto-responsive fiber architectures. In this work, passive chelation of ferric iron is explored as an MNP-free alternative in the magnetic functionalization of silk-based biomaterials. Silk fibroin microfibers (mSF) treated with aqueous ferric chloride ( $\text{FeCl}_3$ ) exhibit significantly increased iron content relative to the nascent protein as determined by x-ray photoelectron spectroscopy (XPS). Coupled with the absence of detectable chlorine traces and iron oxide species, the predominantly ferric oxidation state of iron within  $\text{FeCl}_3$ -treated mSF ( $\text{Fe}^{3+}$ -mSF) suggest incorporation of iron, without reduction, at innate oxygen-containing ligands of mSF. On exposure to an external magnetic field,  $\text{Fe}^{3+}$ -mSF displays paramagnetic magnetization behaviors that facilitate field-parallel alignment. Both magnetization and directional uniformity increased concomitantly with iron exposure during  $\text{FeCl}_3$  treatment, suggesting the observed magnetic response of  $\text{Fe}^{3+}$ -mSF is derived from the chelated iron. In vitro biocompatibility of the  $\text{Fe}^{3+}$ -mSF has been confirmed using human dermal fibroblasts and neuroprogenitor cells (NPCs). This work is the first to investigate the magneto-responsive properties and biocompatibility of ferric iron chelated SF, demonstrating a novel, MNP-free alternative approach to magnetic functionalization of TE scaffolds. Ongoing work is underway to evaluate NPC alignment and axonal growth, differentiation, and function in response to the aligned guidance architecture.

### 8:00 PM SB09.06.01

**Microvascular Imaging in Brain Tumors by Supramolecular MR Contrast Agents** Atsushi Mahara<sup>1</sup>, Soni Raghav<sup>1</sup>, Shigeyoshi Saito<sup>2</sup> and Tetsuji Yamaoka<sup>1,3</sup>; <sup>1</sup>National Cerebral and Cardiovascular Center, Japan; <sup>2</sup>Osaka University Graduate School of Medicine, Japan; <sup>3</sup>Komatsu University, Japan

**[Introduction]** Magnetic resonance angiography (MRA) is used clinically to diagnose brain diseases. Although the MRA visualizes the main cerebral artery such as Willis arterial circle and middle cerebral artery without any contrast agents, it is hard to imagine the microvasculature and entire vascular network due to low MR signals. In our previous study, we developed the fluorescein and Gd-chelate conjugated 8-arm PEGs (8-arm PEG-FGd<sub>3</sub>) as the MRA contrast agents, and microvascular structure was enhanced on MRA scan by the administration of these contrast agents<sup>1,2</sup>. Here, we discuss the structural feature of the 8-arm PEG-FGd<sub>3</sub> and its blood circulating profile. Furthermore, the microvascular formation in the brain tumor would be presented.

**[Methods]** The 8-arm PEG conjugated with one fluorescein and three Gd-chelates (8-arm PEG-FGd<sub>3</sub>) was synthesized by the reported procedure<sup>2</sup>. Briefly, fluorescein isothiocyanate and 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) mono-N-hydroxysuccinimide ester were added into the 8-arm PEG with 15 kDa of the molecular weight. The polymers were purified by a dialysis membrane. After the addition of gadolinium, 8-arm PEG-FGd<sub>3</sub> was acquired. The products in each step were confirmed by <sup>1</sup>H-NMR. As the control, 8-arm PEG conjugated with one fluorescein (8-arm PEG-F) was also prepared. Structural features were estimated by dynamic light scattering analysis (DLS) and atomic force microscopy (AFM), and the molecular

environment of fluorescein was analyzed by fluorescence spectroscopy and <sup>1</sup>H-NMR measurements. The brain tumor in the SD-rat was scanned by 7T-MRI with or without contrast agents.

**[Results and Discussion]** The hydrodynamic radius of the 8-arm PEG was 6 to 8 nm within the concentration range from 0.5 to 100 mg/mL. On the other hand, the hydrodynamic radius of 8-arm PEG-FGd<sub>3</sub> largely depended on the polymer concentration. When the concentration of the 8-arm PEG-FG<sub>3</sub> was 1 to 5 mg/mL, the radius was approximately 7 nm. At the concentration ranges higher than 100 mg/mL, the radius was increased to over 1000 nm. As the results of AFM observation, nanoparticles, and fiber structure were observed at the concentration ranges from more than 100 mg/mL. The fiber was formed by the stacking of the nanoparticles. Spectroscopic analysis revealed that fluorescein groups of 8-arm PEG-FGd<sub>3</sub> were in the center part of the particle and stacked with the  $\pi$ -stacking interactions. The brain microvessel and tumors in rats were scanned on MRI. Microvasculature with a minimum diameter of 45  $\mu$ m was clearly visualized on MR images only when the 8-arm PEG-FGd<sub>3</sub> at the concentration of 200 mg/mL was administered. The microvessel structure in the tumors was also visualized with the supra-high resolution, and these data provided information on vascular permeability.

#### 8:00 PM SB09.06.02

**Rapamycin-Loaded Boronic Acid-Based Hydrogel as Artificial Perivascular Tissue for Prevention of Vascular Graft Failure** Hue T. Le<sup>1</sup>, Atsushi Mahara<sup>1</sup>, Takeshi Nagasaki<sup>2</sup> and Tetsuji Yamaoka<sup>1,3</sup>; <sup>1</sup>The National Cerebral and Cardiovascular Center Research Institute, Japan; <sup>2</sup>The Osaka Metropolitan University, Japan; <sup>3</sup>The Komatsu University, Japan

**Introduction:** Excessive proliferation of subendothelial smooth muscle cells (SMC) leads to anastomotic stenosis, resulting in an increase in graft failure rate, a big issue of vascular graft transplantation. Perivascular adipose tissue (PVAT), an adipose tissue adherent on the vessel's external surface, has been shown to inhibit the excessive proliferation of SMC via releasing biomolecules<sup>1</sup>. However, the PVAT is mostly absent in vascular grafts involving native and artificial ones. Phenylboronic acid (PBA)-based polymer has been reported to form a hydrogel with synthetic polyvinyl alcohol (PVA) and bind to cell membranes and tissue surfaces via PBA-sialic acid integration<sup>2</sup>. Rapamycin (RPM) has been clinically approved as an anti-stenosis drug because of its cell anti-proliferative ability<sup>3</sup>. Recently, we synthesized poly (3-acrylamidophenylboronic acid-co-acrylamide) (BAAm) polymer. In this study, we proposed RPM-loaded BAAm/PVA (BAVA) hydrogel serving as an artificial PVAT<sup>4</sup>, thus its tissue adhesive and drug release characterization and anti-SMC proliferative function were investigated. Furthermore, we tested its effectiveness on graft patency in a porcine model.

**Method:** Two hydrogels with 25 and 50 mg/mL of BAAm (named BAVA25 and BAVA50, respectively) were prepared. A decellularized vascular graft with 2.5mm in inner diameter was selected as the graft model<sup>5</sup>. To examine the tissue adhesive ability, the lap-shear test was done after loading the hydrogel on the graft's external surface. To assess drug release ability, the RPM-loaded BAVA hydrogel was immersed in PBS solution, and the released RPM was measured every day of 6d after incubation. To test the anti-cell proliferative function, the BAVA hydrogel with or without RPM was co-cultured with porcine SMC cells, then the cell viability was examined at 1d and 3d. Finally, a porcine carotid artery interposition grafting was performed. The external surface of the transplanted graft was then coated with the RPM-loaded BAVA hydrogel, and its graft patency was followed for six months by computer tomography.

**Result:** The BAVA25 and BAVA50 hydrogels could adhere to the graft surface, and their adhesion was stable for 15d after immersion in PBS solution. In the lap shear adhesion test, initial loading slope (1.5) of the BAVA25 hydrogels was similar to that (1.3) of the BAVA50 hydrogels, and the displacement at fraction point of the BAVA25 hydrogels was approximately two-fold higher than that of the BAVA50 hydrogels. As incubated in PBS solution, the BAVA25 and BAVA50 hydrogels released 83 and 73% of the initial loaded RPM within the first day. As co-cultured with SMC cells, the RPM-loaded BAVA25 and RPM-loaded BAVA50 hydrogels significantly reduced cell proliferation after one day and three days of incubation, respectively. In porcine experiments, the graft without any treatment or with RPM-loaded BAVA50 hydrogel was occluded within three days after transplantation. However, in three cases treated with RPM-loaded BAVA25 hydrogel, two grafts were patent for 10 and 17d and one graft was patent for at least 180d.

**Conclusion:** The BAVA25 hydrogel had a higher tissue adhesive and more rapid drug release potential than the BAVA50 hydrogel. By loading with RPM, the BAVA25 and the BAVA50 hydrogel showed the in-vitro anti-SMC proliferative function. In the porcine model, the RPM-loaded BAVA25 hydrogel effectively maintained the patency of small-diameter decellularized vascular grafts. The RPM-loaded BAVA25 hydrogel, as an artificial PVAT, might be a therapeutic approach for preventing graft occlusion by suppressing SMC proliferation.

**Design of High Throughput Techniques for Functional Medical Devices** Victor M. Villapun Puzas, Luke N. Carter, Daisy Rabbitt, Xue Cao, Billy Plant and Sophie Cox; University of Birmingham, United Kingdom

Since the early designs of medical devices, it has become apparent that implants should act as modulators of specific biological processes to ensure short- and long-term benefits<sup>1</sup>. Nevertheless, standard alloys used in orthopaedics have been repurposed from other industries (e.g. aerospace) as a consequence of their mechanical behaviour, corrosion resistance and biocompatibility. With increased life expectancy requiring longer service life of implantable devices and common alloying elements (e.g. aluminium or vanadium) demonstrated to negatively impact biological processes beyond cytotoxicity, it is clear that novel medical alloys should be developed to modulate clinical outcomes<sup>2</sup>. In this work, the difficulties of designing alloys for implantable devices will be contextualised, providing case studies focused on generating high throughput methods for their use in alloy development with especial attention on the advantages posed by metal additive manufacturing (AM) platforms.

When metallic elements are considered, there exist a plethora of materials with reported effects on biocompatibility, antimicrobial, angiogenic, osteogenic properties and/or their ability to modulate the innate and adaptive immune response<sup>3</sup>. Nevertheless, most effects been reported for single element compounds, reducing their direct correlation to complex alloys and calling for methods to rapidly evaluate biological properties. The first case study will showcase the development of high throughput techniques for both material processing and biological evaluation. The use of AM and novel Reduce Build Volume designs for Powder Bed fusion coupled with powder blending will be shown as a tool to enable the rapid evaluation of alloy systems for antimicrobial applications with conventional and AM Ti-Cu samples used to highlight their benefits over traditional casting. Microstructural variations were assessed through SEM imaging, X-ray diffraction and Vickers microhardness evaluation which were complemented with antimicrobial assays in model strains of *S. aureus* and *P. aeruginosa*. In addition, the power of powder compaction and HIP technologies will be harnessed to enable the rapid analysis of bacterial behaviour and antibiotic synergistic/antagonistic effects through the agar diffuse method and metabolic assays in model strains of Gram-positive and Gram-negative species to enable novel databases in the healthcare industry.

Besides combinations of different metallic elements, alloy design should consider the effect of microstructure and the manufacturing of complex alloys with significantly different processing parameters. Copper and Molybdenum are two elements that have shown promise to tackle antibiotic infection, nevertheless, their disparity in reflectivity or melting point has made their incorporation in titanium alloys a challenge from a manufacturing perspective. Herein, the use of AM, powder compaction and sintering will be used to demonstrate the possibility of providing novel alloys with highly different elemental properties and their use in multicomponent alloys. Through variations in composition and heat treatment, we successfully produced a blended

powder of two dissimilar elements which can be used to manufacture SLM parts with reduced input energies (133J/m instead of 300J/m)<sup>4</sup>. Similarly, the effect of microstructural variations with antimicrobial properties and eukaryotic cell line responses will be shown for the rapid optimisation of novel alloys.

### 8:00 PM SB09.06.04

**Therapeutic Mesoporous Cerium Oxide Nanoparticles for Modulating Excessive Oxidative Stress as a Treatment for Age-Related Macular Degeneration** Seung Woo Choi<sup>1</sup> and Jaeyun Kim<sup>2,3,2</sup>; <sup>1</sup>Seoul National University Bundang Hospital, Korea (the Republic of); <sup>2</sup>Sungkyunkwan University, Korea (the Republic of); <sup>3</sup>Samsung Advanced Institute for Health Sciences & Technology, Korea (the Republic of)

Age-related macular degeneration (AMD), the leading cause of vision loss in the elderly, is characterized by progressive visual impairment caused by destructive changes in the photoreceptor and retinal pigment epithelial cells (RPEs). Since reactive oxygen species (ROS) and chronic inflammation in the retina are believed to be essential contributors to AMD pathogenesis, the regulation of the ROS and inflammation levels may be effective therapeutic targets. As cerium oxide nanoparticles (CeNPs) have attracted attention due to good ROS scavenging activities mimicking the enzymatic activity of superoxide dismutase (SOD) and catalase, many researchers have studied to confirm the therapeutic efficacy of the CeNPs and apply these to treat clinical diseases in the biomedical fields. In addition, mesoporous materials have recently been spotlighted as versatile drug carriers and catalysts due to their high surface area and pore volume, therefore, some studies have been reported on the development of various forms of mesoporous CeNPs (mCeNPs). However, most of the previous reports have been derived from hydrothermal methods with harsh conditions, such as high pressure and temperature, and mainly focused on catalytic ability for industrial use, rather than biomedical applications. To combine the advantages of CeNPs and mesoporous materials, mCeNPs are simply synthesized by using the chemical reaction with 1,1'-carbonyldiimidazole and imidazole in acetone without the need for heating and pressurization. The mCeNPs exhibiting mesoporous structures with a pore size of 2.3 nm show good ROS scavenging properties, suitable biocompatibility for human RPEs and Raw264.7 cells (murine macrophage cells), and cytoprotective effect on RPEs against the harmful effect of high H<sub>2</sub>O<sub>2</sub>, as well as additional anti-inflammatory effects. In addition, the mCeNPs were intravitreally administrated to a NaIO<sub>3</sub>-induced AMD mouse model, and the mCeNP-treated group showed a partial salvage effect of at least 14 % in outer nuclear layer (ONL) thickness, indicating that mCeNPs protected RPEs from NaIO<sub>3</sub> injury by exerting a disease-preventive effect. In addition, the drug-carrying capacity of mCeNPs was demonstrated by loading indomethacin (IDM) as a model drug, and IDM-loaded mCeNPs exhibited an additional 17.3% reduction in interleukin-6 levels *in vitro* compared to the group treated with mCeNPs alone, suggesting that a synergistic anti-inflammatory effect when an additional drug is loaded onto mCeNPs, thereby enhancing their therapeutic potential. These findings suggest that mCeNP can be a therapeutic alternative or adjuvant for the treatment of AMD.

**Glycoprotein Hydrogel-Based Implantable Nerve Guidance Conduits for Peripheral Nerve Regeneration** Melis Ozkan<sup>1,2</sup>, Sujeet Pawar<sup>1</sup>, Xavier Navarro<sup>3,4,5</sup>, Francesco Stallacci<sup>1,6</sup> and Silvestro Micera<sup>2,7</sup>; <sup>1</sup>Institute of Materials, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland; <sup>2</sup>Bertarelli Foundation Chair in Translational Neural Engineering, Center for Neuroprosthetics and Institute of Bioengineering, Ecole Polytechnique Federale de Lausanne, Switzerland; <sup>3</sup>Department of Cell Biology, Physiology and Immunology, Institute of Neurosciences, Universitat Autònoma de Barcelona (UAB), Spain; <sup>4</sup>Institute Guttmann Foundation, Hospital of Neurorehabilitation, Badalona, Spain, Spain; <sup>5</sup>Centro de Investigación Biomédica en Red sobre Enfermedades Neurodegenerativas (CIBERNED), Spain; <sup>6</sup>Institute of Materials, Department of Bioengineering and Global Health Institute, École Polytechnique Fédérale de Lausanne (EPFL), Station 12, CH-1015 Lausanne, Switzerland, Switzerland; <sup>7</sup>Department of Excellence in Robotics & AI, Scuola Superiore Sant'Anna, Piazza Martiri della Libertà, Italy

Peripheral nerve injuries (PNIs) beyond the critical gap length pose a serious problem in neural tissue engineering and regenerative medicine. Research on effective therapeutic strategies has centered primarily on implantable nerve guidance conduits (INGCs) over the past several decades. A significant amount of progress has been made in INGC development. Still, the field has remained stagnant due to the lack of an optimal solution for ensuring target reinnervation accuracy, which requires a delicate balance of biochemical cues, including growth factors that govern tissue formation and regeneration throughout the regeneration process. In recent years, researchers have utilized heparin-based materials for sustained growth factor delivery owing to the intrinsic characteristic of heparin to bind and stabilize the growth factors through electrostatic interactions to afford more efficient regenerative outcomes. However, several shortcomings of heparin, such as immunogenicity, could hinder the successful clinical translation of heparin-based INGCs. For this reason, structurally well-defined synthetic mimics fulfilling the same function without triggering immune response are in demand. In this work, we introduce a silk fibroin-modified gelatin tyramine hydrogel matrix fabricated through enzymatic crosslinking. Both 2D-shaped (planar film) and 3D-shaped (tubular INGC) protein hydrogel scaffolds with the same composition were produced for *in vitro* and *in vivo* investigations, respectively. At the macroscale, silk fibroin modification facilitated enhanced mechanical strength to provide the native nerve tissue-like mechanical properties and prolonged the degradation time of the hydrogel implant. It acted as a biocompatible scaffold for Sprague Dawley rat Schwann cells (SCs). Then, we directed our efforts toward creating a small library of synthetic small-molecule heparin glycomimetics to address the limitations of native heparin. We synthesized monosaccharides and disaccharides with different sulfation patterns to conjugate to the hydrogel matrix covalently via a PEG linker for cellular-level nerve regeneration. The binding affinities of these synthetic heparin glycomimetics to nerve regeneration-promoting biochemical cues, namely, brain-derived neurotrophic factor (BDNF), nerve growth factor (NGF), and fibroblast growth factor 2 (FGF2), were screened using isothermal titration calorimetry (ITC) and surface plasmon resonance (SPR) techniques and our findings showed sulfation pattern-dependent binding affinity. The best-performing molecule was able to bind to NGF and FGF2 with acceptable affinity. We covalently conjugated this compound to the hydrogel matrix. Fluorescence assays and gel permeation chromatography (GPC) confirmed small molecule sugar conjugation to the hydrogel. Hydrogel scaffold, which bears small molecule heparin glycomimetic complexed with NGF, referred to as glycoprotein-based hydrogel, accelerated the neurite growth of Sprague Dawley rat dorsal root ganglion (DRG) neurons and extended retention time of NGF. Inspired by *in vitro* evaluations, we currently fabricated 3D tubular glycoprotein hydrogel-based INGCs (heavily grafted with our small molecule heparin glycomimetic and with native heparin having the same degree of grafting for comparison) to assess *in vivo* nerve regeneration in Sprague Dawley rat sciatic nerve defect model. Our final goal is long-term monitoring of INGC to unveil how heparin glycomimetics affect the cumulative release of NGF *in vivo* compared to native heparin and as well as to analyze the immunogenicity of both INGCs at the same degree of grafting. To the best of our knowledge, it is the first report systematically investigating the structure-activity relationship of small molecule heparin glycomimetics for *in vivo* nerve regeneration applications. This approach could be further extended to related regenerative medicine and tissue engineering disciplines.

### 8:00 PM SB09.06.06

**Direct Delivery of Nanobeads into Cells with Nanoinjector** Kazuhiro Oyama, Bowen Zhang, Bingfu Liu and Takeo Miyake; Waseda University, Japan

Delivering biomolecules into living cells has become an important challenge in medical and biological fields. Conventional techniques such as virus vector and electroporation are utilized commonly for small molecule delivery, but still remain several problems of low efficiency and low viability for large molecules such as biological proteins and organelles. To overcome this problem, we demonstrate the macromolecular delivery into adhesive cells with

metallic nanotube ducts, which is called as nanoinjector. The metallic nanotubes were developed by an electroless plating of gold onto track-etched polycarbonate template and wet/dry etching [1-2]. To insert Au nanotubes into the cells (such as HeLa and NIH3T3), we have developed an autostamping system that can be integrated with the microscope. Here we demonstrated the delivery of macro molecules (a few hundred nanobeads) into the cells and compare it with the endocytosis delivery. The nanoinjector system provide the high efficient delivery of 200nm diameter beads for 10min injection, while the endocytosis was at low efficiency, which takes for 24h to deliver the nanobeads. Furthermore, our nanoinjector can deliver the nanobeads uniformly into the cells.

**Light-Degradable Nanocomposite Hydrogels for Antibacterial Wound Dressing Applications** Changhao Fang, Yingnan Zhang, Qiming Shen and Michael J. Serpe; University of Alberta, Canada

Bacterial infections in skin injuries can lead to life-threatening human diseases if not treated appropriately. Wound dressings can function as a barrier that can cover the infected sites and inhibit further bacterial infection, thus promoting wound healing processes. In recent years, hydrogel-based materials have emerged as ideal candidates for wound dressing applications due to their biochemical and mechanical similarity to human tissues, high biocompatibility, ability to conform to irregular wound surfaces, and their capability to encapsulate a variety of antibacterial agents. Nanocomposite hydrogels, on the other hand, possess novel nanostructures and/or incorporate nanomaterials into the hydrogel matrix to afford interesting properties such as enhanced mechanical strength and unique drug release profiles.

However, there are still many limitations associated with current hydrogel-based wound dressings, such as the on-demand release of antibacterial agents and triggered degradation. Therefore, the focus of my research project is to address these limitations by developing a light-degradable nanocomposite hydrogel that can achieve both of these goals using light (365 nm) as the single stimulus.

The approach we are taking involves incorporating triclosan-loaded, poly(*N*-isopropylacrylamide)-based nanogels (TCS-NGs) into a light-degradable poly(ethylene glycol)-based hydrogel matrix via a simple physical entrapment method. Upon exposure to 365 nm light, the hydrogel matrix can rapidly degrade, which subsequently releases the entrapped TCS-NGs into the surrounding environment.

Our results have first demonstrated that TCS-NGs possessed potent antibacterial activities. Moreover, TCS-NGs could be entrapped in light-degradable hydrogel matrix with high encapsulation efficiency. Upon exposure to light (365 nm), TCS-NGs can be released from light-degradable nanocomposite hydrogels, which still possess remarkable antibacterial efficacy in terms of inhibiting the growth of *Staphylococcus aureus* both in solution and on bacteria-infected porcine skins. Next, based on Alamar Blue assay on human dermal fibroblasts, each component of the nanocomposite hydrogel exhibited excellent biocompatibility and would not cause significant cytotoxicity. Finally, we showed that the nanocomposite hydrogel can be rapidly degraded by exposure of light, and the extent of degradation was dependent on exposure time. The results here indicate that the fabricated light-degradable nanocomposite hydrogels could serve as novel materials for antibacterial wound dressing applications.

#### 8:00 PM SB09.06.09

**The Role of Discoidin Domain Receptor 2 (DDR2) and Collagen on Neuroblastoma Cellular Mechanosensing** Theadora Vessella, Steven Xiang, Madelyn Stilwell, Qi Wen and Susan Zhou; Worcester Polytechnic Institute, United States

Increased extracellular matrix (ECM) stiffness is a characteristic commonly observed in tumors. Cancer cells can sense changes in substrate stiffness and adjust their migration, proliferation, and differentiation accordingly. Cell-ECM adhesion is crucial for cells to sense substrate stiffness. Discoidin Domain Receptor 2 (DDR2) is a collagen receptor and has been shown to play a role cell-ECM adhesion. Elevated levels of DDR2 in tumor cells have been associated with unfavorable outcomes and metastatic disease. In this study, we aim to investigate the significance of DDR2-collagen interaction in substrate stiffness sensing by studying how DDR2 downregulation affects the responses of SHY5Y cells, a neuroblastoma cell line that expresses DDR2, to substrate stiffness changes. Cells were cultured on collagen-coated polyacrylamide gels with stiffness ranging from 800 Pa to 20 kPa. On stiffer substrates, we observed cells with larger spreading area, more polarized shape, stronger traction force, greater cytoskeletal stiffness, and upregulated neuroblastoma-associated gene expression. These suggest that SHY5Y cells are sensitive to sense ECM stiffness. In contrast, the sh-DDR2 SHY5Y cell line, in which DDR2 expression was downregulated by sh-RNA mediated depletion, did not demonstrate substrate stiffness sensitivity. Our results indicate that DDR2 plays an important role in cellular substrate stiffness sensing. This highlights the potential significance of DDR2 as a target for cancer treatment, as modulation of DDR2-collagen interactions could potentially impact cancer cell behavior and invasion.

#### 8:00 PM SB09.06.13

**Elucidating the Mechanism of Gelation for Decellularized Extracellular Matrix Hydrogels** Alexander Chen and Karen Christman; UCSD, United States

Naturally derived, decellularized extracellular matrix-based hydrogels (ECM hydrogels) have been increasingly investigated as biomaterial scaffolds for tissue repair and regeneration in a variety of disease models due to their injectability through minimally invasive methods, tunable properties, ability to assemble and form a hydrogel *in situ*, and intrinsic regenerative properties. Most commonly, their rheological, mechanical, optical properties, and protein composition have been studied to understand the gel's stability, gel formation kinetics and the extracellular matrix protein component type and distribution. Natively within mammals, type I collagen is the most abundant structural fibrillar protein and forms a hydrogel through fibril self-assembly and crosslinking when it is pure and has been assumed to be the main driver for hydrogel formation within heterogeneous ECM hydrogels. The goal of this study was to provide more fundamental materials characterization of ECM hydrogels and determine whether type I collagen is in fact the driver for ECM hydrogel formation.

Using three batches of a porcine derived decellularized myocardial ECM hydrogel, we first ensured batch consistency by quantifying residual dsDNA, quantifying sGAG concentration and rheological measurements. We also employ Fourier transform infrared spectroscopy (FTIR) to analyze the bonds within our ECM hydrogels, thermal gravimetric analysis (TGA) from 30 to 700°C to analyze degradation temperatures, and turbidimetry analysis to observe gelation kinetics. Finally, using cryogenic transmission electron microscopy and two photon microscopy, we analyze the fibril structures within our ECM hydrogel and quantify the differences in fibril diameters before and after incubation at 37°C.

All batches contained less than 1 ng DNA per mg of ECM showing adequate decellularization and 10 µg of sGAGs per mg of ECM. We observed

consistent complex viscosity across all samples that had not been incubated, and similar storage and loss moduli values for gels after 24 hours of incubation. The FTIR revealed the same peptide-related peaks (amides I, II and III) at similar peak intensity ratios also seen in a pure type I collagen control. TGA of our ECM hydrogel revealed degradation onset temperatures around  $304.6 \pm 1.7^\circ\text{C}$  and  $624.9 \pm 16.8^\circ\text{C}$  [KCl] C, consistent with literature reported values for collagen. Turbidimetry analysis revealed similar kinetics of gelation evidenced through similar times to achieve 50% of maximum equilibrium absorbance at around 15 minutes. ECM hydrogel batches were imaged before and after incubation at  $37^\circ\text{C}$  for 24 hours using two photon microscopy through second harmonics generation and two photon fluorescence, which leveraged the intrinsic property that only fibrillar, helical collagens produce signal. Incubated samples revealed distributed linear fibers in a grid-like conformation signifying the formation of a hydrogel network. Using cryogenic transmission electron microscopy, we analyzed fiber diameters within our samples for fresh, unincubated samples and samples incubated at  $37^\circ\text{C}$  for 24 hours. Fibers in fresh samples averaged  $45.6 \pm 21.7$  nm,  $48.7 \pm 10.8$  nm, and  $43.7 \pm 15.5$  nm in diameter across batches showing consistency. Incubated samples averaged significantly higher fiber diameters when compared to their fresh counterparts at  $113.1 \pm 48.2$  nm,  $156.1 \pm 79.3$  nm and  $128.9 \pm 56.8$  nm, respectively, where all measured fibers within the incubated group revealed a distinct 67 nm D-periodicity unique to fibrillar collagens. Combined, these data reveal batch to batch consistency using more sensitive materials characterization techniques for the ECM hydrogel while also providing visual evidence, through two microscopy techniques, that type I collagen self-assembly occurs during incubation at  $37^\circ\text{C}$  and is one of the main drivers of ECM hydrogel formation.

**A High-Throughput Micropatterning Platform for Screening of Nanoparticles in Regenerative Engineering** Cheryl Koh, Liu Ying Chen, Lingyan Gong, Shao Jie Tan, Han Wei Hou and Chor Yong Tay; Nanyang Technological University, Singapore

Engineered nanoparticles (ENPs) have been gaining traction in the field of regenerative engineering due to their unique physical, chemical and biological properties that are able to modulate cellular behaviour by influencing cell adhesion, migration, and proliferation. These nanomaterial-cellular interactions are important in directing tissue regeneration processes at the cellular level. However, the usage of nanoparticles brings about safety concerns with regards to impairment of cellular dynamics. In this context, micropatterning platform has emerged as a high-throughput tool for assessing stress response of ENPs. This platform not only allow the analysis of biological responses to nanoparticles in a controlled and reproducible environment, but also provides the identification of subtle effects that may not be discernible using traditional methods. This abstract discusses how two commonly incorporated engineered nanoparticles in regenerative engineering, specifically zinc oxide (ZnO) and titanium dioxide (TiO<sub>2</sub>) have an influence on collective epithelial rotation via the use of micropatterned platform. The confinement of cells in geometrical constraints were achievable through the precise control over the geometry and size of the adhesive fibronectin islands which aids in cell attachment. Collective rotation is essential in tissue morphogenesis and wound healing, and disruption to this collective behaviour could lead to a wide range of biological dysregulations. Through this approach, it was observed that the micropatterned human keratinocytes clusters exhibited spontaneous rotation without external stimulus, at relatively constant uniform speeds of  $10 \mu\text{m/h}$ . However, acute (6 h) exposure to non-cytotoxic doses of ZnO and TiO<sub>2</sub> NPs ( $\leq 100$  nm) resulted in a loss of directionality and slowing down of cell rotation, respectively. The loss in collective cell rotation (CCR) was determined to be attributed to reactive oxygen species (ROS)-induced proliferation by ZnO. While cell proliferation is desired in regenerative engineering, the generation of new, heterogeneous localised velocity fields by the increased cell density led to cell jamming within the epithelial units. On the other hand, the retardation of the velocity of TiO<sub>2</sub>-treated units was most likely as a result of degradation of membrane recycling integrins that are necessary for continued cell migration. This is because TiO<sub>2</sub>-treated units were found to induce autophagy, which has been reported to compete with endocytosis-driven recycling. Taken together, our findings offer nano-biological insights into the distinct signalling pathways exerted by different nanoparticles - ZnO NPs promoting cell proliferation, yet disrupting cell migration, and TiO<sub>2</sub> NPs decreasing cell migration. This suggests that when it comes to the usage of ENPs in regenerative engineering, further studies have to be done to ensure that cellular dynamics are not compromised.

#### 8:00 PM SB09.06.15

**Directing Phase Separation to Harness Biomaterial Microstructures for Controlled Cellular Behavior** Saniya Yesmin Bubli, Jenifer Sidhwa and Linqing Li; University of New Hampshire, United States

The compositional heterogeneity and structural diversity of native extracellular matrix are essential in regulating cell behavior and promoting tissue regeneration. Thermoresponsive polysaccharide-based materials with tunable transition temperatures and phase-separated microstructure offer substantial opportunities in tissue engineering, drug delivery, and wound healing applications. To develop novel synthetic thermoresponsive polysaccharides, we employed versatile chemical routes to attach intrinsically hydrophobic adducts to the backbone of hydrophilic dextran and developed protocols to form hydrogels with defined microstructures. Systematically conjugating methacrylate moieties to the dextran backbone yielded a continuous increase in macromolecular hydrophobicity that induced a reversible phase transition whose lower critical solution temperature can be systematically modulated *via* variations in polysaccharides concentration, molecular weight, degree of methacrylation, ionic strengths, and Hofmeister salts. Photo-initiated radical polymerization permits facile chemical crosslinking and kinetic capture of phase separation, enabling the formation of hydrogels with defined microdomains. The resulting heterogeneous hydrogels feature tunable microstructures and exhibited both microspheres and continuous phases that promoted enhanced cell adhesion in 2D and interfacial-driven cell migration in 3D. Engineering macromolecular hydrophobicity with temperature-triggered phase separation of conventional hydrophilic, non-phase separating polysaccharides to generate heterogeneous hydrogels with controlled microstructures will find potential applications in chronic wound healing.

#### 8:00 PM SB09.06.16

**Study of The Senescence Progress of Human Skin Fibroblast on Silica Nanobeads Array** Yerin Choi, Soojin Roh and Jin Seok Lee; Hanyang University, Korea (the Republic of)

Senescence is a physiological process that progresses with age. Cellular senescence is induced by stimuli such as telomere shortening and oxidative stress. In particular, it refers to the cell cycle arrest state. Senescence cells are characterized by reduced cell proliferation, migration, and speed. In addition, aging proteins p16, p21, and p53 are expressed.

We study the adhesion changes of senescence cells on silica nanobeads (SiNBs) of various sizes. In particular, it analyzes how senescence changes due to different adhesion. We induced aging by adding Paclitaxel (PTX) to WS1 cells, which are human skin fibroblasts. PTX causes cellular senescence due to damage from ROS. The optimal PTX concentration was fixed, and the cell survival rate was confirmed by MTT assay. In particular, we have identified different adhesion on SiNB arrays of various sizes. In addition, changes in cell proliferation, migration, speed, and aging proteins were analyzed. As a result, we observed the correlation between the topographic factors of SiNB arrays and cellular senescence.

#### 8:00 PM SB09.06.18

**Tensile Testing of Two Amniotic Membrane Products: Artacent Wound® and Artacent AC®** Abigail Poland, Olivia Logan, Mora Melican and Isabella Sledge; Tides Medical, United States

Amniotic membrane is a promising biomaterial for regenerative medicine and a plethora of placental membrane products exist in the market today

and are used for varying applications. When assessing and characterizing the multitude of amniotic products on the market, it is important to ensure that each product meets user need for handling capabilities so that the membrane can be properly applied to the wound. One way this characterization can be achieved is via tensile testing using an Instron 5544. The process of tensile testing amniotic products with the Instron 5544 has not previously been well-standardized or optimized for this material. With this study, a standardized test method for tensile testing of dehydrated amniotic membrane has been established. In this study, the established tensile testing procedure is used to distinguish differences in the handling capabilities of Artacent Wound, a dual layer amniotic scaffold, and Artacent AC, a tri-layer amniotic scaffold composed of a layer of chorion between two layers of amnion. In addition, this repeatable test method is also used to assess a modified version of Artacent AC where one of the tissue processing steps has been altered.

#### Methods:

##### Tensile Testing

1. Nonslip material is cut to size and applied to Instron Jaw Faces.
2. ASTM D1708 dog bone die cutter is used to cut samples to the proper size and shape.
3. Width and thickness measurements of the sample are taken in triplicate and averaged.
3. The force sensor is calibrated.
4. Tare load of 0.5N is applied to the sample prior to test start.
5. Length measurements of the product are taken.
6. Length, width, and thickness measurements are entered into Bluehill Software.
7. Strain Rate of 0.40mm/min. is entered into software.
8. "Zero displacement" is selected.
8. Test is started until full sample break is achieved.
9. Test is stopped and data is collected.

##### Data Analysis:

One – Way ANOVA Multicomparison Tukey Tests were used to compare each test group.

##### Results:

Comparative graphs summarize the failure stress (MPa), failure strain (%) and Young's Modulus (Mpa) of the following test groups:

- Artacent Wound
- Artacent AC
- Modified Artacent AC

##### Discussion:

There are no significant differences between the measured biomechanical properties of Artacent Wound and Artacent AC, although Artacent Wound has slightly increased strength when compared to Artacent AC.

The modified version of Artacent AC did not show any significant difference when compared to original Artacent AC. However, the modified Artacent AC is shown to have higher Young's Modulus and failure stress when compared to original Artacent AC. This demonstrates that modifying certain tissue processing steps could be advantageous for improving material handling properties.

##### Conclusion:

Artacent Wound has increased failure stress and Young's Modulus when compared to Artacent AC.

Modifying certain steps of the Artacent AC tissue processing procedure is shown to be beneficial for improving handling properties of the scaffold, as it demonstrates increased Young's Modulus and failure stress when compared to that of original Artacent AC.

#### 8:00 PM SB09.06.19

**Balancing Charge Density and Hydrophobicity in Polysaccharide Biomaterials to Regulate Cell Behavior** [Tran Truong](#), Linqing Li and Nathan J. Oldenhuis; University of New Hampshire, United States

Hydrogel surface properties play an important role in regulating cellular behavior for tissue engineering and biomedical device design application. Alterations in the biointerface can activate specific cellular signals, resulting in different physiological outcomes. Developing a hydrogel system where surface physiochemical characteristics such as stiffness, charge density, and hydrophobicity can be independently tuned would provide significant insights to tailor material-cell interactions at tissue interface for various therapeutic applications. In this study, we synthesized methacrylate and carboxylate dual-functionalized dextran derivatives, and investigated the impact of the intricate balance between hydrogel surface charge density and hydrophobicity on cell behavior. We are leveraging the defined chemical moieties and tunable surface properties of modified dextran hydrogels to probe the impact of our materials on regulating cell adhesion and spreading. By synthetically tuning these two parameters in dextran-based substrates, we revealed that increased surface charge density and decreased hydrophobicity enhance hydrogel surface wettability and prevent cell adhesion. On the contrary, increasing surface hydrophobicity facilitates the adsorption of fibronectin that supports cell adhesion. Our findings suggest an optimized balance between charge density and hydrophobicity that can be engineered to promote desired cell behavior. Imbalances between these two parameters resulted in an inhibition of cell attachment, emphasizing the importance of fine-tuning charge density and hydrophobicity in biomaterial design. This project will differentiate and identify critical chemical characteristics of hydrogel surface properties responsible for cell behaviors and develop a new class of synthetic polysaccharide biomaterials.

#### 8:00 PM SB09.06.20

**Crimping Process Investigation to Enable Informed Design of 3D Printed Bioresorbable Vascular Scaffolds** [Caralyn Collins](#)<sup>1</sup>, Junqing Leng<sup>1</sup>, Rao Fu<sup>2</sup>, Yonghui Ding<sup>2</sup>, Guillermo Ameer<sup>1</sup> and Cheng Sun<sup>1</sup>; <sup>1</sup>Northwestern University, United States; <sup>2</sup>Worcester Polytechnic Institute, United States

With cases of coronary and peripheral artery disease on the rise, vascular stenting has become a popular procedure which is crucial to the health of millions of patients across the United States and more across the globe. In the past several decades, the field has seen a shift from bare metal and metal drug eluting stents to bioresorbable vascular scaffolds (BVS) with the goal of addressing restenosis, thrombosis, and stent migration concerns. These BVS utilize polymeric materials to degrade over time *in vivo*, and as a result, have drastically different mechanical responses to deformation than the preceding metal stents. As such, additional consideration of the BVS mechanical deformation response both prior to and post-deployment is important to enhancing the performance of these polymeric scaffolds *in vivo*. The crimping process, or diameter reduction of the stent or BVS prior to deployment, marks the first time after manufacturing that the scaffold must undergo a significant amount of mechanical deformation. As it is also an easy deformation step to monitor, crimping serves as a good baseline for understanding the mechanical response of BVS. Simulation of this step can not only provide information on BVS radial force as a function of diameter to mimic results from experimental testing, but can also give additional information on the response of the BVS as it

undergoes this deformation in a fraction of the time required in experiment. This allows for a time-effective solution to enable understanding of both the deformation of different scaffold designs and the deformation of scaffolds with different material additives incorporated, like those utilized to enable visibility of the BVS when imaged *in vivo*. Here, we utilize a finite element crimping simulation in ABAQUS to rapidly reproduce experimentally validated qualitative design comparisons between several designs of 3D printed bioresorbable vascular scaffolds made of a previously developed citrate-based polymer, taking into consideration both the properties of the base polymeric material and the properties of the polymeric material with a radiopaque additive. By doing so, it is possible to harness the advantages of additive manufacturing to allow for more optimal bioresorbable vascular scaffold design and production, simultaneously elucidating the relationship between material, structure, and mechanical response of scaffolds.

#### **8:00 PM SB09.06.21**

***In-Vitro* Human Cell Behavior: Using Cell Culture to Assess Biocompatibility and Cell Proliferation on Artacent Products** [Olivia Logan](#), Sadhana Joshi, Babak Safavieh, Mora Melican and Isabella Sledge; Tides Medical, United States

##### Introduction:

Cell culture is a useful method of determining cell interactions and assessing product safety in-vitro before completing in-vivo testing, such as animal models. In this study, cell culture is utilized to assess the proliferation and attachment of various cell types on amniotic scaffolds. The selected cell types represent cells that are known to play a part in the wound healing process and include Human Umbilical Vein Endothelial Cells (HUVEC), Neonatal Human Dermal Fibroblasts (NHDF), Normal Human Epidermal Keratinocytes (NHEK) and L929 cells (an adherent type of mouse fibroblast cell line).

##### Methods:

###### Cell Culture

All cell lines are maintained in appropriate culture media supplemented with necessary growth factors, antibiotics, and serum per manufacturer's protocol. These cells were incubated at optimal conditions in a humidified cell culture incubator.

###### Cell Treatment

Optimal seeding density for each cell type was determined from preliminary testing. Determined seeding densities were then used to seed each cell type on circular 6mm diameter samples from each test group. Cells were seeded for 2,3,7 and 9 days in 96 well Low cluster microplates.

###### Alamer Blue Assay

After the treatment period, the culture medium was removed from each well or plate and Alamar blue was added to the wells. The cells were treated with the Alamar Blue reagent for 6 hours and under appropriate conditions. The absorbance of these wells was measured using a microplate reader at 570nm and 600nm.

###### Microscopy

To validate the Alamer Blue Assay results, the cells seeded on Artacent product were labelled with DAPI and Vimentin 647 and observed under Zeiss LSM 800 with Airyscan.

##### Results:

Graphs summarize the Alamer Blue reduction (%) for the following test groups at the following time points. Chosen time points reflect when the most Alamer Blue reduction was observed for each cell type.

- HDF at 7 day time point
- NHEK at 7 day time point
- HUVEC at 9 day time point

##### Discussion:

HDF cells showed improved proliferation and attachment on Artacent AC compared to other test groups.  
NHEK cells showed improved proliferation and attachment on Artacent Wound compared to other test groups.  
NHEK cells showed improved proliferation and attachment on Artacent Wound compared to other test groups.

##### Conclusion:

Different types of amniotic scaffolds are shown to be optimal for the proliferation and attachment of different cell types.  
- HDF cells showed improved proliferation and attachment on Artacent AC.  
- NHEK cells showed improved proliferation and attachment on Artacent Wound.  
- NHEK cells showed improved proliferation and attachment on Artacent Wound.

#### **8:00 PM SB09.06.22**

**Comparison of Amniotic Products in Full Thickness Rat Wound Model: Artacent Wound and Artacent AC** [Olivia Logan](#), Isabella Sledge and Mora Melican; Tides Medical, United States

##### Introduction:

It is well understood that human placental tissue contains a multitude of factors that play a part in the healing process [1]. Placental membrane is an attractive biomaterial for regenerative medicine applications due to its natural factors that aid in wound healing, angiogenic and regenerative remodeling, as well as immunomodulation. However, the processing methods used to create final product have an impact on the growth factors that are retained [2]. A plethora of placental tissue processing methods has led to the creation of an array of placental product compositions and applications. Two products currently being used in the field are Artacent Wound®, a dehydrated dual layer amniotic graft and Artacent AC®, a tri-layer graft composed of a chorion sandwiched between two layers of amnion. In this study, we assessed these wound coverings in Sprague Dawley rats to elucidate the influence these scaffolds have on a healing wound. Additionally, this test is used to assess a modified version of Artacent AC to see if modifying certain tissue processing steps has implications on wound healing.

##### Methods:

Two full thickness wounds were created on the dorsal side of each rat using a 2 cm x 2 cm square stencil and scalpel. Implant dimensions were

approximately 2.5 x 2.5 cm. Samples were randomized into implantation sites across the animals. Implants were harvested at 7 days and grossly assessed for healed wound geometry, remodeling and re-epithelialization. Implants were fixed in neutral buffered solution (NBS). Samples were stained with H&E and stained cross sections were evaluated for surface re-epithelialization, cellular infiltration, and remodeling. A numerical scoring system was utilized to quantify re-epithelialization and granulation tissue formation based on histological images.

**Results:**

Initial and final wound measurements were used to calculate the percentage of wound closure for each test group. Re-epithelialization and granulation tissue formation ratings are used to calculate average values for each test group.

**Discussion:**

No adverse effects were noted during this 7 day study. Partial wound healing is observed during the 7 day study, and healing is accelerated by the addition of a placental scaffold. Modified Artacent AC shows increased wound closure, equivalent re-epithelialization, and increased granulation tissue formation when compared to positive control (original Artacent AC).

**Conclusion:**

No adverse effects were noted.

The 2x2 Challenge Full Thickness Wound model in the rat shows partial healing at 7 days that is accelerated by the addition of a human placental membrane product to the wound bed.

Modified version of Artacent AC shows improved wound healing when compared to original Artacent AC.

- Increased wound closure
- Equivalent re-epithelialization
- Increased granulation tissue formation

**8:00 PM SB09.06.23**

**Protein Characterization of Placental Membrane Products: Artacent Wound and Artacent AC** [Olivia Logan](#), Babak Safavieh, Isabella Sledge and Mora Melican; Tides Medical, United States

**Introduction:**

Placental membrane is a highly biocompatible natural scaffold and is a source of several native factors that may aid in wound healing. Some of the many factors that make placental membrane such an attractive material are the natural anti-inflammatory, angiogenic, and antibacterial properties of the membrane. These properties are mostly dictated by released growth factors and cytokines. The angiogenic properties are attributed mostly to its capacity to produce VEGF and platelet-derived growth factor (PDGF), both of which mediate wound healing. The anti-inflammatory and immune-modulatory effects are largely attributed to the secretion of IL-10 and IL-6 [1].

Here, we characterize the protein content in Artacent Wound (a dual layer amniotic product) and Artacent AC (a tri-layer composed of a layer of chorion in between layers of amnion) using a Microarray assay. In addition, immunohistochemistry (IHC) was used to quantify protein composition of extracellular matrix (ECM), growth factors, and immune modulating cytokines. This analysis provides further insight into the protein composition and cell interactions of hAM scaffolds currently on the market.

**Methods:**

The chosen assay for testing is Quantibody® Human Cytokine Antibody Array 1000 assay from RayBiotech Inc., a multiplexed ELISA that enables the detection and quantification of up to 1000 human cytokines in a single experiment. To prepare samples for testing, they were first incubated on captured antibody for 2 hours. The biotinylated antibody cocktail was then added, followed by another 2 hour incubation. After the final incubation, streptavidin labeled dye was added. The results were then analyzed using fluorescent microarray reader.

**Results:**

The various cytokines and growth factors observed in each test group were categorized based on Angiogenetic cues, immune modulating cytokines and Regenerative growth factors.

**Discussion:**

Protein microarray analysis reveals that Artacent AC and Artacent Wound have various factors that are attributed to angiogenetic and regenerative remodeling as well as immunomodulation. The Artacent Wound protein distribution shows that factors are uniformly distributed amongst the angiogenetic (28%), regenerative (34.1%), and immunomodulatory (37.8%) categories. In contrast, the protein distribution for Artacent AC shows that a large portion of the observed factors are regenerative growth factors (78.4%), with a smaller portion of results falling into the angiogenetic (8.3%) and immunomodulatory (13.2%) categories.

**Conclusion:**

The varying products are each shown to contain a unique profile of proteins that play a role in angiogenetic and regenerative remodeling as well as immunomodulation.

- Artacent Wound proteins are evenly distributed amongst the angiogenetic, regenerative, and immunomodulatory categories.
- Artacent AC protein distribution largely falls in the regenerative category, with smaller percentages of proteins falling into angiogenetic and immunomodulatory categories.

**Subcutaneous Implantation of Amniotic Products in Sprague Dawley Rats: Artacent Wound and Artacent AC** [Olivia Logan](#), Isabella Sledge and Mora Melican; Tides Medical, United States

**Introduction:**

Although there are numerous placental membrane products currently being used in wound healing applications, it is not yet well-understood how these products interact with the wound bed as the wound heals. In this study, we assess subcutaneous implantation of varying amniotic membranes to better understand how these products support the wound healing process.

**Methods:**

Four incisions were made on the back of each rat—two incisions left of the spine and two incisions to the right with each incision measuring approximately 2 cm. Four individual pouches were created by bluntly dissecting laterally at each incision site with scissors. A 1 x 1 cm implant was placed in each implantation site and samples were randomized in location. Implants were fixed in neutral buffered solution (NBS). Samples were stained with H&E and

stained cross sections were evaluated for surface re-epithelialization, cellular infiltration, and remodeling.

**Results:**

Representative histological images from each test group.

**Discussion:**

In both Artacent Wound and Artacent AC, tissue ingrowth within the placental membrane product can be observed. Results support that the biological membranes provide an extracellular matrix that provides a natural scaffolding which supports the wound healing process.

**Conclusion:**

In both Artacent Wound and Artacent AC, tissue ingrowth within the placental membrane product can be observed. Results support that the biological membranes provide an extracellular matrix that provides a natural scaffolding which supports the wound healing process.

**Stimulus-Responsive Double Network Hydrogels with MoS<sub>2</sub> Nanosheets for High Toughness and Self-Healing Smart Biomaterials for Tissue Engineering** Francesca A. Sepúlveda<sup>1,2</sup>, Humberto Palza<sup>1,2</sup>, Felipe Olate-Moya<sup>1,2</sup> and Juan Pablo Acevedo<sup>2,3</sup>; <sup>1</sup>Universidad de Chile, Chile; <sup>2</sup>IMPACT, Chile; <sup>3</sup>Universidad de los Andes, Chile

The design of stimulus-responsive smart hydrogel actuators for tissue engineering holds great promise, as they enable the creation of 3D structures mimicking the functionality of natural tissues, responding in a controlled manner to changes in temperature, light, or pH. To achieve near-infrared (NIR) light-induced responses in smart hydrogels, molybdenum disulfide (MoS<sub>2</sub>) nanosheets have gained recent attention due to their layered structures and strong NIR absorbance, making them promising photothermal agents. Among various hydrogels, we focus on double-network hydrogels (DN) composed of chitosan (C) and polyvinyl alcohol (P), known for providing a robust and flexible matrix for cell growth and tissue regeneration. In this study, we developed C-P DN hydrogels with MoS<sub>2</sub> nanoparticles to create 3D printed scaffolds (3D C-P) and evaluated their mechanical properties, water content, NIR light irradiation response, and cell viability.

By adjusting manufacturing parameters like freezing temperature, chitosan cross-linking time, and lyophilization, we tailored the mechanical properties of C-P DN hydrogels. These inks were successfully extruded using a fourth-generation 3D Bioplotter™ (Envisiontec, Germany), enabling precise scaffold production. After 2 hours of crosslinking, the 3D C-P scaffold exhibited high toughness and mechanical stiffness resembling native heart tissue, with a stiffness value of 0.78 MPa. Interestingly, DN C-P\_MoS<sub>2</sub> hydrogels with 0.5% w/w MoS<sub>2</sub> incorporation did not show improved mechanical stiffness compared to pure DN, maintaining material structural stability. Furthermore, MoS<sub>2</sub> incorporation led to a slight decrease in water content, attributed to its hydrophobic nature.

The material's responsiveness was evident through rapid contraction and bending upon NIR light irradiation due to dehydration, and this response was 40% faster than that of DN C-P hydrogels. This confirmed their potential as candidates for generating light-stimulated smart DN hydrogels. Additionally, MoS<sub>2</sub>-incorporated hydrogels exhibited mechanical self-healing under NIR light exposure, enhancing their tissue engineering applications. These multifunctional behaviors arise from MoS<sub>2</sub>'s ability to convert light energy into thermal energy, triggering NIR light-induced contraction. Furthermore, NIR-induced heat facilitates polymer chain diffusion, enabling a self-healing process through hydrogen bond reformation in MoS<sub>2</sub>-incorporated hydrogels. MoS<sub>2</sub> absorbs NIR light, releasing heat, and leading to hydrogel contraction, while reconstituted hydrogen bonds allow the material to 'heal,' restoring structural integrity and functionality.

Viability studies on umbilical cord-derived mesenchymal stem cells (UC-MSCs) cultured on MoS<sub>2</sub> hydrogels showed improvement from day 1 to day 7, suggesting that DN and DN C-P MoS<sub>2</sub> hydrogels offer a conducive environment for UC-MSC growth and survival, serving as a three-dimensional support and suitable substrate matrix.

The results demonstrate that the incorporation of MoS<sub>2</sub> nanosheets into C-P DN hydrogels achieves a rapid actuation response to NIR light irradiation and a mechanical self-healing behavior, making them ideal for light-stimulated flexible hydrogels. Additionally, cell viability studies indicate MoS<sub>2</sub>-containing hydrogels' suitability as three-dimensional support in regenerative medicine and tissue engineering.

**Development of Bio-Hybrid Nanoparticles based *In Situ* Raman Imaging for Intracellular miRNA Detection** Yeochan Yun<sup>1</sup>, Hyeon-Yeol Cho<sup>1</sup>, Won-Jun Lee<sup>2</sup>, Kyeong-Jun Kim<sup>2</sup>, Md. Khaled Hossain<sup>2</sup> and Jeong-Woo Choi<sup>2</sup>; <sup>1</sup>Kookmin University, Korea (the Republic of); <sup>2</sup>Sogang University, Korea (the Republic of)

Currently, microRNAs (miRNAs) were widely recognized as valuable biomarkers to identify in typical cancer characteristics. These small RNA molecules frequently exhibited dysregulation in various cancers, leading them to serve as either oncogenic or tumor-suppressor miRNAs, depending on their specific target genes. Moreover, miRNAs can modulate cancer cells to chemotherapy. Real time polymerase chain reaction (RT-PCR) was currently used as a method to detect intracellular miRNA. However, it required cell lysis, miRNA isolation, purification that makes hard to use in live cells. Therefore, several fluorescence-based analysis techniques (e.g., fluorescence resonance energy transfer (FRET)) were used for live cell detection, but they had limitation in detecting miRNA with low expression levels. We aimed to overcome these limitations by using surface-enhanced Raman spectroscopy (SERS), a technique widely used as a tool for sensing application, which analyzed based on the distances between molecules, to detect intracellular miRNA in live cells.

In this study, we developed highly sensitive Raman activating gold nanoparticles (HS-RGNs) which were containing gold nanoparticles, Raman reporter, and single strand DNAs (ssDNAs) complementary to target miRNA. When HS-RGNs hybridized with target miRNA, these particles amplified the Raman signal. We selected microRNA 200c (miR-200c) as a model biomaterial which was related to the chemoresistance of cancer cells. After treatment of HS-RGNs to SK-BR-3 and MCF-7 which are cancer cells, the ssDNAs of HS-RGN were hybridized with miR-200c, bringing two HS-RGNs closer, thereby enhancing the Raman signal. The higher expression level of miR-200c in SK-BR-3 compared to MCF-7 led to the observation of a higher Raman signal in SK-BR-3 cells. When treated with HS-RGNs, increased expression levels of Zinc finger E-box binding homeobox 1 (Zeb1) and Tropomyosin receptor kinase B (TrkB), which were inhibited by miR-200c, indicated the effective binding of HS-RGNs to miR-200c. Additionally, when assessing the cytotoxicity of doxorubicin, SK-BR-3, which exhibited higher miR-200c expression, showed a lower survival rate compared to MCF-7. However, when treated with HS-RGNs, miR-200c was effectively consumed, resulting in a higher survival rate in both SK-BR-3 and MCF-7 cells. This result suggested that HS-RGNs can hybridize with miR-200c, impact of miRNA on cell behavior.

Our study showed that HS-RGNs effectively amplified the Raman signal, indicating their potential applicability for in situ intracellular analysis. Additionally, they can be applied as a platform technology to investigate the impact of miRNA on cell behavior by consuming miRNA within cells.

**Bioprinting Hydrogels for Dentin Pulp Regeneration and Disinfection** Saranya Anantapantula<sup>1</sup>, Abdel Mahmoud<sup>2</sup>, Aaron Sloutski<sup>2</sup>, Kuan-Che Fang<sup>2</sup> and Miriam Rafailovich<sup>2</sup>; <sup>1</sup>Spring Ford Area High School, United States; <sup>2</sup>Stony Brook University, The State University of New York, United States

Oral and maxillofacial complications pose challenges due to issues like lack of material biocompatibility and invasive treatments. One common example is the endodontic treatment, where the infected pulp is removed. Bacteria and their byproducts that interact with host tissues in the dental pulpal and periradicular regions are the primary cause of endodontic pathosis. The elimination of microorganisms from the root canal system (RCS) is essential for effective endodontic therapy. This process can leave the tooth brittle in the long-term. Because they can promote, in a biologically based framework, the continuation of root development and apical closure, regenerative endodontic therapies (RETs) in necrotic immature teeth have drawn a lot of interest recently. Getting a sufficient disinfection of the root canal system is a must for success in RETs since bacterial persistence in root canals in such instances considerably impede healing and root maturation. Moreover, additive manufacturing can facilitate the development of hydrogels that can regenerate lost dentin pulp, restoring tooth strength and longevity and achieve sustainable drug release. This research aimed to identify a scaffold, which possesses optimal degradability, chemical, mechanical, cyto-compatible features, that can deliver antibiotics or induce stem cell differentiation for regenerative endodontic treatment while maintaining durability. For this purpose, methacrylated Pluronic polymers were chosen due to their well researched drug releasing capabilities, as well as their potential injectability, stemming from their reverse thermo-responsive nature.

Initially, the studies focused on F127-DMA and F88-DMA hydrogels and their crosslinking efficiency with two photoinitiators (Irgacure- 651 and 2959). Different assays, such as mechanical properties characterization by rheology, swelling ratio, crosslinking efficiency and drug release analysis, were conducted. Crosslinking was mediated by UV lamp and by 3D printer (BioX 3D Bioprinter) where the durability of the constructs was researched. Irgacure 2959 showed superiority both in terms of crosslinking efficiency (~16% difference) and mechanical stiffness. Comparing both Pluronics, the data collected showed that F88 had a higher swelling ratio than F127. Elastic modulus measurements confirmed that F127 was inherently stronger, and its cross-linking efficiency was superior due to its lower swelling ratio. Aiming at imparting degradability, the Pluronic were end capped with L-Lactide prior to methacrylation and similar studies were conducted throughout prolonged time incubated in aqueous medium at 37 degrees. The lactide-containing matrix exhibited elevated swelling until full degradation after several weeks, demonstrating the rapid degradability. Furthermore, aiming at exploring drug release capabilities, release profiles of Clindamycin, Metronidazole and Ciprofloxacin (Triple paste antibiotic) were researched.

In conclusion, while F127's stiffness and effective crosslinking make it a promising candidate in terms of mechanical features and F88's hydrophilic properties and favorable degradation profile also make it a favorable option in regards to hydrophilic affinity and mass loss, further research is required to assess the biocompatibility of photoinitiators and their concentrations in terms of cell viability. Thus, further studies will be conducted on the hydrogels' bio-printability, cell viability, cytotoxicity, antibacterial efficiency of drugs added and osteogenic differentiation or the ability of stem cells to differentiate into bone cells. The gels developed will present multiple potential endodontic applications: it could be placed on the top of the pulp cavity to induce dentin regeneration or disinfect the canal area. Thus, these hydrogels will ultimately pave the way for more potent dental treatment approaches.

**The Influence of Donor Age and Cholesterol Inhibition on Fibroblast Mechanical Properties and Susceptibility to Bacterial Infection** Sharis Hsu<sup>1</sup>, Pia V. Sodhi<sup>2</sup>, Avi Talsania<sup>3</sup>, Samuel D. Coopersmith<sup>4</sup>, Richard A. Wong<sup>5</sup>, Sai Pranav Kota<sup>6</sup>, Adam Hansen<sup>7</sup> and Miriam Rafailovich<sup>7</sup>; <sup>1</sup>Valley Christian High School, United States; <sup>2</sup>The Brearley School, United States; <sup>3</sup>Sachem High School North, United States; <sup>4</sup>Casa Grande High School, United States; <sup>5</sup>Plainview-Old Bethpage John F. Kennedy High School, United States; <sup>6</sup>Cedar Falls High School, United States; <sup>7</sup>Stony Brook University, The State University of New York, United States

Cell mechanics depend upon cell membrane mechanics (which, in part, depends upon cholesterol content) and the rigidity and organization of the cytoskeleton. The latter was shown to depend on the properties of the substrate upon which cells are cultured, where tensegrity models were used to explain reorientation of the scaffold. With aging, measurements of the viscoelastic properties of cells were shown to stiffen, but these measurements were performed on individual cells without mechanical cues from surrounding tissue or the substrate. We report on experiments performed on dermal fibroblasts, which were obtained from female donors: “young” (ages 28 and 29 years) and “old” (ages 69 and 71 years), where we applied the technique of scanning force modulation microscopy (SFMM) which allows for measurements of cell modulus that account for the underlying substrate mechanics. The results represent an average of n=9 measurements.

Cells were cultured on polybutadiene thin films whose moduli were varied (ratio of 3:1) by adjusting the film thickness without additional chemical additives. On both substrates the moduli of the cells became significantly harder with age, consistently  $40 \pm 1.6\%$ , in agreement with previous work. For both young and old cells the cell modulus responded to changes in the substrate, where the moduli between cells plated on the hard and soft substrates differed significantly,  $50 \pm 2\%$  and  $60 \pm 2.4\%$  for the old and young cells, respectively. These results indicate that even though cells become harder as they age their ability to adjust to mechanical changes in their environment is not diminished. We were also able to image the actin filaments and we found that the moduli of the filaments in the older cells were consistently  $20 \pm 0.8\%$  higher than those of the younger cells independent of substrate.

Cholesterol is the most dominant sterol found in mammalian tissue and is a major structural component of the cell membrane. We investigated the impact of cholesterol on the moduli of dermal fibroblasts. To prevent uptake of cholesterol, we cultured cells in lipid-free media. We then added AY9944, a known disruptor of cholesterol synthesis, which has been shown to cause a shift to 7-dehydrocholesterol (7DHC), a precursor to cholesterol, as the major sterol. In the lipid-free media, we observed that while the proliferation of the cells was reduced, the moduli of the cells increased significantly by  $100 \pm 4\%$  and  $66 \pm 2.64\%$  for the young and old cells, respectively, relative to the cultures in standard media. Introduction of AY9944 at a concentration of 50nM decreased the modulus in the lipid-free media by  $25 \pm 1\%$  for both ages, which represented an overall increase relative to the control media of only  $20 \pm 0.8\%$  for young and  $60 \pm 2.4\%$  for old. This confirmed prior observation of increased membrane ductility.

Finally, it has been shown that cholesterol increases the susceptibility of cells to infection by *Staphylococcus aureus* bacteria. Therefore, we exposed cells to *S. aureus* at an MOI of 1000 for 90 minutes. The infection rate of old cells appeared to be approximately  $\frac{1}{3}$  that of younger cells, and the infection rate overall was nearly zero when AY9944 was added. These results illustrate that changes in the sterol composition of the membrane can have a significant impact on dermal fibroblasts. Hence, further studies are in progress to quantify the cholesterol to 7DHC quantities, as well as the impact on fibroblast functions, which are affected by aging such as collagen contraction, deposition, and turnover.

**Osteogenic Differentiation of Dental Pulp Stem Cells via Titanium Deposition in a Static Magnetic Field** Ethan Lai<sup>1</sup>, Michael Wang<sup>2</sup>, Aman Yarlagadda<sup>3</sup>, Dvita Bhattacharya<sup>4</sup>, Catherine Chun<sup>5</sup>, Anita A. Gaenko<sup>6</sup>, Alexander C. Wang<sup>7</sup>, Adam Zaidi<sup>8</sup>, Kuan-Che Fang<sup>9</sup> and Miriam Rafailovich<sup>9</sup>; <sup>1</sup>Phillips Academy, United States; <sup>2</sup>Mounds View High School, United States; <sup>3</sup>Newman Smith High School, United States; <sup>4</sup>Kent Place School, United States

States; <sup>5</sup>Ardley High School, United States; <sup>6</sup>Huron High School, United States; <sup>7</sup>Sewickley Academy, United States; <sup>8</sup>San Francisco University High School, United States; <sup>9</sup>Stony Brook University, The State University of New York, United States

Osteogenic differentiation of dental pulp stem cells (DPSCs) offers potential treatments for bone-related diseases such as osteoporosis. DPSCs are preferred over other stem cells due to their ease of preservation and relative ease to obtain. Previous literature has shown that continuous exposure to a static magnetic field (SMF) induces osteogenic differentiation in rat DPSCs [1]. Past studies also suggest titanium-treated surfaces improve the rate of differentiation of DPSCs. [2] We report the degree of osteogenic differentiation with the combined effects of titanium deposition and an SMF, and compare each treatment individually. Investigating these factors will provide crucial insight to the differentiation of DPSCs and the discovery of a stem cell-based treatment for endemic bone diseases.

DPSCs of strain 13 were isolated from third molar teeth and prepared via trypsinization every 4 days for 16 days.  $4 \times 10^4$  cells were plated on each sample with agarose, along with MEM- $\alpha$ , 10% fetal bovine serum, and 1% glutaMAX. After 1 day, the media was changed to ascorbic acid and  $\beta$ -glycerophosphate, which has been shown to induce cell biomineralization. [2] 4 groups contained 2-inch x 2-inch silicon wafers while 2 others were in tissue culture plastic (TCP). All wafers were coated with Polylactic Acid (PLA). Half the wafers were further treated with titanium via atomic layer deposition (ALD). Half of all groups were placed in an SMF parallel to the surface for the duration of their incubation period of 28 days.

Images produced by atomic force microscopy for ALD and PLA groups were analyzed via NanoScope Analysis to quantify the roughness of the wafers. Roughness did not play a role in differentiation, as it was in the nanometer scale for all groups. Cells were also counted via alamarBlue staining on days 1 and 5 to ensure similar proliferation rates.

RT-PCR was performed after incubation to measure the expression of the following genetic markers: osteocalcin (OCN), dentin sialophosphoprotein (DSPP), and bone sialoprotein (BSP). RNA lysed from DPSCs on day 0 was used as a baseline to compare the relative expression levels of each gene for each treatment group after the 28 days. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) served as the housekeeping gene. Our results show an upregulation of BSP expression for the ALD/SMF group compared to PLA/SMF and TCP/SMF groups, confirming titanium deposition's inductive effect on osteogenic differentiation. ALD/SMF produces the greatest osteogenic differentiation with respect to BSP expression. OCN expression was also upregulated by a factor of two for ALD groups compared to PLA, and by a factor of four when compared to TCP. DSPP expression was downregulated for ALD groups in comparison to PLA and TCP, and further downregulated for ALD/SMF. Addition of other magnetic materials, such as iron oxide, may further induce osteogenic differentiation.

Collagen triple helices are abundant in osteoblasts. Scanning electron microscopy will be used to further analyze collagen triple helix formation, allowing us to understand the role of an SMF on the rate of collagen triple helix formation and thus osteogenic differentiation. Raman spectroscopy will be used to determine the nature of mineralization.

#### 8:00 PM SB09.06.30

**Mechanical Characterization of Poly(vinyl alcohol) and Resorcinol Diphenyl Phosphate Clay Blend Vascular Grafts** Hannah Oh, Leora Stochel, Haoyu Xu, Megha Gopal, Robert Wong, Aaron Sloutski, Adam Hansen, Reza Dashti, Chander Sadasivan and Miriam Rafailovich; Stony Brook University, The State University of New York, United States

Poly(vinyl alcohol) is suitable for vascular grafts in patients due to its biocompatibility and tunable mechanical properties, but its documented bioinert nature limits cell-adhesiveness, which is critical for the long-term patency of grafts in vivo [1]. We have previously found that Resorcinol Diphenyl Phosphate (RDP)-clay, a phosphate ester flame retardant, can enhance mechanical and cell-adhesive properties when blended with other polymers[2]. Here, we report on the effect of RDP-clay on the mechanical properties of PVA hydrogels towards manufacture of small-diameter vascular grafts.

PVA/RDP-clay blend solutions were synthesized by combining 10% PVA (w/w) solution with RDP-clay at 0%, 1%, 5%, and 10% (w/w), respectively. These solutions were crosslinked with 15% (w/w) sodium trimetaphosphate (STMP) and 30% (w/w) sodium hydroxide (NaOH). This solution was poured into 26mm diameter molds and allowed to dry overnight, after which the resulting discs were rehydrated in Dulbecco's Phosphate Buffered Saline (DPBS) for about 24 hours. Rheology of these discs was characterized using a Kinexus Pro+ rheometer (Netzsch), with oscillatory amplitude sweeps with parameters 0.1 to 100 Pa range, 1 Hz frequency, and 25 C temperature.

To create small-diameter grafts from this polymer blend, we devised a 3-step process. Melted wax was injected into a metal tube and allowed to harden, creating a 2 mm diameter wax rod. For all RDP-clay concentrations, these rods were affixed to a single-axis spinner and dipped 10 times in PVA blend, with 15 minutes of spin-drying between dips. After the final dip, rods were allowed to spin-dry overnight, rehydrated the next day, and the wax rods were removed to obtain patent vascular grafts. These grafts were orthogonally cut into thin rings, allowing wall thickness measurements to be found using a Keyence VHX-7000 microscope. 2 cm lengths of vascular graft tubes were also orthogonally cut, then attached to a PG-5 Digital Pressure Gauge and pressurized until rupture to determine vessel burst pressure.

Blend characterization through rheology indicated an average modulus of 35 kPa, with a slight increase as RDP-clay concentration increased. The described manufacture method for these small-diameter grafts was successful at creating patent vessels at all RDP-clay concentrations tested. Vessel thickness was significantly larger in 10% RDP-clay vessels than in 0%, 1% and 5%. 10% RDP-clay vessels were also visibly less smooth and homogenous than lower RDP-clay concentration vessels. Burst pressures were greater than physiological values for all RDP-clay concentrations (200-700 mmHg), but 10% RDP-clay vessels were more prone to pin-prick bursts. As such, we posit that 10% RDP-clay may be an upper limit for organoclay additive concentration to maintain mechanical integrity of the PVA hydrogel.

The mechanical properties of the PVA/RDP-clay blends under these manufacture and processing techniques show great promise for use as vascular grafts in patients. Future steps include characterizing endothelial cell adhesion and proliferation within these manufactured vessels as well as better controlling drying time between dips during manufacture to attain consistent wall thickness.

#### 8:00 PM SB09.06.31

**Characterizing Thrombogenic and Cell-Adhesive Properties of Poly(vinyl alcohol) Blended with Resorcinol Diphenyl Phosphate-Clay towards Vascular Graft Manufacture** Hannah Oh, Leora Stochel, Haoyu Xu, Megha Gopal, Robert Wong, Aaron Sloutski, Adam Hansen, Reza Dashti, Chander Sadasivan and Miriam Rafailovich; Stony Brook University, The State University of New York, United States

Poly(vinyl alcohol) (PVA) is an excellent candidate for manufactured vascular grafts to replace occluded arteries due to its mechanical and biocompatibility properties, but its lack of cell-adhesion prevents it from being used in humans [1]. Previously, we found that resorcinol diphenyl

phosphate (RDP)-clay can improve cell adhesion within polymer blends [3]. We aim here to characterize the thrombogenic and cell-adhesive properties of PVA/RDP-clay blends on both thin films and hydrogels.

2% PVA (w/w) solutions with each of 0%, 0.1%, 0.5%, 1%, 2%, 3%, 5%, 7% and 10% (w/w) RDP-clay added were spun cast onto silicon wafers. Human umbilical vein endothelial cells expressing green fluorescent protein (HUVEC-EGFP) were plated on the spun-cast wafers at a concentration of 20,000 cells/cm<sup>2</sup>, then imaged on an EVOS M7000 fluorescent microscope.

Good HUVEC cell adhesion with notable elongated cell morphology and cell-to-cell connections were observed on all spun cast films regardless of RDP-Clay concentration, indicating that in the absence of cross linker, PVA polymer was biocompatible, supporting cell adhesion and proliferation.

Potential thrombogenicity of the spun cast films was assayed by placing the substrate in a 4mg/ml solution of human fibrinogen. When fibrinogen contacts a hydrophobic surface, protein unfolding has been reported [3], which frees the alpha-C domains and exposes interior of the molecule in the absence of thrombin. Soluble fibrin is then recruited, forming large fibers which have been shown [3] to initiate clots in the presence of plasma. While multiple large fibers were observed here on the unfilled PVA films via Atomic Force Microscopy, the number of fibers and their diameters decreased with increasing RDP clay concentration, disappearing completely at a maximum loading of 5% RDP clay. This correlated with a continuous decrease in water contact angle with increasing RDP-Clay concentration, with a critical value between 1 and 2% RDP-clay.

Formation of the PVA hydrogels for the grafts, though, require cross linking with NaOH followed by rehydration of the PVA. In this case, samples with different clay concentrations were produced by dissolving 10% PVA with 0% and 10% RDP-clay, then crosslinking the solution with 15% sodium trimetaphosphate (STMP) and 30% sodium hydroxide (NaOH). The crosslinked solution was poured into 35 mm diameter molds and dried, creating hydrogel discs for cell plating. Discs were sterilized in isopropyl alcohol for 5 minutes, then rehydrated in media. Fibroblasts expressing Green Fluorescent Protein were plated atop the discs at a concentration of 2000 cells/cm<sup>2</sup>, then imaged after 12 hours with the EVOS microscope. Without extensive washing of the discs, cells were unable to adhere to the hydrogel due to leaching NaOH from the polymer matrix. However, after hydrogel discs were subjected to daily DI exchanges for 5 days and placed under constant agitation from a magnetic stirrer, high fibroblast adhesion to both 0% and 10% RDP-clay gels was observed. This finding contradicts previous studies that show little endothelial cell adhesion to pure PVA [1], which we believe can be attributed to a lack of extensive hydrogel washing.

Our novel processing method of PVA hydrogels as well as the hemocompatibility of PVA/RDP-clay blend thin films show great promise towards using this material for long-term, implanted vascular grafts in humans.

**Developing a Skin Construct for Wound Healing Associated with Endothelial Cell Network** Caitlyn Limbert<sup>1</sup>, Sahana Dhama<sup>2</sup>, Michael Lotwin<sup>3</sup>, Jacqueline Han<sup>4</sup>, Grace Wang<sup>5</sup>, Chunuo Chu<sup>6</sup>, Annika Joshi<sup>7</sup>, Rachel Na<sup>8</sup>, Shi Fu<sup>9</sup> and Miriam Rafailovich<sup>9</sup>; <sup>1</sup>British School Jakarta, Indonesia; <sup>2</sup>The Wheatley School, United States; <sup>3</sup>Rambam Mesivta, United States; <sup>4</sup>Great Neck South High School, United States; <sup>5</sup>Detroit Country Day School, United States; <sup>6</sup>Shenzhen Middle School, China; <sup>7</sup>Johns Creek High School, United States; <sup>8</sup>Washington University in St. Louis, United States; <sup>9</sup>Stony Brook University, The State University of New York, United States

Researchers have recently engineered skin constructs incorporating epidermal and dermal layers from the collagen matrix. A significant disadvantage in designing this organotypic culture for wound healing applications is the lack of a vascular network that promotes anastomosis of the graft-host vasculature. Meanwhile, relying on the additive growth factor to promote vascularization and angiogenesis is not sustainable and could be costly. Mesenchymal cells like fibroblasts and dental pulp stem cells are known to secrete several pro-angiogenic growth factors. Hence, our objective in this research is to (a) establish a microvascular network by co-culturing human umbilical vein endothelial cells (HUVECs) with mesenchymal cells in vitro without additional growth factors, (b) develop a series of altered mediums where both the endothelial and the epithelial cells can be co-cultured, (c) determine the role of an endothelial cell network in predicting vascularization and anastomosis response in vivo and (d) evaluating the impact of these constructs on wound healing.

Living skin equivalents were prepared for 17 days according to the procedures from our previous work [1], modified with the HUVECs-EGFP and mesenchymal cells co-culture layer on the bottom of skin constructs, cultured in the altered mediums to enhance both vascularization and epithelial differentiations. The non-vascularized skin equivalents with the same bottom layer without HUVECs were prepared similarly for comparison. Three SCID Hairless Outbred mice were used as hosts for wound healing experiments. 8mm diameter wound beds were created on the back of the mice. The harvested skin equivalents were then placed on the wound beds and bandaged with silicone film to prevent dehydration during healing.

Following a 7-day period of postoperative recovery, skin tissue samples were collected for histological analysis. Hematoxylin and eosin (H&E) staining revealed a seamless integration between the graft and the surrounding epithelium and dermis. Additionally, lumens were scattered throughout the grafted tissue, identified as human using anti-EGFP staining, and filled with blood cells. The luminal diameters of the human blood vessels ranged from approximately 10um to 40um without observable leakage, confirming successful anastomosis. The joining of blood vessels between graft and host is a necessary milestone for successful tissue regeneration and long-term engraftment.

In conclusion, we have designed a highly effective scaffold that enables the simultaneous culture of HUVEC networks with skin organotypics, promoting anastomosis and accelerating wound healing.

**Promoting Angiogenesis via HGF Upregulation using Titanium Dioxide Nanoparticles** Grace Wang<sup>1</sup>, Michael Lotwin<sup>2</sup>, Caitlyn Limbert<sup>3</sup>, Jacqueline Han<sup>4</sup>, Annika Joshi<sup>5</sup>, Chunuo Chu<sup>6</sup>, Sahana Dhama<sup>7</sup>, Rachel Na<sup>8</sup>, Shi Fu<sup>9</sup> and Miriam Rafailovich<sup>9</sup>; <sup>1</sup>Detroit Country Day School, United States; <sup>2</sup>Rambam Mesivta, United States; <sup>3</sup>British School Jakarta, Indonesia; <sup>4</sup>Great Neck South High School, United States; <sup>5</sup>Johns Creek High School, United States; <sup>6</sup>Shenzhen Middle School, China; <sup>7</sup>The Wheatley School, United States; <sup>8</sup>Washington University in St. Louis, United States; <sup>9</sup>Stony Brook University, The State University of New York, United States

Titanium dioxide (TiO<sub>2</sub>) nanoparticles (NPs) have high biocompatibility, antimicrobial properties, and light-scattering abilities, making them a valuable tool across various industries. As such, TiO<sub>2</sub> NPs have become strong points of interest in the modern biomedical field. Previous research has demonstrated that TiO<sub>2</sub> NPs induce the activation of human umbilical vein endothelial cells (HUVECs) due to increased expression of adhesion and other molecules associated with inflammatory response [1]. Such NPs may be linked to promoting angiogenesis, the process by which new capillaries are formed from existing vascular structures in the human body. Hence, this study examines the effects of TiO<sub>2</sub> NPs on HUVECs angiogenesis through flow

cytometry and cell sorting based on TiO<sub>2</sub> uptake, imaging time lapses of vascular development using EVOS microscopy, network quantification with Celleste Image Analysis software, scanning electron microscopy (SEM), and Reverse Transcription Polymerase Chain Reaction (RT-PCR).

HUVECs were cultured with and without 0.1mg/ml Rutile TiO<sub>2</sub> particles for 24 hours. The cultures were then sorted using FACS, where cells were sorted by a low and high scattering angle window, and it was assumed that the high scattering fraction would increase with TiO<sub>2</sub> uptake. The results showed that 91% of the treated cells contained TiO<sub>2</sub> particles.

The high scattering fraction and the control untreated cells were then plated on a 10mg/ml matrigel substrate, and the progress of angiogenesis was recorded using an EVOS microscope with a CO<sub>2</sub> onstage incubator. Images of triplicate cell cultures were captured every 20 minutes over 18 hours. The images were then analyzed using Celleste Image Analysis software. From the images, it was found that the culture with TiO<sub>2</sub> nanoparticles nucleated a network, and the network was more robust and persisted longer than the control. SEM analysis of the networks indicated that TiO<sub>2</sub> particles were present in the cells, which constituted the nodes, splines, and all aspects of the network.

RT-PCR was performed on the cultures, and the results of the treated cultures were compared to those of the control. The data showed that while the housekeeping gene, GAPDH, was significantly upregulated by the particles, no difference with the control group was observed for the other housekeeping gene, Actin Beta. Hence, only the latter was used for normalization.

The data demonstrated that TiO<sub>2</sub> exposure upregulated the hepatocyte growth factor (HGF) expression by more than an order of magnitude. In contrast, Vascular endothelial growth factor A (VEGFA) expression, which was previously observed to be upregulated in tumors with HGF, did not occur. These results indicate that despite no evidence of TiO<sub>2</sub> nanoparticle penetration into the nucleus, exposure to TiO<sub>2</sub> can result in upregulation of multiple genes. Further research into the precise mechanism is underway to determine whether the findings can serve as a beneficial factor in promoting wound healing.

We acknowledge the Morin Charitable Trust for funding.

#### 8:00 PM SB09.06.34

**Thrombosis: An Analysis of Pseudo-Thrombi to Understand Collagen-Fibrin Interaction** Sripradha Manikantan<sup>1</sup>, Huiting Luo<sup>2</sup>, Shi Fu<sup>2</sup>, Robert Wong<sup>2</sup>, Shiffoni Sukhlal<sup>2</sup> and Miriam Rafailovich<sup>2</sup>; <sup>1</sup>James Logan High School, United States; <sup>2</sup>Stony Brook University, The State University of New York, United States

When vascular injury occurs, the exposed tissue factor initiates thrombosis through a cascade of events including the aggregation of platelets and their coagulation, which in turn triggers the formation of fibrin and collagen to wrap around the coagulated platelets. Clinical treatment of thrombosis in patients with deep vein thrombosis or pulmonary embolism uses fibrinolytics in order to break down the fibrin and cause thrombolysis [1]. However, for arterial thrombi, fibrinolytics do not often respond well. Research shows that collagen plays a dual role in thrombosis [2] by stimulating glycoprotein VI to promote platelet accumulation and by activating factor XII to promote blood coagulation. In this research, we intend to understand the disparity between venous and arterial thrombosis by studying the interaction between collagen and fibrin in thrombi which prevent lysis. A model scaffold was produced where fibrinogen and collagen were mixed at low temperature and then allowed to crosslink at 37 C. The scaffold was submerged in osteogenic media for 21 days and biomineralization was assayed using XRF and Raman spectroscopy.

Results show that in-vitro XRF of scaffold revealed that biomineralization is significant in collagen when compared to fibrin. The calcium to phosphate ratio for the mixture of collagen and fibrin samples is 1.67, consistent with the formation of hydroxyapatite in the sample. Raman spectroscopy confirmed the formation of crystalline HA in the matrix. The spectra showed a greater peak for collagen when compared to fibrin or the collagen/fibrin scaffold mix, consistent with the XRF results. This means that fibrin has very little biomineralization. Also, unique peaks identified in the fibrin-collagen mix graph suggest the possible formation of a new biomaterial.

Venous thrombi were analyzed histologically and it was shown that they were predominantly composed of fibrin, while arterial thrombi were shown to contain collagen. XRF confirmed the absence of biomineralization in the venous thrombus, consistent with the in-vitro model. Results on the arterial thrombus will be presented, where the presence of mineral deposits will be investigated, as a function of collagen content and the hypothesis that they interfere with lysis will be investigated.

#### 8:00 PM SB09.06.35

**Neurogenic Differentiation of Micro-Spheric Dental Pulp Stem Cells via Poly-Lactic Acid, Poly(4-vinylpyridine) and Resorcinol Diphosphate Clay Polymer Scaffoldings** Divita Bhattacharya<sup>1</sup>, Catherine Chun<sup>2</sup>, Anita A. Gaenko<sup>3</sup>, Alexander C. Wang<sup>4</sup>, Adam Zaidi<sup>5</sup>, Ethan Lai<sup>6</sup>, Michael Wang<sup>7</sup>, Aman Yarlagadda<sup>8</sup>, Kuan-Che Fang<sup>9</sup> and Miriam Rafailovich<sup>9</sup>; <sup>1</sup>Kent Place School, United States; <sup>2</sup>Ardley High School, United States; <sup>3</sup>Huron High School, United States; <sup>4</sup>Sewickley Academy Senior School, United States; <sup>5</sup>San Francisco University High School, United States; <sup>6</sup>Phillips Academy, United States; <sup>7</sup>Mounds View High School, United States; <sup>8</sup>Newman Smith High School, United States; <sup>9</sup>Stony Brook University, The State University of New York, United States

Neurodegenerative diseases such as Alzheimer's pose a major risk to the central nervous system due to the intrinsic non-dividing nature of neurons. Therefore, it is imperative to find methods of generating functionally and morphologically neuronal-like cells from non-neuronal cells under biomimetic conditions. Previously, dental pulp stem cells (DPSCs) have been shown to differentiate into neurons via plating on Poly(lactic Acid (PLA), Poly(4-vinylpyridine) (P4VP), and Poly(lactic Acid with Resorcinol Diphosphate (RDP) Clay. A concentration of 20% RDP-Clay was found to provide the highest extent of differentiation into neurons on rough PLA surfaces [1]. Also, the usage of micro-sphere forming U-bottomed StemFit 3D suspension well plates increased the differentiability of DPSCs [2]. Therefore, in this experiment, we are investigating the effects of PLA, P4VP, and RDP Clay scaffolding on neuronal differentiation of DPSCs plated on 3D micro-sphere forming plates.

DPSC micro-spheres (created using suspension well plates) were plated onto silicon wafers spin-casted with pure PLA, PLA with 20% RDP-Clay, PLA with 30% RDP Clay, pure P4VP, P4VP with 20% RDP-Clay, and P4VP with 30% RDP-Clay. These spin-coated surfaces were analyzed with Atomic Force Microscopy (AFM) to ensure homogeneous roughness across the samples so that roughness wouldn't be a confounding factor in the growth and differentiation of the DPSCs. The RDP-Clay particles dispersed throughout the PLA with 20% RDP-Clay sample became nuclei for PLA crystals. Conversely, P4VP does not crystallize around the RDP-Clay.

The plated cells were incubated for 28 days with regular media changes. EVOS images of the DPSCs were taken on Day 1, 6 days after the cells were cultured in TCP and 1 day after plating on polymer scaffolds, confirming microsphere formation following suspension well culturing.

On Day 4, the elastic modulus of the DPSCs was measured for each group of polymer scaffolding via AFM. Cells plated on TCP served as a baseline for modulus. Lower modulus values indicate neuronal differentiation, as neurons are softer cells compared to DPSCs. P4VP had lower modulus (half that of

TCP), which indicates that cells plated on pure P4VP had the highest elasticity and were therefore likely differentiating into neurons at a higher rate. Adding RDP-Clay concentration corresponded to a significant difference in modulus for cells plated on PV4P, but an increasing concentration of RDP-Clay was not consistent with a significant change in modulus for PLA scaffolds.

On Day 28, the expression of early-stage neuronal development markers TUBB3 and NES and late-stage marker NEFM was measured using RT-PCR and compared to expression in undifferentiated DPSCs. In differentiated neuronal cells, expression of TUBB3 and NES is expected to be downregulated, and NEFM is expected to be upregulated. Corresponding to our modulus data's implications, adding RDP-Clay to PLA did not lead to significant downregulation of TUBB3, NES, or upregulation of NEFM. However, an increasing concentration of RDP-Clay in P4VP correlated with significant downregulation of TUBB4, NES, and upregulation of NEFM in comparison to undifferentiated DPSCs, indicating that the cells likely underwent neuronal differentiation. Further data will be collected to analyze the effects of these polymer scaffoldings on the neuronal functionality of these morphologically and genetically differentiated cells.

**ECM Based Hydrogel Delivery Vehicles and 3D In Vitro Injection Model for Human Retinal Progenitor Cells Transplantation** Rebecca Carrier<sup>1</sup>, Peng Zhao<sup>1</sup>, Sidi A. Bencherif<sup>1</sup> and Michael J. Young<sup>2</sup>; <sup>1</sup>Northeastern University, United States; <sup>2</sup>Schepens Eye Research Institute, an affiliate of Harvard Medical School, United States

Retinal degenerative diseases caused by photoreceptor cell loss and damage are the leading cause of blindness worldwide<sup>1</sup>. Treatments, including gene therapy, drug, and neuroprotective approach, mainly focus on slowing down the degeneration process rather than reversing it. Retinal cells implanted into the subretinal space have been shown to integrate within host retina, improving visual function in models of retinal degeneration<sup>1</sup>. One barrier to clinical success is the loss, through efflux and death, of the majority (>99%) of implanted cells<sup>2</sup>. A factor likely contributing to cell death is the host microenvironment of the subretinal space after a high cell density (~105 cells/ul) bolus injection (e.g., lacking oxygen/nutrients, missing physical support, and chemical cues). Recent studies have demonstrated that the delivery of retinal progenitor cells (RPCs) using polymer scaffolds results in improved cell survival and differentiation with associated increases in RPC integration<sup>3-4</sup>. However, current polymer scaffolds still result in minimal overall integration (<2%). We have established an in vitro bolus injection model mimicking clinical subretinal injection to explore the impact of bolus injection on human RPCs viability. Studies using this model have revealed that indeed RPCs are damaged during the injection process, leading to cell death. To better understand what cues may improve survival of RPCs in the post-injection bolus microenvironment, inert hydrogel systems (oxidized low viscosity alginate) were employed in conjunction with retinal ECM cues including glycosaminoglycans (GAGs): hyaluronic acid (HA) and chondroitin sulfate (CS), laminin (important component of basement membrane), and RGDS (adhesive peptides). The effects of the stiffness and chemical modifications of the delivery vehicles on cell survival/death mechanisms in the bolus injection environment were investigated using fractional factorial design, revealing advantages of stiffer substrates and laminin in promoting RPC survival. Ultimately, this information can be used to guide design of cell delivery vehicles for human RPCs transplantation with improved post-injection survival.

**Poly 1,8-Octanediol Citrate Breast Biopsy Scaffold and Deployment System** Darnell R. Campbell, Marcos Benavides, Jordan Forte, Clifford Howard and Nicole Levi; Wake Forest University School of Medicine, United States

During a breast biopsy, it is crucial to accurately identify regions of concern and deliver markers accurately for subsequent imaging and surgical procedures. If surgical removal is not required, it is essential for the marker to be biocompatible, as it will remain in the tissue for the remainder of the patient's lifetime. Current breast biopsy systems employ a forceful deployment during marker administration leaving a void within the tissue that contributes to marker migration. Furthermore, current marker-encapsulating-meshes are not robust and lack compliance to breast tissue which further contributes to rapid mesh disintegration and marker migration.

To address the aforementioned problems present in the current standard of care, our group developed a three-pronged approach consisting of the creation of an elastic biodegradable scaffold to encapsulate the marker, a deployment device for *in vivo* testing on rats that does not utilize forces during administration, and a transparent breast tissue phantom to determine real-time expansion of the scaffold.

First, a biodegradable Poly 1,8-Octanediol co-citrate (POC) elastic scaffold capable of securing both metallic and non-metallic markers was developed and characterized. Our initial results indicate that POC's properties can be tuned to user-preference by changing crosslinking time, porogen size and leaching time during fabrication; to ensure elasticity of the scaffold, we optimized the pore size by using 400µm NaCl as a porogen. Next, we optimized POC compression and expansion by testing tensile forces at different crosslinking and porogen leaching times. Interestingly, we encountered that during subsequent crosslinking after leaching, POC develops limited self-healing capabilities which allowed for previously embedded markers to be repositioned within a completed scaffold.

Secondly, we developed a 3D-printed deployment device which releases the encapsulated breast biopsy marker passively in a retractable motion, eliminating the forces that cause an increase in void size within the biopsy incision. The device was subsequently employed during *in vivo* testing in rats, from which initial results demonstrate little to no marker migration when compared to current standard of care.

Finally, an optically transparent breast phantom was made from Dermasol. This reusable, insensitive to temperature or dehydration phantom allows for POC scaffold deployment and expansion in real time.

Here we presented our solutions to address the challenges associated with breast biopsy marker placement. We achieved this by developing a biodegradable POC scaffold capable of encapsulating markers and expanding to fill the biopsy void, a retractable deployment device to release the scaffold passively, a breast tissue phantom for visualization of sponge expansion, and tested of our approach *in vivo*. We are currently determining POC's degradation profile as well as continuing to evaluate our prototype scaffold and deployment system *in vivo* to measure the reduction in metallic marker migration compared to commercially available devices.

##### **Responsive Antimicrobial Biomaterials for Treatment of Wound Infections** Anita Shukla; Brown University, United States

The wound repair and regeneration process is greatly complicated by the presence of infections. Chronic wounds in particular are highly prone to infection. As a prominent example, nearly 60% of individuals with diabetic foot ulcers develop infections. Preventing and treating wound infections is a critical challenge in promoting successful tissue repair. The existence of biofilms and antimicrobial-resistant microorganisms within wound environments further complicates the effective treatment of these infections. In this talk, I will describe recent approaches we have taken to treat wound infections using hydrogel biomaterials and nanoparticle therapeutic formulations. I will discuss the development of a bacteria-responsive hydrogel drug delivery platform that can provide on-demand treatment of wound infections, while facilitating tissue repair. These hydrogels respond to the presence of beta-lactamases, which are bacteria-produced enzymes that are a common cause of antibiotic resistance. Upon exposure to beta-lactamases, the hydrogel backbone undergoes degradation, leading to the release of encapsulated antibacterial liposomes. Our findings using a *Pseudomonas aeruginosa*-infected murine skin abrasion wound model indicate complete clearance of infection within one day of treatment. Importantly, there were no instances of infection recurrence during the four-day wound monitoring period. Furthermore, timely eradication of the infection helped promote wound healing, as evidenced by histological analysis revealing rapid regeneration of the epidermis. Notably, the hydrogel itself exhibited no signs of toxicity. I will also describe our work on the development of bacteria-responsive gelatin nanoparticles that have demonstrated promising antibiofilm efficacy against prevalent wound infection-causing bacteria, including *Vibrio vulnificus* and *P. aeruginosa*. Overall, the technologies described in this talk are biocompatible and effective at eliminating wound infections, thus holding immense potential for promoting effective wound healing.

#### 9:15 AM SB09.07.05

##### **Biomimetic Semi-Flexible Hydrogel with Reduced Inflammation for Bone Defects** Jaeseo Lee<sup>1,2,3</sup> and Il Keun Kwon<sup>3</sup>; <sup>1</sup>Harvard Medical School, United States; <sup>2</sup>Brigham and Women's Hospital, United States; <sup>3</sup>Kyung Hee University, Korea (the Republic of)

Engineered 3D scaffolds must be biomechanically capable to substitute injured tissues, and have typically been made of tissue-mimicking stiffness. However, this paradigm is shifting towards the understanding that the stiffness of scaffolds can be directly responded to by cells. Herein, we have designed a soft hydrogel to meet two criteria that can shift from soft to progressively hard tissue, similar to tissue development in nature. First, inspired by clotting of blood at the wound site, the goal is to achieve strong bonding with adjacent tissues through physical crosslinking of fibrinogen (FBG). Second, the hydrogel is needed mattress to dissipate energy such as existing collagen (COL) in the body. This scaffold promotes energy dissipation by strengthening the elastic and soft fibers of the FBG through COL to form a dense structure. As a crucial fundamental substrate, soft hydrogels initially induce rapid cell adhesion due to their soft surface. Sequentially, the cells increase to penetration inner part and make rigid themselves, and leading to bone formation. Furthermore, this hydrogel was composed of ECM-like tissue, which could reduce inflammation in the early stage. Therefore, our dual-function system provides a promising strategy for natural tissue-mimicking bone regeneration by reducing inflammation, and concurrently bridging defect area through harmonizing the newly assemble cells and ECMs.

#### 9:30 AM SB09.07.06

##### **Neuron Viability and Maturation on Electroactive Materials and Effect of Electroactive Stimulation on Neural Cell Response** Teresa Marques-Almeida<sup>1</sup>, Clarisse Ribeiro<sup>1</sup>, Igor Irastorza<sup>2,3</sup>, Patricia Miranda<sup>4</sup>, Ignacio Torres-Alemán<sup>4</sup>, Unai Silvan<sup>2</sup> and Senentxu Lanceros-Mendez<sup>2,1,3</sup>; <sup>1</sup>University of Minho, Portugal; <sup>2</sup>BCMaterials, Basque Center for Materials, Applications and Nanostructures, Spain; <sup>3</sup>University of the Basque Country, Spain; <sup>4</sup>Achucarro Basque Center for Neuroscience, Spain; <sup>5</sup>Ikerbasque, Basque Foundation for Science, Spain

Electric cues are intimately related connected to physiological functions of cells and tissues. The ability to control and direct electric signals within tissue-engineered constructs is therefore increasingly important for proper tissue engineering strategies, as they influence cell behaviour and guide tissue development towards more functional and biomimetic outcomes. IN this context, smart materials, able to react in a controllable and reversible way to external stimuli by varying a specific physical or chemical quantity, show great potential for the development of advanced biomedical strategies, including biosensing, tissue regeneration and repair, immuno- and cancer therapy. Among the different types of smart materials, piezoelectric ones, that convert mechanical solicitations into electrical potential variations and vice versa, represent as suitable candidates to induce specific cell behaviors through electric cues, mainly by improving biomimicry of the cell microenvironment.

The presence of piezoelectric properties in different tissues is known and the effect of surface charge and piezoelectric stimulation has been proven to be beneficial in a variety of cells, including mesenchymal stem cells, myoblast and osteoblasts, among others, has been evaluated. Since neurons were first cultured outside a living organism more than a century ago, a number of experimental techniques for their *in vitro* maintenance have been developed. These methods have been further adapted and refined to study specific neurobiological processes under controlled experimental conditions. Nevertheless, the impact of fundamental properties of the surfaces to which neurons adhere when cultured *in vitro* has not been sufficiently considered.

In the present work we have analyzed the response of primary neurons when cultured on piezoelectric poly(vinylidene fluoride), PVDF, surfaces with different surface electric charge and electric charge type, allowing to establish the effect of the net charge on neuron behavior. It is shown that PVDF films promote the attachment, viability and maturation of primary neurons. More cells per unit area and longer neurites were already present in neurons cultured for one day on PVDF surfaces. Early neurite outgrowth was induced using poled PVDF as culture substrates, since by day 4 of culture neurons already show significantly increased neural process development, and by day 7, this development is even more obvious in neurons cultured on PVDF-. Negative surface charges particularly increased cell metabolism, being about 3 times higher than in control and around 1.7 times higher than in the absence of charge (PVDF NP). When adhering to PVDF-, neurons undergo maturation at a faster rate, as revealed by the higher expression levels of MAP2 and NeuN. Further, the effect of surface charged PVDF films (positive, negative, and non-poled (average neutral surface charge)) on adhesion, proliferation and differentiation of neural-derived cell line, under static and dynamic mechano-electrical stimulation was assessed.

Upon mechano-electrical stimulation, PVDF with average positive surface charge allows to significantly improve cellular adhesion compared to PVDF with negative or without average surface charges. Independently of the PVDF surface charge type, the applied electrical stimulus throughout the assay improved neurite extension and differentiation.

The obtained results highlight the importance of considering the electric charge of the culture surface for the *in vitro* maintenance of neurons, demonstrating the suitability of the use of 2D PVDF based surface-charged substrates. Further, these findings highlight the possibility of novel therapeutic strategies for the regeneration of neural tissues based on the dynamically surface charge variation that can be induced in the electroactive films.

#### 10:15 AM SB09.07.08

**Magnetic Hyperthermia Enhances *In Vivo* Tissue Regeneration Through Intracellular Ros Production** Giuseppina Tommasini<sup>1</sup>, Susel Del Sol-Fernández<sup>1</sup>, Angela Tino<sup>2</sup>, Claudia Tortiglione<sup>2</sup> and Maria Moros<sup>1,3</sup>, <sup>1</sup>Institute of Nanoscience and Materials of Aragon (INMA-CSIC), Spain; <sup>2</sup>Institute of Applied Science and Intelligent System (ISASI-CNR), Italy; <sup>3</sup>Centro de Investigación Biomédica en red en Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Spain

Regenerative medicine is a pioneering field aimed at restoring and regenerating damaged tissues and organs through numerous strategies, including the use of new materials and de novo generated cells<sup>1-2</sup>. As a dynamic biological process, tissue regeneration requires a variety of intracellular and extracellular molecular mechanisms to facilitate cell division and regeneration. In recent years, multiple studies have demonstrated a central role of reactive oxygen species (ROS) in tissue regeneration, acting as signaling molecules that trigger the activation of molecular pathways involved with cell proliferation and differentiation<sup>3</sup>. Recently, regenerative medicine has found a surge of interest in magnetic nanoparticles, using their magnetomechanical and heating potential to activate different pathways. In this optics, a promising therapeutic approach could be the possibility of manipulating the ROS production to enhance tissue repair using mild magnetic hyperthermia (MH).

Here, we present a novel approach for enhancing tissue regeneration *in vivo* through mild magnetothermal stimulation using manganese iron oxide nanoparticles (MnxFe3-xO4) with improved heating performance. We evaluated the biological effect of internalized MNPs subjected to an alternating magnetic field on the regeneration process that physiologically occurs in the freshwater invertebrate polyps *Hydra vulgaris*. To decipher the molecular mechanism underlying this process, we performed gene expression analysis of molecular markers normally modulated in ROS homeostasis in regenerated polyps after the MH stimulation. This innovative approach has not been applied before to improve tissue regeneration and thus could represent a breakthrough in tissue engineering.

**The Effects of Varying Ratios of PEGDA:PDMS on the Mechanical Properties of Hydrogels with Differing PEGDA Concentrations for Bone Tissue Engineering** Sam Lloyd-Harry<sup>1</sup>, Ozgul Yasar-Inceoglu<sup>1</sup> and Ozlem Yasar<sup>2</sup>; <sup>1</sup>California State University Chico, United States; <sup>2</sup>The City College of New York, United States

The mechanical properties of hydrogels play a crucial role in determining their suitability as scaffolds for cell growth. Properties such as biocompatibility, porosity, and mechanical properties dictate the success of a candidate scaffold material. The effects on the mechanical properties of varying ratios of Poly (ethylene glycol) diacrylate (PEGDA) to polydimethylsiloxane (PDMS) have been reported; however, the effects of differing PEGDA:PDMS ratios in varying amounts of water have not been studied. In this work, the effects of varying ratios of PEGDA:PDMS (90:10, 85:15, 80:20) on the mechanical properties of PEGDA concentrations (20%, 40%, 60%, 80%, 100%) were investigated and compared with the embedment of SiO<sub>2</sub> nanoparticles (NPs). PEGDA, PDMS, water, and photoinitiator were mixed and cured under a 365 nm UV light for 10-30 minutes (increasing by 5 minutes with increasing PEGDA concentrations). Compressive testing was performed on all samples using a QT/50 Universal Testing Machine at a 5mm/min rate until breaking. Results indicate that introducing silicon and increasing oxygen strengthens PEGDA hydrogels significantly, regardless of concentration. The comparison of SiO<sub>2</sub> embedded samples to varying PEGDA:PDMS samples reflects the tunability that makes PEGDA hydrogels ideal candidates for tissue engineering.

**Building Cardiac Valves with Focused Rotary Jet Spinning** Michael Peters<sup>1,1</sup>, Sarah Motta<sup>1,1,2</sup>, Christophe Chantre<sup>1,1</sup>, Huibin Chang<sup>1,1</sup>, Luca Cera<sup>1,1</sup>, Qihan Liu<sup>1,1</sup>, Elizabeth Cordoves<sup>1</sup>, Emanuela Fioretta<sup>2</sup>, Polina Zaytseva<sup>2</sup>, Nikola Cesarovic<sup>3,4</sup>, Maximilian Emmert<sup>2,3,5</sup>, Simon Hoerstrup<sup>1,2,5</sup> and Kevin K. Parker<sup>1,1</sup>; <sup>1</sup>Harvard University, United States; <sup>2</sup>University of Zurich, Switzerland; <sup>3</sup>Deutsches Herzzentrum der Charite, Germany; <sup>4</sup>ETH Zürich, Switzerland; <sup>5</sup>University of Zurich and ETH Zurich, Switzerland

Pediatric patients suffering from heart valve disease often require multiple highly invasive valve replacement surgeries throughout their childhood. Building heart valve replacements that remodel and grow alongside the patient could provide a potential solution to avoid these repeat interventions. Here, we present Fibravalves as heart valve replacements that mimic the multiscale structure of the native valve, ranging from the nanoscale of the extracellular matrix (ECM) to the macroscale of the native leaflet geometries. Current valve manufacturing processes struggle to recreate these hierarchical structures. With Focused Rotary Jet Spinning (FRJS), we fabricated these valve scaffolds in less than ten minutes. Utilizing centrifugal forces to extrude synthetic polymer fibers and a focused air stream to direct them, FRJS prints micro- and nanofibers onto customizable trileaflet valve shaped collection mandrels. Fiber production and valve formation occur simultaneously. The micro- and nanofibers serve as ECM analogs, interacting with the native tissue at the cellular level, while the macroscale shape of the valve leaflets control unidirectional cardiac flow. We manufactured Fibravalves using Poly(L-Lactide-co-ε-Caprolactone) fibers, due to their elastic mechanical properties and ability to facilitate rapid cellular infiltration. To evaluate clinical translatability, Fibravalves were implanted in sheep using a minimally invasive transcatheter approach. The stented valves were deployed successfully and provided one-way cardiac flow control in initial acute studies. This work indicates the potential viability for FRJS to be used for future heart valve manufacturing as well as other medical implants.

#### 11:00 AM SB09.07.11

**Cell-Seeding Promotion of Phages Functionalized Surfaces** Grazia M. Messina<sup>1</sup>, Giovanna Calabrese<sup>2</sup>, Salvatore Guglielmino<sup>2</sup> and Giovanni Marletta<sup>1</sup>; <sup>1</sup>University of Catania, Italy; <sup>2</sup>University of Messina, Italy

Regenerative medicine is a developing field of interdisciplinary research that includes a combination of *in vitro/ex vivo* and *in vivo* techniques, including the transplantation of stem/progenitor, differentiated, or modified cells, either alone or in biomaterial scaffolds. Many strategies have been developed based on the stimulation of body's endogenous process to grow and repair.

Phage display represent a powerful, high-throughput method for discovering peptide ligands for a specific target. The method uses a library of phage particles containing a wide range of peptides or proteins to identify those that bind to a specific target. This technique has evolved and now it contributes to a variety of different areas of medicine and technology, i.e., targeted drugs, imaging diagnosis, gene delivery and nanomaterials. It is a low-cost technique for screening peptide ligands on cells or tissues, distinguishing between small changes in cell surface phenotypes and between normal and sick tissues. In particular, phage-derived peptides can be used to functionalize synthetic scaffolds to drive stem cell proliferation and differentiation in vitro. In this communication we will show how self-organization processes of phages on model substrates, at the liquid/solid interface, promotes anisotropic nanometric alignments of these macromolecular systems, characterized by peculiar nanosized diameters, with lengths of the order of micrometre. The further goal, however, is to correlate the capability of organized phage assemblies to efficiently promote specific processes of "cell seeding" and, in turn, developing suitable control strategies of the phage organization, based on the tuning of pH and surface free energy, as a preliminary step in the development of efficient scaffold functionalization strategies for tissue regeneration. The efficiency of the adopted surface functionalization technique was evaluated by using AFM, while the cell-response has been assessed by optical microscopy and by Force Spectroscopy, focusing the attention on the effect of phages on the mechanical properties of the extracellular matrix. We think that these studies may pave the way to a tailored use of surfaces functionalized with phages, as a smart scaffold able to increase the beneficial cell response.

11:15 AM SB09.07.12

**3D Printed High-Strength, Void-Free, Heterogeneous Microneedle Flexible Patch for Multi-Drug Delivery** Jaeho Kim<sup>1</sup>, Sang H. Ahn<sup>1</sup>, SeungHyun Park<sup>2</sup> and WonHyung Ryu<sup>1</sup>; <sup>1</sup>Yonsei University, Korea (the Republic of); <sup>2</sup>Pukyong National University, Korea (the Republic of)

Microneedle (MN) has been extensively studied for drug delivery with the rapid development of various designs and fabrication methods. Dissolving MN made of fast-dissolving biomaterial such as hyaluronic acid (HA) has shown great potential and has been the most popular MN type. However, dissolving MNs have several unsolved issues: less reliable tissue insertion and inconsistent drug delivery to the tissue. Dissolving MNs are usually fabricated with an aqueous polymer solution, which requires a solvent evaporation step for solidification. However, evaporation deforms MN's shape and results in air voids trapped in MN. This inevitably affects each MN's stiffness, insertion ability, and dose distribution. Nevertheless, most of the studies on dissolving MNs have focused on studying their clinical effects and neglected the reliability of MN insertion and drug delivery to the tissue. Multi-drug delivery from MNs have been introduced as an advanced form of MNs when more than one drug needs to be administered for cancer treatment. They are mostly fabricated by micro-molding two drugs together or dip-coating the second drug formulation on dissolving MNs containing the first drug. However, these MNs can have unwanted interactions between drug compounds and can have difficulty with accurate dose control at the MN insertion site. A heterogeneous MN (h-MN) device which contains different drugs in different MNs in a single patch can be a great alternative since it can avoid drug interaction. Nevertheless, the fabrication process of the h-MN array is challenging since the traditional micro-molding process produces an array of MNs with a single material. This study established a vacuum-assisted extrusion 3D printing process for high-strength, void-free h-MN flexible patch fabrication. We confirmed reliable tissue penetration and accurate drug delivery to a target tissue. Negative pressure was applied beneath a PDMS mold to remove the air void remaining after molding the polymer solution. For efficient removal, the mold was fabricated with a thickness of less than 1 mm. The mold was located on the customized vacuum jig which was connected to a vacuum pump to apply negative pressure beneath the mold. An array of poly (lactic-co-glycolic acid) (PLGA) and HA MNs were fabricated in a single flexible patch for long-term and short-term drug delivery. For PLGA MN fabrication, PLGA5050 57.14 wt.% solution was prepared using dimethyl sulfoxide (DMSO) with rhodamine b (0.1 w/v %) at 60 °C for 1 h. The solution was extruded single time by an extrusion 3D printer (Nordson Pro4L EFD) with 20 kPa of pneumatic pressure into the cavity. DMSO was evaporated after the extrusion at 130 °C for 60 min. For HA MN fabrication, HA 9.09 wt.% solution was prepared using 0.2 w/v % fluorescein isothiocyanate–dextran (FITC-Dextran) aqueous solution. The solution was extruded 9 times with 90 kPa of pneumatic pressure and a humidifier was applied to maintain relative humidity over 50 %. After the MNs fabrication, the mechanical properties of each MNs were analyzed by the penetration test conducted on porcine skin. The penetration force of each MNs was up to 30 g on the porcine skin which was inserted into tissue to a depth of about 550 µm. Afterward, the drug release rate of h-MNs was estimated by measuring the fluorescence intensity using a plate reader. Drug release test showed that PLGA MN released rhodamine b for 98 h and HA MN released FITC-Dextran for 3 h. Finally, HA solution (13.04 wt.%) was extruded in a mesh pattern over a fabricated 3 x 3 h-MN array to form an h-MN flexible patch. After preparing the h-MN patch, it was again inserted into the porcine skin to identify the penetration ability by confirming the cross-sectional view using a cryo-sectioning machine. Through the development of the fabrication process and analysis result, vacuum-assisted extrusion 3D printed h-MN patch has demonstrated its mechanical, and clinical feasibility.

SESSION SB09.08: Scaffolds for Regenerative Engineering II

**Bioinspired Flexible Helical Electrospun Mat for Cardiac Patch Application** Alexi Switz, Darryl A. Dickerson and Anamika Prasad; Florida International University, United States

**Overview:** Fiber orientation dictates mechanical properties such as mechanical flexibility and porosity. Controlling these properties allows for increased and improved growth of cardiomyocytes for cardiac patch applications. Our work focused on developing helically coiled fiber mats made of polycaprolactone produced via electrospinning, then testing the biocompatibility and function of these fibers in a cardiac patch application and comparing these results to patches reinforced with aligned fibers and patches without fibers.

**Background:** Helically coiled structures are found in nature from animal to the plant world and provide mechanical support, higher porosity, and increased flexibility. Replicating these structures via electrospinning as a manufacturing method, helically coiled nanofibers promote elasticity and flexibility and have a large surface area for biomolecular interactions, which is suitable for cardiovascular applications due to the demanding dynamic environment of cardiovascular tissue.

**Methods and Results:** Two types of polycaprolactone fibers were produced via electrospinning; aligned fibers and helically coiled fibers. Fiber formation was dictated by the electrospinning parameters, specifically the flow rate of the polymer solution through the syringe. The biocompatibility and function of these fiber scaffolds were tested by encasing the fiber scaffolds in a hydrogel comprised of gelatin glycidyl methacrylate. Fibronectin was added to this hydrogel to increase biocompatibility and aid in cardiomyocyte attachment and spreading. This hydrogel was seeded with cardiomyocytes differentiated from human-induced pluripotent stem cells to form a preliminary cardiac patch. In total three types of patches were produced: a cardiac patch containing aligned fibers, a cardiac patch containing helically coiled fibers and a third cardiac patch containing no fibers. The cardiac patches were then placed on a holder made of PDMS that provided a passive mechanical stimulus to the cardiomyocytes. These holders were placed in a 12-well plate, and the cardiomyocytes seeded in the cardiac patch scaffold were incubated for 28 days. Cell media was regularly changed to provide the cells with nutrients. Cell

growth, cell viability, and cardiomyocyte function were monitored and compared within the three patches. Additionally, the cardiac patch mechanics were examined using nanoindentation, tensile testing, and Raman spectroscopy to discuss the overall suitability of the fibrous mat in cardiac tissue engineering applications.

#### 1:45 PM SB09.08.02

**Cancer Testbeds for Bone Metastasis Therapeutics** Kalpana Katti<sup>1</sup>, Preetham Ravi<sup>1</sup>, Quyen Hoang<sup>1</sup>, Jiha Kim<sup>1</sup>, Anu Gaba<sup>2</sup>, Parth Vyas<sup>2</sup> and Dinesh R. Katti<sup>1</sup>; <sup>1</sup>North Dakota State University, United States; <sup>2</sup>Sanford Health, United States

Worldwide over a million deaths occur each year from breast and prostate cancer bone metastasis. Majority of the deaths due to breast and prostate cancer are attributed to metastasis, the process of migration of cancers from the primary site to a remote location which happens to be bone for breast and prostate cancer. Bone metastasis of cancer often causes skeletal failures that become the cause of death in patients. The anticancer drugs available are ineffective for bone metastasis treatment. The inefficacy of anticancer drugs and failure of animal models necessitates the need for reliable in vitro models. We have developed a novel nanoclay tissue engineering scaffold that enables development of a remodeling stage fetal bone, a preferred niche for breast and prostate cancer metastasis. The bone mimetic scaffold utilizes modification of the clay galleries with amino acids to allow biomimetic mineralization of hydroxyapatite inside clay galleries. The bone scaffold is further sequentially seeded with commercial and patient derived cell lines of prostate and breast cancer to generate in vitro models of bone metastasis in breast and prostate cancer. A specially designed horizontal flow bioreactor enables physiologically relevant fluid flow through the scaffolds thus creating a realistic testbed of bone metastasis. The cancer testbed serves as a useful platform to investigate new biomarkers using FTIR spectroscopy, RAMAN imaging and nanomechanical investigations. We have developed unique mechanics-based biomarkers that use direct nanoindentation to evaluate the change in elastic modulus, mechanical plasticity and viscoelasticity of cancer cells as a measure of metastasis progression. We have developed unique FTIR based spectroscopic biomarkers with the help of the testbed that also demonstrate the use of FTIR in developing markers for progression of metastasis<sup>9</sup>. Since clinical observations indicate extensive skeletal problems and failures in bone metastasis patients, we use the testbed to evaluate the mechanisms of influence of cancer cells on the Wnt/β-catenin pathway an important osteogenesis pathway. We observe the specific role of cancer cell factors DKK and ET-1 on influence osteogenesis at the bone site. Lastly we demonstrate the use of testbed for screening new drugs and plant-based compounds for efficacy in treatment of bone metastasis. Overall the cancer testbed presented here is a useful in vitro system for development of new metastasis therapies and personalized medicine.

#### 2:00 PM SB09.08.03

**Lacunar Bone-Inspired Biodegradable Constructs: Towards Mini-Invasive Bone Repair** Federica Buccino<sup>1</sup>, Giuliana Tromba<sup>2</sup>, Sandra Hofmann<sup>3</sup> and Laura Maria Vergani<sup>1</sup>; <sup>1</sup>Polytechnic University of Milan, Italy; <sup>2</sup>Elettra Synchrotron, Italy; <sup>3</sup>Technische Universiteit Eindhoven, Netherlands

Advancements in the field of medicine have resulted in increased life expectancy but have also led to a rise in age-related illnesses, with osteoporosis being one of the most prevalent and widespread diseases. Each year, approximately 9 million fragility fractures occur globally, imposing a significant economic and psychosocial burden for disease management. While accidents and bone tumors directly cause pain and deformity, bone fragility often remains undetected, gradually deteriorating quality of life and creating a pressing need for effective regenerative strategies.

Despite notable progress in microsurgical techniques in recent decades, achieving satisfactory functional and structural repair of damaged bone tissue remains challenging. Although bone tissue possesses intrinsic regrowth and self-restoration capabilities to some extent, the injured bones frequently fail to regain their load-bearing function, resulting in fracture nonunion. Current approaches for treating large bone injuries involve the use of autografts, allografts, and scaffolds, but none of these methods are entirely satisfactory due to specific limitations. These limitations include reduced bioactivity, potential spread of pathogens, inflammation, the need for additional surgery, limited availability, inappropriate shape and size, and a lack of monitoring for newly formed bone. In particular, difficulties in detecting bone-scaffold interactions and understanding the complex relationships between bone formation and local scaffold geometry are currently impeding the clinical applicability of minimally invasive constructs for bone healing.

To overcome these challenges, we propose the design of a novel construct for bone healing that has the potential for scalability, while addressing the current geometric, biological, and monitoring issues. The geometry of the construct is inspired by the natural lacunar micro-porosity and interconnectivity found in human bones, facilitating an improved cell seeding process. The constructs are fabricated using silk fibroin and seeded with mesenchymal stem cells. Two different culture media are considered: the state-of-the-art fetal bovine serum (FBS) and the human platelet lysate (hPL). To assess the mechanical response of cellularized constructs, we employ image-guided failure assessment within a synchrotron using a newly developed X-ray and human eye testing equipment, performing micro-compression tests on the seeded constructs. Scans are acquired at various time frames, corresponding to increasing levels of applied displacement to the construct.

To evaluate the interplay between bone regeneration and the architecture of the silk fibroin scaffold, we utilize neural networks (NN). With a NN accuracy of 0.92, our findings demonstrate the following: i) there is a statistically significant correlation ( $p < 0.05$ ) between pore density and bone formation; ii) constructs seeded with hPL exhibit enhanced bone regeneration (+26%) compared to those seeded with FBS; iii) pore shape may play a crucial role in modulating bone remodeling.

The unprecedented resolution of synchrotron imaging, coupled with the ability to gain novel insights into the mechanical response of constructs for bone healing, enables us to elucidate the intricate connections between scaffold geometry, woven bone formation, and the restoration of mechanical function. Future endeavors will focus on the utilization of shape-responsive materials in construct design, allowing the shape of the construct to be adapted according to specific requirements and needs.

#### 2:15 PM SB09.08.04

**Nanotube Scaffolds: Versatile and Customizable Long-Term Culture Platform for Primary Cells and Adult Tissues** Astrid Kupferer<sup>1,2</sup>, Sabrina Friebe<sup>1,2</sup>, Philine Jauch<sup>1,2</sup>, Sonja Kallendrusch<sup>3</sup>, Ivonne Nel<sup>4</sup>, Bahriye Aktas<sup>4</sup> and Stefan G. Mayr<sup>1,2</sup>; <sup>1</sup>Leibniz Institute for Surface Engineering, Germany; <sup>2</sup>University of Leipzig, Faculty of Physics and Earth Sciences, Division of Surface Physics, Germany; <sup>3</sup>HMU Health and Medical University Potsdam, Germany; <sup>4</sup>University of Leipzig, Medical Center, Germany

A personalized therapy for each patient is one of the milestones in medicine. Associated with this is the organotypic culture of endogenous tissue. In this context, the extracellular matrix plays a major role, because it is unique for every part of the body. Hence, each tissue requires a specific microenvironment when cultured or grown *ex vivo*. For instance, topography and prominent chemical characteristics of the surface are crucial for protein adsorption, cell and tissue adhesion. Usually, the discrepancy between tissue demands and culture conditions results in a loss of physiological properties such as structural integrity, function, or viability of healthy tissues and tumors when the culture period exceeds seven days. This indicates that a one-size-fits-all approach of commonly used Teflon membranes is not effective for an organotypic culture. In contrast, the systematic tailoring of titania nanotube scaffolds aims to enable enhanced culture of adult human tissues *ex vivo* and preserves its structure and viability.

As an example, we present long-term cultured human mammary carcinomas that are highly responsive to the underlying nanostructures. Characteristic structural features as blood vessels, glands and connective tissues that contain for instance adipocytes, fibrocytes, immune cells (like macrophages) and tumor cells show a surface-mediated preservation. In order to maintain a normal degree of proliferation, migration and apoptosis that corresponds to the endogenous state, to preserve the extracellular matrix overall, glands and blood vessels in specific, and to observe active immune cells, we designed advanced titania nanotube scaffolds with the desired functionality.

Altogether, we aim to realize a platform for organotypic tissue culture of up to several weeks, where primary cells and adult tissues are maintained in physiologic condition *ex vivo*. In particular, we aim to maintain an intact histomorphology, proper function, infiltration with immune cells and preserved physiological niches. Chemical and physical characteristics of the titania nanotube scaffolds are tunable with regard to e.g. surface morphology and topography, surface functionalization and overall conductivity. In this way, the scaffolds can also serve as a tailorable basis for primary cells and 3D bioprinted organ structures. Hence, we pave the way for reliable drug testing and personalized medicine.

We acknowledge the Heinrich-Böll-Stiftung and the German Federal Ministry of Education and Research, project EYECULTURE, as well as the Saxon State Ministry for Economic Affairs, Labor and Traffic (SMWA), project NanotubeUpscaling, for funding.

### 2:30 PM SB09.08.05

**Advances in Cell Coculture Porous Membranes to Mimic *In Vivo* Microenvironments** Jin Yoo; Korea Institute of Science and Technology, Korea (the Republic of)

In this presentation, we will discuss the advancements in cell coculture platforms that integrate engineered porous membranes to recapitulate *in vivo* microenvironments and facilitate diverse cell-cell signaling. The utilization of a porous membrane-based coculture platform holds great importance in cell research as it enables the creation of modular interfaces for cells and tissues, while also establishing barrier models for tissue-on-a-chip applications. *In vitro* coculture systems that incorporate porous membranes are commonly employed to mimic *in vivo* microenvironments, such as inducing differentiation of stem cells by recapitulating naturally occurring cell-cell communications. Using porous membrane-based coculture to induce stem cell differentiation proves to be a more cost-effective approach compared to relying on growth factors or specific mediums. A widely used commercial coculture membrane, typically a Transwell®, has played a significant role in fundamental and practical studies involving heterogeneous cell coculture systems. However, due to its relatively thick membrane thickness (~10 µm) and low porosity, it has limitations in facilitating sufficient interactions between cocultured cells. To address these limitations, we have developed advanced coculture membranes using polymers. These new membranes have a thinner thickness and higher porosity, resulting in improved cell-cell interactions that more closely mimic native tissue microenvironments. We have successfully applied these newly developed porous coculture membranes to enhance stem cell differentiation efficiency and establish endothelial barrier function.

**The Dynamic Interplay Between Tumor Stromal Discoidin Domain Receptor 2 (DDR2) and Collagen on Neuroblastoma Cellular Mechanics** Theadora Vessella<sup>1</sup>, Esteban Rozen<sup>2</sup>, Jason Shohet<sup>2</sup>, Qi Wen<sup>1</sup> and Susan Zhou<sup>1</sup>; <sup>1</sup>Worcester Polytechnic Institute, United States; <sup>2</sup>UMass Chan Medical School, United States

Cancer development, progression, invasion, metastasis, and responses to therapy rely on a permissive tumor microenvironment. The migration invasion of cancer cells through 3D confined extracellular matrices is coupled with cellular mechanics. Abnormal or dysregulated receptor tyrosine kinase (RTK) signaling is common within neuroblastoma. Fibrillar collagen RTK discoidin domain receptor 2 (DDR2) is studied in this project as it is presented in both tumor cells and tumor stromal cells, with high DDR2 levels correlated with poor outcomes and metastatic disease. Because DDR2 is upregulated in various cancer cells, we hypothesized that DDR2 binds to collagen within the extracellular matrix (ECM) to promote cellular mechanics during cancer migration. In this work, a comparative study between neuroblastoma cells with normal and down-regulated DDR2 levels is conducted. Downregulated DDR2 cell areas and aspect ratios were significantly decreased when plated on collagen coated substrates. Protrusive speeds were found to be comparable among all cell lines. However, contractile speeds were significantly slower in DDR2 downregulated cells, resulting in decreased detachment of cell edges to participate in migration. Additionally, the depletion of DDR2 was shown to reduce cellular traction forces on collagen coated soft substrates (2kPa), when compared to the control cells. Together, our findings suggest that DDR2 is vital to the role of collagen binding in mediating cellular mechanics and cellular migration in neuroblastoma cells.

### 3:30 PM SB09.08.07

**3D Printed Nanofibrous Multidomain Peptide Hydrogels for Regenerative Medicine** Adam Farsheed and Jeffrey Hartgerink; Rice University, United States

Tissues vary in their biological, mechanical, and structural properties. In the field of regenerative medicine, 3D printing has emerged as a powerful technique for producing hydrogel scaffolds that replicate the geometric complexity of tissues. Biologically derived polymers are commonly used as hydrogel inks in 3D printing due to their inherent bioactivity. However, these polymers lack the mechanical flexibility offered by synthetic counterparts. In addition, many biologically derived polymers lack the fibrous composition that naturally exists at the nano and micro scale within the body. This necessitates the development of hydrogel inks that are both bioactive and fibrous in structure to better replicate tissues. Here, we present the use of Multidomain Peptides (MDPs), a class of self-assembling peptides that form a nanofibrous hydrogel, as a novel ink for 3D printing [1]. After optimizing MDPs for 3D printing, we show that they can be used to create complex, overhanging structures, and multi material prints. In addition, we demonstrate how cationic and anionic MDPs can be strategically patterned to influence cell behavior. Building upon this work, we have developed a novel fabrication method for producing MDP hydrogels with aligned nanofibers, resembling the alignment present in tissues such as skeletal muscle and peripheral nerve. We show that these anisotropic MDP scaffolds can guide cell growth and spreading. Further, by fabricating hydrogel scaffolds with controlled degrees of alignment, we observe that cells exhibit distinct growth patterns in response to nanoscale differences. Leveraging 3D printing, we have scaled this fabrication method to create multilayer hydrogel scaffolds with precise control over the direction of fibrous alignment. The ability to generate aligned hydrogel scaffolds in a scalable manner sets this fabrication technology apart from other techniques. This work highlights the unique potential of using self-assembling multidomain peptides as 3D printable inks, enabling the creation of improved scaffolds for regenerative medicine.

**Nature-Inspired Functional Biomaterials to Reduce Biofouling for Medical Implants and Devices** Woo Kyung Cho; Chungnam National University, Korea (the Republic of)

The formation of bacterial biofilms on medical implants and devices has been recognized as a major cause of healthcare-acquired infections. These infections not only affect the quality of patient care but can also result in implant or device failure. To address healthcare-acquired infections, we have developed anti-biofouling materials that can suppress bacterial adhesion and biofilm formation. Drawing inspiration from mussel's adhesive foot proteins,

we synthesized a zwitterionic derivative of 3-(3,4-dihydroxyphenyl)-L-alanine (L-DOPA) and catechol-conjugated fucoidan. Robust antibacterial coatings were achieved through oxidative polymerization and the complexation between catechol groups and Fe(III) ions. These synthesized biomaterials can be applied to silicone implants for plastic surgery and various medical-grade substrates. Additionally, we have recently explored polyphenol chemistry to prevent thrombus formation on blood-contacting medical devices in a substrate-independent manner. In this presentation, I will discuss the development of these biomaterials and surface modification methods. The antibacterial and antiplatelet properties will be discussed in terms of non-specific protein adsorption, bacterial and platelet adhesion, as well as relevant infections and side effects associated with biomedical implants and tools.

**Shear-Responsive Boundary-Lubricated Hydrogels Attenuate Osteoarthritis** Yiting Lei; The First Affiliated Hospital of Chongqing Medical University, China

Lipid-based boundary layers formed on liposome-containing hydrogels can facilitate lubrication. However, these boundary layers can be damaged by shear, resulting in decreased lubrication. Here, a shear-responsive boundary-lubricated drug-loaded hydrogel is created by incorporating celecoxib (CLX)-loaded liposomes within dynamic covalent bond-based hyaluronic acid (HA) hydrogels (CLX@Lipo@HA-gel). The dynamic cross-linked network enables the hydrogel to get restructured in response to shear, and the HA matrix allows the accumulation of internal liposome microreservoirs on the sliding surfaces, which results in the formation of boundary layers to provide stable lubrication. Moreover, hydration shells formed surrounding the hydrogel can retard the degradation process, thus helping in sustaining lubrication. Furthermore, *in vitro* and *in vivo* experiments found that CLX@Lipo@HA-gels can maintain anabolic-catabolic balance, alleviate cartilage wear, and attenuate osteoarthritis progression by releasing CLX and shear-responsive boundary lubrication. Overall, CLX@Lipo@HA-gels can serve as shear-responsive boundary lubricants and drug-delivery vehicles to alleviate friction-related diseases like osteoarthritis.

#### 10:45 AM SB09.09.02

**Application of Degradable Porous Scaffold for Bone Regeneration** Ben Zhang; SINOPEC Beijing Research Institute of Chemical Industry, China

Bone defects caused by trauma and disease present severe threat to human health. At present, allografts and autografts are the most utilized methods to repair bone defects. However, these treatments have inherent shortcomings such as high failure rates due to poor graft fixation/tissue integration, potential disease transmission and limited supplies, as well as additional surgical hurt. Synthetic bone grafts, if properly engineered with physical properties enabling stable graft fixation, robust osteoconductive and osteoinductive properties encouraging new bone growth, and safe degradation, could help address these challenges.

We report here degradable scaffolds based on poly(lactic acid) derivatives modified with poly(ethylene glycol), which exhibit high-efficiency shape recovery around body temperature and hydration induced stiffening and swelling effects. Composites of these polymers mixed with nanosized hydroxyapatite were electrospun to fabricate meshes composed of nano/micro fibers with size range from 150 nm to 10  $\mu$ m. With the help of hydroxyapatite, the morphology of electrospun meshes improved wherein bulk nodules in the fibers reduced and nano/micro fibers become more smooth. As the content of hydroxyapatite increased, the average size of nano/micro fibers decreased and mechanical strength of electrospun mesh lowered. These electrospun meshes showed to support the attachment, proliferation and osteogenesis of osteoprogenitor cells *in vitro*. However, mouse bone marrow stromal cells (BMSCs) cultured on electrospun meshes exhibited suppressed activity with high hydroxyapatite content of 30 wt% indicated by CCK-8 result. Gene expressions of RUNX2, ALPL, COL1A1 and OCN increased at 14th day shown with q-PCR data, demonstrated potential osteogenic differentiation.

#### 11:00 AM SB09.09.03

**3D Printing using Oxygen-Generating Filaments for Bone Scaffold Tissue Engineering** Adnan Memic; King AbdulAziz University, Saudi Arabia

The latest advancements in bone scaffold technology have introduced novel biomaterials that have the ability to generate oxygen when implanted, improving cell viability and tissue maturation. We developed a new oxygen-generating nanocomposite filament that can be used in FDM based 3D printing of bone tissue scaffolds. Initially, the polymer nanocomposites were characterised using an X-ray diffraction analysis, surface morphology assessment, evaluation of filament extrudability, microstructural analysis, and examination of their rheological and mechanical properties in order to optimized filament production. Next, the filaments were optimized in terms of nanocomposite content to control oxygen release, porosity, and antibacterial activities. Our results indicate that an optimized oxygen releasing filament with a holds great promise for improving bone generation through supporting bone cell oxygenation and resistance to bacterial infections.

#### 11:15 AM SB09.09.04

**Multifunctional Patch Systems for Breast Cancer Treatment** Jalal Karimzadehkhoei<sup>1</sup>, Eda Güney<sup>1</sup>, Beril Ustunkaya<sup>1</sup>, Buğra Senel<sup>2</sup>, Ozlem Kutlu<sup>3</sup> and Gozde O. Ince<sup>1,3</sup>; <sup>1</sup>Faculty of Engineering and Natural Sciences, Materials Science and Nano-Engineering Program, Sabanci University, Turkey; <sup>2</sup>Faculty of Engineering and Natural Sciences, Molecular biology, Genetics and Bioengineering Program, Sabanci University, Turkey; <sup>3</sup>Nanotechnology Research and Application Center (SUNUM), Sabanci University, Turkey

Breast cancer, although treatable in its early stages with available chemotherapy drugs, remains a significant challenge in the field of oncology due to treatment difficulties, high risk of recurrence, and increased metastasis development, particularly in advanced stages. There is a pressing need in oncology for efficient therapies that provide long-term protection against cancer recurrence. However, the clinical application of chemotherapy drugs is hindered by the lack of efficient drug delivery systems, resulting in diminished treatment success and severe side effects that negatively impact patients' quality of life. In this study, we present the development of a multi-functional patch system for both short-term and long-term treatment of breast cancer. The patch system comprises two components: drug-loaded nanoparticles dedicated to the therapy and antigen epitope-loaded polymer patches designed to enhance the immune response against potential recurrence. These patches are fabricated using Solution Blow Spinning (SBS), a technique that utilizes a biodegradable polymer for the controlled release of growth factors alongside the drug-loaded nanoparticles. To evaluate the patch's degradation properties, degradation tests are performed by incubating the fabricated patch in phosphate buffered saline (PBS) solution and a lysosome-mimicking solution (LMS). The morphology of the fibers is assessed using scanning electron microscopy (SEM) before and after the spinning process, as well as after the degradation

process. Fourier transform infrared spectroscopy (FTIR) is employed to analyze changes in the chemical composition of the fibers. To monitor the release of antigen epitopes from the patches and drugs from the nanoparticles, enzyme-linked immunosorbent assay (ELISA) is employed. Furthermore, in vitro studies are conducted to assess the effectiveness of the patches in stimulating the immune system. Overall, this study presents a promising approach to address the challenges associated with breast cancer treatment. The development of a multi-functional patch system that combines drug delivery and immune response enhancement may pave the way for more efficient therapies and improved outcomes for patients with breast cancer.

#### 11:30 AM SB09.09.05

**Synthesis and Characterization of Carbon-Based Nano-Adsorbent for Dyes Removal from Wastewater** Angeles I. Licona Aguilar<sup>1</sup>, Aidé Minerva Torres Huerta<sup>2</sup>, Miguel A. Domínguez Crespo<sup>2</sup>, María de la Luz X. Negrete Rodríguez<sup>1</sup>, Eloy Conde Barajas<sup>1</sup>, Silvia Beatriz Brachetti Sibaja<sup>3</sup> and Issis C. Romero Ibarra<sup>4</sup>; <sup>1</sup>TecNM/ Instituto Tecnológico de Celaya, Mexico; <sup>2</sup>UPIIH - Instituto Politécnico Nacional, Mexico; <sup>3</sup>TecNM/ Instituto Tecnológico de Ciudad Madero, Mexico; <sup>4</sup>UPIITA- Instituto Politécnico Nacional, Mexico

Water pollution is the main part of environmental pollution and it has been increased due to factors such as urbanization and rapid industrialization, considering to human activities in various industrial fields *e.g.* textile industry, metallurgical, and others. In particular, dyes are hazardous and toxic components, present in trace amounts in wastewater effluents, for its treatment the adsorption method has been the most promising and widely used treatment technique due to its efficient and its flexible operation compared to other methods. Currently, in the nanotechnology field, there are substantial studies researching the potential application of nano- adsorbents for dye removal such as carbon nanotubes (CNTs) and activated carbon (AC) due their physical-chemical properties *e.g.*, large surface area associated with the availability of active binding sites, chemical and thermal properties. These materials can be modified chemically with metallic nanoparticles to increase the surface area and their adsorption capacities through high selectivity and active centers generation. In the present work, multiwalled carbon nanotubes (MWCNTs) and activated carbon from orange peel (AC) were modified to obtain adsorbent materials. Firstly, a functionalization using a mixing acid (HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>) was proposed, to improve groups such as oxygen, nitrogen and sulfur on carbon surface materials. Furthermore, MWCNTs and AC surface were modified with nanoparticles with oxide zinc (ZnO) at different concentration (15 and 30 wt%) by precipitation method. The carbon materials were tested to remove methylene blue (MB) and the optimum adsorption conditions were evaluated. The carbon materials (CM) were analyzed by X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR), thermogravimetric analysis (TGA), scanning electron microscopy (SEM), Nitrogen (N<sub>2</sub>) adsorption-desorption, zeta potential and UV-VIS technique were used to quantify the concentration of MB. Results revealed that CM developed a large surface area from 200 to 1100 m<sup>2</sup>g<sup>-1</sup> and chemical groups such as OH, C=O and C-O were conserved; adsorption studies reveal that materials with nanoparticles at 30 wt% can removal until 89.5 % of MB considering conditions such as pH 10, time 24 h, adsorbent dose 20 mg, concentration 80 ppm. The overall all results indicated that CM are promising candidates for dye removals.

**Keywords:** carbon nanotubes, activated carbon, nanoparticles, dyes, adsorption.

#### 11:45 AM SB09.09.07

**Development of Metabonegenic Citrate Biomaterials for Orthopedic Engineering** Jian Yang; Westlake University, China

Background: Although significant progress has been made in the development of orthopedic biomaterials, the currently available materials are limited by their inability to mimic the native tissue composition, weak mechanical strength, minimal osteoinductivity, significant inflammatory responses, poor bone integration, and slow bone regeneration. Metabolic factors such as glucose were shown to regulate the energy needs of stem cells during osteoblast differentiation. However, a full picture of the metabolic processes guiding or supporting osteogenic differentiation is far from complete. Citrate is a small molecule participating as the starting metabolite in the TCA cycle, is also a key component of bone. However, very limited information is available on what role the citrate plays in bone development and bone biomaterial design despite of its well-known unusual high abundance in bone.

Methods: In this study, a new class of highly versatile and functional citrate-based biomaterials has been developed by reacting citric acid with various carefully selected compounds including amino acids, diols and other functional molecules. We seek to answer several unexplored questions: 1) Can exogenous soluble citrate be uptaken by MSCs? 2) What is the role of extracellular citrate on the energy metabolism of bone forming cells? 3) Can the citrate-regulated cell energy metabolism crosstalk with MSCs signaling pathways involved in osteogenic differentiation? 4) Can the citrate-presenting materials mediate MSCs differentiation through the same mechanism as the soluble citrate? We also explore how these understandings can be applied to novel citrate-presenting biomaterial design and validate if the use of citrate-presenting anatomically similar and mechanically compliant scaffolds can enhance tissue integration and bone regeneration in a critically sized bone defect model.

Results: Our studies showed that extracellular citrate uptake through solute carrier family 13, member 5 (SLC13a5) supported osteogenic differentiation via regulation of energy-producing metabolic pathways, which led to elevated cell energy status to fuel osteo-differentiation of hMSCs with high metabolic demands. We next identified citrate and phosphoserine (Pser) as a synergistic pair in polymeric design, exhibiting concerted action not only in metabonegenic potential for orthopedic regeneration, but also in facile reactivity into a fluorescent system for materials tracking and imaging. We herein designed a novel, citrate/phosphoserine-based photoluminescent biodegradable polymer (BPLP-Pser), which was lastly fabricated into BPLP-Pser/hydroxyapatite composite microparticulate scaffolds, demonstrating significant improvements in bone regeneration and tissue response in rat femoral condyle and cranial defect models.

Discussion and Conclusion: We have revealed a previously unexplored expression pattern of SLC13a5 citrate transporter along osteo-differentiation, and a mechanism focusing on the metabolic regulation of citrate to elevate cell energy status for bone formation, referred to as citrate metabonegenic regulation. These findings not only identify citrate as a new metabolic factor in the stem cell micro-environment favorable for osteo-differentiation, but also suggest that citrate should be considered in bone biomaterials design, providing guidance to develop biomimetic BPLP-Pser/HA for prolonged citrate metabonegenic effect well into late stage of differentiation, which demonstrated therapeutic potential for bone injuries [1-3]. The unprecedented knowledge on the citrate mechanism enables us to design the next generation of biomimetic dynamic orthopedic implants that may present citrate signals in demand during cellular and tissue development.

**Designing Biocompatible Hydrogel Nanoparticle Emulsions for Regenerative Engineering** Georgia Papavasiliou, Shadi Motamed, Fernando Borges and Fouad Teymour; Illinois Institute of Technology, United States

Polymeric nanoparticle (NP) emulsions have shown significant promise for regenerative engineering applications as they can be designed as topical and/or

injectable formulations for *in vivo* administration of therapeutic compounds. Hydrophilic therapeutic delivery often requires water-in-oil-in-water (w/o/w) double emulsions which are difficult to produce and have limited storage life because of their inherent instability. Inverse, water-in-oil (w/o) emulsions for encapsulation of hydrophilic therapeutics are far less common as they involve use of organic solvents. Highly biocompatible and biodegradable crosslinked hydrogel NP are perfectly suited for controlled and sustained diffusive-based release of therapeutics, enhanced tissue-targeted delivery and bioavailability of hydrophilic drugs. Hydrogel NP, however, come in contact with cytotoxic organic solvents and surfactants during emulsion polymerization requiring subsequent purification and isolation before being administered directly *in vivo*. This leads to limitations, including significant drug loss, dosage uncertainty, compromised drug release kinetics, and loss of particle stability, thereby minimizing *in vivo* therapeutic efficacy. To address these limitations, we have developed novel biocompatible NP emulsions (BCNE) consisting of stable poly(ethylene) glycol (PEG) crosslinked hydrogel NP dispersed in a naturally-derived consumable organic phase that can be formulated as a liquid (or as an ointment) and administered *en masse*, directly to target tissues. BCNE are synthesized with biocompatible components including PEG diacrylate (PEGDA) crosslinking macromer, N-vinyl pyrrolidone or ethylene glycol comonomers, polyphosphate (PPi) or NaCl as the lipophile, soybean oil (SO), as the organic phase, with PolyGlycerol PolyRicinoleate (PGPR) emulsifier (FDA recognized as safe for human consumption) and with V50 initiator using inverse phase miniemulsion polymerization. We synthesized BCNE with varying mesh dimensions to accommodate the encapsulation and sustained release of hydrophilic therapeutics of varying size and conformation including PPi (PPi-BCNE), NaCl (NaCl-BCNE) and the  $\alpha$ -helical pro-angiogenic peptide QK (QK-BCNE). BCNE NP size measurements (Nanosight LM10, Malvern) yielded mean NP diameters of  $111 \pm 7.2$  nm and  $96 \pm 3.9$  nm for PPi-BCNE and NaCl-BCNE, respectively. To define mesh dimensions suitable for encapsulation and release of PPi and QK, experimental measurements of hydrogel mass swelling ratio were coupled with theoretical kinetic and thermodynamic interpretations we recently developed to characterize the network architecture of hydrogel networks comprised of macromeric crosslinkers. Our approach accounts for crosslinker size, and its behavior under swelling, both neglected by the Flory-Rehner theory. This allows for quantification of two new hydrogel mesh dimension variables that establish bounds on the maximum size and aspect ratio of therapeutics that can be encapsulated and released from crosslinked hydrogel NP networks. Using this approach to guide our experimental design, QK-BCNE were designed to release QK for 46 days whereby 90% of the encapsulated peptide was retained for 36 days *in vitro*. *In vitro* findings indicate that PPi-BCNE completely disperse PAO1 *P. aeruginosa* biofilms compared to blank BCNE and no treatment controls. Preliminary experiments conducted with *en masse* topical application of BCNE in a *Staphylococcus aureus* C57BL/6 mouse model of burn injury and impaired healing demonstrated incontrovertible evidence that PPi-BCNE improves wound healing compared to blank BCNE treatment. These results highly suggest that BCNE provide a versatile platform whereby hydrogel nanoparticle mesh dimensions can be precisely tuned for encapsulation of hydrophilic therapeutics of varying size and complex conformation (peptides, growth factors and iRNA) to enable sustained tissue-targeted delivery *in vivo* for regenerative medicine applications.

**Panthenol Citrate Biomaterials Accelerate Wound Healing and Restore Tissue Integrity** Huifeng Wang, Chongwen Duan, Rebecca Keate and Guillermo Ameer; Northwestern University, United States

The global surge in diabetes has led to diabetic foot ulcers (DFU) becoming a predominant diabetes-related complication, resulting in hospitalizations and, in severe cases, lower limb amputations. A staggering 34% of individuals with diabetes will encounter a DFU during their lifetime, with 15-20% becoming chronic or non-healing wounds. These wounds differ significantly from normal wounds, plagued by persistent oxidative stress, abnormal inflammatory responses, impaired vascularization, and innervation, among other patient-specific challenges. Furthermore, suboptimal physical properties of regenerated tissue often lead to recurrent or reopened wounds, with alarming statistics indicating recurring DFUs may result in amputation in 71-85% of cases. Meeting the pressing need for wound treatments that not only expedite wound closure but also enhance the quality of regenerated tissue is paramount in improving diabetic wound care outcomes. In this study, we present the synthesis and characterization of panthenol citrate (PC), a versatile compound with potential applications in soluble form as a cleansing solution and as a regenerative dressing to address impaired wound healing in diabetes. PC is derived by reacting citric acid with panthenol, offering intriguing optical, chemical, and biological properties conducive to protecting and regenerating skin tissue. With citric acid's established safety record and panthenol's known skin benefits, PC represents a promising candidate. PC demonstrates antioxidant, antibacterial, anti-inflammatory, and proangiogenic properties, facilitating wound closure in diabetes while restoring skin's mechanical and electrophysiological properties. In both solution and hydrogel forms, PC stimulates keratinocyte and dermal fibroblast migration and proliferation, resulting in improved re-epithelialization, granulation tissue formation, and accelerated wound closure. Remarkably, PC significantly enhances the mechanical strength and electrophysiological properties of regenerated skin. To our knowledge, this is the first study to demonstrate such comprehensive improvements in the histological and physical properties of regenerated skin following treatment with both monomeric and polymeric forms of a compound. Our approach encompasses the utilization of PC as a wound cleansing solution or as a component of a thermoresponsive biomacromolecule for use as a regenerative dressing. In conclusion, PC emerges as a pivotal building block for advanced tissue regeneration therapies, holding the promise of markedly improving wound care management for diabetic patients.

**Advanced Soft Hydrogel Materials: New Theoretical Frameworks for Their Chemical and Physical Structure** Nicholas A. Peppas; The University of Texas at Austin, United States

Soft hydrogel materials are water-swollen polymer networks that can be tuned to mimic the physical and biochemical properties of their surrounding environment. The signaling mechanisms between the hydrogel properties and their environmental behavior are not always clear, especially because hydrogels and exterior matrix serve the dual functions of mechanically supporting other materials (including tissues or cells) and regulating how chemical signals travel between. In hydrogels, stiffness and solute diffusivity are closely associated with the hydrogel's polymer network structure. The structure-property relationships of hydrogels are summarized by numerous mathematical modeling systems. We present robust, well-tested predictive models that describe how structural changes affect hydrogel properties to make hydrogels into the precise, nuanced tools needed to solve modern engineering problems. We have coordinated swollen polymer network models based on four structural parameters and demonstrate how those four parameters work together to decouple stiffness and other parameters in hydrogels without changing the chemical properties of the network. The resulting decoupling and associated fundamental models facilitate more nuanced investigations of polymer-environment interactions.

**Interfacial Reinforcement of a 3D-Printable Double Network Granular Hydrogel** Tianyu Yuan, Chenzhuo Li, John Kolinski and Esther Amstad; École Polytechnique Fédérale de Lausanne, Switzerland

Load-bearing soft materials that can be processed into 3D shapes gain increasing importance in the biomedical field. Granular hydrogels have the potential to be used as 3D-printable artificial tissues and their local composition can be tuned over micrometer-length scales. However, the development of mechanically strong granular hydrogels that can be used for load-bearing applications remains challenging. To overcome this challenge, a secondary hydrogel network that covalently crosslinks adjacent microgels can be introduced.<sup>[1]</sup> However, the resulting double network granular hydrogel is relatively brittle because of the weak interparticle interactions and the lack of energy dissipation mechanisms.

In this work, two types of oppositely charged polyelectrolyte microgels, one made of the negatively charged polyacrylic acid (PAA), the other made of the positively charged poly(3-Acrylamidopropyl)trimethylammonium chloride (PATC) are used to produce a double network granular hydrogel (DNGH). Due to the electrostatic interactions between the oppositely charged PAA and PATC microgels, the hydrogel exhibits values for the Young's modulus and fracture energy that are similar to those of cartilage<sup>[2,3]</sup> and skeletal muscles.<sup>[4]</sup> We experimentally investigate the contribution of the interparticle reinforcement to the overall fracture energy of the hydrogel. Based on these studies, we propose an empirical model that takes into account the damage zone size, contact area, and adhesion energy. We demonstrate that this model, albeit being simple, can predict the mechanical properties of DNGHs with a reasonably high accuracy. Thanks to the interfacial reinforcement between PAA and PATC microgels, free-standing structures can be 3D-printed with high printing resolutions, providing new possibilities for designing strong and tough soft materials with versatile processability.

**1:30 PM \*SB10.02.01**

**Influence of Solvent Quality on the Swelling and Deswelling and the Shear Modulus of Semi-Dilute Solution Cross-Linked Poly(vinyl acetate) Gels** Jack F. Douglas<sup>1</sup> and Ferenc Horkay<sup>2</sup>; <sup>1</sup>National Institute of Standards and Technology, United States; <sup>2</sup>National Institutes of Health, United States

We systematically examine the influence of varying temperature ( $T$ ) over a large range in model poly(vinyl acetate) gels swollen in isopropyl alcohol. The theta temperature  $\Theta$  of our gels, at which the second virial coefficient  $A_2$  vanishes, is found to be equal to within numerical uncertainty to the corresponding high molecular mass polymer solution value without cross-links, and we quantify the swelling and deswelling of our model gels relative to their size at  $T = \Theta$ , as customary for individual flexible polymer chains in solution. We also quantify the "solvent quality" dependence of the shear modulus  $G$  relative to  $G(T = \Theta)$  and compare to the hydrogel swelling factor,  $\alpha$ . We find that all our network swelling and deswelling data can be reduced to a scaling equation of the same general form as derived from renormalization group theory for flexible linear polymer chains in solutions so that it is not necessary to invoke either the Flory-Huggins mean field theory or the Flory-Rehner hypothesis that the elastic and mixing contributions to the free energy of network swelling are separable to describe our data. We also find that changes of  $G$  relative to  $G(T = \Theta)$  are directly related to  $\alpha$ . At the same time, we find that classical rubber elasticity theory describes many aspects of these semi-dilute solution cross-linked networks, regardless of the solvent quality, although the perfector clearly reflects the existence of network defects whose concentration depends on the initial polymer concentration of the polymer solution from which the networks were synthesized.

**Tunable Surfaces and Interfaces from Responsive Polymers for Biomedical Applications** [Namita Choudhury](#), Nisal Wanasingha, Rajkamal Balu and Naba K. Dutta; RMIT University, Australia

Design of responsive surfaces, interfaces and nanostructures, whose characteristics can be modulated on demand is an important challenge in diverse applications. In this presentation, we discuss the responsive behaviour of soft surfaces, interfaces and solid-liquid interfaces derived from biomimetic polymers. The unique structural features of such polymers and the changes in their characteristics properties and conformation induced by a change in the environment have been evaluated in detail using highly sensitive tools such as quartz crystal microbalance (QCM-D), surface plasmon resonance (SPR), dynamic light scattering, small angle neutron scattering, UV-Vis, and spectroscopy. The talk will illustrate how this responsiveness could be used towards the construction of novel hydrogels, hybrids, conjugates and functional nanoparticles such as high surface area nanoparticles for specific applications. It will also highlight the new classes of multifunctional biomimetic polypeptide synthesis, 3D fabrication of hydrogel and the nano-bioconjugates, that we are developing for biomedical and injury applications, including effective therapeutic, adhesion and repair.

**Textile Electronics for Long-Term Electrophysiologic Signal Recording Application** [Chansoo Kim](#), Junyi Zhao and Chuan Wang; Washington University in St. Louis, United States

Long-term electrophysiologic signal collecting is important since it provides a prior warning to people by detecting diseases such as heart failure or arrhythmia before the diseases progress to a more dangerous stage. It also provides fundamental data for training to improve performance by identifying the accurate amount of exercise and muscle usage for athletes. For this purpose, flexible and stretchable sensors have shown great potential for wearable and ambulatory electrocardiography signal monitoring applications. These soft sensors are comfortable, conform to human skin, and daily wearable in contradistinction to rigid metal-based conventional electronic devices. Nevertheless, most of long-term electrophysiologic sensors have focused on sticky dry electrodes for long-term signal collection because conformal contact of electrodes on the human skin can decrease contact impedance. Here, we propose an interesting approach for long-term electrophysiologic signal collecting electrode in dry condition by E-textile system. This system consists of textile and microfiber electrode that were coated by Poly(3,4-ethylenedioxythiophene) polystyrenesulfonate (PEDOT:PSS). For the textile electrode, PEDOT:PSS was simply printed on the nylon-based textile through screen printing manner and the stretchability of electrode was enhanced via polyethylene oxide (PEO) crosslinking process. In addition, hydrophobic treatment through 1H,1H,2H,2H-Perfluorooctyl-trichlorosilane (FTOS) effectively prevent water permeation that can cause erosion and dissolving of the electrode. Consequently, the textile electrode shows high durability in water. Moreover, the microfiber electrode offers greatly reduced contact impedance between skin and electrode, and improved signal-to-noise ratio (SNR) through dramatically increasing contact area. These electrodes combined via electrolyte conductive gel pad and build E-Textile system. Therefore, we achieve  $1.1 \times 10^5 \Omega \times \text{cm}^2$  contact impedance. In addition, the SNR of the electrocardiogram (ECG) and electromyography (EMG) SNR were 27 dB and 29 dB in dry atmosphere.

### 2:45 PM SB10.02.04

**Understanding Hydrodynamic Wear in Self-Similar Superhydrophobic Coatings Subjected to Rapid Droplet Impacts** [Daniel Braconnier](#)<sup>1</sup>, Terence Davidovits<sup>2</sup> and Randall M. Erb<sup>1</sup>; <sup>1</sup>Northeastern University, United States; <sup>2</sup>Thermobionics LLC, United States

Superhydrophobic materials rely on both chemical apolarity and surface roughness to achieve the high contact angles and the low roll-off angles that lead to self-cleaning and antibacterial properties. Current superhydrophobic coatings tend to be delicate and lose their properties easily when subjected to droplet impact. Such impact quickly deteriorates these coatings through hydrodynamic wear; changing structure, eroding hydrophobic chemistry, and quickly leading to full wet out of the substrate. In fact, hydrodynamic wear is more detrimental to coatings than seemingly more aggressive mechanical wear including scratching with sandpaper - a common approach used to claim both self-similarity of a material and extreme robustness against wear. What makes certain coatings more robust against hydrodynamic wear? To understand this answer, we systematically study ten disparate self-similar superhydrophobic coating approaches from academia to industry by subjecting them to hydrodynamic wear with rapid droplet impacts. We find rapid droplet impact that simulates a medium rain can deteriorate most coatings within seconds or minutes. Meanwhile, the more resilient coatings share common attributes including robust apolar chemistry, hierarchal topography, and a slow loss of sacrificial material. In addition, we offer an analytical model that nicely characterizes the hydrophobic lifetimes of these systems.

### 3:30 PM \*SB10.02.05

**Characterization of the Network Structures of PEGDA and Dextran Hydrogels by Complementary Methods** Joseph M. Scalet and [Stevin H. Gehrke](#); University of Kansas, United States

The physical properties of hydrogels are directly affected by their network structure; thus, characterization of that structure is a key part of their development for specific applications. There are generally several different characteristic length scales from the molecular to macroscopic dimensions. Additive manufacturing of hydrogel components introduces additional levels of network structures, depending on the manufacturing methods. Thus, many different methods of characterizing network structures have been developed and used to characterize gels. In this presentation, two fundamentally different but complementary methods will be examined for their potential to evaluate the network structure. The first is the most widely used method – mechanical testing –, but the data is examined in terms of multi-parameter models. The second is the use of time domain low-field NMR (LF NMR), a method that has not been widely used but has the potential for rapid screening of hydrogel formulations. Two hydrogels with quite different network structures widely used in a variety of applications, including 3D printing, are examined: poly(ethylene glycol diacrylate) (PEGDA) and thiol-ene crosslinked dextran.

PEGDA hydrogels were synthesized from monomers of molecular weight from 575 to 8000 Da by photopolymerization at polymer concentrations ranging from 7% to 50 wt.% in water. Dextran gels were made by functionalization of dextran with pentanoate groups which makes it possible to crosslink them by a photopolymerized thiol-ene reaction with dithiothreitol.

Generally, hydrogels are assumed to follow the classic neo-Hookean elastic model under compression or tension, from which network mesh size is estimated. However, not all gels fit this model well, often with deviation increasing with strain. Multiple parameter models can accurately fit data over a broader range of strains and provide further structural information than the standard model. For PEGDA, molecular weights, and concentrations were varied. As the polymer concentration at hydrogel formation increases, the covalent and the entanglement contributions of the modulus both increase. For dextran, a range of molecular weights and polymer concentrations were tested, as well as pentanoate functionalization and thiol:ene ratio. As the thiol:ene ratio was varied, the covalent contributions increased, but the entanglement contributions were less strongly affected. When the polymer concentration at formation was increased, however, both contributions increased.

LF-NMR is an experimentally simple, quick, and non-destructive technique that has the potential to determine a distribution of characteristic length scales in hydrogels. Its speed and experimental simplicity suggest a potential use for the rapid characterization of hydrogel formulations in application development. Proton relaxation times in the time domain ( $T_2$ ) are related to surface-solvent interactions, and theory can be used to convert the  $T_2$  distributions into network mesh sizes. PEGDA gels were characterized in solution before polymerization, after polymerization, and after equilibration with water. A noticeable reduction in  $T_2$  was observed for PEGDA gels upon cross-linking, indicative of the mobility constraint caused by the formation of the hydrogel network.

**Effects of Zig-Zag Hydrogen Bonding and Movable Cross-Linking on the Physical Properties of Poly(ether-thioureas)-Based Elastomer** [Sojung Seo](#) and Ji-Hun Seo; Korea University, Korea (the Republic of)

It is important but challenging to overcome the trade-off in mechanical properties by simultaneously increasing the tensile strength and elongation of elastomers for many applications requiring diverse mechanical properties of polymeric materials. Here, we fabricated an elastomer that forms two types of physical bonds (hydrogen bond and host-guest interaction). The combination of poly(ether-thiourea) (TUEG) with zig-zag array of hydrogen bonds and polyrotaxane (PRX) with movable cross-linking junctions simultaneously increased the mechanical strength (tensile stress of 15 MPa) and elongation (tensile strain of 600%) of the elastomer. It was investigated that degradation of mechanical properties of polymer network against repeated deformation (10 times, tensile strain of 150%) was prevented owing to movable cross-linking junction of PRX. Therefore, this work presents a dual physically cross-linked elastomer having a short main chain (3k) with high tensile strength, tensile strain, and resilience.

#### 4:15 PM SB10.02.07

**Nonlocal Intrinsic Fracture Energy of Polymer-Like Networks** Bolei Deng, Shu Wang, [Chase Hartquist](#) and Xuanhe Zhao; Massachusetts Institute of Technology, United States

Connecting the molecular level details of chain scission to the macroscopic fracture of polymer networks remains a long-standing problem. The Lake-Thomas model predicts the intrinsic fracture energy of a polymer network is the energy to scission a layer of polymer chains. However, recent experiments showed that the Lake-Thomas model underestimated the intrinsic fracture energy by about one to two orders of magnitude. We show that the intrinsic fracture energy of polymer-like networks mainly results from nonlocal energy dissipation by relaxing polymer chains far away from the crack tip. Experiments and simulations show that increasing nonlinearity in single chain mechanics amplifies the intrinsic fracture energy in 2D and 3D polymer-like networks and sustains despite varying defects, dispersity, topologies, and length scales. Our findings not only provide new physical insights into the fracture of polymer networks but also offer design guidelines for tough architected materials.

#### 4:30 PM SB10.02.08

**Network Materials with Soft Matrix with Extreme Properties** [Catalin R. Picu](#) and Mithun Dey; Rensselaer Polytechnic Institute, United States

Most biological materials and many engineering materials, including those used in sports equipment, are network materials with matrix. Their mechanical function is conditioned by the presence of a stochastic network of crosslinked fibers. The embedding matrix is typically a hard thermoset (e.g. epoxy) or a soft hydrogel. The interplay of the two constituents is pronounced when the stiffness of the network tested independently is equal to the stiffness of the matrix. We explore the design principles of this type of composite to determine the parametric space in which special properties can be obtained. Matrices with extreme properties, i.e. incompressible and auxetic, lead to the most pronounced effects. Of special interest is the response to indentation/impact, case in which the interplay of the network and matrix is enhanced. The results are relevant for the design of hybrid materials with exceptional properties and with applications in multiple areas, including in sports equipment design.

**The Role of Hyaluronic Acid in the Organization of Aggrecan in the Extracellular Matrix** [Ferenc Horkay](#), Emilios K. Dimitriadis, Iren Horkayne-Szakaly and Peter Bassar; National Institutes of Health, United States

Aggrecan is a negatively charged bottlebrush shaped biopolymer molecule. Bottlebrush structures provide excellent lubrication in living systems. Inspired by the lubrication properties of biological systems (e.g., synovial fluid), synthetic bottlebrush polymers have been designed and synthesized. In the extracellular matrix (ECM) aggrecan exists as an aggregate where aggrecan molecules are noncovalently attached to long hyaluronic acid (HA) chains. Aggrecan-HA complexes are important for the mechanical response of cartilage. They exhibit high osmotic modulus, which defines the resistance of the tissue to compressive stress. We studied the hierarchical organization and the scattering properties of hyaluronic acid solutions and aggrecan-hyaluronic acid complexes. Small angle neutron scattering (SANS) and static and dynamic light scattering (SLS and DLS) measurements reveal a domain structure of size greater than several hundred nanometers. At higher values of wave vector, the SANS response corresponds to rod-like structures, of length consistent with the hydrodynamic correlation length associated with the fast diffusion coefficient. Calcium ions do not affect the geometric properties of these domains. DLS is used to investigate the effect of charge valence on the relaxation rates of the concentration fluctuations. The fast diffusive mode in the autocorrelation function becomes slower in the presence of calcium ions relative to sodium counter-ions. The slow mode, however, becomes faster with calcium ions. Reasonable agreement is found between the scattering intensity of the osmotic concentration fluctuations obtained from DLS and from the SANS response. Atomic Force Microscopy is used to determine the morphology of the aggrecan-HA complexes.

**8:00 PM SB10.03.02**

**Surface Function Transformation Through Deformation of 3D Structure using Soft Materials** Yejin Oh, Hyemin Lee and Hyunsik Yoon; Seoul National University of Science and Technology, Korea (the Republic of)

Recently, the study of surface morphology alterations has been extensively studied due to their ability to control material properties by changing surface morphology. As for materials, hydrogels are gaining attention due to structural changes through water penetration into the hydrogel network in a wet environment. And as for technology, there are various processes to fabricate three-dimensional (3D) structures but issues of low throughput or low resolution remain. Therefore, we propose a novel approach that 2D structures, made of conventional lithography, transform into complicated 3D structures using hydrogels. By swelling hydrogels under constrained conditions, we achieved the desired shape transformations. We replicated the swollen pattern because of its moisture transport behavior. To optimize material for replication, we investigated about affinity for water of prepolymer and identified that the lower the affinity for water compared to hydrogels the better the swollen pattern retained its shape. In this way, we manufactured molds for buckling and inversely tapered structures and noted that replication from complicated 3D shapes was possible due to the softness of swollen hydrogel. In this method, buckling structures made of polydimethylsiloxane (PDMS) can be utilized as protective films due to their ability to disperse forces laterally. Also, the inverse tapered patterns made of perfluoropolyether (PFPE) exhibit oleophobic surfaces, enabling self-cleaning properties for oil. We also identified that as swelling ratio increased, dispersion capability in buckling film and oleophobicity in inversely tapered film were improved. Therefore, this research demonstrated the potential of utilizing surface shape modifications to achieve various properties using desired materials. It is expected that function transformation can be a platform to create unprecedented functions arising from unique shapes morphed from conventional straight shapes.

**8:00 PM SB10.03.04**

**Blood Oxygen and Heart Rate Monitoring by a Flexible Hybrid Electronics Device Fabricated by Multilayer Screen-Printing** Gábor Méhes<sup>1,2</sup>, Ayako Yoshida<sup>2</sup> and Shizuo Tokito<sup>2</sup>; <sup>1</sup>Waseda University, Japan; <sup>2</sup>Yamagata University, Japan

Finger-based pulse oximetry (SpO<sub>2</sub>) and heart rate monitoring are widely used in medical settings and are penetrating the everyday life. However, SpO<sub>2</sub> response measured on the peripheral parts of the body (such as fingers and wrists) has a time lag and is less accurate compared to measuring on forehead. In addition, current devices are centimeter-thick, making seamless integration with the body difficult, hindering continuous monitoring and wide adoption. We designed, fabricated, and evaluated an SpO<sub>2</sub> and heart rate sensing device based on flexible hybrid electronics (FHE) technology. The marriage of flexible electronics with high performance commercially available IC chips makes it possible to have advanced sensing, data processing and wireless data transmission functionalities on a thin (1.5 mm) and flexible form that can be attached to various parts of the body. Differently from most devices using FHE technology, here we describe a cost-efficient and mass production compatible multilayer screen-printing process based on conducting Ag-based and non-conducting inks for making the flexible interconnection circuitry in detail, including advanced topographic analysis. By optimizing the printing steps, we could fabricate interconnecting lines vertically traversing up to five printed layers over several tens of micrometers, increasing the spatial density of functional units. By this, we widen the possibilities to utilize screen-printing for advanced wearable devices. Indeed, our FHE device reliably detects induced hypoxemia, and when applied on forehead, detects changes in SpO<sub>2</sub> more than 10 seconds earlier compared to a finger-based medical grade reference device.

**8:00 PM SB10.03.05**

**Highly Entanglement Hydrogel-Coated Sticker for Diverse Surface Applications via Copolymerization Method** Joon Hyung An<sup>1</sup>, Junsoo Kim<sup>2</sup> and Seongmin Kang<sup>1</sup>; <sup>1</sup>Chungnam National University, Korea (the Republic of); <sup>2</sup>Harvard University, United States

High entanglement hydrogel has advantages such as low friction and high stiffness. However, its applicability is limited by its tendency to easily delaminate when adhering to a surface, which is caused by its high swelling property. In this study, we propose a simple method for surface coating highly entangled hydrogels. By utilizing the designed copolymerization of polymers with hydrogel, we enable high entanglement hydrogels to adhere strongly to various surfaces, even under high swelling conditions. The copolymerized polymers are fabricated into a bilayer film of hydrogel and hydrophobic polymer, creating a freestanding sticker that can be used. The hydrophobic polymer layer prevents moisture transfer, thereby preventing the delamination of the hydrogel caused by swelling. Through this study, we have expanded the potential applications in various fields by enabling the application of high entanglement hydrogel regardless of the surface material.

**8:00 PM SB10.03.06**

**A Fully Self-Healable, Temperature Tolerant and Stretchable Supercapacitor for Operating Integrated Self-Healing Strain Sensor** Yeon Ji Choi and Jeong Sook Ha; Korea University, Korea (the Republic of)

With the rapid advancement in wearable technology, there has been extensive effort on the development of high performance flexible/stretchable energy storage devices. Among various energy storage devices, supercapacitors are considered to be one of the most promising devices as integrated power supply of wearable electronics owing to many advantages of high power density, high cyclic stability and simple structures. Since the wearable devices are frequently exposed to extreme conditions of environments and/or physical damage, however, durability issue has evolved to be a serious challenge for their practical applications. Thus, addition of novel functionality such as self-healing from mechanical damage and tolerance over dramatic changes in temperature to stretchable supercapacitors can be a solution for that. Up-to now, most of the reports showed the self-healing of electrolyte only instead of fully self-healing supercapacitors. Even though many temperature tolerant supercapacitors were reported, there is a few supercapacitors with both self-healing and stability over wide temperature ranges which requires a deliberate design of device structure and materials.

In this work, we report on the fabrication of a fully self-healing, temperature tolerant, and stretchable supercapacitor and its application as a powering device for integrated strain sensor. Organohydrogel with a self-healing via the diol-borate bonding as well as the hydrogen bonding, and the stability over wide temperature range via hydrogen bonding between water and ethylene glycol, could be obtained, respectively. As a self-healing encapsulating film as well as a substrate, a polyurethane film based on oxime-carbamate bonding and hydrogen bonding was synthesized. As a self-healing stretchable electrode, CNT/polyaniline spray-coated on Au nanosheets functionalized with a poly(ether-thioureas) triethylene glycol was used.

By sandwiching the self-healing and temperature tolerant electrolytes with self-healing electrodes on both sides, the fully self-healing supercapacitor stable over temperature changes from -20 to 100 °C was completed. Such fabricated supercapacitor showed the fully self-healing efficiency of 83% even after 5 repetitive cycles of bisection and thermal healing at 65 °C for 6 hr. Also, the supercapacitor was mechanically stable over stretching by 40%, with a capacitance retention of 99%. Furthermore, the whole supercapacitor recovered the electrochemical performance even after bisection and self-healing. The capacitance of the supercapacitor at room temperature was retained over 85% with the temperature changes between -20 and 100 °C. After attachment of the vertically integrated device of the supercapacitor and the strain sensor, bio-signals such as finger-bending and wrist bending could be detected by using the supercapacitor as a self-healing energy storage device. This work suggests that our fabricated fully self-healing, temperature-tolerant, and stretchable supercapacitor should be widely applied to future wearable electronics with a longevity.

**8:00 PM SB10.03.08**

**Vapor-Responsive Impact Energy Absorbing and Dissipating Eutectogel** Youna Kim and Jinkee Hong; Yonsei University, Korea (the Republic of)

Every year 2 million people have experienced sports injuries. Especially, in ball games such as basketball, baseball, and golf, serious injury could be caused by a high-speed ball. To prevent sports injuries, players should wear sports protective equipment. For example, in a baseball game, catchers wear protective equipment such as chest protectors, protective helmets, and shin guards. However, as the total weight of the protective equipment approaches 5 kg, the catchers suffer from extreme physical fatigue during the game. Therefore, it is necessary to develop materials for protective equipment that are lightweight and block impact.

As shock-preventing materials, there are representative viscoelastic hydrogels and organogels. These materials are effective in blocking impact due to their viscosity properties that absorb impact and elastic properties that dissipate impact. However, hydrogels have limited ability to withstand the impact energy of spherical projectiles due to their weak mechanical properties. In addition, it is difficult to apply to sports games due to shrinkage and weakening of physical properties due to water evaporation. Organogels overcome the limitations of hydrogels but use harmful solvents. It is necessary to develop viscoelastic protective materials that are lightweight, non-harmful, and can block impact.

In this study, a shock-preventing viscoelastomer (SPV) is designed by using non-toxic deep eutectic solvents (DES) and polyvinyl alcohol (PVA). Shock-preventing materials should absorb all impact energy and convert it into kinetic energy, preventing the energy from being transferred to the wearer. SPV could regulate the dissipation and absorption of impact energy through hydrophobic vapor treatment.

The entangled polymer chains within the amorphous phase could dissipate impact energy. PVA is a hydrophilic semi-crystalline polymer. DES is an azeotropic mixture composed of hydrogen bond donors and hydrogen bond acceptors, which hinder hydrogen bonds between PVA chains. For the increment in the amorphous phase, DES is used as an additive. As the amorphous phase increases in SPV, SPV shows viscoelasticity and could dissipate impact energy. Moreover, SPV is tougher than conventional hydrogels.

Hydrophilic SPV has a different chemical affinity with hydrophobic methyl salicylate (MeS), an analgesic and mint flavoring agent. Due to the different affinity, the solvation effect of MeS within SPV increases the chain entanglement density by H-bonding PVA chains. However, as the MeS treatment does not affect the crystallinity of SPV, MeS-treated SPV still maintains the rubbery phase at a high amplitude sweep. That is, MeS-treated SPV could absorb the impact energy to break the H-bonding and dissipate impact energy.

The MeS-treated SPV is restored to its original state after 50 min. It can be used as protective equipment for baseball and hockey within 1 h per inning. In addition, SPV can be applied to sports protective equipment in various forms such as thin film, fiber, and spray coating. We expect that SPV is suitable as an impact protection material to prevent sports injuries.

**8:00 PM SB10.03.09**

**Auxetic Metamaterials with Structurally Programmed Reconfigurability** Josef Jancař, Jan Zidek and Jakub Peroutka; Brno University of Technology, Czechia

Low density engineering materials capable of reacting to mechanical stimuli in a manner programmed by their structural architecture can improve design of shock and impact resistant or tunable acoustic damping structures, robust actuators, and adaptable heat insulators. Similarly to computers, structural programming translates the human developed algorithm into a string of structural commands obeying syntax enabling to perform the desired task. The structural coding of commands converts the materials programming language (MPL) into a low-level language understandable by the executing architected structure. While constitutive materials capable of carrying the basic structural information already exist, designing the source code, commands compiler, assembler, and linker for the MPL remains a foundational challenge. Here, we outline the strategy for developing the source code for simple MPL commands using functional polymer nanocomposites as the units of structural information (USIs). USIs are spatially organized within simple geometrical elements of the re-entrant auxetic unit cell constituting the basic storage units of structural information (SUSIs). SUSIs are combined in a library of bending eigenmodes and rotations forming the structural source code enabling to program simple MPL commands. Primitive algorithms are developed, and simple commands are structurally coded at the auxetic unit cell array and lattice levels to achieve desired stimuli induced reconfigurations of the auxetic structure. Finally, multi-port FDM fabrication process is employed for physically compiling, assembling, and linking the structural commands into the auxetic structure with structurally pre-programmed system level response.

**8:00 PM SB10.03.10**

**Multi-Responsive 3D Printed Nanocellulose-Based Hydrogels Programmable in Space and Time** Beatriz Arsuffi<sup>1,2</sup>, Gilberto Siqueira<sup>3</sup>, Silvia Titotto<sup>2</sup>, Tommaso Magrini<sup>1</sup> and Chiara Daraio<sup>1</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>Federal University of ABC, Brazil; <sup>3</sup>Empa-Swiss Federal Laboratories for Materials Science and Technology, Switzerland

Stimuli-responsive materials are desirable for a variety of functional applications, that range from biomedical devices, sensors and actuators to adaptive surfaces and deployable structures. However, as the natural environment offers multiple stimuli at the same time, current solutions often lack multi-responsiveness and display poor control over their properties over time. Here, I will introduce a new multi-stimuli-responsive material platform, realized via additive manufacturing, that can be precisely programmable to morph both in space and time. In my talk, I will highlight the fabrication steps that led to the development of composite inks for Direct Ink Writing (DIW), formed by double-network hydrogel matrices, reinforced by a high content of cellulose nanofibers and nanocrystals. Thus, I will display how the alignment of the reinforcing particles, induced by intense shear forces during DIW, provides composites with a highly anisotropic microstructure, key to tune the stiffness as well as the swelling/shrinking behavior of printed actuators [1, 2]. Additionally, I will highlight how the reversible shape-morphing capability of bilayer systems, as well as their activity in time, as a fourth dimension, can be tailored through processing parameters and geometrical design [3], in response to multiple stimuli scenarios, such as simultaneous variations in humidity, temperature, pH, and ion concentration. Finally, I will show how the performance of multi-responsive hydrogels can be leveraged to design and fabricate, by additive manufacturing, mechanically versatile architectures and mechanical sensors with outputs structured through the Boolean logic and logic gates, paving the way to multi-logic stimuli-responsive materials.

**Graphene-Based Bidirectional Neural Interfaces** Eduard Masvidal-Codina<sup>1</sup>, Nicola Ria<sup>1</sup>, Fikret T. Duvan<sup>1</sup>, Bruno Rodríguez-Meana<sup>2</sup>, Xavi Illa<sup>3</sup>, Kostas Kostarelos<sup>1,4</sup>, Xavier Navarro<sup>2</sup>, Anton Guimerà-Brunet<sup>3</sup> and Jose A. Garrido<sup>5</sup>; <sup>1</sup>Catalan Institute of Nanoscience and Nanotechnology (ICN2), Spain; <sup>2</sup>Institute of Neurosciences, Physiology and Immunology, Centro de Investigación Biomédica en Red sobre Enfermedades Neurodegenerativas (CIBERNED), Universitat Autònoma de Barcelona, Spain; <sup>3</sup>Instituto de Microelectrónica de Barcelona IMB-CNM (CSIC), Esfera UAB, Spain; <sup>4</sup>Nanomedicine Lab, National Graphene Institute and Faculty of Biology, Medicine & Health, United Kingdom; <sup>5</sup>ICREA, Spain

Establishing a reliable bidirectional communication interface between the nervous system and electronic devices is crucial for exploiting the full potential of neurotechnology. Despite recent advancements, current technologies evidence important shortcomings, e.g. lack of focal stimulation, low signal-to-noise ratio, etc. Thus, efforts to explore novel materials are essential for the development of next-generation neural interfaces. Graphene and graphene-based materials possess a very attractive set of physicochemical properties holding great potential for biomedical applications, in particular for implantable neural interfaces. This presentation provides an overview on fundamentals and applications of several graphene-based technologies and devices aiming at developing an efficient bidirectional communication with the nervous system. The main goal of this talk is to discuss opportunities of graphene-based neurotechnologies in neuroscience and implantable medical applications, and at the same time to identify the main challenges ahead.

This work has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement N. 881603 (GrapheneCore3); from the European Union's Horizon Europe research and innovation programme under grant agreement N. 101070865 (MINIGRAPH), that is supported by the Swiss State Secretariat for Education, Research and Innovation (SERI) under contract number 22.00163); and from the Proyecto PCI2021-122095-2A financiado por MCIN/AEI /10.13039/501100011033 y por la Unión Europea NextGenerationEU/PRTR.

**Insights into Biocompatible and Bioorthogonal Fluorous-Phase Neural Probe for *In Vivo* Detection of Acetylcholine** Maral Mousavi, Farbod Amirghasemi and Abdulrahman Al-Shami; University of Southern California, United States

Acetylcholine (ACh) is one of the least understood neurotransmitters, mainly due to difficulty in its selective detection in biological matrices. ACh appears in the brain and body of mammals, and is released as a messenger by the nerve cells to communicate with other nerve cells, muscle cells, and gland cells. In the brain, ACh functions both as a neuromuscular transmitter and neuromodulator, and thus plays key roles in learning and memory, motivation, and muscle control. Alterations in ACh concentration in the cerebral cortex was correlated to dementia and Alzheimer's disease, psychiatric disorders such as schizophrenia and major depressive disorder, as well as anxiety and depression. Tools for selective sensing of ACh are crucial for better understanding the role of this neurotransmitter in disease progression, as well as rational design and testing of therapeutics that interact with the cholinergic receptors. For successful in-vivo recording of ACh levels, the neural probe (1) should have high selectivity to enable detection of ACh in the large background of other species in the complex brain environment, (2) should be flexible to minimize tissue scarring during probe insertion, (3) should be resistant to biofouling and remain functional after implantation, and (4) should be non-toxic and safe. This talk will discuss the strategies we have taken to address these requirements for an ACh in-vivo probe through development of new materials for sensing and for electrode fabrication. We detect ACh using its permanent positive charge and a potentiometric sensing membrane. This membrane is made of a unique fluorophilic-phase material that provides outstanding selectivity and biocompatibility to the electrode. Fluorophilic compounds (not to be mistaken with fluorescent compounds) are molecules with high content of fluorine atoms. They are extremely non-polar to the extent that they are NOT miscible with oil and water. In fact, mixing water, hexanes, and perfluorohexane results in formation of three distinct phases. That is, fluorinated compounds are both hydrophobic and lipophobic. This sets apart fluorocarbons for novel biomedical applications. As a matter of fact, living systems are made of water and lipophilic compounds, making fluorocarbons bio-orthogonal, meaning that they do not interfere with biology. This work will show how the low polarity of the fluorophilic phase can enhance the selectivity and biocompatibility of our ACh sensor by orders of magnitude. We integrate this fluorophilic sensing membrane with a porous graphene electrode that is engraved on a flexible

polyimide film using a CO<sub>2</sub> laser. This talk will discuss integration of laser-induced graphene electrodes (LIGs) with fluororous-phase sensing membranes to produce a new generation of highly selective, biocompatible, and resilient neural probes.

**9:30 AM \*SB11.01.04**

**Implantable Graphene Electrode for Diagnosis and Treatment of Brain Diseases** Jong-Hyun Ahn; Yonsei University, Korea (the Republic of)

Various electrophysiological and imaging techniques have been studied for the diagnosis and treatment of brain diseases such as epilepsy. In particular, electrocorticography (ECoG) provides valuable information that can guide clinical treatment in patients with brain diseases. In this talk, we report a highly flexible graphene electrode that stably wraps onto the cortex surface of the brain, exhibiting a remarkable signal-to-noise ratio and providing enhanced data quality. The graphene multichannel electrode successfully detects brain signals with high-throughput spatiotemporal resolution. Furthermore, the exceptional flexibility of graphene electrodes enables the fabrication of injectable electrodes that can be introduced through tiny skull openings. These injectable electrodes allow precise measurement of ECoG signals without the need for extensive surgical procedures. The results highlight the immense potential of flexible graphene electrode array in improving both diagnostic capabilities and therapeutic interventions for brain diseases. This technology holds promise for revolutionizing current treatment strategies and opening new avenues for effectively managing various medically significant brain diseases.

**Conformable Ultrasound Breast Patch for Deep Tissue Scanning and Imaging** Canan Dagdeviren; Massachusetts Institute of Technology, United States

Ultrasound is widely used for tissue imaging such as breast cancer diagnosis; however, fundamental challenges limit its integration with wearable technologies, namely imaging over large-area curvilinear organs. We introduced a wearable, conformable ultrasound breast patch (cUSBr-Patch) that enables standardized and reproducible image acquisition over the entire breast with less reliance on operator training and applied transducer compression. A nature-inspired honeycomb-shaped patch combined with a phased array is guided by an easy-to-operate tracker that provides for large-area, deep scanning and multi-angle breast imaging capability. The clinical trials reveal that the array using a piezoelectric crystal (Yb/Bi-PIN-PMN-PT) exhibits a sufficient contrast resolution (~3 dB) and axial/lateral resolutions of 0.25/1.0 mm at 30 mm depth, allowing the observation of small cysts (~0.3 cm) in the breast. This research develops a first-of-its-kind ultrasound technology for breast tissue scanning and imaging which offers a non-invasive method for tracking real-time dynamic changes of soft tissue.

**10:45 AM SB11.02.03**

**Heavy-to-Light Electron Transition in Quasi-2D Organic Semiconductor Enabling Real-Time Spectra Detection of Charged Particles** Dou Zhao<sup>1,2</sup>, Tomoyuki Yokota<sup>1</sup>, Takao Someya<sup>1</sup>, Wanqi Jie<sup>2</sup> and Yadong Xu<sup>2</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>Northwestern Polytechnical University, China

Wearable/implantable personal dosimeter achieving real-time and in-vivo radiation safety monitoring are significant for aerospace, medical diagnosis, and radiotherapy, while the current challenge is the lack of suitable detector materials possessing both excellent biocompatibility and high detection performance.

Here, we report a novel biocompatible organic single crystalline semiconductor (OSCS) with 2D anisotropic crystallographic structure, achieving excellent electron's transport and real-time spectral detection for charged particles. For the first time, the charge-transport mechanism responsible for such superior performance is clarified in this quasi-2D OSCS from the viewpoint of high-energy physics. Radiation-excited electrons occupy the high-energy L1 level with smaller effective mass than LUMO level, leading to a high electron drift velocity of  $5 \times 10^5$  cm s<sup>-1</sup> under the electric field of 4000 V cm<sup>-1</sup> at "radiation-detection mode". In addition, nanoscale surface layer edges on the OSCS, originating from its 2D crystallographic structure induced molecular self-assembly during the solution growth process, also promote the excitons dissociation along the in-plane direction of this OSCS.

As a result, the OSCS detector exhibit the record spectra detection for <sup>241</sup>Am  $\alpha$  particles among their organic counterparts, with the energy resolution of 36%, the electron's  $\mu t$  product of  $(4.91 \pm 0.07) \times 10^{-5}$  cm<sup>2</sup> V<sup>-1</sup>, and the spectra detection time down to 3 ms. In addition, the OSCS shows good biocompatibility that the cell viability still overs 90% after 24-hour incubation with 2 mg ml<sup>-1</sup> OSCS. This work reports a quasi-2D organic semiconductor with superior electron transport property and biocompatibility towards to real-time and in-vivo personal radiation dosimeters.

**11:00 AM SB11.02.04**

**Transparent Flexible Strain Gauges for Wearable Devices based on Tiled Graphene Films** Joseph Neilson<sup>1</sup> and Brian Derby<sup>2</sup>; <sup>1</sup>Trinity College Dublin, The University of Dublin, Ireland; <sup>2</sup>University of Manchester, United Kingdom

Here we present a novel transparent strain gauge, with a large gauge factor (GF) and usable strain range, based on 2D materials confined to the surface of an elastomeric substrate. These have good optical transmittance and demonstrate repeatability, under cyclic straining at frequencies > 1 kHz. Gauges have also been mounted on a thin polymer glove to demonstrate its capability as a transparent e-skin strain sensor.

During manufacture, closely packed films of graphene oxide are confined to a 2D plane, through assembly at an immiscible H<sub>2</sub>O/hexane interface. These films have predominantly edge-to-edge nanosheet contact and show little overlap after deposition onto a polydimethylsiloxane (PDMS) substrate. The films are treated in a hydroiodic acid (HI) reducing atmosphere to introduce electrical conductivity, with the consequent reduced graphene oxide (rGO) films showing < 900  $\Omega$ /sq sheet resistance, and > 88% optical transmittance. Piezoresistivity is generated through a pre-straining process that introduces a population of cracks, normal to the straining direction, into the conducting film. After relaxation the cracked films show a repeatable change in resistance when strained to values smaller than the initial pre-strain. Through careful control of the HI chemical reduction phase, it is possible to generate strain gauging devices with different operating ranges and sensitivity. Films pre-strained after reduction for 30 s form an array of parallel cracks that do not individually span the membrane. Subsequent straining of the cracked membrane does not further extend these cracks and the sheet extends in a kirigami manner as the cracks open. This cracking behaviour results in a strain gauge with a usable strain range > 0.2 and GF of 20 - 100 at low strains, however, this GF increases with increasing pre-strain. In all cases, GF decreases with increasing applied strain and asymptotes to a value of about 3 as it approaches

the pre-strain value. However, if the rGO film is reduced for a longer time of 60 s, the cracks extend during pre-straining to fully span the width of the PDMS membrane, leading to a much more sensitive strain gauge with GF ranging from 1000 - 16000. However, in this case, the usable strain range reduces to < 0.01. We present a simplified, equivalent resistor model, that can be used to interpret the behaviour of both gauge cracking configurations.

### 1:30 PM \*SB11.03.01

**Input/Output (I/O) Bioelectronics using Two-Dimensional Nanocarbons** Tzahi Cohen-Karni; Carnegie Mellon University, United States

My team's efforts are focused on the development and engineering of nanocarbons-based flexible platforms to interrogate and affect the properties of cells and tissue, with a specific goal to understand signal transduction (chemical or electrical) in tissue or complex three-dimensional (3D) cellular assemblies. Our highly flexible bottom-up nanomaterials synthesis capabilities allow us to form unique hybrid-nanomaterials that can be used in various input/output bioelectrical interfaces, i.e., bioelectrical platforms for chemical and physical sensing and actuation. In this talk I will review our current efforts for monitoring (and affecting) the complex signal transduction in 3D in vitro systems toward disease progression investigations. Utilizing graphene, a two-dimensional (2D) atomically thin carbon allotrope, we can simultaneously record the intracellular electrical activity of multiple excitable cells with ultra-microelectrodes that can be as small as an axon (ca. 2µm). The outstanding electrochemical properties of the synthesized hybrid-nanomaterials allow us to develop highly efficient catalysts, that can be deployed as electrical sensors and (chemical) actuators. We demonstrated sensors capable of exploring brain chemistry and sensors/actuators that are deployed in a large volumetric muscle loss animal model. In summary, the exceptional synthetic control and flexible assembly of nanomaterials provide powerful tools for fundamental studies and applications in life science and potentially seamlessly merge nanomaterials-based platforms with cells, fusing nonliving and living systems together.

### 2:00 PM SB11.03.02

**3D Printed Electronic Skin for Strain, Pressure and Temperature Sensing** Akhilesh K. Gaharwar; Texas A&M University, United States

Electronic skin, or e-skin, is an innovative material designed to emulate human skin's flexibility and stretchability. With its capability to detect environmental changes like pressure, temperature, and humidity, it has the potential to revolutionize fields such as robotics, wearable technology, and healthcare. Nevertheless, developing e-skin poses significant challenges: creating durable materials with skin-like flexibility, integrating biosensing abilities, and using advanced fabrication techniques like 3D printing for wearable or implantable applications. To overcome these hurdles, we have fabricated a 3D-printed electronic skin utilizing a novel class of nanoengineered hydrogels with tunable electronic and thermal biosensing capabilities. Our methodology takes advantage of shear-thinning behaviour in hydrogel precursors, allowing us to construct intricate 2D and 3D electronic structures. We simulate the elasticity of skin using triple crosslinking in a robust fungal exopolysaccharide, pullulan, while defect-rich 2D molybdenum disulfide (MoS<sub>2</sub>) nanoassemblies ensure high electrical conductivity. The addition of polydopamine (PDA) nanoparticles enhances adhesion to wet tissue. Our nanoengineered hydrogel exhibits outstanding flexibility, stretchability, adhesion, mouldability, and electrical conductivity. A distinctive feature of this technology is the precise detection of dynamic changes in strain, pressure, and temperature enabled by the combination of triple crosslinking and defect-rich MoS<sub>2</sub>. As a human motion tracker, phonatory-recognition platform, flexible touchpad, and thermometer, this technology represents a breakthrough in flexible wearable skins and holds transformative potential for the future of robotics and human-machine interfaces.

### 2:15 PM SB11.03.03

**Interaction Of Graphene And WS<sub>2</sub> With Neural Cells, Neutrophils And Mesenchymal Stem Cells: Implications For Peripheral Nerve Regeneration** Domenica Convertino<sup>1</sup>, Laura Marchetti<sup>1,2</sup> and Camilla Coletti<sup>1,1</sup>; <sup>1</sup>Istituto Italiano di Tecnologia, Italy; <sup>2</sup>University of Pisa, Italy

The employment of graphene and 2D materials in tissue engineering has been recently exploited for the repair and regeneration of nerve tissue. Among the possible applications, these relatively new materials display a great potential as peripheral neural interfaces, especially for their unique combination of electrical, optical and tribological properties<sup>1-4</sup>.

In this work we present recent results on graphene (G) and tungsten disulfide (WS<sub>2</sub>) interaction with some of the key players involved in nerve regeneration, namely peripheral neurons, neutrophils and mesenchymal stem cells (MSCs).

Firstly, we will discuss the effect of G on primary peripheral neurons, i.e. neonatal dorsal root ganglions (DRG) neurons. Graphene obtained via chemical vapor deposition (CVD), a promising candidate to realize functional nerve conduits, was used as a culture substrate. There, axons were found to be significantly longer (up to >70%) with respect to controls during the early developmental phase (up to 2 days), confirming the trend previously reported by our group for embryonic DRG neurons on G on silicon carbide (SiC)<sup>5</sup>. Notably, with the same time-dependent fashion, we found a significative modification of the axonal transport of nerve growth factor (NGF), the neurotrophin involved in the development of peripheral neurons. The amount of retrogradely moving vesicles was strongly reduced in favor of a locally stalled population in the first two days of culture<sup>6</sup>. In addition, electrophysiological and ultrastructural analysis concurred to show the rearrangements that occur in axons developing on G<sup>6</sup>. Our results provide a broad structural and functional understanding of the impact of G on DRG neurons, key information toward the development of G-based devices for neural regeneration. Similarly, we tested WS<sub>2</sub>, another 2D material with promising biomedical applications. CVD-grown WS<sub>2</sub>, known for its optoelectronic properties, was used to culture neuronal-like cells (SH-SY5Y) displaying neurite length and viability comparable to the controls<sup>4</sup>.

However, the use of these innovative materials has raised questions about their interaction with the other players involved in nerve regeneration, including neutrophils, whose immune response affects the regenerative outcome<sup>7</sup>, and MSCs, a novel therapeutic avenue for peripheral nerve regeneration<sup>8</sup>.

Therefore, in the third part of the study we tested WS<sub>2</sub> on sapphire and different graphene, namely G on sapphire, G on SiC, both as-grown and H-intercalated, G-CVD transferred on glass, to assess the effect of the production method on neutrophils and MSCs<sup>9</sup>. We first characterized neutrophil activation and discussed how material properties influenced the NETs production and adhesion to the substrates. Furthermore, G resistance to NETs-induced degradation was carefully investigated and compared with the results reported for graphene oxide<sup>10</sup>. Ultimately, 2D materials cytocompatibility for MSCs are tested to estimate cell viability, morphology and mitochondrial health.

Overall, our results aimed at understanding the interface between 2D material and some of the key players involved in nerve injury, with special attention to the molecular mechanisms that govern axon outgrowth in neurons, a critical point for regenerative medicine.

**Wearable Graphene Biosensors for Microfluidic Sweat Analysis** [Wei Gao](#); California Institute of Technology, United States

Wearable sweat biosensors have the potential to provide non-invasive molecular analysis toward predictive analytics and treatment. However, it is highly challenging to accurately detect low-concentration analytes in situ and manufacture high-performance flexible biosensors at large scale and low cost. In this talk, I will introduce our efforts in developing microfluidic wearable sweat biosensors based on laser-engraved graphene. Through materials and sensor design innovations, such wireless wearables can autonomously access human sweat via iontophoresis across activities and seamlessly measure a broad spectrum of analytes including metabolites, nutrients, hormones, proteins, and drugs. The clinical value of our wearable systems is evaluated through various human trials involving healthy and patient populations toward precision nutrition, mental health assessment, gout management, and systemic inflammation monitoring. I will also discuss our research progress on energy harvesting from the human body and the environment to realize battery-free wireless wearable biosensing. These wearable technologies could open the door to a wide range of personalized monitoring and diagnostic applications.

#### 4:00 PM SB11.03.05

**Wearable and Implantable Bioelectronics Enabled by 2D Materials-Based Layer Transfer** [Jiho Shin](#)<sup>1</sup>, Yeongin Kim<sup>2</sup>, Jun Min Suh<sup>1</sup>, Hyunseok Kim<sup>1</sup>, Suresh Sundaram<sup>3</sup>, Young Joon Hong<sup>4</sup>, Abdallah Ougazzaden<sup>3</sup> and Jeehwan Kim<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>University of Cincinnati, United States; <sup>3</sup>Georgia Tech Lorraine, France; <sup>4</sup>Sejong University, Korea (the Republic of)

2D materials-based layer transfer (2DLT) is an emerging lift-off technique for producing large-area freestanding single-crystalline epitaxial films, which offer high electronic/optoelectronic performance and ultrathin form factor that are essential for wearable and implantable bioelectronic device applications. Single-crystalline III-V/III-N compound semiconductor membranes can be epitaxially grown on substrates coated with 2D materials such as graphene or boron nitride, which results in weak van der Waals interface that facilitates mechanical exfoliation of the device layer from wafer [1]. In this talk, I will discuss our recent efforts that utilize 2DLT to build: (i) chipless wireless electronic skins based on gallium nitride surface acoustic wave sensors capable of low-power and high-sensitivity detection of a broad range of external stimuli [2], and (ii) 3D-integrated micro-LED heterostructures that achieve extremely high device densities and suggest potential applications in optoelectronic-based neural interfaces [3].

#### 4:15 PM \*SB11.03.06

**Biointegrated Interfaces with Carbon Nanostructures** [Maurizio Prato](#)<sup>1,2</sup>; <sup>1</sup>Università Degli Studi di Trieste, Italy; <sup>2</sup>CIC biomaGUNE, Spain

Nanostructured interfaces can be shaped for the molecular control of physical/chemical adsorption, with enhanced surface area to promote interfacial chemistry, nano-catalysis, and bio-inspired interfaces. For instance, connecting nanostructured materials to biological compartments is a crucial step in prosthetic applications, where the interfacing surfaces should provide minimal undesired perturbation to the target tissue. Ultimately, the (nano)material of choice has to be biocompatible and promote cellular growth and adhesion with minimal cytotoxicity or dis-regulation of, for example, cellular activity and proliferation. In this context, carbon nanomaterials, including nanotubes and graphene, are particularly well suited for the design and construction of functional interfaces. This is mainly due to the extraordinary properties of these novel materials, which combine mechanical strength, thermal and electrical conductivity. Our group has been involved in the organic functionalization of various types of nanocarbons, including carbon nanotubes, and graphene. The organic functionalization offers the great advantage of producing soluble and easy-to-handle materials. As a consequence, since biocompatibility is expected to improve upon functionalization, many modified carbon nanomaterials may be useful in the field of nanomedicine. In particular, we have recently shown that carbon nanotubes and graphene can act as active substrates for neuronal growth, a field that has given so far very exciting results. Nanotubes and graphene are compatible with neurons, but, especially, they play a very interesting role in interneuronal communication. Improved synaptic communication is just one example. During this talk, we will discuss the latest and most exciting results obtained in our laboratories in these fast developing fields.

#### 4:45 PM \*SB11.03.07

**Heterogeneous Integration of 2D Sensors for Wearable and Healthcare Applications** Christian Lopez Angeles, Yiyue Luo, David Morales Loro, Jiadi Zhu, Mantian Xue, Wojciech Matusik, Jing Kong and [Tomas Palacios](#); MIT, United States

The next wave of innovation and business opportunities related to electronics will probably be about enabling “edge intelligence”. These are new microsystems with unprecedented levels of autonomy in terms of energy harvesting, sensing and information processing. Heterogeneous integration of new materials will be necessary to provide these microsystems with functionality not possible today in Si chips alone. This talk will discuss a few examples of how edge intelligence enabled by the use of two-dimensional (2D) materials will impact wearable devices for healthcare applications. The first example uses metallic fibers coated with a graphitic material to embed hundreds of pressure sensors on fabrics and garments. These sensors are then coupled to an RF harvesting chip based on a MoS<sub>2</sub> rectifier to enable autonomous sensing of people’s movements. A second example uses arrays of hundreds of graphene-based chemical sensors inside a breathalyzer chamber to analyze the volatile organic compounds in patients’ breath. Finally, the low temperature synthesis of MoS<sub>2</sub> allows for the integration of high performance devices based on this material on flexible polymer substrates for the development of

flexible and active electrodes for electrophysiology.

**Two-Dimensional Cs<sub>2</sub>AgBiBr<sub>6</sub>-Based Biosensor for the Sensitive Detection of Cardiac Biomarkers** Yin-Cheng Lu<sup>1</sup>, Evan Darius<sup>1</sup>, Mei-Chin Lien<sup>1</sup>, I-Hsiu Yeh<sup>1</sup>, Hung-Wen Chen<sup>1</sup>, Ching Yuan Su<sup>2</sup>, Ru-Yin Hsu<sup>3</sup> and Keng-Ku Liu<sup>1</sup>; <sup>1</sup>National Tsing Hua University, Taiwan; <sup>2</sup>National Central University, Taiwan; <sup>3</sup>National Taiwan University Hospital Hsinchu Branch, Taiwan

Inspired by graphene and transition metal dichalcogenides, 2D layered materials that possess excellent electronic, optical, physical, and chemical properties have been actively investigated and explored to further expand their applications. In particular, 2D lead-free double perovskite with strong quantum confinement and excellent electronic performance are promising for optoelectronic applications. Owing to its nontoxicity, inherent stability, and high optical and electrical sensitivity, 2D lead-free double perovskite has attracted significant research interests. Cardiac troponin I (cTnI), a protein with molecular weight of 23.8 kDa, plays an important role as the regulator that is involved in the process of skeletal and cardiac muscle contraction. Owing to its superior cardiac specificity and selectivity, cTnI has been widely employed as the biomarker for the detection of myocardial damage and risk stratification in acute myocardial infarction (AMI) patients. In this study, we report the synthesis of 2D layered Cs<sub>2</sub>AgBiBr<sub>6</sub> and the fabrication of biological sensors based on plasmonic nanomaterials-decorated 2D Cs<sub>2</sub>AgBiBr<sub>6</sub> for the sensitive detection of cardiac biomarker, cTnI.

#### 8:00 PM SB11.04.02

**Enhancing Mechanical Strength of Wearable Microneedles using Silica Nanoparticle Coatings** Hyewon Choi, Sohyun Kim and Hyunsik Yoon; Seoul National University of Science and Technology, Korea (the Republic of)

Wearable medical devices are currently being developed for a wide range of healthcare systems, and microneedles (MNs) have emerged as promising transdermal delivery systems due to their painless and non-invasive characteristics. Polymers are commonly used as MN materials because of their simple, low-cost fabrication, and biocompatibility. However, their mechanical strength may be insufficient compared to metals and ceramics, resulting in potential penetration failures that can leave fractured MNs under the skin, leading to unsuccessful delivery. Therefore, enhancing the mechanical strength of polymeric MNs is essential. In this study, we employed silica (SiO<sub>2</sub>) nanoparticles (NPs) and poly(diallyldimethylammonium chloride) (PDADMAC) through a Layer-by-Layer (LbL) assembly on MNs. Subsequently, we applied hydrothermal (HT) treatment to sinter the coated silica NPs, thereby increasing the mechanical stability of the thin film. Initially, we conducted dye loading and release tests using fluorescent dyes, which demonstrated that MNs coated with the LbL thin film and LbL/HT-treated MNs exhibited significantly higher loading and release efficiency compared to unmodified MNs. This improvement was attributed to the increased surface area facilitated by the silica NPs coating. Additionally, we assessed the mechanical properties of MNs through abrasion and penetration tests, revealing that silica NPs-coated MNs showed higher mechanical stability, which was further enhanced after the HT treatment. The LbL system described in this study holds great potential for application in various three-dimensional structures, including MNs, which will contribute to the advancement of wearable drug delivery systems.

#### 8:00 PM SB11.04.03

**Folic Acid-Gold Nanoparticle@MoSe<sub>2</sub> for Targeted Photothermal Cancer Therapy** Chang Hyeon Ha, Han Been Lee, Se Hwa Cheon, Su Jeong Lee, Do Hyeon Kim and Gi hun Seong; Hanyang University, Korea (the Republic of)

Transition Metal Dichalcogenides (TMDs) have recently emerged as novel 2D materials, possessing significant electrical, mechanical, and optical properties. These materials consist of a single metal combined with two chalcogens (known as dichalcogenides), and their unique characteristics are determined by the specific elements comprising them. Moreover, TMDs exhibit gifted potential for clinical applications, thanks to their remarkable photothermal capabilities. Photothermal and photodynamic therapies (PTT and PDT) represent notable light-based treatment modalities. PTT involves generating heat through light-to-heat conversion, while PDT involves inducing the production of Reactive Oxygen Species (ROS) using light-sensitive agents. These therapies have gained significant attention in the field of cancer therapy due to their sensitivity and usefulness. Among these approaches, PTT has garnered interest due to the high light-to-heat conversion capability of TMDs. However, relying solely on TMDs may not be sufficient for effective therapy. Therefore, we have incorporated gold nanoparticles (AuNPs) to enhance the PTT potential of TMDs through spontaneous reduction. AuNPs possess biocompatible properties, exhibit photothermal capabilities through Localized Surface Plasmon Resonance, and can be easily modified. As a result, they can be effectively utilized as clinical materials in conjunction with TMDs. To specifically target cancer cells, we have additionally introduced Folic acid (FA). FA is an artificial molecule that closely mimics natural folate, enabling it to bind with folate receptors present in the cellular membrane. This targeted approach allows for precise cancer cell localization, particularly in cases of folate receptor-overexpressed cancer, such as Triple Negative Breast Cancer (TNBC). TNBC, which lacks the widely utilized targeting receptor and carries a high risk of metastasis, exhibits significant potential for successful cancer targeting utilizing FA.

In this study, we synthesized complex materials for PTT by coating MoSe<sub>2</sub> with AuNPs and FA (FA-Au@MoSe<sub>2</sub>, FAM). Glycyrrhizic acid was utilized to exfoliate bulk MoSe<sub>2</sub> into 2D monolayers. This exfoliation process induced a transition from an indirect to a direct-band gap, enhancing the PTT capabilities of the TMDs. MoSe<sub>2</sub> was selected as the primary TMD due to its well-known high light-to-heat transfer properties in PTT applications. AuNPs were employed as enhanced photothermal agents. To modify the gold surface, cysteine was used and FA was linked to the gold surface through EDC/NHS coupling. Lastly, MDA-MB-231 breast cancer cells, known for their folate receptor overexpression, were used as the target cells since MDA-MB-231 cells are representative of TNBC.

The deposition of AuNPs and FA led to an increase in both size and surface charge. This was confirmed by the UV-visible spectra, which exhibited peaks corresponding to AuNPs and FA. SEM and TEM images demonstrated the presence of AuNPs on the surfaces of TMDs. Consequently, the successful synthesis of FAM was achieved. Regarding biocompatibility and PTT, the temperature elevation reached a level sufficient for PTT within biocompatible concentrations. Furthermore, FAM exhibited a significantly greater effect compared to MoSe<sub>2</sub>, indicating that AuNPs effectively enhanced the PTT capability of MoSe<sub>2</sub>. Specifically, FAM demonstrated non-toxicity to cells at a concentration of 30 µg/mL, similar to MoSe<sub>2</sub>, but displayed a higher therapeutic effect when exposed to a NIR laser (808 nm, 0.8 W cm<sup>-2</sup>). These findings, confirmed by WST-1 assay and calcein-AM staining, highlight the biocompatibility and photothermal ability of FAM. As a result, this easily synthesized 2D material, achieved through simple sonication and stirring

processes, has exhibited remarkable biocompatibility, photothermal activity, and targeting capability. These findings position it as a promising candidate for utilization in cancer therapy.

#### 8:00 PM SB11.04.04

**Biocompatible Molybdenum Diselenide Nanosheets: A Two-Dimensional Nanomaterial for Near-Infrared Photothermal Cancer Therapy** Su Jeong Lee, Se Hwa Cheon, Han Been Lee, Chang Hyeon Ha, Do Hyeon Kim and Gi hun Seong; Hanyang University, Korea (the Republic of)

Transition metal dichalcogenide (TMD) nanosheets are two-dimensional (2D) nanomaterials composed of layered structures. In the 2D TMD structure, denoted as 'X-M-X', two layers of X chalcogen atoms (such as S or Se) are sandwiched between a layer of M transition metal atoms (such as Mo or W). The interaction between adjacent layers in the nanosheet structure is driven by van der Waals forces. These forces play a crucial role in holding the layers together and are essential for the development of the band structure. 2D TMD possesses outstanding optical, electronic, mechanical, and thermal properties due to its adjustable band gap and interaction with light. Consequently, they have gained significant attention in recent years for applications in electronic devices, energy storage, and photothermal therapy.

Among various TMDs, molybdenum diselenide (MoSe<sub>2</sub>) has emerged as a prominent focus of research due to its remarkable chemical and physical properties. Notably, when MoSe<sub>2</sub> transitions from multiple layers to a single layer, its electronic bandgap undergoes a significant change from an original indirect bandgap of 1.1 eV to a direct bandgap of 1.55 eV. As a result, single-layer MoSe<sub>2</sub> represents a novel semiconductor material that exhibits strong light absorption in the proximity of the band-gap energy.

In this study, we employed an inexpensive liquid exfoliation method to fabricate MoSe<sub>2</sub> nanosheets. This approach enables high-yield production and renders the nanosheets suitable for application in photothermal cancer therapy. To disperse MoSe<sub>2</sub> in water, we utilized glycyrrhizic acid (GA), an amphiphilic natural surfactant from licorice root, as the exfoliating agent. Notably, this study marks the first instance of GA being used as an exfoliating agent for preparing nanosheets. Additionally, we enhanced biocompatibility and intracellular uptake by conjugating polyethylene glycol (PEG), resulting in PEG-modified GA-MoSe<sub>2</sub> (PGM) nanosheets.

The successful exfoliation utilizing GA was confirmed by SEM and TEM analysis, revealing the presence of monolayer nanosheets. The PEGylation of the nanosheets was validated through an observed increase in size and zeta potential. Thermogravimetric analysis (TGA) results demonstrated the thermal stability of PGM as a material. Furthermore, UV-visible spectra of PGM exhibited an absorption peak at 808 nm, and when PGM was subjected to NIR laser irradiation (808 nm, 0.8 W cm<sup>2</sup>), they demonstrated the highest photothermal effect. Based on these findings, PGM was identified as a promising agent for photothermal cancer therapy, offering a minimally invasive treatment option with reduced side effects.

To assess the cytotoxicity and anticancer potential of PGM in MDA-MB-231 human breast cancer cells, we conducted a WST-1 assay and a live-dead cell staining assay. The PGM group without laser irradiation displayed remarkably high cell viability at 98.6%, whereas the group subjected to laser irradiation exhibited viability of 22.7%, indicating a substantial inhibitory effect on cancer cells. Additionally, PGM demonstrated significantly higher intracellular uptake. Subsequently, we directly administered PGM to a breast cancer-bearing mouse model to evaluate its in vivo anticancer effect. Tumors exposed to Near Infrared (NIR) laser exhibited a notable decrease in size or complete disappearance, and no significant weight loss was observed during the treatment period.

The findings obtained from experiments strongly indicate that PGM possesses minimal cytotoxicity and holds great promise as a valuable biomaterial for cancer therapy, particularly in harnessing the photothermal effect of PGM through hyperthermia. Building upon these results, our future objectives include incorporating anti-cancer drugs into PGM to develop drug delivery platforms, as well as directly fabricating PGM scaffolds for transplantation at the target site, thereby enabling effective implementation of photothermal cancer therapy.

#### 8:00 PM SB11.04.05

**Synthesis of Transition Metal Dichalcogenides Nanosheets and its Application to Photothermal Immunoassays** Do Hyeon Kim, Chang Hyeon Ha, Han Been Lee, Su Jeong Lee, Se Hwa Cheon and Gi hun Seong; Hanyang University, Korea (the Republic of)

Two-dimensional nanomaterials, including graphene, transition metal oxides, and carbon nitrides, have gained significant attention due to their large surface area, mechanical properties, and unique electro-optical characteristics. Among these materials, transition metal dichalcogenides (TMDs) have emerged as particularly promising in biosensing, electronics, and photothermal therapy, due to their distinctive properties. Most TMDs feature an MX<sub>2</sub>-type structure, where M represents transition metals like Mo and W, and X represents chalcogenides such as S, and Se. TMDs exhibit a sandwich-like structure, with hexagonal planes of transition metal atoms separating the chalcogen atoms.

TMD, a two-dimensional semiconductor material, exhibits unique electrical, mechanical, and optical properties. One of its most notable characteristics is the photothermal effect. TMD demonstrates the ability to absorb light in the near-infrared region and convert it into heat. Monolayer TMD, in particular, possesses enhanced photothermal capabilities compared to multi-layered TMD, thanks to its altered band gap. The transition from an indirect to a direct band gap occurs when TMD forms monolayers. This transition facilitates more efficient electron transfer and shifts the band gap position from the infrared to the near-infrared region. Consequently, the change in the band gap enables higher photothermal efficiency at near-infrared wavelengths.

To obtain a monolayer of TMD, various methods including mechanical separation and chemical vapor deposition have been employed. However, these methods suffer from drawbacks such as high costs and time consumption. In contrast, the liquid exfoliation method offers a simple and cost-effective approach for producing monolayers. Traditionally, organic solvents have been used in the liquid exfoliation. However, by utilizing glycyrrhizic acid (GA), a natural compound, deionized water can be employed as a solvent. The inclusion of GA in the liquid exfoliation weakens the van der Waals forces between the TMD layers, simultaneously serving as a stabilizer and enhancing the colloidal stability of the resulting TMD monolayer.

Lateral Flow Immunoassay (LFIA) is a powerful method used for the analysis of target molecules. It offers several advantages, including simplicity and short assay times. In general, LFIA utilizing gold nanoparticles (AuNPs) as a colorimetric indicator demonstrates high sensitivity in detecting target molecules. However, there remains a challenge in further enhancing the sensitivity of LFIA. Therefore, novel approaches are necessary to overcome this challenge and achieve increased sensitivity.

In this study, we synthesized monolayer MoSe<sub>2</sub> and investigated its application in a photothermal-based LFIA. The MoSe<sub>2</sub> nanosheets were successfully obtained through GA-mediated liquid exfoliation, as confirmed by TEM images showing well-dispersed monolayers. UV-vis spectra of GA-MoSe<sub>2</sub> exhibited an absorption peak at 808 nm, within the near-infrared region. Subsequently, we irradiated GA-MoSe<sub>2</sub> with a NIR laser at 808 nm and observed an increase in temperature, validating its role as a photothermal agent.

To develop a detection probe for the LFIA, we conjugated GA-MoSe<sub>2</sub> with goat-anti mouse immunoglobulin G (IgG) antibodies, resulting in GA-MoSe<sub>2</sub>/mAb. In the immunoassay, as GA-MoSe<sub>2</sub>/mAb interacted with IgG and reached the test line, the capture antibody on the test line bound to the conjugate, producing a distinct color line. The intensity of the test line's color increased with the IgG concentration. Additionally, the temperature change associated with laser irradiation also increased with increasing IgG concentration. These results suggest that GA-MoSe<sub>2</sub> holds the potential to serve as a platform for high-sensitivity photothermal LFIA. Looking ahead, the utilization of TMDs as photothermal agents is expected to open up various applications, including biosensors for diagnosing virus infections and wearable sensors.

#### 8:00 PM SB11.04.06

**Structural Deformation using Metal Deposition for Bio-Adhesive Patch** Chorong Kim, Jaekyuong Kim and Hyunsik Yoon; Seoul National University of Science and Technology, Korea (the Republic of)

Recently, adhesive patches have been studied for medical treatment. Depending on their characteristics, these can be applied in various situations such as wound healing, drug delivery, and biosensor attachment. Given that the body is a moist environment, current research focuses on incorporating chemical adhesives or utilizing structural properties for surface attachment such as suction effects. Additionally, liquid-repellency is essential to prevent the risk of detachment caused by wetting. We adopted structural adhesives to avoid allergic reaction due to toxicity of chemical adhesives. This research presents a method of structural deformation through different metal deposition on hyperbola structure to achieve new properties such as wet adhesion (Au) or liquid-repellency (Al). Hyperbola structures were fabricated by wrapping liquid prepolymer around micropillars driven by capillary force. Due to its flexible edges, the metal, deposited on top surface, caused structural deformation depending on its residual stress. In the case of Au, tensile stress of Au thin film made edges shrink inward, created an empty space inside for adhesive behavior. Conversely, in the case of Al, edges expanded outward because of compressive stress of Al thin film caused by oxidation. So, this structure had more liquid-repellency characteristics. These novel structures can be easily replicated and mass-produced using soft lithography, offering the advantage of non-allergic reactions as no additional adhesives are required. Furthermore, deformation can be easily controlled by adjusting the deposition thickness and Young's modulus of the structure's material. This technology is expected to contribute to the medical industry as for skin/organ-attachable patches.

**8:00 PM SB11.04.07**

**Improving Stability of Nickel Hydroxide/Oxyhydroxide Visible Light-Induced Actuators by Aluminum Doping** Nan He; University of Hong Kong, Hong Kong

Material-based actuation systems have been an emerging field of interest because of their direct and simple mechanism without the need to use bulky and complicated hydraulic, electric or magnetic motors. Material-based actuators utilize external stimuli such as light, temperature or humidity to drive mechanical movements. In recent research studies, transition metal oxides/hydroxides (TMOs) were introduced and studied for light-induced actuation based on their simple and effective photothermal mechanism for water de-intercalation from the turbostratic crystal structures of these materials. Turbostratic phases of nickel hydroxide/oxyhydroxide (NHO) have been found to be high-performing multi-stimuli driven actuating materials. However, these material phases are known to be unstable, and over time they become crystallized and lose their actuating properties. In this work, aluminium doping is used to stabilize the turbostraticity and actuation performance. Visible-light actuation experiments are conducted on NHO samples with and without aluminium doping to characterize their actuation performance over time. Turbostraticity is examined and quantified by techniques including XRD, Raman spectroscopy and high resolution TEM, via information such as d-spacings, intensity ratio and band peak changing. The turbostraticity difference between aluminium-doped and pure NHO actuators is correlated with their actuation performances.

**8:00 PM SB11.04.08**

**Injectable Neural Sensor Array for Post-Surgery Brain Monitoring** Kyungtae Park, Juyeong Hong, Jejung Kim and Jong-Hyun Ahn; Yonsei University, Korea (the Republic of)

Brain diseases, such as epilepsy and traumatic brain injury, affect millions of people worldwide, causing severe side effects. Monitoring postoperative seizures and the recovery of brain function after surgery is crucial for diagnosing and treating these conditions, providing vital information. However, conventional neural implants involve a large-area craniotomy and rely on bulky sensors, which restrict the natural movement of patients. In this study, we present an injectable neural sensor array for monitoring the brain after surgery. The device utilizes a thin and flexible mesh-structured substrate that can be injected onto the cortical surface through a small hole, minimizing the invasiveness. This approach allows the 12mm diameter device to spread out from a 2mm diameter syringe and achieve conformal contact with the surface of the cortex. The device performs neural recording and micro-stimulation for seizure alleviation using multichannel electrocorticography (ECoG) electrodes and a stimulation pad. Additionally, it integrates a sensor array for multimodal sensing of intracranial pressure (ICP) and intracranial temperature (ICT). This technology provides a convenient healthcare solution for the comprehensive assessment of the patient's post-surgery brain condition.

**8:00 PM SB11.04.09**

**The Development of Choline, Calcium and pH Sensors based on Laser-Inscribed Graphene Electrodes** Abdulrahman Al-Shami, Ali Soleimani, Farbod Amirghasemi, Victor Ong, Sina Gharahatekan and Maral Mousavi; University of Southern California, United States

**Introduction:** Graphene, a two-dimensional layer of carbon atoms arranged in a hexagonal lattice, has gained significant attraction in electrochemical biomedical sensors. Graphene exhibits high electrical conductivity, flexibility, and a high surface-to-volume ratio. That makes graphene ideal for developing sensitive, selective, reliable, precise, and accurate sensing platforms for detecting biomarkers and other substances. Another interesting feature of graphene is its high hydrophobicity. This property is important for developing solid contact potentiometric sensors for quantifying biologically important ions. This is because the hydrophilic electrodes allow the formation of a water layer between the electrode surface and the ion-selective membrane, which adversely affects the sensor's sensitivity and selectivity toward the targeted ion. Graphene is conventionally produced by wet chemistry and chemical vapor deposition which are usually complicated, expensive, and labor-intensive. Producing graphene by laser engraving on carbon-rich materials (mostly in the form of repeated aromatic rings) is an attractive approach to overcome the limitations of conventional production methods. The laser-engraving method is simple, precise, cost-effective, fast, scalable, safe, and highly reproducible. In this work, we produced graphene electrochemical electrodes using laser engraving technology. We characterized the produced graphene and employed the electrodes to develop three different sensors for detecting choline and calcium ions and pH levels for human and animal health applications. Choline is a vital infant nutrition factor, supporting brain and nervous system development and functions. Quantifying choline in infant formulas can ensure that infants receive enough choline to grow healthy. The calcium sensor will be used to detect calcium levels in cows' blood, which is important for diagnosing calcium imbalances in dairy cows and preventing milk fever. The pH sensor helps monitor different physiological processes, such as wound healing.

**Methods:** We produced the electrochemical electrodes by ablating a polyimide film (127  $\mu\text{m}$  thickness) using a CO<sub>2</sub> laser cutter machine with a 1060 nm laser wavelength. The engraving was conducted with an auto-focused laser beam with power and speed of 3 W and 105 mm/s, respectively. A choline-selective membrane was produced of a mixture of PVC (structural polymer), o-nitrophenyl-octyl-ether (plasticizer), Sodium tetrakis[3,5-bis(trifluoromethyl)phenyl]borate (ionic site), and Calix 4 arene (ionophore) in THF solvent. The membrane was cast on the electrode surface and dried overnight before measurements. The calcium selective membrane was prepared in the same way as choline but used as an ionophore. The graphene electrode was electrochemically modified for pH sensing by layers of IrO<sub>2</sub> NPs. The deposition solution was prepared from IrCl<sub>4</sub> using alkaline hydrolysis followed by acidic condensation. The deposition was conducted using cyclic voltammetry in a potential window between 0.6 to 0.65 V for 300 cycles.

**Results and discussion:** the laser engraving method successfully produced flexible electrochemical electrodes. The scanning electron microscopy images of the laser-engraved areas demonstrated the formation of three-dimensional highly porous graphene on the PI film. Raman spectroscopy revealed the formation of multiple graphene layers on the PI film with some defects that can be attributed to the presence of oxygen during the engraving in ambient conditions. The graphene-based choline selective electrode demonstrated Nernstian response toward choline ions with a detection limit of 0.1 mM. Also, the sensor could quantify choline concentration in commercially available infant formulas with a measurement error of less than 5%. The calcium-selective electrode exhibits high sensitivity with a detection limit of 0.01 mM. IrO<sub>2</sub>-modified graphene electrode demonstrates a linear response in pH values between 4 and 10.

**8:00 PM SB11.04.10**

**Measuring Electrodermal Activity Underwater using Graphene Electronic Tattoos** [Wendy Rossi](#)<sup>1</sup>, Ning Liu<sup>1</sup>, Dmitry Kireev<sup>2</sup> and Deji Akinwande<sup>1</sup>;  
<sup>1</sup>The University of Texas at Austin, United States; <sup>2</sup>University of Massachusetts Amherst, United States

Oxygen, while essential for human function, can be harmful in the context of underwater diving. Divers, to stay safe underwater, need to breathe pure, pressurized oxygen known as hyperbaric oxygen; however, breathing too much of this hyperbaric oxygen at certain depths and pressures risks the development of Central Nervous System Oxygen Toxicity (CNS-OT). CNS-OT can lead to sympathetic overstimulation and cause seizures, which are due to abnormal electrical activity in the brain. Electrodermal Activity (EDA) is a quantitative index of sympathetic nervous system activity measured through changes in skin conductance, which vary according to sweat levels caused by emotional arousal or stress. A significant surge in EDA amplitude is a precursor to epileptic seizures and used as an early indicator for CNS-OT risk. Developing a method to identify the onset of CNS-OT risk underwater means introducing a safety monitoring approach previously unavailable in diving. Currently, commercial EDA devices, while effective, lack the flexibility and wearability of GETs and are not waterproof. We propose a graphene electronic tattoo (GET) capable of EDA data processing while immersed in saltwater conditions through a four-part experimental process. First, we established a control group by measuring bioimpedance with uncovered GETs in air, DI water, and saltwater. Next, we found the best waterproofing sealant by comparing the baseline measurements of bare GETs to GETs covered individually by three sealants. After finding that Nexcare Skincrack Care (NCC) produced the clearest bioimpedance readings in each condition, we used this sealant for electrocardiogram measurements in the same fluid conditions to validate our GETs capacity for underwater measurements. Finally, we took EDA measurements using a Neulog device by simulating three emotional states: meditative, focused, and stressed through meditation, boring videos, and horror videos. We established an EDA baseline using the commercial electrodes in each emotional state in air then proceeded to measure EDA with our GET sealed by NCC in the conditions of air, DI, and saltwater. The maximum stimulated EDA change obtained by our graphene electrodes in saltwater is 0.217  $\mu$ S with a response time of 4 seconds, which is comparable to the commercial electrodes in air with a similar response time. As a result, we find that the combination of NCC and a GET enabled successful EDA monitoring in seawater conditions, advancing GETs in underwater medicine.

**8:00 PM SB11.04.12**

**Scalable Fabrication of Soft MXene-Coated Fiber Microelectrodes for Bio Interfacing** [Lingyi Bi](#)<sup>1</sup>, Raghav Garg<sup>2</sup>, Natalia Noriega<sup>3</sup>, Ruocun (John) Wang<sup>1</sup>, Kseniia Vorotilo<sup>1</sup>, Justin Burrell<sup>2</sup>, Hyunho Kim<sup>1</sup>, Christopher E. Shuck<sup>1</sup>, Anh Le<sup>2</sup>, Flavia Vitale<sup>2</sup>, Bhavik A. Patel<sup>3</sup> and Yury Gogotsi<sup>1</sup>;  
<sup>1</sup>Drexel University, United States; <sup>2</sup>University of Pennsylvania, United States; <sup>3</sup>University of Brighton, United Kingdom

The development of flexible fiber-based microelectrodes opens up opportunities for long-term studying and modulating neural activities and diseases by increasing targeting precision while inducing fewer side effects, thanks to the minimized mechanical mismatch between artificial devices and soft tissues. However, the current manufacturing of such microfabrication faces scalability, reproducibility, and handling challenges, making large-scale deployment of fiber-based microelectrodes difficult. Moreover, few designs allow capturing both electrical and chemical signals, which are necessary for understanding and interacting with complex biological systems.

Here, we report a novel method that leverages the unique combinations of electrical conductivity, functional surfaces, and solution processibility of MXenes, a large family of 2D nanomaterials, to apply a thin layer of MXene coating continuously to commercial nylon filaments (30-300  $\mu$ m in diameter) at a fast speed (up to 15 mm/s), resulting in a resistance down to 15  $\Omega$ /cm. The MXene-coated filaments can be batch-fabricated into arrays of fiber electrodes, encapsulated with Parylene C, and exposed only at the tip upon application for localized detection and stimulation. We demonstrated the usability of these multifunctional fiber electrodes for both *in-vivo* and *ex-vivo* studies, including neuromodulation and electrical sensing in a rat and H<sub>2</sub>O<sub>2</sub> chemical sensing in bladder cells. These electrodes offer excellent performance, significantly simplified use, and improved flexibility (with no performance changes even when knotted). These versatile MXene filament microelectrodes offer a robust, miniaturized platform for monitoring and stimulating neural activities, facilitating a deeper understanding of health and disease.

SESSION SB11.05: 2D Transistors as Biosensors

**CRISPR-Powered Graphene Electronics for CRISPR Editing Quality Control** [Kiana Aran](#), Keck Graduate Institute, United States

The discovery of CRISPR technology has revolutionized the fields of transcriptional activation and repression, genome editing, gene-based therapeutics, and diagnostics. The applications of this technology have been rapidly expanding as researchers continue to discover new Cas enzymes, engineer high fidelity Cas orthologs, and modify and synthesize guide RNAs to efficiently direct these Cas enzymes to their targets. In this talk, we will introduce the first-generation DNA biosensors that combine CRISPR technology with the ultra-sensitivity of graphene-based field effect transistors (gFETs) to detect target DNA sequences within the whole genome without the need for DNA amplification. This technology, termed CRISPR-Chip™, utilizes the genome searching capability of Cas and reprogrammable RNA molecule to unzip the double-stranded DNA and bind to its target. This binding event causes a change in graphene conductivity which can be detected in real-time within the gFET construct. CRISPR-Chip was utilized to detect target genes within clinical samples obtained from patients with Duchenne Muscular Dystrophy (Cover of Nature BME-2019), and single cell point mutations in Sickle cell disease and ALS without the need for amplification (Nature BME 2021), within less than 30 minutes. The applications of this technology platform go beyond diagnostics. CRISPR-Chip can provide greater insights on the mechanism of CRISPR and can lead to safe and more effective utilization of this gene editing technology for therapeutic applications. By precisely predicting CRISPR editing outcomes based on key drivers of success like RNP stability and cleaving activity, the CRISPR-Chip enables us to confidently identify the best gRNAs, Cas proteins, and conditions for CRISPR gene editing experiment from the outset.

**9:00 AM SB11.05.02**

**Microneedle Graphene Field-Effect Transistors for Wearable Biosensing** [Martin Holicky](#)<sup>1</sup>, Benji Fenech Salerno<sup>1</sup>, Anthony E. Cass<sup>1</sup> and Felice Torrisi<sup>1,2</sup>;  
<sup>1</sup>Imperial College London, United Kingdom; <sup>2</sup>Universita' di Catania, Italy

Microneedle-based biosensing provides an attractive path towards continuous health monitoring - the use of microneedles causes substantially lower pain to the user than traditional hypodermic needles while providing accurate sensing information [1]. Due their small footprint and ease of application, such

biosensors are easily worn with minimal nuisance to the user, enabling wearable health sensing anywhere and at any time. Graphene and other two-dimensional materials have emerged as a suitable platform for high performance printed electronics, enabling graphene field-effect transistors (GFETs) on ubiquitous substrates [2,3]. We have recently developed a scalable method for creating high resolution GFETs through spray-coating[4] and demonstrated their use in biosensing.

In this work, a new type of sensor is created by forming the GFETs directly on the tips of polycarbonate microneedles to enable biosensing of interstitial fluid within the skin. The GFETs are formed on the three-dimensional needles through a scalable combination of laser lithographic patterning and spray-coating and uses injection-moulded polycarbonate microneedles. The graphene channels are approximately 2000  $\mu\text{m}$  wide and 80  $\mu\text{m}$  long, with a resistance of 150 Ohms and display characteristic ambipolar modulation under solution gating. We fully characterise the sensors through microscopic and electrochemical methods and demonstrate their biosensing properties through in solution and in-vitro skin measurements. The results demonstrate a new class of sensors that can take advantage of the FET signal amplification directly in situ and enable the development of more sensitive and accurate microneedle biosensors in the future.

**Microneedle-Based Potentiometric Sensing System for Continuous Monitoring of Multiple Electrolytes in Skin Interstitial Fluids** [Huijie Li](#) and Yi Zhang; University of Connecticut, United States

Electrolytes play a pivotal role in regulating cardiovascular functions, hydration, and muscle activation. The current standards for monitoring electrolytes involve periodic sampling of blood and measurements using laboratory techniques, which are often uncomfortable/inconvenient to the subjects and add considerable expense to the management of their underlying disease conditions. The wide range of electrolytes in skin interstitial fluids (ISFs) and their correlations with those in plasma create exciting opportunities for applications such as electrolyte and circadian metabolism monitoring. However, it has been challenging to monitor these electrolytes in the skin ISFs. In this study, we report a minimally invasive microneedle-based potentiometric sensing system for multiplexed and continuous monitoring of  $\text{Na}^+$  and  $\text{K}^+$  in the skin ISFs. The potentiometric sensing system consists of a miniaturized stainless-steel hollow microneedle to prevent sensor delamination and a set of modified microneedle electrodes for multiplex monitoring. We demonstrate the measurement of  $\text{Na}^+$  and  $\text{K}^+$  in artificial ISFs with a fast response time, excellent reversibility and repeatability, adequate selectivity, and negligible potential interferences upon the addition of a physiologically relevant concentration of metabolites, dietary biomarkers, and nutrients. In addition, the sensor maintains the sensitivity after multiple insertions into the chicken skin model. Furthermore, the measurements in artificial ISFs using calibrated sensors confirm the accurate measurements of physiological electrolytes in artificial ISFs. Finally, the skin-mimicking phantom gel and chicken skin model experiments demonstrate the sensor's potential for minimally invasive monitoring of electrolytes in skin ISFs. The developed sensor platform can be adapted for a wide range of other applications, including real-time monitoring of nutrients, metabolites, and proteins.

#### 9:30 AM \*SB11.05.04

**Graphene Transistors for Biosensing Applications** [Amaia Zurutuza](#); Graphenea, Spain

Over the past years, extensive efforts have been placed in the research and development of graphene-based applications, as a result certain applications have experienced an increased level of maturity and achieved higher technology readiness levels (TRLs) among them is that of sensors.

Graphene's electronic and mechanical properties make it an ideal candidate to be applied in various types of sensors. The market for sensors is extremely large since it includes many industries such as automotive, electronics and healthcare industries among others. Therefore, it is an excellent starting platform for graphene applications. For example, the COVID-19 pandemic demonstrated the urgent need for fast diagnostics in order to minimise and control its effects, here, biosensors based on graphene field effect transistors (GFETs) have shown great potential as a platform for future diagnostics.

During this talk, I will cover the fabrication of graphene at wafer scale (up to 200mm) and the use of graphene in various types of sensors including ion sensors (ISFETs) [1-3], gas sensors [4] and biosensors [5].

**Mxene and Conjugated Polymer-Based Hybrid Systems for Electronic Biosensing** [Sahika Inal](#); King Abdullah University of Science and Technology, Saudi Arabia

Among the existing two-dimensional materials, MXenes stand out for their excellent electrochemical properties. MXene-based inks and films hold great potential for the scalable production of skin-conformable electronics and for constructing electronic sensors and actuators that operate in physiological media. On the other hand, conjugated polymer films, due to their softness and conformability, enable seamless interfacing with the skin and cells. In this talk, I will demonstrate how the combination of soft conducting polymers and printed MXene electrodes brings together the best of both worlds for biointerfacing. The functionalized MXene films serve as multifunctional biosensing units for cation and protein sensing, as well as for capturing physiological signals. Conducting polymers act as both substrates and interconnects. In another platform, the incorporation of MXene as a co-dopant in a conjugated polymer structure results in hybrid films with remarkably high volumetric capacitance and stability. These microfabricated hybrid devices outperform their single-component counterparts in chronic biochemical sensing and stimulation applications. Our findings illustrate how MXene films can streamline the fabrication of next-generation bioelectronic platforms incorporating multimodal sensors.

**11:00 AM SB11.06.02**

**Deformable and Stretchable EGaIn/Graphene-Based Electrochemical Biosensors** [Dongwook Lee](#), Don-Hui Lee, Won-Yong Lee and Jayoung Kim; Yonsei University, Korea (the Republic of)

EGaIn has attractive properties for soft electronics, such as wearable and implantable electronic devices for healthcare applications, due to its high conductivity and deformability near room temperature. However, the formation of an insulating native oxide film of EGaIn impedes its application to soft and stretchable electrochemical biosensors. Herein, we introduce reduced graphene oxide to EGaIn to achieve electrochemical stability and excellent conductivity as well as deformable properties. Graphene oxide easily undergoes galvanic replacement reaction on the surface of EGaIn particles forming reduced graphene oxide capped EGaIn core-shell particles (LM-RGO CSPs), which can be further fabricated to patternable stretchable electrochemical biosensing devices. The resulting deformable electrodes show excellent electrochemical conductivity and stability by preventing the native oxide film growth of EGaIn, even under repetitive stretching with 30% strain without any delamination of RGO. Also, the outer layer of RGO can be further decorated with metals which can effectively catalyze enzymatic reactions for glucose biosensing. In this talk, we will discuss the deformable mechanisms of LM-RGO CSPs-based electrochemical biosensors revealing specific interfacial attractions between RGO and LM, and excellent electrochemical biocatalytic activity for sensitive glucose detection under strains, based on sub-micro sized particle characteristics and their facilitated electron transfer between electrodes and glucose oxidase enzyme. We envision such an electrochemical device system can serve as a platform for multi-modal deformable wearable biosensing devices for healthcare applications, overcoming the inherent limitations of EGaIn as a soft conductor and taking advantage of the excellent conductivity of graphene.

**11:15 AM SB11.06.03**

**The Effect of Partially Reduced Graphene Oxide on The Enzymatic Activity of Yeast** [Rebecca Isseroff](#)<sup>1</sup>, [Sophia Bracco](#)<sup>2</sup>, [Dominic Rosiello](#)<sup>2</sup>, [Sergio Rosa](#)<sup>2</sup>, [Sam Specht](#)<sup>3</sup> and [Miriam Rafailovich](#)<sup>1</sup>; <sup>1</sup>Stony Brook University, The State University of New York, United States; <sup>2</sup>South Side High School, United States; <sup>3</sup>The Stony Brook School, United States

Enzyme biocatalysts are important for the synthesis of drugs, vitamins, and other products, but research is being done to increase their stability and activity. Previously we have found that partially reduced graphene oxide (pRGO) acts as an enzymatic enhancer for the catalytic activity of microbial transglutaminase in the cross-linking of gelatin. We now set out to determine whether graphene oxide (GO) and/or pRGO would have an effect on the enzymatic activity of yeast to decompose hydrogen peroxide, thereby testing whether these 2D materials are biocompatible with a living organism that produces an enzymatic reaction rather than just testing the effect on the enzyme itself.

A solution of pRGO reduced in a concentration of 18 mM sodium borohydride, as well as an unreduced GO solution, were compared with water as a control. While initial qualitative results suggested that GO had no effect on yeast's catalytic activity, H<sub>2</sub>O<sub>2</sub> decomposition seemed to be enhanced by 18 mM pRGO. However, further quantitative measurements were conducted by collecting O<sub>2</sub> by water displacement. Twenty milligrams of yeast were suspended in two milliliters of water containing 0.2% sucrose by weight and incubated at 41 degrees Celsius for 4 minutes. (As a third variable, twenty milligrams of yeast were suspended in two milliliters of water containing 0.2% sucrose by weight but with 0.5 ml pRGO added to the yeast + water before incubation.) Then, 5 ml of 3% H<sub>2</sub>O<sub>2</sub> + 0.5 ml DI water for the control, and 5 ml of 3% H<sub>2</sub>O<sub>2</sub> + 0.5 ml pRGO for the test solution, were added and the time it took to displace 25 ml of water was measured. After 5 minutes, an additional 4 ml of 3% H<sub>2</sub>O<sub>2</sub> were added, and the time it took to displace 25 ml water was again measured, to determine whether the yeast maintained its activity. Results showed that yeast activated in water had the same rate of decomposition of H<sub>2</sub>O<sub>2</sub> containing pRGO as the control containing no pRGO, but yeast incubated in water containing pRGO actually had a slower rate of H<sub>2</sub>O<sub>2</sub> decomposition, both initially as well as retesting five minutes later by adding additional H<sub>2</sub>O<sub>2</sub>. Macroscopic changes observed in the pRGO-yeast include darkening of the yeast, suggesting incorporation of pRGO by the cells. Microscopic examination of pRGO-incubated yeast at various time points provides further insight on the biocompatibility of partially reduced graphene oxide with living cells.

**11:30 AM \*SB11.06.04**

**Advances in Pressure and Chemical Sensing with 2D Materials** [Paolo Samori](#); University of Strasbourg, France

Physical and chemical sensor bear a direct societal impact on well-being, which includes, among others, the monitoring of human's health, the quality and composition of the air we breathe, the water we drink, and the food we eat.

Physical sensors are essential components for the fabrication of devices for medical diagnosis and health monitoring, upon use of active materials with sensitivities in the low-pressure or medium-pressure range, respectively. In this framework, flexible piezoresistive pressure sensors are compatible with wearable technologies for digital healthcare, human-machine interfaces and robotics. Among active materials for pressure sensing, graphene-based materials are extremely promising because of their outstanding physical characteristics. Currently, a key challenge in pressure sensing is the sensitivity enhancement through the fine tuning of the active material's electro-mechanical properties. We have achieved this by combining chemically reduced graphene oxide (rGO) with (macro)molecular materials with controlled mechanical properties. Among these, the use of a polybenzoxazine thermoresist matrix in combination with rGO made it possible to tailor electrically conductive nanocomposites where the thermally triggered resist's polymerisation modulates the active material rigidity and consequently the piezoresistive response to pressure. [1]

In chemical sensing higher sensitivity, faster response time and fast recovery time can be achieved by using 2D materials as active components. Instead, selectivity can be achieved either through the optimization of the energy levels of the analyte with respect of those of the active material, as demonstrated via the fabrication of sensors of heavy metals[2] or polyaromatic molecules[3], or through the functionalization of the latter with supramolecular receptors ensuring a high discrimination of ions and small molecules in the sensing event.[4]

Strategies for simple integration of working devices with electrical read-outs will be presented.

**Intracranial, Subcutaneous and Scalp Electroencephalography with Multiscale Arrays Based on 2D MXenes** Flavia Vitale; University of Pennsylvania, United States

Electroencephalography (EEG) is commonly used for neurological diagnostics and monitoring, and in neuroscience research. Depending on the application and degree of invasiveness, EEG can be acquired with gelled electrodes placed on the scalp or invasively with intracranial electrodes. Recently, subcutaneous EEG has emerged as a minimally invasive, mobile, and reliable alternative solution for long-term epilepsy monitoring and seizure forecasting.

In this talk I will present multiscale arrays for intracranial, subcutaneous, and scalp EEG based on high-throughput liquid-phase processing of 2D Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub> MXene. Leveraging the colloidal stability of MXenes in aqueous dispersions, we have developed a rapid fabrication process to produce EEG arrays with fully customizable geometry, scale, and density. For scalp EEG, the devices feature 3D pillars of varying diameter and height fabricated from PVA aerogel templates infiltrated with Ti<sub>3</sub>C<sub>2</sub>T<sub>x</sub>. Due to the high electrical conductivity ( $155 \pm 4 \Omega$ ,  $n=5$ ), porosity, and surface area, these 3D electrodes can establish a low impedance interface with the scalp without the need for any gel or conductive adhesive (10 Hz impedance of 8 mm pillar electrodes:  $2.1 \pm 1.8 \text{ k}\Omega$ ,  $n=5$  participants).

To illustrate examples of applications of these multiscale MXene EEG arrays, I will present our most recent studies on intraoperative recordings in large animals and humans, longitudinal monitoring of post-traumatic epilepsy evolution with subcutaneous EEG in murine models, and clinical scalp EEG in epilepsy patients.

#### 2:15 PM SB11.07.02

**Wireless, Graphene-Based Multifunctional EEG and ECG Sensor for Clinical Monitoring** Juyeong Hong and Jong-Hyun Ahn; Yonsei University, Korea (the Republic of)

With the advent of advanced digital healthcare technologies, the need for imperceptible user-friendly portable devices for clinical monitoring of physiological anomalies has greatly increased. The brain and the heart are two major organs that would benefit greatly from such real-time monitoring apparatus, as the symptoms of various diseases readily manifest themselves in their operation. Brain diseases, such as stroke, epilepsy, and Parkinson's disease, and cardiovascular diseases, including arrhythmia, heart attacks, and atrial fibrillations, known for their high fatality, are among the many conditions where quick diagnosis and preventative measures may be taken via the continuous monitoring of the brain and the heart. As such, electroencephalogram (EEG) and electrocardiogram (ECG) have become an essential tool in the monitoring and diagnosis of patients. However, conventional monitoring devices are hard-pressed to facilitate prolonged real-time monitoring of patients. These devices typically fail to support the simultaneous monitoring of vitals on a single wearable device and causes discomfort owing to the bulky, wired electrodes and recording devices, thus limiting their daily use and leaving patients vulnerable to unpredictable medical emergencies. As such, in this research, a wireless, graphene-based EEG and ECG sensor for clinical monitoring is proposed. We demonstrate a simultaneous monitoring and analysis of EEG and ECG with improved accuracy for both clinical monitoring and brain-to-computer interface (BCI) applications. The ultrathin and imperceptible graphene-based electrodes exhibit lower contact impedance, high signal-to-noise ratio (SNR), and stable properties owing to the excellent mechanical and electrical properties of the constituent materials and structural design. Paired with a high-throughput portable wireless recording device for clinical monitoring, the system enables user-friendly, real-time monitoring of EEG and ECG for up to 11 hours on a single charge with accuracy and precision on par with that of conventional clinical systems. The simultaneous monitoring of both EEG and ECG enables accurate and holistic analysis of the patient's status. We also demonstrate a clinical BCI speller system augmented by deep neural networks to exhibit the diagnostic capabilities of the monitoring system. These personalized, wearable, and highly imperceptible devices are expected to aid in the advancement of daily healthcare for patients.

#### 3:00 PM SB11.07.04

**A Wearable Nanobiosensor for Automatic, Non-Invasive and Wireless Monitoring of Systemic Inflammation** Jiaobing Tu and Wei Gao; California Institute of Technology, United States

Real-time monitoring of inflammatory proteins allows remote disease progression tracking and early intervention, thus improving patient outcomes and lowering economic burdens in chronic diseases. However, most current commercial protein sensing technologies rely on invasive blood draws, and require lengthy target incubation and labor-intensive washing steps to reach nanogram-level sensitivity. Although sweat is a non-invasive source for disease monitoring, wearable immunosensing is complex and sweat protein secretion is extremely underexplored, presenting a major challenge for personalized inflammation monitoring. Here, we present a wearable nanoengineered electrochemical biosensing technology that allows real-time and non-invasive analysis of a crucial inflammatory biomarker, C-reactive protein (CRP). Highly sensitive, selective, and fully automatic *in situ* inflammatory protein analysis across human activities was realized through seamless integration of a mesoporous graphene-gold nanoparticle modified immunosensor (coupled with thionine-tagged detector antibody-conjugated gold nanoparticles for signal transduction and amplification), autonomous sweat gland-driven microfluidics, and multimodal graphene sensor calibration. Through *in vitro* and *in vivo* clinical studies, we discovered the presence of CRP in chemically-induced human sweat and identified substantially elevated sweat CRP levels from patients with heart failure, chronic obstructive pulmonary disease, and active and past infections (e.g., COVID-19). We obtained a high correlation between sweat and blood CRP levels, demonstrating the potential of this technology toward non-invasive chronic disease management.

**Thermal Drawing of Graphene-Integrated PVDF Fiber for Improved Performance in Wearable Triboelectric Nanogenerator** Md Sazid Bin

Sadeque, Mahmudur Rahman, Md Mehdi Hasan and Mustafa Ordu; Bilkent University, Turkey

Triboelectric nanogenerators (TENG) exploit the phenomenon of triboelectrification enabling energy harvesting from low-frequency mechanical and biomechanical energy. Flexible ferroelectric polymers such as polyvinylidene difluoride (PVDF) are excellent candidates for fabricating a TENG device due to its high triboelectric charge density. Embedding 2D materials that have a high specific surface area into the PVDF matrix has proven to be an efficient strategy to affect surface morphology and friction property to improve the performance of TENG. Graphene and its derivatives have become a desired multi-functional material for fabricating high-performance TENGs. In this study, we demonstrate the successful fabrication of continuous PVDF/graphene nanocomposite fiber via scalable thermal drawing process. Fibers were fabricated with varying concentration of graphene in the PVDF matrix (1 wt%, 3 wt% and 5 wt%) by optimizing the fiber drawing parameters. The 5 wt% graphene integrated PVDF TENG fiber generates peak power up to 12.08  $\mu$ W, which is more than two times higher compared to pristine PVDF TENG (5.80  $\mu$ W). This research will further expand our understanding on the dynamics of 2D nanomaterials into the polymer matrix of a thermally drawn fiber, leading to the performance optimization of wearable triboelectric devices and sensors.

### 3:30 PM SB11.07.06

**Highly Piezoelectric, Biodegradable and Flexible Amino Acid Nanofibers for Medical Applications** Thanh D. Nguyen; University of Connecticut, United States

Amino acid crystals are an attractive piezoelectric material as they have an ultra-high piezoelectric coefficient and possess an appealing safety profile for medical implant applications. Unfortunately, solvent-cast films made from glycine crystals are brittle, quickly dissolve in body fluid, and lack of crystal orientation control, reducing the overall piezoelectric effect. Here, we present a material processing strategy to create biodegradable, flexible, and piezoelectric nanofibers of glycine crystals embedded inside polycaprolactone (PCL). The glycine-PCL nanofibers film exhibits stable piezoelectric performance with a high ultrasound output of 334 kPa (under 0.15Vrms), which outperforms the state-of-the-art biodegradable transducers (Nguyen et al., highly piezoelectric, biodegradable and flexible amino acid nanofibers for medical applications, Science Advance, 2023). We employ this material to fabricate a biodegradable ultrasound transducer for facilitating the delivery of chemo-drug to the brain. The device significantly enhances the animal survival time (2-fold) in mice-bearing orthotopic glioblastoma models. The piezoelectric glycine-PCL presented herein could offer an excellent platform not only for glioblastoma therapy but also for developing medical implantation fields.

### 3:45 PM \*SB11.07.07

**Electronic Skins with Air-Stable Ultraflexible Organic Photonic Devices** Tomoyuki Yokota<sup>1</sup>, Kenjiro Fukuda<sup>2</sup>, Sunghoon Lee<sup>2,1</sup> and Takao Someya<sup>1,2</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>RIKEN, Japan

Inspired by the human skin, which is a large-area, multi-point, multi-modal, stretchable sensor, electronic skins that simultaneously detect pressure and thermal distribution have been developed. By improving its conformability, electronic skin can be directly attached on the human skins as next-generation wearables. In particular, ultraflexible organic photonic devices have been utilized as electronic skins that continuously monitor biological information in humans non-invasively. In this paper, we report recent progress of ultraflexible organic photonic devices that consist of organic light-emitting diodes and photodiodes. The environmental stability has been improved significantly using an inverted structure that does not employ atmospherically unstable cathode materials. We will also address issues and the future prospect of electronic skin using organic photonic devices.

**2D Materials-Based Acoustic Sensors and Actuators** He Tian; Tsinghua University, China

There is a great demand of developing 2D materials-based wearable electronics. In this talk, I will introduce several wearable electronics: 1. Graphene-based thermoacoustic device can enable sound emission with transparent properties. 2. We have developed graphene artificial throat, which can help mute people to speak again. 3. We also have created Mxene-based eardrum with high sensitivity. Our work can great promote the wearable electronics toward practical applications.

### 8:30 AM \*SB11.08.03

**Skin-Integrated Wearable Sensors and Systems** Shideh Kabiri Ameri; Queen's University, Canada

Skin-integrated wearable sensors and systems are a group of different types of sensors and their integrated electrical circuits that are laminated on skin and enable real time monitoring of the body and the surrounding environments for the applications in mobile health care, Internet of Things (IoT) and Human Machine Interfaces (HMI). The grand challenge in making reliable sensors and systems of such is the interface between conventional sensors and rigid electronics and soft, stretchable, and dynamic skin. Novel materials, designs and approaches are required to overcome this challenge. In this talk a group of nano materials based non-intrusive wearables with superior performance and visual imperceptibility and their applications for electroencephalography (EEG), electrocardiography (ECG), electromyography (EMG), Electrooculography (EOG), sensing skin temperature and hydration, human machine interface and IoT will be presented.

### 9:00 AM \*SB11.08.04

**Wearable Self-Powered Biosensors Based on 2D Materials on Textile Platforms** Kavya Sreeja Sadanandan, Ievgeniia Kovalska, Mashael Habab Albuqami, Ana Neves, Saverio Russo and Monica Craciun; University of Exeter, United Kingdom

Revolutionary advancements in healthcare and well-being rely on the integration of cutting-edge self-powered sensing technologies within textiles. A pivotal breakthrough in this field involves the emergence of nanoscale self-powered sensors specifically triboelectric nanogenerators (TENG). The underlying principle of TENGs lies in the combination of the triboelectric effect, based on the interaction between materials with different electronegativity and electrostatic induction. TENG devices have the capacity to effectively harness untapped energy resources, for example they can convert biomechanical energy from human movements such as walking, running, and breathing into electricity. TENG based biosensors are emerging as a viable alternative to battery-powered devices due to their self-powered and environmentally friendly properties. As a result, they are well-suited for wearable health monitoring applications, where they can behave as self-powered sensors. To pave the way for these transformative advancements, it is crucial to develop flexible, mechanically robust, lightweight, and resilient TENG biosensors.

In this invited talk, I will present our recent work on the solutions we explored to the design and fabrication of such generators, which possess the vital characteristics to meet the demands of practical applications. I will present several approaches for the development of textile-based triboelectric nanogenerators using 2D materials both as active sensing layers and as electrode materials. In our earlier work we demonstrated various methods to integrate graphene with textile substrates and create electrodes displaying displayed a good range of conductivity, and resilience to bending, compression and tension.

These textile electrodes are used in the fabrication of TENGs along with a triboelectric layer of polydimethylsiloxane (PDMS) polymer and nylon fabric as a counter triboelectric layer. Different parameters affecting the TENG output such as chemical modification of the PDMS layer, frequency, contact force, contact area and separation distance between the two triboelectric layers are studied to provide insights into the working mechanisms of the device and to enhance the TENG output. The flexible textile TENG presents a stable output performance under strong deformation and its sensitivity to movement was explored as wearable sensor to monitor biomechanical movements. Due to the conformation ability of the triboelectric sensors, they were able to be implemented on key moving parts of the human body and used to monitor biomechanical motion through electrical signals. The self-powered sensors demonstrate their potential for wearable bioelectronics, intelligent robotics, prostheses, and rehabilitation purposes. Furthermore, we have demonstrated the use of 2D Transition Metal Dichalcogenides materials for wearable sweat sensors of uric acid for applications in personalised healthcare. Among the emerging technologies for continuous monitoring wearable technologies, triboelectric nanogenerators have emerged as a particularly promising and innovative approach for self-powered sensors in the detection of sweat biomarkers.

These results show that the distinctive combination of electrical, morphological, and mechano-elastic properties positions these 2D materials attractive candidate for the development of self-powered sensing textile technologies.

**Atomic-Scale Perspective at Alloy-Design for Additive Manufacturing** Dierk R. Raabe; Max Planck Institute for Iron Research, Germany

Additive Manufacturing is capable of producing highly complex parts directly from a computer file and raw material powders. Its disruptive potential lies in its ability to manufacture customised products with individualisation, complexity and weight reduction for free [1-3].

The lecture provides a brief overview of our research which aims to understand the impact of this manufacturing process on complex engineering alloys at the atomic- and nanoscale as well as to develop metallic materials suitable for and exploiting the unique characteristics of Additive Manufacturing.

While Additive Manufacturing, and in particular Laser Additive Manufacturing, is by now fairly well-established as a process to produce metallic parts, studies targeting the segregation and structural interface features at the atomic- and nanoscale for microstructure-optimisation of existing alloys and the design of novel advanced alloys tailored specifically to Laser Additive Manufacturing are still sparse. The established alloys currently in use do not exploit the enormous opportunities inherent in this technique at all, leaving a gap towards its further development.

**Direct Ink Printing of Thermoelectric Materials** David C. Dunand, Ming Chen, Alexander Proschel and Yunjia Zhang; Northwestern University, United States

3D ink extrusion printing (i.e., direct ink writing) enables powder deposition in a layer-by-layer fashion, in air at ambient temperature, to create 3D complex geometries. For thermoelectric materials (TEs), this versatile manufacturing technique can unlock the potential of fully printed TE modules consisting of p-type and n-type TE legs. Recently, pre-alloyed particles (e.g.,  $Nb_{1-x}CoSb$ ) were suspended in inks, printed and then densified via sintering; also, bismuth and tellurium oxide particles deposited from inks resulted in  $Bi_2Te_3$  after hydrogen reduction. Here, we demonstrate inks, containing blended elemental powders, which are printed into TE legs and reacted during sintering to synthesize the high-temperature TE phases  $Yb_{14}MnSb_{11}$  and  $La_5Te_4$ . To build mechanically robust TE module with high density and phase purity, several approaches are explored during post treatments of printed green bodies. Infiltration of lower-melting elements in pre-sintered structures followed by annealing can close open porosity and help achieve targeted compositions. By blending low-melting elements like Sb into precursor powders, liquid phases are formed which facilitate interdiffusion and densification during sintering. For blended elemental powders, sublimation of elements with high vapor pressure (such as Yb and Te) during sintering introduces deviations from phase stoichiometry and formation of secondary phases. We demonstrate strategies - *via* addition of excess elements and/or binary compounds in precursors - to mitigate elemental losses and increase phase purities in sintered TE legs. We discuss the effects of microstructure and phase purity on the thermoelectric figure of merit ( $zT$ ), which is controlled by the Seebeck coefficients and the electrical and thermal conductivities.

**11:30 AM \*SF01.01.03**

**Additive Manufacturing and Natural Medicine in Bone Regeneration: Opportunities and Challenges** Susmita Bose; Washington State University, United States

An estimated one million bone grafting procedures are performed annually in the U.S. and a few million worldwide to repair fractures, cysts, bone defects, tumors, and hip and knee replacements. An increase in the number of procedures is strongly tied to increased musculoskeletal disorders, the aging population segment, and sports-related injuries. Sometimes, patient-matched devices are necessary for patients with special anatomical needs or concerns related to specific defect size complexity.

3D printing (3DP) or additive manufacturing (AM) is becoming essential in patient-matched implants due to lower cost and shorter manufacturing lead time. Additively manufactured components must be controlled and optimized carefully for their reproducibility, machine-to-machine part quality variations, and process-specific material properties. Establishing process-property relationships for different AM techniques is vital to successfully implementing these manufacturing practices in biomedical devices. Complex biomaterials, e.g., calcium phosphate (CaP) ceramics compositionally similar to the inorganic part of the bone, show significant promise toward implant applications in both 3DP tissue engineering scaffolds and surface-modified hip and knee implants. It is worth noting that even with all the excitement on 3DP in recent years, *reliable and reproducible 3DP ceramic scaffold* manufacturing *is rare compared to* porous polymeric or metallic structures due to their ease of processability.

We have used extrusion-based and commercial binder jetting 3D Printing machines (ExOne, PA) with various ceramic powders for the past 25 years to critically identify and understand the effects of process-property variations on 3DP CaP scaffolds. Our CaP scaffolds using 3DP have an average designed pore size of 300-400 microns, with 40 volume % porosity and compressive mechanical strength of >15 MPa, followed by NMC loading on those CaP scaffolds. We have designed and built a 3DP machine capable of printing high-viscosity slurry to directly print doped CaP-polymer scaffolds with similar inorganic composition as bone. 3D interconnected channels in CaP scaffolds provide pathways for micronutrients, improved cell-material interactions, and increased surface area, allowing improved mechanical interlocking between scaffolds and surrounding bone.

*In vivo* studies show improved osteogenesis, angiogenesis, and controlled drug delivery using natural medicinal compounds (NMCs) in these 3D-printed scaffolds and coatings. The use of NMCs in CaP or CaP-polymer composites can eliminate the need for autografts and related second-site surgery for harvesting. NMCs can also replace growth factors (GFs) and proteins for faster healing. NMCs work with CaPs and other materials, such as titanium metals, to enhance early-stage bone tissue ingrowth for applications in load-bearing or non-load-bearing implants. These systems show promise for use in orthopedic and dental devices while eliminating the need for autografts and the second site surgery for harvesting and improving current hip/knee implant lifetime. The presentation will address the design of next-generation bone tissue engineering scaffolds and hip/knee devices based on clinical needs in the fixation of bone disorders and scientific challenges.

## SESSION SF01.02: Session II

Session Chairs: Sarah Wolff and Rayne Zheng

Monday Afternoon, November 27, 2023

Sherraton, Second Floor, Republic B

**1:30 PM \*SF01.02.01**

**Advances in Additive Manufacturing of Architected and Functional Materials** Christopher M. Spadaccini; Lawrence Livermore National Laboratory, United States

In this presentation, we will cover some of the latest work in advanced and custom additive manufacturing processes for the fabrication of architected materials and functional structures. The concept of architected materials revolves around the notion that material properties are traditionally governed by the chemical composition and spatial arrangement of constituent elements at multiple length-scales. This usually limits material properties with respect to each other creating trade-offs when selecting materials for specific applications. For example, strength and density are inherently linked so that, in general, the more dense the material, the stronger it is in bulk form. We will review advanced additive micro- and nanomanufacturing techniques to create new material systems with previously unachievable property combinations. These processes include, but may not be limited to, projection microstereolithography (PuSL), direct ink writing (DIW), and electrophoretic deposition (EPD) as well as more advanced concepts such as volumetric additive manufacturing (VAM), computed axial lithography (CAL), parallel two-photon polymerization, liquid metal jetting, and diode-based additive manufacturing of metals (DiAM). The performance of the resulting material constructs is fundamentally controlled by geometry at multiple length-scales,

from the nano- to the macroscale, rather than chemical composition alone. We have fabricated and will review the resulting properties of these mechanical metamaterials in polymers, metals, ceramics, and combinations thereof. These new processes and concepts can also be applied to functional materials such as those for supercapacitor electrodes, optical components, and even for fluidic system such as the recently published cellular fluidics concept. A review of these functional systems will be followed by a brief discussion of future directions.

#### 2:00 PM SF01.02.02

**Additively Manufacturing Smart Cellular Materials: Self-Healing Protection for Space Applications** [Marlini Simoes](#)<sup>1,2</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>University of Cambridge, United Kingdom

Metallic cellular materials, such as lattices and honeycombs, are of interest in the design of lightweight and impact-resistant structures (high energy absorption capacity). However, the use of cellular materials in engineering applications has been hindered due to the challenges associated with the fabrication of such complex geometries. Additive manufacturing (AM) technologies have enabled the fabrication of geometries of significant complexity. Nevertheless, the design optimization of AM cellular materials for high strain rate loading scenarios remains relatively underdeveloped. Furthermore, even if those material structures dissipate energy efficiently during dynamic crushing, they do not recover their shape after impact. It is, therefore, necessary to understand the relationship between the AM process parameters, cellular material structures and dynamic performance, but also to develop the recovery of those structures after suffering an impact.

In this work, the opportunities created by additive manufacturing processes have been explored by: (1) studying the process-geometry-property interactions of metallic cellular materials, and (2) manufacturing cellular structures which can exhibit a “self-healing” functionality through shape memory effect. Firstly, quasi-static and dynamic mechanical testing on stainless steel 316L cellular geometries is combined with a wide range of material characterization techniques to understand the interplay between AM process parameters, geometry and high strain rate performance. Five cellular structures were investigated, finding that the geometry played a dominant role, relative to the Laser Powder Bed Fusion (LPBF) AM process. Secondly, bulk and complex cellular structures that exhibit shape memory effect have been successfully manufactured. A diamond lattice structure and a new auxetic structure obtained through topology optimization recovered up to 70% of their shape after impact. The main motivation and focus are on space applications to mitigate against impacts but this research is of relevance to a wide range of sectors: e.g., automotive crashworthiness, structural defence, and civil blast protection.

#### 2:45 PM \*SF01.02.04

**Additive Manufacturing as a Unique Platform for Fabrication of (Meta-)Materials with Complex Topologies and Designer Microstructures** [Lorenzo Valdevit](#); University of California, Irvine, United States

Additive Manufacturing (AM) is a family of disruptive technologies that allow rapid fabrication of parts of nearly arbitrary geometrical complexity without the need of expensive tooling, vastly simplifying production of elaborate assemblies for a wide range of industries. The established approach to materials design for additive manufacturing (AM) generally consists of attempting to reproduce the uniform structures and properties of conventionally processed materials. While this certainly helped facilitate material certification and rapid introduction of AM technologies in a number of industries, the opportunity to exploit the fundamentally local nature of AM processes to fabricate novel heterogeneous materials with accurately controlled distributions of properties remains largely untapped. Here we discuss two recent and exciting demonstration of this new AM-enabled design concept: (a) novel shell-based architected materials with topological disorder spanning multiple length-scales, and (b) metal/metal architected composites produced by Laser Powder Bed Fusion of stainless steel with locally tailorable microstructure and phase distributions.

#### 2:45 PM BREAK

#### 3:15 PM \*SF01.02.05

**Programmable Strength and Damage-Tolerant Meta-Crystals for Safety Critical Applications** [Minh-Son \(Son\) Pham](#); Imperial College London, United Kingdom

Architected materials are lightweight with high specific strength and excellent energy absorption, holding great promise for a range of structural applications. However, the absolute strength of such materials is low due to the removal of base material, making them unsuitable for safety-critical applications in automobiles, aerospace and space. We recently developed a new approach in which the crystalline microstructure is mimicked to bring key metallurgical strengthening mechanisms to mesostructure scales, creating artificial crystals (i.e. meta-crystals) with new strengthening sources. This presentation will discuss a new horizon in which we synergistically combine the crystal-like architecture and metallurgical engineering (via heat treatments) to significantly push the strength and toughness of metallic meta-crystal for load-bearing and safety critical applications. The talk also discusses new ways of tuning mechanical behaviour to specific locations to enhance the spatial programming of local deformation.

#### 3:45 PM SF01.02.06

**Design of Three-Dimensional Complex Truss Metamaterials with Graph Neural Networks and Deep Reinforcement Learning** [Marco Maurizi](#) and [Rayne Zheng](#); University of California, Berkeley, United States

The rapid development of additive manufacturing technologies has enabled the fabrication of truss metamaterials, i.e., a novel class of lightweight-yet-strong materials with engineered complex hierarchical structures. Manipulating the architecture over chemical composition dramatically expands the achievable materials design space, allowing to largely control the mechanical response of metamaterials. While methods such as topology optimization and machine learning have demonstrated to be powerful tools to discover structures with desired material properties, designing three-dimensional (3D) complex truss metamaterials with programmable mechanical behaviors is still a challenge. Here we propose a paradigm, based on graph neural networks (GNNs) and deep reinforcement learning, to design 3D truss metamaterials with programmable nonlinear quasi-static and dynamic responses. By combining the ability of our GNN-based model to accurately predict the mechanical response across multiple orders of magnitude and the explorative power of deep reinforcement learning, together with numerical simulations and mechanical testing, we inverse design truss metamaterials for compressive loading up to 30 % of strain and dynamic transmissibility with desired band gaps. Our method not only demonstrates a pathway to design mechanical metamaterials with desired mechanical behaviors but also provides a flexible framework that can be applied to tailor the response of 3D photonic or robotic metamaterials.

#### 4:00 PM SF01.02.07

**Tuning Local and Global Disorder in Architected Materials via Frequency-Based Noise** [Alexander Groetsch](#), [Kate Ainger](#) and [Lorenzo Valdevit](#); University of California, Irvine, United States

The beauty of architected materials lies in the opportunity to tune their properties *via* their geometrical and topological features [1-3]. We are not limited by the material constituents and can surpass classical engineering materials. Inspired by nature, where structural and mechanical heterogeneity enhances energy dissipation [4] and ductility [5], recent efforts in the metamaterials' community are targeted to harness the effect of irregularities to achieve superior functionalities [6]. These include stress de-localization and imperfection insensitivity, and recent advancements in additive manufacturing allow us to

fabricate architectures that incorporate this randomness. However, current efforts to introduce disorder in metamaterials are often restricted to periodicity-disturbances on a global scale. Here, we propose a new design approach that allows us to study the influence of both local and global disorder on the material performance of periodic and random metamaterials. Shell-based topologies are used throughout as model architectures, due to their mechanical advantages (e.g., higher specific strength and energy absorption) over more common truss-based lattices [7]. The mathematically described shell topology is superimposed with frequency-based signals to disturb the “short-range” order, with different frequencies and amplitudes used to tune this local disorder parameter. Characteristic power spectral densities [8] of three frequency-based noise signals – white, pink, brown – are then used to tune the local disorder across the structure, thus introducing a global disorder gradient. To test the influence on both periodic and random metamaterials, triply periodic minimal surfaces (TPMS) and spinodal shell architectures are printed using two-photon lithography, which provides the necessary resolution to incorporate local features in the printing process. The impact of the various levels of disorder on the elasto-plastic behavior of the metamaterial is characterized by means of *in situ* micro-compression tests performed at different strain rates. Our approach allows us to study the effect of local disorder on globally periodic and random structures by overlaying local features with frequency-based signals. In addition, the characteristic rates of power loss from three different colors of noise introduce a global and tunable disorder gradient opening up new opportunities to design highly multifunctional (meta-)materials.

**4:15 PM SF01.03.33**

**Embedded 3D Printing of Soft Materials and Ultrafine Hair Structures** Wonsik Eom<sup>1</sup>, Mohammad A. Hossain<sup>1</sup>, Vidush Parasramka<sup>1</sup>, Ryan W. Siu<sup>1</sup>, Jeongmin Kim<sup>1</sup>, Katherine Sanders<sup>2</sup>, Dakota Piorkowski<sup>3</sup>, Andrew Lowe<sup>3</sup>, Michael D. Volder<sup>2</sup>, Douglas S. Fudge<sup>3</sup>, Randy H. Ewoldt<sup>1</sup> and Sameh Tawfik<sup>1</sup>; <sup>1</sup>University of Illinois at Urbana-Champaign, United States; <sup>2</sup>University of Cambridge, United Kingdom; <sup>3</sup>Chapman University, United States

Embedded 3D printing enables the direct ink writing of ultrasoft materials which, due to gravity, cannot support their own weight in air. For this reason, embedded 3D printing is a platform to replicate nature's complex, branching, and tortuous fibrous structures. However, this recent technology has been limited by a complex interplay of factors such as interfacial tension ratios between the printing materials and the support gel, the viscosity of the ink, and the yield stress of the gel. Because of these complexities, the minimum feature diameter is limited to around 50  $\mu\text{m}$ . Recently, a feature diameter of 8  $\mu\text{m}$  was achieved by tailoring the interfacial tension. This limitation prevents the accurate replication of natural structures, many of which feature dimensions at the micrometer scale, such as long aspect ratio mechanosensing stereocilia and the hairs on the feet of beetles and geckos.

Here, we introduce solvent exchange between the ink and the support gel as a key mechanism to expand the capabilities of embedded 3D printing and allow the fabrication of ultrafine and tortuous structures from a variety of soft materials. This method facilitates the immediate solidification of the extruded polymer solution upon its interaction with the gel's solvent, enabling the printing of ultrafine features as small as 2.1  $\mu\text{m}$  in diameter. Our work exploits the rheological underpinnings that make such precision possible. We elucidate the critical roles played by the gel's yield stress and solvent concentration in achieving this high resolution, thereby offering a comprehensive understanding of the mechanics behind this proposed approach. Solvent-exchange extends to the versatility of materials available for embedded 3D printing. We demonstrate printing of soft thermoplastic elastomers like styrene-ethylene-butylene-styrene (SEBS) copolymers as well as rigid polymers such as polyvinyl chloride (PVC), and electrically conductive carbon nanotube composites. We applied this method to produce intricate hair arrays, thereby meeting the requirements for bio-mimicking applications. These arrays feature fibers with diameters less than 2  $\mu\text{m}$  and lengths exceeding 1500  $\mu\text{m}$ .

In summary, the solvent exchange method presents a notable advancement in polymer 3D printing. The solvent exchange of direct ink writing embedded in support gels enables the fabrication of biomimetic high ultrafine tortuous structures, overcomes previous resolution limitations, and expands the palette of polymeric materials available for printing. This capability opens new avenues for replicating nature's intricate fibrous morphologies towards the design of new architected composite materials. This work was sponsored by the Defense Advanced Research Project Agency (DARPA), under contract no. N660012124036.

SESSION SF01.03: Poster Session I

Hynes, Level 1, Hall A

**8:00 PM SF01.03.21**

**Mechanical Characterization of Additively Manufactured Ceramic Nanocomposites Reinforced by Boron Nitride Nanotubes** Dingli Wang, Nasim Anjum and Changhong Ke; State University of New York at Binghamton, United States

Ceramic materials face significant challenges in industrial applications due to their inherent fragility and limited manufacturability. These limitations can potentially be overcome through the use of reinforcements and additive manufacturing (AM) techniques. Boron nitride nanotubes (BNNTs) exhibit many exceptional structural and physical properties, making them promising candidates for reinforcing ceramics and creating lightweight, strong, and durable ceramic materials. These characteristics are attractive to a number of industries, such as aerospace, automotive, and biomedical sectors. The reinforcement potential of BNNTs for ceramic composites is supported by our recent findings of efficient interfacial load transfer in BNNT-ceramic nanocomposites, which is attributed to the partially ionic B-N bonding and the resulting rugged anisotropic energy landscape. Here, we investigate the bulk mechanical properties of AM-produced BNNT-reinforced silica ( $\text{SiO}_2$ ) nanocomposites. Our study aims to elucidate how the superior interfacial load transfer characteristics observed at the nanoscale translate into enhancements in the bulk mechanical properties of these nanocomposites. The BNNT-silica nanocomposites employed in our study are additively manufactured using digital light processing (DLP) techniques. Our study shows that the addition of a small quantity of BNNTs can substantially enhance the AM-produced ceramic nanocomposite's bulk mechanical properties (flexural modulus and strength, and fracture toughness). We further analyze the local interfacial load transfer within the AM nanocomposite through *in situ* Raman micromechanical measurements. The findings provide valuable insights into the role of the nanotube-ceramic interfacial strength in enhancing the mechanical properties of the nanocomposite. Our research contributes to a better understanding of the relationship between process, structure, and properties in AM-produced ceramic nanocomposites and the development of durable and reliable ceramics technology.

**8:00 PM SF01.03.27**

**Urethane-Water-Cellulose Composite: Improving Mechanical Properties of Urethane-Based Photocurable Resin for Stereolithography 3D-Printing** Akira Kudo<sup>1</sup>, Atsuya Fujita<sup>2</sup>, Kazuya Eguchi<sup>2</sup>, Kota Matsuhashi<sup>1</sup>, Kota Toyama<sup>1</sup>, Takeharu Yoshii<sup>1</sup>, Dmitri Louzguine<sup>1</sup>, Hiroto Nishihara<sup>1</sup>, Mingwei Chen<sup>3</sup> and Satoko Kuwano<sup>2</sup>; <sup>1</sup>Tohoku University, Japan; <sup>2</sup>Tohoku Gakuin University, Japan; <sup>3</sup>Johns Hopkins University, United States

3D printing has become one of the most attractive fabrication techniques in materials science and engineering, offering its immense degree of freedom in designing complicated architectures with feature sizes smaller than millimeters or even micrometers. Since the earliest stage of 3D printing, polymeric materials, especially thermoplastic polymers for fused deposition modeling (FDM) and photocurable resins for stereolithography (SLA), have been playing a major role in this field. As the utility of 3D printing expands, eco-friendly development of these polymeric materials will garner increasing attention. In this presentation, we introduce a composite photocurable resin compatible with SLA 3D printing based on urethane, water and cellulose. A commercially available urethane-based photocurable resin was homogeneously mixed with water and printed into microhoneycomb architectures at a mass ratio of resin:water=3:1. We demonstrated that, despite a considerable portion (20-25% by mass) replaced by water, adding water increased compressive strength and stiffness of fabricated microhoneycomb architectures by 50% or more. Miscibility of urethane-based resin with water also enabled homogeneous dispersion of cellulose nanofibers (CNFs), which would not disperse in pure urethane-based resin. Microhoneycombs made of the urethane-water-cellulose composite showed even more improved properties than the ones without CNFs, achieving strength of 7.5MPa and stiffness of 80MPa at  $0.25 \text{ g} \cdot \text{cm}^{-3}$ . Structural characterization by Raman spectroscopy, Fourier transform infrared (FTIR) absorption spectroscopy and optical microscopy was performed to investigate the origin of this unintuitive enhancement in mechanical properties and the impact on microstructures brought by water. Using water and cellulose, both of which are natural materials, our results can inspire a simple, sustainable and high-performance polymeric material compatible with SLA 3D printing.

#### 8:00 PM SF01.03.06

**Machine Learning-Based Predictive Model for Jet Flow Rate in Electrohydrodynamic Direct-Writing** Dongwoon Shin, Yongrae Kim, Pil-Ho Lee and Joonphil Choi; Korea Institute of Machinery & Materials, Korea (the Republic of)

Electrohydrodynamic direct-writing (EDW), also known as near-field electrospinning, is an extrusion-based additive manufacturing (AM) approach. One of the prominent advantages of EDW over other extrusion-based printing techniques is its utilization of electric forces to deposit fibers with orders of magnitude smaller diameters compared to nozzle diameters, enabling much faster printing speeds. As a result, the fiber diameters achievable through EDW can range from the micro to nanometer scale. Furthermore, EDW employs polymer solutions in a liquid state as printing inks, which broadens the range of available polymers and solvents. Consequently, EDW has been employed to print various functional polymers, finding applications in diverse fields including fiber lithography platforms, energy harvesting, gas sensors, and scaffolds for tissue engineering.

Having precise control over the fiber diameter and shape is of great importance in order to tailor the desired properties of the printed fibers, such as electrical resistance, birefringence intensity, sensor sensitivity, and porosity. However, the Electrohydrodynamic direct-writing (EDW) technique has encountered challenges due to the lack of prediction methods for the printing outputs, including fiber diameters or deposition patterns. As a result, the EDW process has heavily relied on a time-consuming trial-and-error approach to achieve the desired fiber properties. Therefore, the development of practical and purposeful predictive models is crucial for driving innovation and potentially commercializing the EDW method, similar to other state-of-the-art extrusion-based additive manufacturing (AM) techniques. Nevertheless, due to the complex multiphysics mechanism of EDW and the wide range of process parameters involved, developing a predictive model to identify the optimal process parameters presents a highly challenging task.

Machine learning (ML) is a branch of artificial intelligence (AI) that involves an ML model learning the relationship between input and output features to uncover hidden patterns. The application of ML has gained significant popularity in additive manufacturing (AM) processes, particularly due to the complex physics involved in AM processes such as rapid evaporation, solidification, and ingestion, which surpasses traditional manufacturing methods. Unlike traditional physics-based equations that require explicit programming, ML models can learn these relationships, making them rapid, practical, and analytical prediction tools for AM processes. Consequently, ML-based models have been developed for tasks like geometrical design, process optimization, and anomaly detection in various AM techniques, including fused deposition modeling, power bed fusion, direct energy deposition, direct ink write, and aerosol jet printing. Moreover, ML-based models hold promise as potential candidates for optimizing the Electrohydrodynamic direct-writing (EDW) process, surpassing the capabilities of physics-based models in practical applications.

In this poster presentation, we will introduce a framework for developing an ML-based predictive model of jet flow rate in Electrohydrodynamic direct-writing (EDW). To accomplish this, a monitoring system was established to capture actual images of the jet profiles during the EDW process.

Subsequently, image analysis techniques were employed to extract jet profile data, which was then utilized to train a multi-output regression model using artificial neural networks (ANNs). A comparison between the predicted and observed jet profiles demonstrated the model's high prediction accuracy. The proposed approach presented here represents a futuristic method for optimizing the EDW process and holds tremendous potential for realizing smart manufacturing of functional micro/nanofibers through EDW.

#### 8:00 PM SF01.03.11

**Impact of Nanoparticle Size and Loading on Printability of Polymer-Nanoparticle Composite Inks for Direct Ink Writing** Yun Li<sup>1</sup>, Aidan Flynn<sup>1</sup>, Christopher Masternick<sup>1</sup>, Brandon Kolanovic<sup>1</sup>, Bin Li<sup>2</sup> and Bo Li<sup>1</sup>; <sup>1</sup>Villanova University, United States; <sup>2</sup>Wichita State University, United States

Direct ink writing (DIW) is a most inclusive 3D printing technology in which polymer can be mixed with different nanoparticles and create 3D structures with a wide range of mechanical properties and functionalities. The key challenge of DIW process is the creation of printable inks. Although a significant process has been made to develop printable recipes with different combinations nanoparticles, polymers, and solvents, two fundamental questions have not been elucidated: 1) how to evaluate the printability of the ink and 2) how nanoparticle size and loading affect ink printability. To bridge this gap, this work utilizes the SiO<sub>2</sub> nanoparticle-Polydimethylsiloxane (PDMS) system and evaluates three commonly used printability analysis methods—dual-layer printing analysis, ink rheology, and printing line width analysis. The influence of particle size (diameter = 26 nm-847 nm) and loading (0-66.67 wt.%) were systematically studied. Through the comparison, dual-layer printing analysis (DLPA), in which the merging behavior of two vertically stacked printing layer was analyzed, is found to be the most direct and reliable method to evaluate printability. The printability factor (Pr) in DLPA approaches 1 means less merging between layers and good printability and empirically Pr = 0.9 is set as a critical value for printable ink. To achieve this critical value, for 26 nm nanoparticles, a small loading of 2.91 wt% is required, while for 847 nm nanoparticles, 28.57 wt % is required. Increase the particle size will improve Pr but there is an upper limit under the fixed printing pressure and nozzle size. The highest printable particle loading is 66.7 wt% for 847 nm nanoparticles under 120 psi with a nozzle diameter of 300 μm. Our results conclude that nanoparticles can be utilized to tailor the DIW materials from soft bio gels to strong ceramics. Moreover, the comparison of different analysis methods highlights the need for developing generic standards to evaluate printability.

#### 8:00 PM SF01.03.48

**Synthesis of Scaffolded Carbon Electrodes via Catalytic Graphitization** Ethan Klein, Sammy Shaker, Yuchun Sun, Seneca J. Velling and Julia R. Greer; California Institute of Technology, United States

Graphitic electrodes are widely used in lithium-ion batteries due to their electrical performance and resistance to chemical degradation. However, the inherent geometry of slurry-based graphite electrodes limits the ability to tune key parameters, such as the diffusion length within the electrode, the path of ions in the electrolyte/electrode region, the extent of active material loading, and the overall mechanical strength. By contrast, electrodes with scaffolded three-dimensional (3D) structures offer freedom over such tunable parameters. While the tunability of scaffolded electrodes may appear attractive, there

exists a tradeoff: current 3D printing techniques used to fabricate such scaffolded electrodes offer limited control over the intrinsic material properties, namely the crystal phase and microstructure. In turn, improvements in diffusion length and the intercalation of lithium ions within the electrode are still limited. Achieving the desired microstructure and phase control requires significant thermal activation, with temperatures greater than 3000°C in the case of carbon, that is infeasible in most tube furnaces and especially challenging for larger samples.

Here, we offer a repeatable method for microstructural and crystal phase tuning of scaffolded carbon electrodes via catalytic graphitization. Electrodes are 3D printed using a hygroscopic resin capable of swelling in an aqueous solution, offering significant compositional control in post-printing. In this study, samples are submerged in a solution of nickel salts, where the 3D printed polymer swells with nickel cations and water to produce a hydrogel. These samples are then pyrolyzed in a vacuum furnace between 800-1000°C to form a carbon electrode, in which the presence of nickel catalytically produces graphite.

In this study, we first investigate the impact of the aqueous nickel concentration on the resultant nickel incorporated in the pyrolyzed electrodes. We also examine how the nickel concentration leads to the presence of a crystalline graphite phase, as opposed to the glassy carbon phase typically observed during pyrolysis. X-Ray Diffraction (XRD) patterns display pure glassy carbon at zero nickel concentration, while both glassy and graphitic carbon signatures appear as nickel incorporation increases. The ratio of graphite (G) to disorder (D) Raman peaks improves from less than 1:1 to greater than 10:1 in catalytically produced samples. Future studies using Transmission Electron Microscopy (TEM), in-situ high temperature TEM, electrochemical cycling, and capacity measurements are discussed. We also compare the electrochemical performance of slurry and scaffolded electrodes with varying degrees of graphitic microstructure and architectural features.

**Finite Element Analysis of Weathering Resistant Spherical Robot Shell** Wei-Lin Wu, Yen Shuo Chen and Fu-Hsiang Ko; National Yang Ming Chiao Tung University, Taiwan

With the fast pace of human civilization development, various types of robots, particularly autonomous amphibious robots, have seen significant advancements in recent research(1). As robots increasingly work in challenging environments to perform specialized tasks, it is critical to have a robot shell that can adapt to various conditions to ensure proper functioning of internal sensing components(2). Therefore, it's crucial to find a material with strong mechanical reliability and good optical properties.

This paper presents a proposed 3D printing resin for spherical robot shells with high transparency in the visible region. The use of 3D printing technology in creating various robots has gained widespread acceptance(3), and the stereolithography (SLA) method has many advantages over other methods, such as relative precision and higher mechanical strength(4). We also conducted a two-month accelerated corrosion test on our print samples. The weather resistance of the printable resin was then evaluated by measuring changes in surface tension, tensile strength, UV-visible and FTIR spectrums. For the purpose of enhancing the impact resistance, we also performed a mechanical study of 3D printed shells with different layer structures through finite element analysis. The finite element technology has many advantages such as less time, manpower, energy and material resources(5). Our simulation results showed that a protective layer with larger holes offers better protection for the inner cooling ball compared to one with smaller holes, leading to a reduction of 80% in residual deformation energy compared to a single-layer ball.

Besides mechanical test, Passive cooling is an important consideration for the robot shell given the proper functioning of the internal electronic sensors. Recently, radiative daytime radiative cooling (PDRC) has become a high-profile topic due to the intensification of Earth's climate problems (6, 7). Because of the heat dissipation to outer space (3 K) through the 1st atmospheric transparency window (8–13 μm) and in the 2nd atmospheric transparency window (16–25 μm)(8). This approach requires the cooling material to have high emissivity around those atmospheric windows.

In this work, a multiple functional shell fabricated by stereolithography (SLA) technology was developed. we demonstrate the mechanical and weatherability of a spherical robot shell made of SLA 3D printed resin.

**Stress Management by Design in Two-Photon Polymerization Printed Structures** Sarah M. Fess<sup>1</sup>, David R. Harding<sup>1,2</sup>, Mark Bonino<sup>1</sup> and Yongfeng Lu<sup>3</sup>; <sup>1</sup>University of Rochester's Laboratory for Laser Energetics, United States; <sup>2</sup>University of Rochester, United States; <sup>3</sup>University of Nebraska-Lincoln, United States

Two-photon polymerization (TPP)-printing millimeter size components with sub-micron features and resolution is an attractive alternative to traditional chemical and machining processes, as it holds potential for increased yields and high controllability. However, maintaining design fidelity can be a challenge in the face of stress-induced deformations which occur during and after the printing process, caused by localized volumetric shrinkage as polymer networks form. This is especially true when many print blocks must be stitched together to form a contiguous larger structure. The extent and manner of deformation can vary greatly depending on print conditions and structural design, even for a single resin, and can lead to misalignment and discontinuity at the stitching boundaries.

Within the limitations of a commercially available TPP system and resin (Nanoscribe PPGT+/Zeiss 63x NA1.4/IP-Dip2) we seek to fabricate millimeter-scale thin-wall spherical shells with stochastic foam liners for laser-driven fusion experiments. For this application, it is important to maintain wall uniformity and structural integrity across stitching boundaries, and to minimize bulk out-of-roundness. Observed bulk structural shrinkage for IP-Dip2 is typically 5-10%, which can be compensated for by oversizing the design. However, individual high aspect ratio or cantilevered print blocks such thin-wall curved surfaces can deform by >10-μm over a 200-μm arc length. Here we present a method for preemptive stress management via design by using nTop software to section and pre-deform print blocks to correct for anticipated in situ polymerization shrinkage, to within 1.5-μm of the intended location, or on

par with the stage repeatability. Characterization of the stitching boundaries via scanning electron microscopy (SEM) and atomic force microscopy (AFM) provides critical feedback for the design and print approach. The intended result is a printed structure with minimal stitching defects and high fidelity compared to the original design.

This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003856, the University of Rochester, and the New York State Energy Research and Development Authority.

**Laser Powder Bed Fusion Fabricated Near Grain-Oriented and Near Non-Oriented Silicon Steel: A Study on Texture Components and Magnetic Properties** Fanbo Meng, Sheng Huang, Xiaojun Shen and Christopher H. T. Lee; Nanyang Technological University, Singapore

The rapid development of additive manufacturing techniques has opened up new possibilities for the production of complex metallic components with tailored properties. Silicon steel, as the most widely used soft magnetic material, necessitates different texture components to meet diverse requirements of various applications (i.e., static machine and rotating machine), and thus is typically categorized as grain-oriented and non-oriented. However, how to fabricate such types of silicon steel via laser powder bed fusion (LPBF) has not been comprehensively investigated until now. In this study, LPBFed near grain-oriented and near non-oriented Fe-3.5 wt.%Si silicon steel is obtained by designing processing parameters. The morphology of the molten pool is characterized through optical microscopy (OM) and scanning electron microscopy (SEM), and various texture features are explored using electron backscatter diffraction (EBSD). Besides, dynamic magnetic properties are assessed by conducting the alternating current (AC) method. The results indicate that the reduction of linear energy density (LED) and laser power induces the side morphology of the molten pool to change from large, flat, and well-overlapped to small, protuberant, and less-overlapped, where this change leads to the formation of an exceptionally pronounced  $\langle 001 \rangle$  building direction (BD) (i.e.,  $\theta$ -fiber texture) or random distribution of grain orientations, respectively. Meanwhile, by simultaneously decreasing the laser power and scanning speed, the top morphology of the molten pool transforms from a teardrop shape to an elliptical shape at the trailing edge, which ultimately causes a shift in the angle between the  $\langle 001 \rangle$  crystallographic orientation of grains in the  $\theta$ -fiber texture and the scanning direction from  $45^\circ$  to  $30^\circ$ . Moreover, samples with fewer defects (i.e., larger grain size and fewer pores) and a larger area fraction of  $\langle 001 \rangle$  paralleling to applied magnetic field perform better in dynamic magnetic properties (specifically, higher permeability and flux density), although the extent of this superiority is limited by residual stress and high dislocation density in the as-built samples. This study provides insight into the correlation of processing parameters, texture evolution, and dynamic magnetic properties in LPBFed silicon steel. The results could provide a design reference for LPBFed soft magnetic materials, which further provides the possibility of utilizing additive manufacturing in assisting in fabricating electromagnetic machines.

**Rigid and Tough Composite Additive Manufacturing using Co-Axial Material Extrusion of Hard Thermoplastic and Soft Elastomer** Taemin Kim and Sanha Kim; Korea Advanced Institute of Science and Technology, Korea (the Republic of)

Multi-material additive manufacturing (MMAM) can realize three-dimensional products with extreme complexity not only in their shape but also in their mechanical behavior. Direct writing, vat photopolymerization and material jet type AM techniques have shown their versatile capability to print multiple polymeric materials, yet materials are limited to UV-curable resins and thermoset polymers. Material extrusion 3D printers had also been attempted to print multiple thermoplastics, but the weak interfacial bond due to the cold-hot welding between one layer and the next causes poor overall mechanical properties. Herein, we invented a new multi-material extrusion 3D printer which can extrude thermoplastic polymers in a core/shell configuration. We design and fabricate the nozzle to independently feed three filaments from right, left, and center, which are heated up to melt and unite each other right before the extrusion. In particular, when we insert the right and left filament as the same material, we can print dual-material layer in a co-axial mode. Such strategy allows strong interfacial bond between the different filaments even when the two materials have large contrast in mechanical properties. As a result, we observe unprecedented properties with certain combinations. By extrusion printing the polylactic acid (PLA) and the thermoplastic polyurethane (TPU) in co-axial configuration, for example, we can realize a 3D specimen which exhibits stiff as the hard PLA yet elongates as the soft TPU before failure, therefore possess an extreme rigidity and toughness. In detail, the core/shell extrusion printing enables the brittle PLA core to elongate about 30 ~ 50 times more than their original fracture strain, and such super-ductility is driven by the chemical bond between the two extruded materials. We further investigate diverse thermoplastic polymer combinations and verify that such exceptional outcome is only possible when a strong interfacial adhesion develops via the existence of hydrogen bonds. We discuss the fracture mechanism of our extruded co-axial polymer fibers and the chemical aspects at the interface. We also show a more variety of functionality that can be realized by extruding three different filaments in the co-axial nozzle. Applications that are now possible via bi-material and tri-material extrusions show that co-axial multi-material extrusion 3D printing opens a new avenue toward versatile material design, for additive manufacturing of fully customizable protective wearable devices and artificial muscles.

**Challenges and Opportunities for Machine Learning Accelerated Materials Qualification for Brittle Particle Cold Spray** Cheng Zeng, Andrew Neils, Nathan Post and Jack Lesko; The Roux Institute at Northeastern University, United States

Brittle particle cold spray is a low-pressure and low-temperature manufacturing technique developed by TTEC, a company based in Virginia. It can produce dense brittle particle coatings at a high deposition rate and low-energy cost with unlimited thickness. Applications include high temperature thermal barrier coatings, all-solid-state batteries and corrosion resistant coatings. However, the application of this technique to new material systems currently requires extensive trial and error to get the correct size and morphology distributions and spray parameters. In order to accelerate qualification of new materials for this process improved understanding of the mechanics of particle impact and consolidation is required. The mechanism of impact consolidation can span in different length scales, ranging from atomic chemical bonding to mechanical interlocking. Moreover, the complex cold spray technique involves multiple physical phenomena, such as fluid dynamics, aerodynamics, heat transfer and deformation. A combined multiscale and multiphysics approach is needed to develop a thorough fundamental understanding of brittle particle cold spray. Recent advances in machine learning approaches have great potentials in improving our understanding for linkages between process-structure-property. Here, we review current multiscale and multiphysics methods, and machine learning algorithms for cold spray technology, and we discuss remaining challenges and present an outlook for future research opportunities in this area.

**Conformal Direct Ink Write Additive Manufacturing via a 6-Axis Robotic Arm** [Robert Lahaie](#), Roneisha Haney, James Hardin and Anesia Auguste; Air Force Research Lab, United States

Reliable printing of materials onto any surface, regardless of its shape, is a key enabling technology for many processes. Traditionally, most additive manufacturing techniques require a 3-axis gantry system which only moves planarly in the XYZ directions, limiting the type of print surface and the orientation achieved relative to the surface. Print direction and orientation is widely known to largely affect the material properties of additively manufactured components especially in prints using anisotropic materials. Recently, there has been increased interest in additive manufacturing using 6-axis robotic arms, however, research is limited on how the additional degrees of freedom of motion affect the material properties compared to a gantry system. This work investigates the effects on the anisotropic material properties by utilizing the additional degrees of freedom the robotic arm enables to maintain the direct ink write (DIW) nozzle constantly normal to a contouring surface. We compared the printed components produced by a 6-axis robotic system to a traditional 3-axis gantry system to investigate how remaining normal to the print surface affects the mechanical properties, fiber alignment, and geometrical accuracy. The research will compare the similarities and differences of the robotic system to the traditional gantry system using anisotropic carbon nanotube carbon fiber Epon 826 resin along a contoured surface, which has relevance on structural materials, electronics, and flexible devices.

**Optimizing Process Parameters in Selective Laser Melting for Enhanced Mechanical Properties of 17-4PH Stainless Steel** [KyuHyun Kim](#) and In-Suk Choi; Seoul National University, Korea (the Republic of)

Selective Laser Melting (SLM) is a key technique in metal 3D printing, involving the repeated melting of metal powder using a laser, followed by its layer-by-layer solidification. This technique enables the fabrication of products with intricate designs and complex geometries, making it indispensable in high-precision industries such as aerospace, automotive, and healthcare. However, the rapid heating and cooling during the layering process could induce porosity and changes in the microstructure, which may significantly reduce the durability and strength of the components.

In this study, we examined the influence of porosity and microstructure on the mechanical properties of components produced using 17-4PH stainless steel powder, a material predominantly employed in the aerospace sector. Initially, we modulated the energy density by varying laser power and scan speed, and monitored the evolution of porosity via Optical Microscopy (OM). Following this, we analyzed the microstructure and phase fraction with Scanning Electron Microscopy (SEM) and Electron Backscatter Diffraction (EBSD), and investigated the correlation with mechanical properties derived from hardness and tensile tests. Ultimately, we aimed to identify optimal process parameters that minimize porosity and maximize mechanical performance through control of phase fraction changes.

The findings of this research underline the importance of porosity and microstructural control in SLM processes, as they significantly impact the quality of materials and performance of parts. This insight is anticipated to draw considerable attention, particularly in the aerospace industry, where high-strength components are of critical importance.

**Ultrahigh-Strain-Rate Tribological Nonlinearity and Adhesion Mechanism of Diblock Copolymers for Polymer-Based Cold Spray** [Ara Kim](#)<sup>1</sup>, Sinan Müftü<sup>2</sup>, Edwin Thomas<sup>3</sup> and Jae-Hwang Lee<sup>1,1</sup>; <sup>1</sup>University of Massachusetts Amherst, United States; <sup>2</sup>Northeastern University, United States; <sup>3</sup>Texas A&M University, United States

The adhesive strength between feedstock microparticles and pre-deposited layers and the collision-induced material behaviors determine the quality of cold-sprayed products. Unlike ductile metals, polymers having weak intermolecular interactions present severe nonlinear dynamic response due to their rate-dependent and temperature-dependent material characteristics resulting from the relatively slow macromolecular dynamics with low phase transition temperature. The distinctive complexity requires a comprehensive understanding of the collision-induced rheological changes near the collision interface, affecting interfacial friction and determining adhesion during impact. However, the interfacial response during ultrahigh-strain rate (UHSR) collision has not been thoroughly studied. As an experimental approach to gain deeper insight into the collision-induced rheological characteristics of polymeric microparticles at the collision interface, the angled laser-induced projectile impact test ( $\theta$ -LIPIT) with an off-normal incidence angle was introduced in this work. A colliding microparticle with 45 degrees of the incidence angle undergoes moderately distributed compression and shear motions without arresting at the target substrate during the UHSR collisions.

Controlling or predicting the dynamic nonlinearity of polymers resulting from the rate- and temperature-dependent material properties is crucial for the applications of polymers in cold spray additive manufacturing. Therefore, diblock copolymers consisting of mechanically distinctive multi-domains are intriguing materials as their material properties are tailorable by adjusting the volume fraction of the respective chain blocks. Polystyrene-block-polydimethylsiloxane copolymers having glassy- and rubbery-domains are used for microparticle production. Using a lab-built ultrasonic atomization system, block copolymer solutions are solidified into spherical microspheres with 10 – 30  $\mu\text{m}$  diameters via spraying and hot-air solvent drying. These microparticles are then impacted onto rigid substrates such as silicon wafers during the  $\theta$ -LIPIT.

Due to the relatively large incidence angle and diameters, adhesion of microspheres does not occur in the  $\theta$ -LIPIT but minor polymeric residues are occasionally found on the surface of the substrate. Impact and rebound velocities are decomposed along the horizontal and vertical directions to the collision surface, and the resultant coefficients of restitution are used to quantify the effective coefficient of friction representing the UHSR rheological changes of a microparticle at the collision interface.

The effective coefficients of friction obtained from the  $\theta$ -LIPIT reveal that the collision-induced rheological changes resulting from thermal softening near the collision interface determine the tribological nonlinearity during the UHSR event. Furthermore, it is further thought that this rheological response could alter the adhesion strength of the polymer microparticles by increasing chain mobility. The rheological changes of polymeric microparticles are thus thought to determine their adhesion behavior as the compression-induced shear stress flow along the tangential direction to the collision surface is expected to generate thermal softening in the material near the interface.

Systematically conducted research with  $\theta$ -LIPIT demonstrates the collision-induced rheological changes near the interface and the resultant tribological conditions for adhesion during UHSR collisions. The demonstrated methodology in this study is expected to be utilized to examine the cold spray applicability of polymers and to predict spraying conditions for cold spray using solid-state consolidations of feedstock powders.

**Metrolgy of Shrinkage-Induced Deformation in Structures Made using Two-Photon Polymerization** [Mark Bonino](#), David R. Harding, Sarah M. Fess, Madelyn J. Jeske and Mitchell J. Anthamatten; University of Rochester, United States

Two-photon-polymerization (TPP) printing provides a deterministic method compared to traditional processes for fabricating millimeter-size spherical and hemispherical polymer parts with nanometer precision. The small print field ( $<0.2 \times 0.2 \text{ mm}^2$ ) needed to achieve the highest resolution, however, requires

individual blocks be printed and “stitched” together to achieve the final component. A consequence of this methodology is that shrinkage from polymerization and the residual stresses in the printed polymer create a misalignment of up to 10  $\mu\text{m}$  with the adjacent print block; these offsets need to be reduced to less than 1  $\mu\text{m}$ . Fortunately, the TPP process is sufficiently precise that the misalignments can be compensated in the design, provided the magnitudes and locations are accurately known.

This presentation describes the metrology used to characterize highly curved surfaces (radius of curvature  $<1$  mm) of spherical and hemispherical structures. The change in curvature of individual print blocks along their lengths and widths is quantified for different laser doses (combination of laser power and scan speed) and print-block sizes, and is used to optimize the printing conditions for improved surface roughness and sphericity. Atomic force microscopy and variable-pressure scanning electron microscopy are used to acquire the data. The quality control and metrology techniques applied to TPP shells are presented.

This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003856, the University of Rochester, and the New York State Energy Research and Development Authority.

#### 8:00 PM SF01.03.15

##### **Reducing the Anisotropy in Fused Filament Fabrication Additive Manufacturing by Blending a Diels-Alder Covalent Adaptable Network with Polycaprolactone** Derek J. Bischoff and Michael E. Mackay; University of Delaware, United States

Additive manufacturing (AM) is an emerging polymer processing technique that allows users to create complex geometries and customized parts with ease in addition to rapidly iterate on prototype designs, making it a valuable tool for product development. The most popular AM technique is based on material extrusion where spools of thermoplastic filament are the raw material that is fed into a hot end where it is melted and extruded through a nozzle on the order of 0.4mm in diameter. The deposited tracks of material are stacked on top of each other in a layer-by-layer sequential manner to build the object. A variety of thermoplastics are commercially available such as polylactic acid (PLA), acrylonitrile butadiene styrene (ABS), and polyethylene terephthalate glycol (PETG) to use on consumer grade desktop machines such as a Prusa i3 MK3S. A limiting factor of these materials is the high degree of anisotropy when 3D printed, as determined by printing tensile testing specimen where the interface between tracks is either parallel (stronger) or perpendicular (weaker) to the tensile stress. The mechanical strength of printed objects is limited by the healing that occurs at the interface. Since interfaces are required to build in the Z-direction off the bed, the term Z-strength is typically used. Due to the highly non-isothermal nature of the printing process, the thermoplastic material only remains above  $T_g$ , enabling the reptation and entanglement of polymer chains across the interface, for a brief period of time, on the order of a second. To eliminate the anisotropy in printed objects, new materials specifically designed for AM are necessary that shift the strengthening mechanism from polymer chain diffusion to something else.

Thermosets are the other major class of polymers that contain crosslinked chains to form a network architecture. The static crosslinks that offer improved mechanical properties and dimensional stability prevent thermosets from flowing, making them incompatible with the AM process. By using reversible covalent bonds in place of static crosslinks, thermosets are transformed into covalent adaptable networks (CANs). CANs behave as thermosets when the reversible covalent bonds are in their adduct state, but can flow when the bond exchange reaction is activated upon exposure to an appropriate level of stimulus (heat, light, pH, etc.). One such reversibly dynamic covalent bond is made from the Diels-Alder (DA) reaction between furan and maleimide functionalities. When exposed to a thermal stimulus, the covalent bonds begin to dissociate and exchange, enabling the CAN to flow as a viscoelastic fluid at elevated temperatures. Upon cooling, the material recovers crosslinking density and the rate of bond exchange slows. CANs have been used successfully in the AM literature to reduce the anisotropy in printed objects since covalent bonds form between tracks, however, they typically require specialized machines using cold air on the build plate to cool the object or use a syringe loaded with the material, necessitating a custom feed system different from the usual thermoplastic spools. In this work, a highly crosslinked DA CAN is blended with polycaprolactone (PCL) to create a semi-interpenetrating polymer network (IPN) that has enough flexibility to be extruded into a spool to be used in commercially available 3D printers without modification. Without the PCL, the DA CAN is too stiff preventing it from being spooled. The CAN/PCL semi-IPN is shown to reduce the degree of anisotropy from  $>60\%$  in PLA for example to only 11%. Microscopy of the cross sections reveal that the void space typically found in between tracks of material has vanished and is attributed to the viscosity of the material at the printing temperature. The fracture surfaces reveal that a ductile failure mechanism takes place in the tensile testing specimen, improving the toughness of the material compared to pure DA CAN.

#### 8:00 PM SF01.03.16

##### **Development of Filament Manufacturing Technology and Selection of 3D Printing Process Parameters for Biodegradable Material Blends to Optimize Print Quality** Piotr Makula, Anna Dmtruk, Pawel Kaczynski, Joanna M. Ludwiczak and Mateusz Skwarski; Wroclaw University of Science and Technology, Poland

Biodegradable materials are increasingly being used, with their utilization being legislated in some cases and a conscious choice of users in others. Poly(lactic acid) (PLA) is a commonly used biodegradable material for 3D printing in Fused Filament Fabrication (FFF) technology. Besides its print hardness, the low purchase cost also contributes to its popularity. The study has shown that effective utilization of mixtures of Poly(lactic acid) (PLA) with poly(butyleneadipate-co-terephthalate) (PBAT) or thermoplastic starch (TPS) for 3D printing is possible. The aim of their production is to modify the mechanical properties of PLA by increasing its flexibility while maintaining the biodegradability of the material.

After analyzing the literature, a successful attempt was made to produce a filament with a diameter of 2.85 mm, which was later used to manufacture samples. The material, after the extrusion process, underwent three consecutive drawing operations through a die on a specially adapted drawing machine. These operations were carried out to reduce and stabilize the filament diameter. The mixtures were prepared in the following mass ratios:

PLA50%-PBAT50%(PBAT50)

PLA30%-PBAT70%(PBAT70)

PLA50%-TPS50%(TPS50)

PLA30%-TPS70%(TPS70)

The printer parameters were calibrated before starting the sample printing, which ensured the correct structure of the prints. The tensile tests were initially conducted on the elements printed perpendicularly to the tensile axis. During the printing process, temperatures ranging from 190-27degree Celsius [C] were set, with a step of 1C. The aim of that test was to determine the optimal temperature that provides the best layer bonding. At the most optimal temperatures (PBAT50 - 230C , PBAT70 - 220C, TPS50 - 210C, TPS70 - 210C), the samples were destroyed by brittle fractures rather than layer delamination.

The next research step was to test the strength of longitudinally printed samples. The experiment showed that when the layers were arranged in this orientation, the material strength was comparable to the homogeneous material obtained through injection molding. The PBAT50 material exhibited layer delamination during stretching, but it did not fracture in a brittle manner. In the case of the second material, PBAT70, the samples behaved like a typical ductile material during stretching. They stretched evenly along their entire length, and no local necking occurred. Mixtures of TPS with PLA, when printed like the previous samples, exhibited more brittle fractures. However, the mechanical values were comparable to those of homogeneous samples. In the summary of the study, a comparison was made between the obtained results and the results obtained from tests on homogeneous samples produced

by injection molding. The results show that the material printed perpendicular to the stretching axis can withstand a 70% of the strength of the homogeneous material. The same result was obtained for all mixtures. Longitudinally printed samples achieved similar results in terms of strength and the shape of the stress-strain curve. However, they present a faster decrease in strength immediately after exceeding the yield point. The conducted research can be effectively utilized in further studies and to model the behavior of the material for finite element analysis methods.

#### 8:00 PM SF01.03.17

**Study on the Multifunctional Sandwich Structure Fabricated by 3D Printing** Hui-Jin Um<sup>1</sup>, Na-Hyun Jeon<sup>1</sup> and Hak-Sung Kim<sup>1,2</sup>, <sup>1</sup>Hanyang University, Korea (the Republic of); <sup>2</sup>Hanyang Research Center for Advanced Semiconductor Packaging, Korea (the Republic of)

Reducing fuel and energy consumption, greenhouse gas emissions, and other air pollutants is a major goal for the global transportation sector, including aerospace, automobiles, and railways. As an approach to achieving this goal, there has recently been a growing movement to change internal combustion engines to hybrid or electric engines. Secondary batteries, such as lithium batteries, are mainly used as energy sources for electric vehicles (EVs), so studies are being conducted to increase mileage. One way to increase mileage is to have a high-capacity battery, which requires more space for batteries and increases the weight of the electric vehicle. For this reason, reducing the weight of the structure is essential to achieve longer mileage. There is a growing interest in structural design using fiber-reinforced plastic composites instead of steel and aluminum. Especially, carbon fiber-reinforced plastic composites (CFRP) with high specific strength and non-rigidity are in the spotlight.

To achieve higher mechanical load-bearing properties using lightweight materials such as CFRP, a sandwich structure consisting of skins and cores can be applied to the structural design. The core of the sandwich structure mainly uses low-density plastic foam or consists of a lattice structure to increase bending properties while lowering the overall weight of the structure. These sandwich structures can be applied to multifunctional structures that can increase energy storage capacity and save space for electric vehicles. The sandwich structure of the neutral axis is hardly affected by the load, so the battery can be integrated into that position to provide reliable energy storage. Thomas et al. integrated a LiPo battery into a foam-core sandwich structure and analyzed mechanical properties through the bending test. However, the flexural failure strength of the multifunctional sandwich structure was reduced by 57% and the bending load partially increased the battery's internal resistance. In other words, the load-bearing properties and energy storage capabilities of multifunctional structures are in conflict with each other.

In this study, the multifunctional sandwich structure using lattice structure cores was designed and manufactured to overcome these limitations. 3D printing technology using continuous carbon fiber filament was applied to implement a lattice structure of complex shapes. The multi-functional composite sandwich structure was manufactured by embedding a LiPo battery using an empty space in the 3D-printed corrugated lattice core. Static and cyclic 3-point bending tests were conducted for analysis of the mechanical characteristics. The battery capacity change was analyzed through battery charge/discharge test before and after the mechanical tests. For the 3D-printed corrugated sandwich structure, the mechanical characteristics were maintained regardless of whether the battery was embedded or not, and the battery was not damaged by external loads. In other words, the battery damage caused by external loads was minimized by utilizing the empty space of the core of the lattice structure, and the degradation of mechanical characteristics was minimized.

**On-Demand Rapid Fabrication of Components using Forward Operating Base Aluminum Waste** Danyang Zheng, Yutao Wang, Mishra Brajendra and Jianyu Liang, Worcester Polytechnic Institute, United States

According to the study conducted by the US Army Research Laboratory (ARL), and the US Natick Soldier Research Development, and Engineering Center (NSRDEC), aluminum waste makes up the Second largest category of metals in solid waste generated on forward operating bases (FOB). Therefore, an agile manufacturing process that can reclaim and recycle aluminum waste on battlefields is highly desirable. In this project, a 3D printing-enabled rapid-casting manufacturing process was developed to reuse Al waste and a mobile foundry system based on this process has been designed.

This remanufacturing process includes three main stages: the preparation stage, the casting stage, and the post-treatment stage. It starts from the 3D design of the casting mold, using advanced software to conduct a simulation to minimize the defects in the cast parts. Then 3D printing is used to fabricate the polymer pattern according to the design. These polymer patterns are covered with coating. After drying, the patterns are removed by a burn-out process to obtain the needed cast molds. On the other hand, the waste metal alloys from FOBs are collected and sorted. The harmful impurities are removed. The Al wastes are then blended according to the desired composition of the target product. This composition can be further adjusted during the melting process. After the molten metal with the desired composition is obtained, it is poured into the cast molds. Finally, after the solidification of the metal, the mold is removed, and necessary post-treatments are conducted to ensure the quality of the parts. The information obtained from quality control can be used as feedback to further improve the mold design and the composition adjustment for re-alloying.

A mobile foundry design that places this rapid casting process in standard-sized shipping containers as developed to efficiently convert battlefield waste into valuable products. The mobile system consists of three containers: the first for investment preparation, the second for casting and heat treatment, and the third for product characterization. A simulation has been conducted to ensure the safety of the casting container.

In this presentation, the results and outcomes of this project will be discussed. The lessons learned and future work will be introduced.

**3D Printing and Biocementation of Hierarchical Porous Ceramics** Alessandro Dutto, Elena Tervoort and André R. Studart; ETH Zürich, Switzerland

Novel low-cost and low-energy strategies for the consolidation of ceramic materials are demanded to reduce the environmental impact of the building sector. Living building materials containing soil microorganisms have shown to be a promising strategy to bind together aggregates or sand-based materials into bricks at room temperature taking advantage of the microbially induced precipitation of calcite (MICP).

The effectiveness of the precipitated calcite network in providing the required structural integrity relies on the uniform distribution and activity of the microbes, as well as the availability and diffusion of nutrients and precursors for the MICP throughout the bulk of the material. Current technologies overcome the limits of diffusion by actively pumping a calcifying solution and by optimizing the calcification setup. Despite the commercial use of this approach, partial clogging or the formation of an outer calcite shell hinder the access of further precursors and thus remain unsolved challenges of this technology.

Here, we take advantage of additive manufacturing to develop and study a bio-cementation process to create strong, porous ceramics at room temperature. Hierarchical porous structures were produced via direct ink writing of cellular grids using bacteria-laden suspensions of ceramic hollow spheres. The effect of geometry, bacterial concentration, and calcification time on the bio-cementation process and the resulting mechanical properties were investigated. The presence of a millimeter-sized open porosity was found to be essential to maintain a high permeability to the precursors during the entire process, ensuring

an optimal MICP throughout the material.

The presence of porosities at multiple length scales has a beneficial effect on both the biocementation process itself and on the mechanical efficiency of the produced structures. Combining 3D printed hierarchical porous structures with the low-energy consolidation process of MICP, allows us to produce strong, porous ceramics with reduced environmental impact.

**High Pressure Heat Treatment for Porosity Reduction of Binder Jet 17-4 PH Stainless Steel** [Ellen Troyanosky](#), Chuhao Li, Richard Sisson and Jianyu Liang; Worcester Polytechnic Institute, United States

The age hardenable 17-4 PH stainless steel has been additively manufactured (AM) using the binder jet (BJ) method. To achieve comparable mechanical properties to wrought steel, the porosity must be reduced in the AM steel. Two sets of BJ, one starting with high porosity and the other low porosity, are treated to the traditional 900H age hardening treatment or a combined hot isostatic pressing (HIP) and 900H treatment, referred to as High Pressure Heat Treatment (HPHT). The effects of change in porosity and pore morphology on the microstructure, mechanical properties, and distortion are examined. These experimental results indicate that the HPHT process is more effective than the 900H treatment at reducing porosity and improving performance.

#### 8:00 PM SF01.03.23

**Dual Material Fused Filament Fabrication via Core-Shell Die Design** [Ahmad Naqi](#)<sup>1,2</sup> and Michael E. Mackay<sup>1,1</sup>; <sup>1</sup>University of Delaware, United States; <sup>2</sup>Kuwait University, Kuwait

In this work a fused filament fabrication (FFF) die design, capable of extruding two thermoplastics simultaneously in a core-shell configuration, is demonstrated as a means to produce composite structures in a single step. Despite the enormous advancements in 3D printing, fabrication of FFF objects with a composite structure remains a challenge due to the difficulty in finding dies to extrude such structures. We used polyethylene terephthalate glycol (PETG) and high-density polyethylene (HDPE) filaments to perform core-shell 3D printing. HDPE is one of the most commonly produced plastics but rarely used in FFF due to the severe warpage caused by volume changes upon its crystallization. Rheological and thermal analyses suggest the use of HDPE as a shell material due to its extremely short reptation time and sharp melting peak that facilitate superior surface contact and interlayer weld strength at the interface between neighboring FFF tracks. PETG is a commonly used 3D printing filament with excellent printability and sufficient zero shear viscosity to help maintain the extruded filament shape against shrinkage induced by the HDPE shell.

Impact and tensile properties of core-shell objects revealed tremendous improvements in the impact resistance and toughness especially at 30 vol % HDPE shell with 1280% and 150% enhancement in impact resistance when compared to individual components: PETG and HDPE, respectively. Scanning electron microscopy was used to analyze the fracture morphology of the tested specimens to obtain an understanding of the fracture mechanism leading to the increased impact resistance. Using this die design can help open avenues of fabricating high impact resistance materials suitable for high performance applications and using HDPE in 3D printed objects with its superior solvent resistance.

#### 8:00 PM SF01.03.25

**Laser Powder Bed Fusion of TiB<sub>2</sub>-Reinforced 316L Stainless Steel Composites with Excellent Mechanical Properties** [Wuxian Yang](#)<sup>1</sup>, Jian Liu<sup>1</sup>, Wen Chen<sup>1</sup> and Tianyi Li<sup>2</sup>; <sup>1</sup>University of Massachusetts at Amherst, United States; <sup>2</sup>Argonne National Laboratory, United States

Laser powder bed fusion (LPBF) additive manufacturing is an emerging technology that enables melting and consolidating powders layer by layer, which has high potential in developing novel alloys with highly refined microstructures. This study discusses the unique microstructure and superior mechanical properties of additively manufactured 316L steel composites reinforced by various amounts of TiB<sub>2</sub> ceramic phase. Scanning electron microscopy (SEM), transmission electron microscopy (TEM), and *in situ* synchrotron X-ray diffraction are used to analyze the microstructure and deformation behavior of the 316L/TiB<sub>2</sub> composites. The TiB<sub>2</sub> particles are homogeneously distributed in the 316L matrix. The 3 vol.% TiB<sub>2</sub> reinforced sample exhibits a high ultimate tensile strength over 1.3 GPa with a large uniform elongation of 18%. Such mechanical properties well surpass those of other additively manufactured 316L steel composites. Hence, the LPBF process shows high potential for fabricating advanced ceramic-reinforced metal matrix composites with outstanding mechanical properties.

#### 8:00 PM SF01.03.28

**Effects of Printing Direction and Layer Thickness on the Mechanical Properties of 3D Printed Polymer Laminates** [Ammar Batwa](#) and Yaning Li; Northeastern University, United States

For polymeric additive manufacturing (AM), printing direction and layer thickness are critical processing parameters that directly impacts the effective mechanical properties of the final polymeric laminates fabricated via polymer jetting AM technology. To fully exploit AM potential for fabricating polymeric composites, it's crucial to have a deep understanding of the effects of these factors during the printing processes. This research aims at evaluating the effects of printing direction and layer thickness on the effective mechanical properties of 3D printed polymer laminates.

The printing direction is defined via the angle of the specimens relative to the movement of the print head. Specimens of stratified composites fabricated via combining glassy and rubbery polymer layers with various layer thickness are designed and fabricated via a multi-material 3D printer (Stratasys Connex3). Mechanical experiments are conducted to evaluate both the layer thickness and printing directions collectively influence the overall mechanical properties of the designs. Digital Image Correlation (DIC) is used to track the local and overall strain of the specimens during deformation. The microstructures of the specimens are explored via Scanning Electron Microscope (SEM) imaging. Nanoindentation experiments are performed to quantify the transition in stiffness across dissimilar material interface. The results show a significant correlation between the mechanical properties of the final printed laminates, the properties of the dissimilar interface/interphase, and the printing direction and layer thickness.

#### 8:00 PM SF01.03.30

**Controlling Microstructures and Modulus in Direct Ink Writing of Stainless Steel for Biomedical Applications** [Havva E. Aysal](#)<sup>1</sup>, Brian K. Paul<sup>2</sup>, Chih-hung Chang<sup>2</sup> and Kostantinos Sierros<sup>1</sup>; <sup>1</sup>West Virginia University, United States; <sup>2</sup>Oregon State University, United States

As metals are employed in additive manufacturing at an accelerated pace, environmentally friendly, and less-cost 3D printing processes are required. Direct ink writing (DIW) is a highly versatile technique that utilizes solution-based formulations, known as inks, which exhibit shear-thinning behavior and can accommodate a wide variety of unique precursors. In this study, we present environmentally safe binders for aqueous bio-based metal inks, specifically exploring cellulose-based binders engineered for rheological compatibility with DIW.

Furthermore, we investigate the use of novel inks to control the microstructures of the printed product. The effects of ink formulation, processing parameters, and post-processing techniques on the microstructure and mechanical properties of the printed objects are being explored. Specifically, the

capability to modify the organic components of the ink to control porosity is demonstrated, enabling the creation of microstructures with different surface properties.

Stainless steels (SS) have been in use as biomaterials for a long time. SS alloys, commonly utilized in biomedical implants, offer advantages such as affordability, availability, biocompatibility, and high strength. However, the presence of toxic nickel in SS poses a significant concern, particularly for patients sensitive to nickel. Therefore, ongoing research aims to develop nickel-free SS alternatives. In our study, we propose SS420 as a potential substitute, considering its suitability for biomedical applications.

In addition to biocompatibility, satisfactory mechanical properties, and osseointegration are essential factors to consider. Mechanical properties such as hardness, tensile strength, Young's modulus, and elongation play a crucial role in determining the suitability of a metallic material. The occurrence of implant fractures resulting from mechanical failures can be attributed to biomechanical incompatibility. Therefore, it is expected that the material used as a bone substitute exhibits mechanical properties comparable to those of natural bone. Osseointegration, which refers to the ability of a material to effectively bond with the bone and surrounding tissues, is a crucial aspect in the use of metallic alloys for bone applications. Porous steels have demonstrated favorable integration with bone implants. However, increasing the porosity of steel can lead to a decrease in its modulus. To address this issue and improve the stiffness of printed stainless steel to match that of bone, we propose the application of a metal-organic framework (MOF) coating to the SS. This coating will allow us to investigate the impact of surface roughness on stiffness. Through further examination of the effects of increased surface roughness on the mechanical properties of the printed SS, our objective is to advance the development of materials with enhanced compatibility for biomedical applications.

#### 8:00 PM SF01.03.31

**Effect of Solidification Rate on Microstructure and Mechanical Properties of Additively Manufactured AlCrFe<sub>2</sub>Ni<sub>2</sub> High-Entropy Alloys** Shengbiao Zhang<sup>1</sup>, Chenyang Li<sup>2</sup>, Wei Chen<sup>2</sup> and Wen Chen<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst, United States; <sup>2</sup>Illinois Institute of Technology, United States

The development of high-entropy alloys (HEAs) has attracted significant attention due to their potential for enhanced mechanical properties. However, the formation of undesired intermetallics in HEAs limits their practical applications. Additive manufacturing (AM) offers a promising approach to overcome this limitation by providing unique thermomechanical processing conditions that result in far-from-equilibrium solidification microstructures, leading to exceptional material properties. To fully harness the benefits of AM and HEAs, understanding the processing-structure-property relationship is crucial but challenging due to the complex phase selection and non-equilibrium microstructures formed during AM. In this study, we investigated the effect of solidification rate on the microstructure and mechanical properties of a laser additively manufactured AlCrFe<sub>2</sub>Ni<sub>2</sub> HEA. By varying the laser scan speed, we observed distinct solidification features, including partitionless single-phase, anomalous eutectic, and coupled lamellar eutectic microstructures. These microstructures offer a wide range of strength-ductility combinations. Thermodynamic modeling and molecular dynamics simulations are performed to gain insights into the solidification mode transition from partitionless through anomalous eutectic to coupled eutectic as the solidification rate continuously decreases. Our findings demonstrate that AM enables access of a rich variety of phase and microstructure space for HEAs, expanding the material design possibilities for technologically relevant alloys.

#### 8:00 PM SF01.03.34

**A Flexible Capacitive Pressure Sensor with High Sensitivity and Linear Response using Size-Distributed Microsphere** Yusaku Tagawa<sup>1</sup>, Sunghoon Lee<sup>2</sup>, Takao Someya<sup>1</sup> and Tomoyuki Yokota<sup>1</sup>; <sup>1</sup>The University of Tokyo, Japan; <sup>2</sup>RIKEN, Japan

Flexible pressure sensors enable to measurement various biological signals for long-term monitoring. Obtaining plantar pressure distributions and body weight measurements through wearable devices is significant for healthcare applications and monitoring various diseases such as diabetes, obesity, and heart failure. To detect the planter pressure of such disease patients, wearable, flexible pressure sensors with a high-pressure sensitivity range (1 MPa) can provide precise critical biomedical information.<sup>[1]</sup>

Among the various flexible pressure sensors, capacitive pressure sensors are among the most promising candidates owing to their simple fabrication process, rapid response, small hysteresis, and low power consumption. Despite these advantages, typical silicone rubber has a relatively low dielectric constant (2-3), contributing to low sensitivity. Therefore, porous structures at the dielectric layer and dielectric/conductor interface are essential for higher sensitivity because they reduce the initial dielectric constant and compression modulus.<sup>[2]</sup> On the other hand, essential characteristics of stable operation, such as linearity over a wide range, have yet to be dealt with enough.<sup>[3]</sup> Balancing the linear response and high sensitivity in porous structures remains challenging owing to the sensitivity saturation of porous materials. To the author's knowledge, no capacitive pressure sensor with porous structures that maintains linearity up to 1 MPa with a high sensitivity ( $> 10^{-3}$  kPa<sup>-1</sup>) exists.<sup>[4][5]</sup>

This study proposes a capacitive flexible pressure sensor containing thermoplastic microspheres (TPM) with linearity and high sensitivity over a wide pressure range. The TPM expanded at relatively low temperatures (95–125 °C) and increased 50 times in volume. The TPM-containing Polydimethylsiloxane (PDMS) was spin-coated to fabricate an elastomeric membrane with a homogeneous porous structure. Notably, the TPM has a large size distribution with the temperature increasing. This size distribution variety of porous TPM may contribute to the high sensitivity and enhance the linear response owing to the deformation of different sizes of porous under the different pressure. Owing to this characteristic of TPM, we achieved a pressure sensor with a high sensitivity ( $3.1 \times 10^{-3}$  kPa<sup>-1</sup>) while maintaining linearity ( $R^2 = 0.996$ ) under a high compression pressure (1 MPa).

Furthermore, the sensor responded within 100 ms under 140 kPa and indicated the durability by 10000 cyclic loadings. As a pressure distribution application, we implemented  $3 \times 3$  multichannel pressure sensors with a large area ( $3.4 \text{ cm} \times 3.4 \text{ cm}$ ) to demonstrate the uniformity of the materials. In addition, we fabricated geta wearables that can detect body weight. As a result, a 4.9 kPa load fluctuation can be detected equally well in a high and low weight range without sensitivity compensation systems, such as non-linear fitting, which implies the significant potential to achieve reliable and simple wearable applications.

**Source Design for Vapor-Based Additive Manufacturing of Drug Substance Particles** Eva Pontrelli and Max Shtein; University of Michigan, United States

Additive manufacturing provides a precise, material-efficient, and rapid route to complex structures for a growing scope of applications. The novel vapor-based process described here offers new additive manufacturing capabilities for formulation-ready active pharmaceutical ingredients. This technique deposits material by jetting organic vapor and an inert carrier gas through a nozzle onto a substrate, where the organic condenses. The deposited material has ultra-fine particle sizes, which leads to enhanced bioavailability. Engineering particle size and morphology requires tight control over vapor flux at the substrate. Stable vapor flux also enables precise, flexible dosing of active ingredients, which is essential for pediatric dosing, high potency drugs, and

personalization of medicines, but difficult to achieve with traditional solid oral dosing and formulation approaches.

While tight control of feed location is easily accomplished using traditional 3D printer hardware, achieving a stable vapor flux is difficult, yet crucial. The source can be operated near vapor-solid or vapor-liquid equilibrium, allowing use of carrier gas flow as a linear control of flux. Faster flow rates drive the system away from equilibrium, presenting boundaries on the process window. In this talk we describe an apparatus configuration that can enable high, yet stable, deposition rates, linear control of rate, and greatly facilitated material handling.

#### 8:00 PM SF01.03.37

**Electrically-Driven Textile using Hierarchical Aramid Fiber** [Abdullah Islam](#) and Shenqiang Ren; University of Maryland, United States

High strength and flexible electronic textiles promise in aerospace, robotics, and extreme environment applications, while it is indispensable to develop functionally integrated fiber building blocks with the durable materials performance. Here we report multifunctional sensory e-textiles driven by using copper-grafted polyaramid (Kevlar®) fiber networks for the integrated electromagnetic interference shielding, thermal and pressure response sensing. The hierarchical structural design and synthesis of flexible conductive networks is accomplished via the synergistic coordination between molecular copper complex and Kevlar® fibers, which facilitate long-term cyclability, stability, and washability. Superior Joule heating capabilities with a rapid thermal response under a low driving voltage (a heating-up rate of 6 degrees C/s and a cooling-down rate of 5.8 degrees C/s), together with a high level of EMI shielding (80 dB from 8 GHz to 13 GHz), are resulted from its multilayer vertically-aligned structure with continuous percolation of conductive coating. This work presents a new and feasible grafting approach for the large-scale fabrication of multifunctional wearable e-textiles for use in extreme environments.

#### 8:00 PM SF01.03.38

**Fully Printed 2D Material-Based Memristors** [Alessandro Grillo](#)<sup>1</sup>, [Zixing Peng](#)<sup>1</sup>, [Aniello Pelella](#)<sup>2</sup>, [Matthew Boyes](#)<sup>1</sup>, [Xiaoyu Xiao](#)<sup>1</sup>, [Minghao Zhao](#)<sup>1</sup>, [Jingjing Wang](#)<sup>1</sup>, [Zhirun Hu](#)<sup>1</sup>, [Antonio Di Bartolomeo](#)<sup>2</sup> and [Cinzia Casiraghi](#)<sup>1</sup>; <sup>1</sup>University of Manchester, United Kingdom; <sup>2</sup>University of Salerno, Italy

The von Neumann architecture relies on separate entities for the processing and memory functions, so these units engage in extensive and continuous data exchange. However, in the last few years the production and use of information has been growing dramatically, leading to a new brain-inspired computing paradigm, where data storage and process are done by the same unit. In this framework, the memristor, which is a circuit element that can store information due to the phenomenon of resistive switching between two resistance states upon application of an external electric field, is gaining significant attention as non-volatile memory. 2D materials (2DMs) are very attractive for the next-generation memristors,<sup>1,2</sup> due to their flexibility, transparency, and compatibility with solution-based processing, enabling to use techniques such as inkjet printing for the cost-effective, and scalable integration of devices onto flexible substrates, like paper and plastic.

In this study, we printed silver as the bottom electrode, graphene (Gr) as the top electrode and MoS<sub>2</sub> as dielectric, creating an Ag/MoS<sub>2</sub>/Gr heterostructure.<sup>3</sup> After optimization of the fabrication process, the fully printed Ag/MoS<sub>2</sub>/Gr memristors on silicon exhibit performance comparable with those achieved in printed devices using silver electrodes or other nanomaterials like TiO<sub>2</sub> and ZrO<sub>2</sub> on rigid substrates.<sup>4</sup> Furthermore, the same device, when printed on Kapton, displays stable memristive behaviour up to 3% of strain. The memristor resistance switching is attributed to the formation of Ag conductive filaments, which can be suppressed by integrating graphene grown by chemical vapour deposition (CVD) onto the silver electrode. Temperature-dependent electrical measurements starting from 200 K show that the memristive behaviour appears at temperature of ~ 300K, confirming that an energy threshold is needed to form the conductive filament. Interestingly, the CVD Gr integration also significantly reduces hysteresis, suggesting that CVD Gr not only serves as a barrier against ion migration but also improves the interface between the electrode and the dielectric layer, enhancing the reliability and reproducibility of the devices.

**Printed Electrochemical Cu<sup>2+</sup> and Cd<sup>2+</sup> Ion-Selective Electrodes for Combinatoric Multi-Heavy Metal Ion Sensing Applications** [Maninder Kaur](#), [Priya Vinayak](#), [Henam Sylvania S. Devi](#), [Bhaskar Mitra](#) and [Madhusudan Singh](#); Indian Institute of Technology Delhi, India

Requirements for onsite monitoring of heavy metals in utility water supply and in effluents include low sensor drift, and high sensitivity.

While it is standard practice to detect ions in lower ppb ranges using laboratory analytical techniques including atomic absorption/emission spectroscopy and inductively coupled plasma-mass spectrometry, these techniques require careful sample preparation, a skilled operator and potentially long turnaround times for measurements from the site to the lab. Recognizing the health hazards posed by heavy metals, regulatory agencies like the Environmental Protection Agency (EPA) have specified permissible exposure limits for copper (1.3 ppm[1]) and cadmium (5 ppb[2]). Previous work [1] has demonstrated the efficacy of low-cost potentiometric ion-selective electrodes for ppb-level detection of such species. Given several such ions of concern, and well-known and significant cross-sensitivities[3] exist amongst them, and with other ions deemed to be safe for human health at naturally occurring levels, it is essential to develop multi-sensor chips for combinatoric sensing of heavy metal ions, possibly aided by machine learning (ML) methods. While individual ion-selective electrodes with custom sensing films can in principle be fabricated, traditional lithographic techniques are a) inapplicable (owing to foundry process contamination), and b) complex (owing to demands for a potentially large number of sensing layers). Thus, multi-ion sensors production at scale needed for realtime regulatory monitoring requires an alternative fabrication technology. In this work, we have used an inkjet printed CdS film to detect copper and cadmium ions in water. Cadmium acetate precursor (98%, Sigma Aldrich) was added (70°C, 15min) to ethylene glycol (98%, Qualigens), followed by addition of thiourea (99%, Sigma-Aldrich) under constant stirring (70°C, 3 hr), resulting in a bright yellow product (CdS). Elemental composition of the ink was validated by energy dispersive X-ray analysis (EDX, Hitachi), and powder X-ray diffraction (PXRD, Rigaku Ultima, Cu-K $\alpha$ , 1.54Å) indicating the formation of a pure hexagonal phase (ICDD: 96-900-8863) of CdS. Hydrodynamic nanoparticle size measurements (dynamic light scattering, Malvern Zetasizer) yield a value of 40.63±4 nm, indicating suitability for inkjet printing (Fujifilm Dimatix DMP2850, DMC11610 cartridge) through the nozzle diameter (20  $\mu$ m). Glass substrates with thermally evaporated Cr (10Å)/Au (1000Å) were subjected to standard DI/solvent clean, followed by an ozone exposure (Novascan PSO-UV4, 5 min), before multiple printing with a 15 $\mu$ m drop spacing using a custom waveform to achieve a film thickness of 150 nm. Test spiked solutions (with fixed 0.1 M KNO<sub>3</sub>) with decadal concentration variation were formed with two analyte series using copper(Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O) and cadmium ions (Cd(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O) with testing starting with the most concentrated spiked solution (0.01 M), and ending with the most dilute solution (10<sup>-9</sup> M) in each series. Potentiometry measurements (PARSTAT MC 1000) for detection of Cu<sup>2+</sup> yield a detection limit of 1.8

ppb in the linear working range of  $10^{-3}$  M to  $10^{-9}$  M with a sensitivity of  $\sim 40$  mV/p[Cu<sup>2+</sup>] (based on weighted linear fit) and a response time of 50-60 seconds. Corresponding measurements for Cd<sup>2+</sup> yield a detection limit of 10 ppb in a wider linear working range of  $10^{-2}$  M to  $10^{-7}$  M with the sensitivity of  $\sim 19$  mV/p[Cd<sup>2+</sup>] and response time of 80-90 sec. The printing process has been demonstrated on a variety of substrates - poly dimethyl siloxane (PDMS) and polyethylene terephthalate (PET). Work is ongoing to demonstrate working sensors on these substrates to enable use of flexible substrates in applications requiring conformal shapes, such as inner surfaces of utility pipes.

**Soft Pressure Sensor Fabricated by Implementation of Ultrathin Silicon Strain Sensors on 3D-Printed Cantilever Structures for Cyber Physical System Car Seats** Seiichi Takamatsu, Junya Nakagawa and Toshihiro Itoh; The University of Tokyo, Japan

To monitor the posture and driving behaviors of drivers in autonomous vehicles, we developed a car seat embedded with a soft pressure sensor array beneath its urethane foam layer. The soft pressure sensors feature a cantilever structure formed using a 3D printer, at the root of which thin MEMS piezoresistive sensors are wired. Monitoring the health and cognitive state of drivers is crucial, especially in the context of semi-autonomous vehicles up to Level 3. Traditional techniques often employ cameras and vital sensors to detect behavior, fatigue, and drowsiness. However, these methods can be limited due to factors such as lighting conditions and the driver's attire. Given that car seats are in direct contact with drivers, there is growing interest in embedding pressure sensor arrays within them to measure body pressure distribution. These sensors can complement cameras for a more robust driver-monitoring system. Previous research has shown that analyzing body pressure distribution can estimate a driver's attention and fatigue levels effectively. Driver posture, which is intricately linked to comfort, influences alertness; deteriorating comfort could lead to distractions. Also, there is a known correlation between a driver's alertness level, fatigue, and their driving posture. Despite its potential, current pressure sensor technology has limitations. Most research relies on expensive and uncomfortable electrostatic capacitive sensors, costing around \$2000 per seat. This has led to a demand for low-cost, comfortable pressure sensors that can be integrated under the car seat's urethane foam layer. However, placing sensors under the urethane foam is challenging. The foam's nonlinear deformation under load leads to reduced sensor sensitivity and inconsistent output. The foam material disperses the applied force between the sensor and its surrounding substrate, affecting the sensor's performance. To be effective, a pressure sensor array needs to maintain high sensitivity levels (0-10 kPa) and produce near-linear outputs in response to the applied force. This study developed a car seat equipped with a pressure sensor array beneath the urethane foam to monitor the driver's posture and driving behavior. Urethane foam exhibits nonlinear behavior, such as maintaining constant stress in response to varying displacement in the plateau region. Sensors placed under the urethane foam face challenges like producing nonlinear output signals and low sensitivity. In this research, we combined a low-cost pressure sensor, made of a 3D printer and MEMS sensors, with a unique embedding structure beneath the foam and a stress-concentrating design. This new driver-monitoring device aims to overcome the issues associated with sensitivity and linearity. The developed soft cover is attached to the pressure sensors to concentrate stress from the urethane foam. Additionally, the area surrounding each sensor includes a base of the same height to prevent geometrically nonlinear responses. The sensors are integrated into the car seat's urethane foam in an array. The proposed pressure sensor exhibits a sensitivity range of 0-20 kPa. Through experiments, we demonstrated that the prototype sensor array could detect changes in the driver's posture as well as braking actions. The sensors in this structure hold promise for future applications in intelligent car seats for autonomous vehicles.

**Computer Vision enabled Eye-In-Hand Robotic *In-Situ* Bioprinting of Multimaterials for Fast Wound Repair** Seolha Jeong and Su Ryon Shin; Harvard Medical School, United States

Current *in-situ* printing techniques depend on pre-determined printing paths in order to directly build complex functional architectures at injured areas, limiting adaptability in clinical scenarios. We present INSIGHT (INtelligence *in-Situ* printing Guided by Eye-in Hand robot Technology), an innovative computer vision enabled system that combines a depth camera with a 6-degree of freedom robot arm, empowering it to identify arbitrary areas at various angles without pre-designed code and calibration procedures. Layer-by-layer volumetric printing approach is performed by dynamic image recognition based on color and contour differences, which achieves highly accurate printing through real-time adjustments and is capable of continuous targeting of multiple wounds. Dual printing modes, extrusion and spray printing, are designed for rapid printing with seamless switching between different bioinks. Through *in vivo* tests, INSIGHT demonstrates its practicality for targeting and treating diabetic wounds, highlighting its adaptability to enable customized care for rapid emergency treatment of trauma patients. In this research, as targeting to treat a diabetic wound healing, a microgel based bioink is introduced, which is mixed with a plant protein-based oxygenating microparticles and mesenchymal stem cells in order to boost angiogenesis and immune response at initial wound healing stage. We not only demonstrate the practicality for targeting and treating diabetic wounds using our system, highlighting its adaptability to enable customized care for rapid emergency treatment of trauma patients, but also verifying the efficiency of the combination of the oxygenated ink and the stem cells in wound repair.

**Printable Silicone Elastomers to Provide Magnetic Resonance Imaging Contrast for Medical Phantoms** Michael Avery, Yasmine Osmani, Ben Dickie, Stephen Edmondson and Brian Derby; University of Manchester, United Kingdom

Phantoms are manufactured structures which mimic the properties of objects that are characterised by a range of different medical imaging technologies. They have a number of applications, including: standards for instrument calibration, reference samples to ensure common performance from multiple site experimentation, replacement for animal studies or human volunteers during training or technique development. Phantom development for magnetic resonance imaging (MRI) is particularly challenging because the imaging modality is the relaxation of the nuclear magnetic resonance excitation of protons that are ubiquitous in biological systems and these relaxation times (T1 and T2) are much longer than in conventional polymeric materials because of the presence of water and the soft matter nature of biological tissue. Thus, conventional MRI phantoms are based on aqueous solutions or weak gelling biological materials, e.g. alginates, agarose or carageen gels, doped with paramagnetic ions to further control the relaxation times. The phantoms themselves are thus limited to simple shapes, e.g. spherical or cylindrical cavities, and have poor long term stability. The use of MRI to guide radiological or surgical procedures requires more advanced shape control for the next generation of medical phantoms. This is particularly the case for surgical training but also for the generation of large datasets for machine learning where precise robotic control of beam placement and motion from intense X-Ray sources is desired for use in clinical radiology such as the MRI-Linac. The ability to replicate the unavoidable motion of internal organs (e.g. heart and lungs), while also mimicking complex tissue geometries, MR imaging properties and radiation response of tissues, is critical for advancing MR-Linac treatment. These medical challenges can be achieved by developing and engineering 3D-printed silicone soft-robotic "4D" phantoms, enabling a transformational step-change in the manufacture and function of medical phantoms. A successful soft robotic phantom must display the appropriate balance of mechanical properties, MRI contrast and manufacturability. Here we present materials development for 3D printable silicone

material that work towards overcoming this challenge.

Robotic phantoms must present MRI relaxation times that simulate biological tissues, typically assessed using the time constants and for longitudinal and transverse relaxation respectively. Human tissue relaxation times can range from 600 – 3000 ms for and 35.-.240 ms for , although the precise range depends on the magnetic field used during a particular MRI scan. a Therefore phantom materials should allow for significant and tunability. For soft robot fabrication, the challenge is to develop compositions that achieve the desired relaxation values while also maintaining mechanical properties comparable to those human tissues and pre-cure viscoelasticity suitable for printing.

Two strategies to achieve these desired material properties have been investigated, both following the principles of formulation of material blends using readily available commercial materials. The first uses commercial silicones that have been successfully used to print soft robotic structures but modified by blending with short chain, relatively mobile silicone oils. This gives good control of T1 and T2 but has limited long term stability of property variation due to the mobility of the sort-chain oils within the polymer network. The second approach uses a multiphase composite concept rather than a blended composition. Both methods have been used with Direct Write Extrusion printing to fabricate 3D structures with defined variation of materials and these have been used in pre-clinical MRI scanners to demonstrate good imaging quality.

**Microstructural Evolution Simulations in Additive Manufacturing and Post Heat-Treatment of Aluminum Alloys** [Jiwon Park](#), Joo-Hee Kang and Chang-Seok Oh; Korea Institute of Materials Science, Korea (the Republic of)

The extreme solidification condition in metal additive manufacturing causes out-of-equilibrium phase transformation and unique microstructures: i) vertically connected grains across several layers along the building direction, ii) severe segregation of alloying elements on the inter-dendritic region and the absence of secondary phases, which expect to be formed under equilibrium condition. These microstructural features are of great importance in tailoring the desired properties. This work simulated the microstructural evolution of as-built and post heat-treated Al-Si-Mg alloy in a phase-field approach. Local grain orientation selection and growth morphology under rapid solidification and extreme thermal gradient conditions are studied and compared to electron back-scatter diffraction analysis. Then, the precipitation behavior of Si from super-saturated solidification microstructure is investigated. The formation of Si precipitate demonstrated above the solution-treatment temperature, which experimentally occurs. It reveals that the precise digital twin of mesoscale microstructure can be fabricated by phase-field modeling with specified thermal conditions.

**On The Development of Bio-Compatible, Chemically Recyclable, 3D-Printable Silicones** [Seneca J. Velling](#)<sup>1</sup>, [Hongyi Zhang](#)<sup>2,1</sup>, [Sammy Shaker](#)<sup>1</sup> and [Julia R. Greer](#)<sup>1,1</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>Tsinghua University, China

Silicone is a versatile polymer material with many desirable characteristics, such as corrosion resistance, thermal stability, low toxicity, and its electrically insulating nature. It has widespread application in commercial, medical, and research scenarios. However, its irreversibly 3D crosslinked structure has impeded its recycling and manufacturing through thermoplastic extrusion-based 3D printing techniques. Similarly, its high gas permeability and crosslinking has prevented its application in UV-curing-based additive manufacturing techniques. Previously, it was reported that the photoinitiated thiol-ene click chemistry, where a thiol and an alkene connect to form a thioether, allowed the UV-crosslinking of mercaptan-functionalized polysiloxane and vinyl- terminated polysiloxane thereby enabling the use of stereolithography 3D printing of silicone elastomers. Separately, introduction of disulfide moieties in polymer chains was shown to facilitate the chemical degradation of the cured material through base-catalyzed thiol-disulfide exchange reactions. This work targets the develop a chemically recyclable, 3D-printable silicone materials by integrating the thiol- disulfide exchange mechanisms within a photoinitiated thiol-ene silicone system. We show that disulfide moieties can be introduced into mercaptan-functionalized polysiloxanes through a clean and facile iodide-catalyzed oxidative coupling reaction, and the resulting partially oxidized mercaptan- functionalized polysiloxanes, when mixed with vinyl-functionalized polysiloxane and photoinitiators, can be UV-cured to form disulfide-containing silicone networks. Ongoing work focuses on performing chemical degradation on the cured disulfide-containing silicone, examining the viability of self-healing in such silicone elastomers via phosphine-catalyzed disulfide metathesis, and characterizing the thermomechanical properties of silicones prepared from the recrosslinking of recycled polysiloxane oligomer. Together, these efforts will make possible the additive manufacturing of complex functional structures (eg. microfluidic devices, cell scaffolds, O-rings and gaskets) from highly oxygen-permeable, hydrophobic, thermally and chemically resistant Silicones capable of self-healing and chemical recycling.

**Laser Powder Bed Fusion of Mixed Powders** [Christopher Hutchinson](#), [Huikai Li](#), [Erin Brodie](#) and [Sebastian Thomas](#); Monash University, Australia

Laser powder bed fusion (LPBF) of metals is a popular mode of additive manufacturing (AM) that has the advantage of producing complex shapes with little or no additional processing. However, an important limitation is that the metallic microstructures obtained are usually relatively simple solidification structures and there are few means available to enrich this without subjecting the components to subsequent thermal processing routines, which has its own difficulties due to dimensional control. This limits the microstructural complexity that can be achieved in components fabricated by LPBF and hence the properties obtainable.

In this work, we present and validate a physically-based model to predict the chemical distribution resulting from LPBF of physically mixed powders of different compositions. We demonstrate that mixing of powders with different compositions can be used to generate a deliberately controlled, mesoscale chemical heterogeneity in LPBF that allows the formation of multiphase microstructures and delivers new microstructural complexity to LPBF. A duplex stainless steel, consisting of equal fractions of ferrite and austenite in the as-built state is used as a demonstration of the approach.

The model describing the chemical distribution in the consolidated build can be extended to describe remelting effects and exploited for the design of spatially varying microstructures. This provides a path towards generating architected materials from random mixes of initial powders. Examples of using spatially controlled remelting to generate architecture materials for random powder mixtures will be shown.

This opens up an interesting path for delivering microstructural complexity to LPBF of metals.

#### 8:30 AM \*SF01.04.02

**Multiscale Process Control in Metal Additive Manufacturing** [Manyalibo Matthews](#); Lawrence Livermore National Laboratory, United States

Tremendous gains have been made over the past several years to improve understanding of defect formation in laser powder bed fusion (LPBF) processes and develop predictive material models that can guide process optimization. However, while control of defects may be achievable at a given length scale for a given material, there remain significant challenges in efficiently predicting and mitigating defects wholistically across length scales, e.g. grain-, melt pool-, feature-, part-scale. In this talk I will present efforts to improve the efficiency and accuracy of predictive models that describe defect formation across the multiple relevant length scales found in LPBF. Beyond predictions, effective means to implement defect mitigation solutions are also required. Efforts to manipulate the optothermal coupling in both custom and commercial LPBF systems will be discussed that begin to address such requirements. Prepared by LLNL under Contract DE-AC52-07NA27344.

**The Use of Mechanically Derived Powders for Additive Manufacturing: Flow and Function** David F. Bahr<sup>1</sup> and John E. Barnes<sup>2</sup>; <sup>1</sup>Purdue University, United States; <sup>2</sup>Metal Powder Works, United States

Metal additive manufacturing (AM) provides the opportunity of “on demand” customizable fabrication to minimize supply chain constraints. However, powder availability could become a similar constraint, and creating affordable regional sources for low-embodied energy powders will be a crucial step in distributed manufacturing. Current gas or water atomization processes methods for form metal powders (which are then often remelted in powder bed fusion) adds significant energy budget to the process. First, atomized powders are regularly sorted so that only a portion of the powder produced reaches the AM user. Secondly, if the alloy already exists in solid form, the energy needed to melt to form the powder form is an energetically “hungry” step. A powder creation method using cold mechanically derived (CMD) of particulates can create a wide range of alloy compositions with approximately 90% less embodied energy than gas atomization (GA). CMD powder is often less spherical than GA powders, and thus the powder flow characteristics in common powder bed systems must be demonstrated. Our study has shown that the flowability of Al 7075 and Copper 14500 powders made via GA and MF are similar at rates appropriate for powder bed additive methods. Particle morphology descriptions (size and shape) do not strongly correlate to tap density in this case, which suggests under common AM bed filling processes the bed density will be similar in both cases. Morphology comparisons and particle size/shape distributions were made by comparing large particle statistics, rather than solely comparing mean particle size. Laser powder bed fusion tensile specimens were formed from AL 7075 and heat treated to T6; the GA and CMD powders showed equivalent tensile test performance to both each other and conventionally wrought 7075.

#### 9:15 AM SF01.04.04

**High Absorptivity Nanotextured Powders for Metal 3D Printing** Ottman Tertuliano<sup>1</sup>, Philip DePond<sup>2,3</sup>, Andrew Lee<sup>2</sup>, Jiho Hong<sup>2</sup>, David Doan<sup>2</sup>, Mark L. Brongersma<sup>2</sup>, Wendy Gu<sup>2</sup>, Manyalibo Matthews<sup>3</sup>, Wei Cai<sup>2</sup> and Adrian Lew<sup>2</sup>; <sup>1</sup>University of Pennsylvania, United States; <sup>2</sup>Stanford University, United States; <sup>3</sup>Lawrence Livermore National Laboratory, United States

The widespread application of metal additive manufacturing (AM) is limited by the ability to control the complex interactions between the energy source and the feedstock material. Here we develop a scalable process to introduce nanoscale grooves to the surface of copper powders which increases the powder absorptivity by up to 70% during laser powder bed fusion. The absorptivity increase enables printing of pure copper structures with densities up to 92% using laser energy densities as low as 82 J/mm<sup>3</sup>. We demonstrate similar effects in silver and tungsten. Simulations show the enhanced powder absorptivity results from plasmon-enabled light concentration in nanoscale grooves combined with multiple scattering events. The approach taken here demonstrates a general method to enhance the absorptivity and printability of reflective metal powders at low energy densities by changing the surface morphology of the feedstock without altering its composition.

#### 9:30 AM \*SF01.04.05

**Additive Manufacturing: Technology Maturation and Synchrotron X-Ray Microscopy Insights** Anthony D. Rollett; Carnegie Mellon University, United States

Additive manufacturing (AM), aka 3D printing is a relatively new technology that has given rise to the “maker culture” and an intense interest in design. That has carried over into metals AM, which has jumped almost immediately into manufacturing of actual parts in a variety of alloys. In doing so it has liberated thinking about part design albeit within certain constraints and complex components have been deployed that were previously inaccessible, e.g., high temperature heat exchangers (HX). An example is described of the co-design of HX against printing constraints, alongside evolution in alloy choice. Nothing is ever as simple as it seems, however, and the reliability of parts that must carry load depends on the internal micro-structure, especially with respect to fatigue loading. This motivates detailed study of all aspects of materials microstructure ranging from defect structures to strain, all of which is ideally suited to the use of intense sources of high energy x-rays as only third generation light sources can deliver. Computed tomography (CT) has revealed the presence of porosity in all additively manufactured metals examined to date and confirmed that appropriate process control can limit it. CT has also provided data on surface condition that we are trying to link to fatigue performance. High speed radiography reveals even more crucial details of how laser light generates vapor cavities that can deposit voids past a critical instability point. “Hot” cracking has been imaged as it happens during the solidification process, which offers the possibility finding printing recipes for alloys previously considered off-limits to 3D printing. High speed, high resolution diffraction in stainless steel, alloy 718 and Ti-6Al-4V reveals unexpected solidification and precipitation sequences. Diffraction microscopy reveals the highly strained nature of printed metals and how microstructure and internal strain state evolves during subsequent annealing. Permeating all these activities is machine learning as an invaluable tool and aid to the researcher.

Support from multiple agencies is gratefully acknowledged, including NASA, DOE/BES, DOE/NNSA, ONR, NSF, OEA, Commonwealth of Pennsylvania, and Ametek.

**Designing Against Failure in Additive Manufacturing: From Fracture in Monolithic Samples to Designing Functionally Graded Materials** Allison M. Beese; The Pennsylvania State University, United States

To adopt metallic materials made by additive manufacturing (AM), it is critical to understand, and design against fracture, particularly under complex stress states accessed in service, and with the possible presence of internal pores. Additionally, when designing functionally graded materials (FGMs) in which composition is deliberately varied with position within a component to result in spatially tailored properties, it is critical to avoid deleterious phase formation and solidification cracking during fabrication. This talk will describe our approach for studying the combined effects of stress state and internal pores on the fracture behavior of stainless steel 316 and Ti-6Al-4V manufactured using laser powder bed fusion AM, providing a pathway for designing against failure under realistic conditions. Additionally, it will describe our framework for considering deleterious phase formation and crack susceptibility when designing compositional pathways for FGMs, and more broadly, compositions amenable to AM in general.

 Sheraton, Second Floor, Republic B

**1:30 PM \*SF01.05.01**

**Mechanics of Extremely Heterogeneous Materials by Additive Manufacturing** Ting Zhu; Georgia Institute of Technology, United States

Our recent studies of additively manufactured alloys (Nature, 608, 62–68, 2022; Nature Materials, 17, 63-71, 2018) have raised fundamental questions on the role of extremely complex microstructural heterogeneities in the mechanical behavior of these novel material systems. We combine mechanics modeling and experimental characterization to elucidate the strengthening effects of microstructural gradients and resultant plastic strain gradients in additively materials alloys. We quantitatively compare the results from crystal plasticity modeling and in situ synchrotron X-ray experiment, highlighting the less recognized concept of different types of back-stress hardening and various stages of extra back-stress hardening in materials with extremely complex microstructural heterogeneities. Mechanistic insights are gained for further enhancing the strength-ductility synergy in the design of materials with extremely heterogeneous microstructures.

**2:00 PM SF01.05.02**

**Improving Measurement and Classification of SLM Feedstock Powders by X-Ray Microscopy and Machine Learning** Daniel Sinclair, Eshan Ganju and Nikhilesh Chawla; Purdue University, United States

Metal Additive Manufacturing (AM) has introduced revolutionary changes in design, production, and innovation sectors over the past decade. This transformative technology, including Laser Powder Bed Fusion (LPBF), Direct Energy Deposition (DED), Binder Jetting (BJ), Metal Extrusion (ME), and Sheet Lamination (SL), has enabled significant advances in aerospace, automotive, medical, energy, and tooling industries. Out of the five, LPBF is favored for its near-net-shape printing, high dimensional accuracy, superior mechanical characteristics, and swift prototype assembly. Within LPBF, Selective Laser Melting (SLM) has gained significant traction in commercial, industrial, and defense applications, specifically for Al alloys. The reliability of SLM parts is often compromised due to defects originating from irregular feedstock powders originating from re-use of powder feedstock or differences in feedstock sources. To accommodate the variation in feedstock required to meet the increasing demands of manufacturing, advanced granulometric methods which are sensitive to varying powder morphologies (as seen in recycled or composite powders) are needed. Lab-scale 3D X-ray Computed Tomography (XCT) presents a viable solution for feedstock powder characterization, enabling non-destructive quantification of changes within recycled particles. Our research delved into a gas-atomized AA7050 feedstock powder with unusual powder morphologies and titanium additives (AA7050-RAM2). Through the synergy of lab-scale x-ray microscopy and automated watershed segmentation, we were able to quantify the shapes and sizes of particles in an aluminum alloy (AA7050-RAM2) powder feedstock. Additionally, to describe nonstandard particles more accurately, we introduced novel 3D shape factors. Furthermore, to optimize efficiency and capture an extensive range of powder morphologies, we compared automated classification methodologies for the feedstock using a combination of algorithmic clustering and the Random Forests machine learning algorithm. Our research provides significant insights into enhancing the consistency and reliability of SLM-fabricated parts. It does this by delivering a nuanced understanding feedstock powder morphology and by proposing innovative classification methods. These insights are poised to assist in broadening LPBF's application and furthering advancing metal additive manufacturing.

**2:15 PM \*SF01.05.03**

**Development of a Low Thermal-Budget, Distortion-Free Process for Binder-Jet 3D Print-and-Sinter Alloys** Christopher A. Schuh<sup>1,2</sup>, Christian Oliver<sup>1,2</sup>, Yannick Naunheim<sup>1</sup> and Jasper Lienhard<sup>2</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Foundation Alloy, Inc., United States

Binder-jet printing and sintering is a pathway to scalable, high-volume, low-cost manufacturing of complex metal parts. It also presents an opportunity to design new alloys produced entirely in the solid state, thus using less energy and involving less residual stress and distortion than other modes of metal 3D printing. This talk will review research aimed at such alloy and process development, with an emphasis on understanding and tailoring sintering mechanisms to effect low-temperature consolidation. New alloys based on Mo- and Ni- will be highlighted, and processing advantages in terms of energy and shape retention elaborated. Finally, the properties of these alloys will be evaluated and opportunities for alloy substitution discussed.

**2:45 PM SF01.05.04**

**Additive Manufacturing of Novel Aluminum Alloys: Structure and Properties** Lin Liu, Jingyu Xu and Cheng Zhang; Huazhong University of Science and Technology, China

Additive manufacturing (AM) offers significant advantages over conventional manufacturing techniques in processing Al alloys, however, high-strength Al alloys produced by AM commonly encounter a few challenges including poor processability and undesirable microstructures with coarse columnar grains and micro-cracks, leading to poor mechanical properties. Here, we demonstrate that these issues can be largely resolved by micro-alloying of Zr element in the Al-based alloys. In this study, a series of novel Al-1Fe-0.6Cu-xZr alloys with different content of Zr (x=0.3, 0.6, 0.8, 1.3at%) are designed and fabricated by laser powder bed fusion (LPBF). It is observed that the LPBF Al alloys all exhibit notably heterogeneous structures with alternate distribution of coarse grain zones (CGZs) and fine grain zones (FGZs). With increasing Zr content, the grain size in both CGZs and FGZs gradually decreases and the columnar-to-equiaxed transition (CET) occurs in the CGZs, which make the processability be improved for the Al alloys with higher Zr content. To understand the formation of the heterogeneous structures and the correlation between microstructure and mechanical properties, the LPBF Al-Fe-Cu-1.3Zr alloy was selected, as an example, for detailed investigations. It is revealed that the formation of FGZs, locating at the low boundaries of the molten pools, is attributed to the pre-formed Al<sub>3</sub>Zr nanocrystals, which sever as nuclei and results in the refinement of grain size, while the CGZs are formed at the interior of molten pools, where no Al<sub>3</sub>Zr precipitates are formed, leading to the formation of relatively coarse grain size. In addition, Fe/Cu co-segregation appears at the GBs in both FGZs and CGZs although Cu and Fe are thermodynamically immiscible. As a result, these unique microstructures allow the LPBF-processed Al-Fe-Cu-1.3Zr alloy to have high strength at both room temperature and elevated temperatures. For example, the yield strength reaches 500 MPa at room temperature and 163 MPa at 573 K, respectively, both are higher than those of additive manufactured Al-based alloys reported thus far. The findings in this work provide a guild for design of novel Al alloys with good processability and advanced mechanical properties for additive manufacturing.

**3:00 PM BREAK**

**3:30 PM \*SF01.05.05**

**Additive Manufacturing: Transforming Engineering Design Through Functionally Integrated Materials, *In-Situ* Imaging, and Alternative Feedstock Materials** Julie M. Schoenung<sup>1</sup> and Xin Wang<sup>2</sup>; <sup>1</sup>University of California, Irvine, United States; <sup>2</sup>The University of Alabama, United States

This presentation will provide an overview of various aspects of additive manufacturing that can lead to transformative materials and engineering design. Directed energy deposition (DED) additive manufacturing enables the precise control of composition for the development of functionally integrated materials (FIMs) with site-specific functionality. This compositional control is enabled by the powder injection delivery system that allows for the sequential and / or co-deposition of multiple feedstock powders through individual powder feeders. This strategy provides a path to the rapid development of novel alloys and components with location-dependent chemical composition and properties. The FIMs concept is demonstrated using two material systems: stainless steel 316L with Haynes 282 nickel superalloy, and nickel with nickel-aluminum. Extensive characterization of microstructure, interfaces, diffusion zones, grain boundary morphology and texture, chemical composition and phase transformations provides insight into the fundamental materials science governing the solidification process and consequential component performance in FIMs. DED also entails complex particle-laser-melt pool interactions due to the powder injection mechanism. In-situ imaging using both thermal imaging and high-speed video provides insight into these complex interactions, as highlighted here for various examples including nickel superalloy powder and TiC reinforcement particles. Lastly, the benefits of using recycled and repurposed alternative feedstock materials are considered.

**4:00 PM SF01.05.06**

**Additive Manufacturing of Co-Based Superalloys via Direct Ink Writing** Jian Liu<sup>1</sup>, Zhiyu Zhang<sup>2</sup>, Shuai Guan<sup>1</sup>, Jonathan Poplawsky<sup>3</sup>, Tianyi Li<sup>4</sup>, Yang Yang<sup>2</sup> and Wen Chen<sup>1</sup>; <sup>1</sup>University of Massachusetts Amherst, United States; <sup>2</sup>The Pennsylvania State University, United States; <sup>3</sup>Oak Ridge National Laboratory, United States; <sup>4</sup>Argonne National Laboratory, United States

Additive manufacturing of superalloys enables innovative, geometrically complex designs combined with excellent mechanical properties. Here, we developed an additive manufacturing method based on direct ink writing (DIW), to fabricate a high-performance Co-based superalloy. The ink consists of metal powders, polymer binders, and volatile solvents. The deposited architectures are thermally sintered to near-full density, followed by ageing. The sintered Co-based superalloy exhibits a homogeneous microstructure of equiaxed grains with MC carbides uniformly distributed in the FCC matrix, which leads to a high ultimate tensile stress in excess of 1.2 GPa and a large tensile ductility over 20% at room temperature. The outstanding combination of strength and ductility originates from the coherent  $\gamma'$  nanoprecipitates and deformation-induced stacking faults, as revealed by in situ synchrotron X-ray diffraction and high-resolution transmission electron microscopy. The introduced additive manufacturing approach provides new opportunities to print a wide range of superalloys for high-temperature applications.

**4:15 PM \*SF01.05.07**

**Understanding Ultrahigh-Rate Behavior of Macromolecules for Advances in Polymer-Based Cold Spray Additive Manufacturing** Jae-Hwang Lee<sup>1,2</sup>, Ara Kim<sup>1</sup> and Anuraag Gangineri Padmanaban<sup>1</sup>; <sup>1</sup>University of Massachusetts, United States; <sup>2</sup>University of Massachusetts Amherst, United States

The solid-state coating and additive manufacturing of polymers are feasible by the cold spray (CS) technique, in which solid feedstock powders or microparticles ( $\mu$ P) conveyed by a high-speed gas stream are subjected to a head-on collision against a stationary surface at transonic or supersonic velocities. Due to the ultrahigh-strain-rate (UHSR) viscoplastic deformation upon collision, polymer  $\mu$ P can be consolidated without volumetric melting or phase transition. In CS,  $\mu$ P adhesion is accomplished by the highly localized thermal softening (or melting), and other inelastic mechanisms, especially brittle fracture, may also become significant. As local temperature fields, the consequence of impact-induced plastic strains, are coupled with temperature-dependent mechanical properties, the UHR adiabatic plasticity of polymers is inherently nonlinear and is very difficult to predict via the time-temperature superposition.

In this talk, we will introduce our recent efforts to understand the UHSR behavior of polymer  $\mu$ P through single-particle experiments realized by laser-induced projectile impact testing (LIPIT). For glassy polymers modeled by polystyrene of various molecular weights (MWs), the MW-dependent interplay of the primary inelastic mechanisms is systematically and comprehensively investigated through ultrafast optical images from LIPIT. Due to the ambivalent effect of MW on fracture toughness and interfacial rheology, our study demonstrates that the proper selection of MW is crucial for the feasibility of the solvent-free and solid-state deposition of glassy polymers. Meanwhile, LIPIT experiments with an incidence angle of 45° are conducted to investigate the tribological response at the contact interface. We elucidate the strain-dependent tribological properties of deblock copolymers under extremely dynamic collisions and the correlation between friction and adhesion properties at the nanosecond time scale. Furthermore, we demonstrate that phase-separated deblock copolymers can be ordered via collision-induced shear flows. The extended knowledge from our study about the UHSR behavior of polymers will be crucial for advances in polymer-based CS additive manufacturing that can also open opportunities for creating novel materials properties.

\* This material is based upon work supported by the National Science Foundation under Grant No. CMMI-1760924 and the US DEVCOM Army Research Laboratory under Cooperative Agreement No. W911NF-19-2-0152.

**4:45 PM SF01.05.08**

**Correlations Between Porosity, Spatter and Process Metrics for Powder Bed Fusion Laser Beam Metallic Additive Manufacturing** J.-A. S. Hocker<sup>1</sup>, Joseph N. Zalameda<sup>1</sup>, Brodan Richter<sup>1</sup>, Andrew R. Kitahara<sup>2</sup>, Sang-Hyon Chu<sup>1</sup> and Edward H. Glaessen<sup>1</sup>; <sup>1</sup>NASA Langley Research Ctr, United States; <sup>2</sup>Analytical Mechanics Associates, United States

The large scale and deposition sequence of powder bed fusion laser-based metallic (PBF-LB/M) additive manufacturing (AM) create tremendous computational challenges for establishing precise 'process-structure' correlations throughout the process. A recent approach, AM model-based process metrics (AM-PM), has addressed the challenge by applying analytical reduced-order models to the heat source position. AM-PMs can reveal quantifiable trends in space and time throughout the PBF-LB/M process. The AM-PMs furnished by the reduced-order models were evaluated against high-speed imaging (coaxial with the laser beam) of weld melt pools, and metrics from ex-situ metallography of the welds. The presentation will discuss how AM-PMs, such as melt pool width, correlate with measurements from in-situ imaging and ex-situ metallography

**8:00 PM SF01.06.01**

**Additive Material Transfer using On-Demand Adhesion Modulation in a Self-Assembled Nanofluidic Structure** [Seongjae Kim](#)<sup>1</sup>, Ji-hun Jeong<sup>2</sup>, Hyun Jun Ryu<sup>1</sup> and Sanha Kim<sup>1</sup>; <sup>1</sup>Korea Advanced Institute of Science and Technology, Korea (the Republic of); <sup>2</sup>Massachusetts Institute of Technology, United States

Transfer printing is one of the attractive routes toward additive manufacturing of flexible/stretchable electronics, micro/nanophotonic devices, micro-LED displays, and healthcare sensors via assembling micro/nano components. However, a major challenge in micro/nano transfer printing is achieving both high throughput and yield. An important factor in minimizing the transfer failure is the adhesion contrast between the picking and placing stages, particularly when manipulating microscopic substances that cannot be placed using gravitational force alone. Accordingly, realizing the large contrast in surface adhesion and its rapid transition is essential for the assembly of miniaturized parts.

Herein, we propose a novel nanofluidic device enabling manipulation of micro components via capillary grasping and releasing mechanism. We fabricate the surface via vertical self-assembly of carbon nanotubes which allows liquids to infiltrate into the nanoscale channels when a strong gripping force is necessary and rapidly evaporate the fluid when a weak releasing force is needed. We quantitatively characterize the adhesive strength and find that the structure can exhibit high adhesion as liquid infiltrates the channel (~17.4 kPa) while it can switch into low adhesion as the surface is fully dried (< 0.1 kPa). The adhesive behavior is evaluated using atomic force microscopy and capacitive force sensing, resulting in an adhesion contrast of greater than 100-fold. Due to the nature of the liquid-solid interface, a minimal preload of 0.8 kPa is sufficient to enable the picking and placing which is particularly ideal for physical-contact-based manipulation of delicate electronic components. Our study demonstrates the successful transfer of  $\mu$ LED chiplets, ultrathin films, and CNT supraparticles, as well as the application of strain sensors by transferring CNT particles onto a flexible PDMS substrate. To further elucidate insights into the underlying mechanism, we develop a mechanics model to analyze the adhesive force with respect to the types of liquid and contact time. Furthermore, we implemented a radiative heater to accelerate the evaporation process, enabling rapid pick-and-place operations that can be completed within a few seconds. Finite-element simulation and experiments reveal that the nanoscale fluid channels of our vertically aligned nanofiber structures are advantageous over planar surfaces by increasing the efficiency of heat transfer. We believe that this study provides a new route toward additive manufacturing of unconventional freeform devices via rapid and reliable assembly of micrometer-sized elements.

**8:00 PM SF01.06.02**

**Selective Gene Expression in Hydrogel Suspended Escherichia Coli Through Optogenetics by Spatiotemporally Controlled Light for the Purposes of Additive Manufacturing** [Borut Lampret](#), Andreas Hadjimitsis, Guy-Bart Stan and Connor Myant; Imperial College London, United Kingdom

Natural and engineered biology offer an immense diversity of biological materials with a wide range of properties and benefits. Nature employs biological materials on all scales and forms various complex structures to further diversify the macroscopic properties of materials. Advances in the ability to manipulate genetic material have enabled the utilization of microbes in production of these biological materials and in combination with additive manufacturing one could attempt to artificially create such complex structures. However, most biological materials are not suitable for use with conventional additive manufacturing. While there have been significant advances in the field of bioprinting, great effort is still required to develop the so-called bioinks, which support both the printing process and the encapsulated cells' survivability.

To combat these challenges a novel method of additive manufacturing is explored, which can employ microbial cell factories suspended in hydrogel and optogenetics to selectively deposit the desired biological or synthetic material in a three-dimensional (3D) volume. Genetically engineered Escherichia coli that produces a synthetic light response system, CcaSR v3.0, was used in order to allow for spatially selective gene expression. A custom designed system was built to both house the hydrogel suspended E. coli and to provide and shape green and red light, which were used to interact with the cells. Green light was used to induce gene expression and red light was used to suppress gene expression. Localized gene expression was achieved within the hydrogel build volume with proper overlap of the green and red light and with the help of a predictive model describing the behaviour of the CcaSR system in response to light. To enable the process of additive manufacturing, a series of spatiotemporal illumination procedures were developed, and their behaviour investigated.

This approach of 3D printing is unique in that it shifts the burden of material from the bioink to the cells, which changes material engineering to bioengineering. This approach effectively exploits the cells for in-situ material production. As the cells are suspended in a hydrogel medium, any mechanical stress during the printing process is eliminated. Provided that the cells' engineered metabolism is not toxic, chemical stress is also eliminated. As opposed to conventional polymerisation, which generates cytotoxic free radicals.

This talk focuses on illumination procedures and slicing methods, which enable the cells to exhibit gene expression in complex 3D geometry within the volume. This system allows for near volumetric 3D printing in a sense that there is no requirement for supports or flat two-dimensional slicing of objects. A concrete example of gene expression in the shape of a double helix will be presented and discussed. Furthermore, both the spatial and temporal resolution limitations of the 3D printing method and system will be discussed along with proposed solutions. This research is the first stepping stone towards a novel bioprinting approach, which can expand the 3D printing material library to biological materials and could also be implemented in tissue engineering through optogenetics.

**8:00 PM SF01.06.03**

**3D Printing of Photoconductive Zinc Oxide-Based Photoresins** [Ozan Karakaya](#)<sup>1,2</sup>, Luis A. Ruiz-Preciado<sup>1,2</sup>, Peter Krebsbach<sup>1,2</sup>, Kai Xia<sup>1,2</sup>, Christian Rainer<sup>1,2</sup>, Ali Tunc<sup>1,2</sup>, Uli Lemmer<sup>1,2,3</sup> and Gerardo Hernandez-Sosa<sup>1,2,3</sup>; <sup>1</sup>Light Technology Institute, Karlsruhe Institute of Technology, Germany; <sup>2</sup>InnovationLab, Germany; <sup>3</sup>Institute of Microstructure Technology, Karlsruhe Institute of Technology, Germany

The interest in 3D-printed functional microstructures has significantly increased over the past decade due to their potential utilization in microelectronics, photonics, optoelectronics, and biological applications.<sup>[1]</sup> Compared to commonly used additive manufacturing techniques such as fused deposition modeling and selective laser sintering, light-based 3D Printed methods (Stereolithography) offer faster processing and higher spatial resolution.<sup>[2,3]</sup> However, for light-based 3D printing, mainly 3D structures based on organic polymers have been assembled due to the limited availability of multifunctional (e.g. conducting, semiconducting, etc.) photoresins. One of the main challenges that have been encountered when designing functional photoresins is the undesired light absorption of the ink, which leads to relatively low spatial resolution or crosslinking efficiency.<sup>[4]</sup>

Here we use an approach for designing a multifunctional photoresin to fabricate 3D-printed ZnO microstructures by mixing a commercial photoresin with a Zinc-based metal-organic complex. This material doesn't have any optical absorption that interferes with the photoresin photopolymerization process and can be transformed to ZnO at low annealing temperatures (< 200 °C). The utilized functional resin is comprised of a commercial photoresin into which the ZnO precursor, a stabilizer, and an organic solvent are added. Additionally, high zinc loading is possible by using a stabilizer in the precursor solution which can lead to high ZnO conversion hence better optoelectronic properties. Depending on the material ratio and optimized composition which favors both printing resolution and optoelectronic properties can be prepared. After printing of the photoresin by Digital Light Processing (DLP) (27  $\mu$ m

resolution, 25  $\mu\text{m}$  slice thickness), the 3D structure is thermally annealed to transform into a Polymer/ZnO composite. Structural and morphological characterization has been performed by scanning electron microscopy and x-ray diffraction showing percolative paths of ZnO in the polymer matrix and good crystalline quality.

Optoelectronic characterization of the 3D printed Polymer/ZnO composite yielded Zinc based 3D printed photodetectors exhibiting photocurrents off 0.5 nA and an on/off ratio of 250 when excited at a wavelength of 395 nm. Reference thin-film samples deposited on glass substrates showed ZnO-based UV-photodetectors exhibiting a photocurrent of 5 nA and an on/off ratio of 600 when excited at the same wavelength.

In future work, we plan to extend the obtained results towards its use in the Direct Laser Writing (DLW) process to obtain micro-architected 3D ZnO structures which will be potentially used in applications such as miniaturized optoelectronic and bioelectronic devices.

***In-Situ Alignment Behavior of Anisotropic NdFeB Magnets in Extrusion-Based 3D Printing Process*** Yongrae Kim, Dongwoon Shin, Taeho Ha, Joonphil Choi, Segon Heo, Yeo-Ui Song, Changwoo Lee, Pil-Ho Lee and Min-Kyo Jung; Korea Institute of Machinery and Materials, Korea (the Republic of)

Permanent magnet materials play a vital role in numerous electronic devices, ranging from electric vehicles and wind turbines to smartphones and smartwatches. Their ability to efficiently convert electrical energy into mechanical energy makes them essential components in modern technology. With the increasing demand for high-performance magnets with diverse shapes, driven by the trend towards miniaturization and lightweight design, there is a need to explore innovative manufacturing techniques which can meet these requirements and improve overall efficiency.

Currently, the production of permanent magnets primarily uses two main methods: sintering and polymer-bonded techniques. Sintered magnets exhibit superior magnetic properties compared to bonded magnets because of their higher density and crystalline structure. However, they possess inherent limitations, including poor corrosion resistance, limited shape complexity, and higher energy consumption during the manufacturing process. On the other hand, bonded magnets are created by combining magnetic powders and polymer binders through compression molding, extrusion, or injection molding. Compression molding allows for magnets with high filler ratios, but it is restricted to producing magnets with simple shapes. Injection molding, although capable of fabricating magnets with complex geometries, results in material waste and requires additional tooling processes.

To overcome these challenges and advance the production of bonded magnets, our research utilizes the additive manufacturing technique known as Fused Deposition Modeling (FDM). Unlike conventional methods that use filament, we employ powders or pellets consisting of binder polymers and anisotropic magnet fillers in our process. This approach reduces process time by skipping the filament manufacturing step and allows for control of the filler ratio. It also enables the creation of complex-shaped bonded magnets and addresses the limitations of conventional manufacturing techniques. Moreover, during the layer-by-layer printing process, we incorporate an in-situ electromagnetic alignment method to orient the anisotropic magnetic fillers along the desired magnetization axis. This alignment technology determines the orientation of the magnetic filler during processing, resulting in bonded magnets with superior magnetic properties, including improved remanence, coercivity, and energy products.

In our presentation, we will provide a comprehensive overview of the FDM-based bonded magnet fabrication process and discuss the crucial parameters involved. One significant parameter is the printing temperature, which determines the viscosity and flow characteristics of the binder polymer and affects the overall quality and integrity of the printed magnet. Additionally, the application of in-situ magnetic fields during the printing process plays a crucial role in aligning the anisotropic magnetic fillers with the magnetization axis and influences the final magnetic properties of the fabricated magnet. Understanding and controlling these variables is essential for achieving magnets with optimal performance.

Continuing our research and development efforts, we aim to further optimize the FDM-based bonded magnet fabrication method. Our goal is to improve the magnetic properties of the magnets produced while increasing the complexity of their small, lightweight, and shaped forms. To achieve these goals, we will explore various aspects, including the formulation of magnet fillers, binder polymers, and their interactions, as well as the optimization of printing parameters and post-processing techniques. By continuously improving this additive manufacturing approach, we aim to provide an efficient and sustainable method for producing high-performance bonded magnets tailored to the specific requirements of modern electronic devices.

#### 8:00 PM SF01.06.05

***3D Printing of Fluidic Systems with Soft Tissue-Like Membranes*** Yafeng Yu<sup>1</sup>, Yi Pan<sup>1</sup>, Yanting Shen<sup>1</sup>, Jingxuan Tian<sup>1,2</sup>, Ruotong Zhang<sup>1</sup>, Wei Guo<sup>1,2</sup>, Chang Li<sup>1</sup> and Anderson Shum<sup>1,2</sup>; <sup>1</sup>The University of Hong Kong, China; <sup>2</sup>Advanced Biomedical Instrumentation Centre, Hong Kong Science Park, China

As a natural fluidic system, blood vessel networks can adjust blood compositions by modulating physicochemical reactions between vessel walls and blood. Such biomimetic strategy in regulating fluids remains underexplored in synthetic systems, despite its relevance to spatiotemporal fluid modulation. The challenge is to build synthetic channels with functionalizable, vessel tissue-like walls. In this work, we produce a fluidic system with soft, membranous, and semipermeable channel walls, thus enabling functional compartmentalization for physical transport of fluids or for chemical reactions with fluids. An extrusion-based 3D printer was utilized to deposit one aqueous solution within another, where oppositely charged polymers self-assemble on the interface between these two solutions to generate channel-like structures. The channel walls are functionalizable for localized physicochemical reactions, for instance, by placing solutions of small molecules beside channels or locally immobilizing enzymes on the outer channel walls. Thus, fluid compositions inside are spatiotemporally programmable: As a demonstration, by modulating interplays between fluids and channels over space, the glucose concentration increases in the upstream fluid and decreases in the midstream channel, and the carbon dioxide concentration decreases in the downstream fluid. Our proposed fluidic system mimics the biofluid regulation in natural systems, inspiring platforms as in-vitro tissue models to synthesize biologically relevant molecules and screen drugs.

***Three-Dimensionally Printed, Vertical Full-Color Display Pixels for Multiplexed Anticounterfeiting*** Shiqi Hu and Ji Tae Kim; The University of Hong Kong, Hong Kong

Since counterfeiting has emerged as a global issue, novel and advanced strategies are in great demand for data storage and encryption to prevent information leakage. To this end, various materials, structuring strategies, and data processing algorithms have been devised. Creating high-resolution, sophisticated anticounterfeiting patterns has mostly relied on photolithography, nanoimprinting, and laser engraving, which are energy-intensive and/or chemically deleterious, difficult to perform on valuable products<sup>1-4</sup>. Alternatively, inkjet printing has also been utilized by taking advantage of its cost-effectiveness and high compatibility with ink and substrate materials. However, the resulting patterns are easily duplicated due to their simple geometry constrained in-plane. Advancing the structural complexity for improving security level remains a longstanding challenge. The utilization of luminescent materials is a strategy to advance anticounterfeiting labels. The intrinsic or stimulus-responsive optical properties of semiconductor quantum dots,

perovskites, or organic dyes can be exploited to configure multilevel anticounterfeiting<sup>5,6</sup>. A luminescent-based anticounterfeiting label consists of an array of pixels which are the fundamental element to encode/display information. Each pixel is typically composed of red, green, and blue subpixels with lateral patchwork to render multi-channel information encryption. However, this lateral configuration is unavoidable for the existence of a subpixel pitch, not only being easily copied but also limiting the improvement of pixel density.

Herein, we propose vertically stacked multicolor micropixels for high-resolution, multiplexed anticounterfeiting. The micropixel is produced by sequentially stacking luminescent dye-doped red-green-blue (RGB) subpixels, realized with high-resolution 3D printing. Our 3D printing approach based on the use of a femtoliter ink meniscus enables vertical stacking of micron-sized subpixels without the existence of a subpixel pitch, drastically increasing the pixel density up to 13,400 pixels per inch (PPI), which is not easily attainable by the traditional lateral subpixel layout. Furthermore, a full-scale color synthesis for each micropixel is achieved by modulating the height ratio of R, G, and B subpixels, which is reflected in the CIE 1931 diagram. These features create high-resolution, multiplexed anticounterfeiting labels, inaccessible by conventional optical imaging, and 3D printing offers the simplest, most versatile route to manufacture. This work demonstrates the exceptional inclusivity of 3D printing to construct vertically stacked structures and highlights the possibility to devise 3D printing for photonic device manufacturing.

**3D-Printed Single-Material Carbon Nanotube Thermocouple Microdevices** Zhuoran Wang and Ji Tae Kim; The University of Hong Kong, Hong Kong

Miniaturized thermocouples have emerged as an essential component for the power generation or thermal management of microelectronic devices due to their capability to convert heat to electricity. Recently, extensive research focused on the structural design of micro-thermocouples to improve the thermoelectric performance, and one resulting insight is that a three-dimensional (3D) geometry can be beneficial in terms of integration density and thermal contact efficiency [1]. However, the construction of a 3D micro-thermocouple typically comprising two dissimilar materials suffers not only from the process complexity with high cost but also from the low mechanical strength of the junction.

Here, we have developed a micro 3D printing method for fabricating a single-material carbon nanotube (CNT) thermocouple device. The device is configured with an electrical junction of two freestanding CNT microwires with different widths, by exploiting the size-dependent Seebeck coefficient at the electron mean free path scale [2, 3] instead of using two different materials. The developed micro 3D printing method that uses a femtoliter ink meniscus enables a single-step, continuous, high-resolution (< 1  $\mu\text{m}$ ) manufacturing of CNT micro-thermocouples in three dimensions. This greatly ensures structural robustness, cost-effectiveness, and design flexibility, which have not been attained by other traditional manufacturing approaches, reinforcing practicality. In this talk, we will present the experimental results including the fabrication and characterization of 3D CNT micro-thermocouples, and discuss the prospects of our work for potential applications.

**Thermal Conductivity Measurement for Aligned Particle Monolayers** Evan Toth, Jessica Faust and Randall M. Erb; Northeastern University, United States

Thermal management poses serious design and size limitations for high power density electronics, and relatively few material options that are both dielectric and thermally conductive can be processed easily (e.g., hexagonal boron nitride, diamond). Hexagonal boron nitride has strong dielectric properties and a theoretical thermal conductivity on par with copper, imbuing it with strong potential for use in power electronics and low-loss RF systems -- especially in thin layers. Hexagonal boron nitride (sometimes called 'white graphene') has excellent in-plane phonon transport, and to exploit this we use a surface assembly technique to create percolated platelet-thick monolayers. Induced planar alignment of the individual platelets at high volume loadings transforms a disjoint collection of particles into a thermally percolated plane for heat to preferentially travel *within* (x-y) but not *through* (z). Regarding conductive behavior, monolayers are particularly interesting due to their low dimensional (2D) morphology but, in turn, make extracting useful thermal parameters (diffusivity, conductivity) significantly difficult with current measurement techniques. Conventional methods like thermal interface measurement and laser flash either cannot accurately measure in-plane heat flow or require highly custom software/hardware for an otherwise highly inaccessible instrument. In this work, we modify the semi-transient method developed by Angstrom in 1861 to measure the thermal diffusivity of 2D materials with the aim of thermally characterizing monolayer composites and more generally to allow for simple planar measurement of thermal diffusivity.

#### 8:00 PM SF01.06.11

**High Resolution Magnetorheological Devices for Advanced Applications Fabricated by Additive Manufacturing Technologies** Ander Garcia<sup>1</sup>, Carmen R. Tubio<sup>1</sup>, Ainara Gomez<sup>2</sup>, Joanes Berasategui<sup>2</sup>, Mounir Bou-Ali<sup>2</sup>, Jon Gutierrez<sup>1,3</sup> and Senentxu Lanceros-Mendez<sup>1,4</sup>; <sup>1</sup>BCMaterials, Basque Center for Materials, Applications and Nanostructures, Spain; <sup>2</sup>Mondragon University, Spain; <sup>3</sup>University of the Basque Country, Spain; <sup>4</sup>Ikerbasque, Basque Foundation for Science, Spain

Magnetorheological elastomers (MREs) can modify their mechanical properties (mainly elastic moduli) in response to a magnetic field. These materials,

comprising a polymeric matrix and inorganic magnetic fillers, have traditionally found use in large scale applications (such as dampers and isolators) that sacrifice accuracy for performance and fabrication simplicity.

With additive manufacturing (AM) technologies, however, complex structures could be fabricated through different techniques, such as direct ink writing (DIW), that allow to achieve higher pattern resolutions and allow new and exciting applications in the field of healthcare, automotive and printed electronics. The issue with traditionally designed MREs is that are typically based on carbonyl iron microparticles that, albeit their high saturation magnetization and low coercivity, are not suitable for AM due to their size and hinder high resolution patterns.

Thus, a transition should be made into using nanoparticles (NPs) for high-resolution applications. To this end, we have studied the impact that magnetic properties, concentration, shape, and orientation have on the performance of nanoparticle based MREs, in order to achieve the optimize performing material compatible with AM.

Nanoparticles with different values of saturation magnetization, coercivity, and remanence have been selected to fabricate the MREs. Six different fillers were tested:  $\text{CoFe}_2\text{O}_4$ ,  $\text{Fe}_3\text{O}_4$ , Co, Ni and  $\text{Ni}_{80}\text{Fe}_{17}\text{Mo}_3$  (Permalloy). The magnetorheological (MR) effect achieved for the  $\text{Fe}_3\text{O}_4$  composite was the highest one at 18%, and comparable to other composites reported in the literature, but with a lower content of magnetic material (only 6 vol% versus 20 vol%), which is expected to improve the processing and integration of the MRE. Moreover, by using different concentrations (20 wt%, 40 wt% and 60 wt%) of the Permalloy filler, we obtained a linear relationship between MR effect and filler concentration, increasing from 8% at 20 wt% to almost 30% at 60 wt%. However, this increase in performance should be carefully balanced with the variation of the mechanical properties.

Further,  $\text{Fe}_3\text{O}_4$  nanorods (NRs) have been synthesized with an aspect ratio of 10 to compare with the 70 nm sized cubic  $\text{Fe}_3\text{O}_4$  NPs. Anisotropic MREs (A-MREs) were then fabricated by curing the composite inside a magnetic field to achieve a preferential orientation and compared them with isotropic MREs (I-MREs) cured without the presence of the magnetic field. The results of the relative magnetorheological effect confirmed that the A-MREs exhibit higher values of the MR effect, as it increased from 12% to 27% in the case of the NPs and from 8.3% to 17% in the case of the NRs. Interestingly, these results imply that lower aspect ratios are more suitable to enhance the MR effect in anisotropic composites, since the relative increase between oriented and non-oriented samples was 125% for the NPs and 104% for the NRs.

The suitability of these materials for DIW additive manufactured devices has been further evaluated in  $\text{Fe}_3\text{O}_4$ -based MREs. We fabricated a fully printed patterned device combining magnetoelectric and magnetorheological properties, where the conversion from applied magnetic field to output voltage could be manipulated by taking advantage of the change in mechanical properties and magnetostriction of the magnetorheological layer.

#### 8:00 PM SF01.06.12

**Additive Manufacturing of Flexible Photonic Waveguides with Active Components** [Maxine Ong](#), Yu Shu, Max Jenkins, Harish Bhaskaran and Peter Bruce; University of Oxford, United Kingdom

An emerging research direction in flexible devices is in photonics. Having the ability to manipulate and deform photonic devices gives the additional benefit of controlling light-matter interaction. Flexible photonic devices are seen in applications such as interconnects, detectors and bio-photonic sensors, where the mechanical flexibility of the devices is exploited. However, there are still many challenges associated with the fabrication due to the poor compatibility of available flexible substrates to conventional methodologies.

In this work, we demonstrate the fabrication of polymeric waveguides on flexible substrates and the integration of active components (e.g. 2D materials, phase-change materials) through additive manufacturing, such as direct laser writing and pick-and-place. These have potential optoelectronic applications in photodetection, and memory devices that can be seamlessly affixed to conformal surfaces.

#### 8:00 PM SF01.06.14

**Expanding the Toolbox of PhotoROMP Additive Manufacturing** [Alex Commisso](#), Annika Jansen and Samuel Leguizamon; Sandia National Labs, United States

Stereolithographic additive manufacturing (SLA) processes provide agility and complex design development of components necessary for a wide range of critical applications. Yet this technique is limited to a small subset of monomers that traditionally produce polymer materials with poor thermal and mechanical properties. Conversely, ring-opening metathesis polymerization (ROMP) can produce relatively tough, high  $T_g$  thermosets using latent ruthenium catalysts. Furthermore, spatiotemporal control of the polymerization using photosensitizers affords high resolution patterning of high  $T_g$  thermosets using photoROMP. Dicyclopentadiene (DCPD), an inexpensive but robust photoROMP monomer, has been featured in SLA resins to generate highly complex three-dimensional geometries at print speeds approaching industry-leading standards using continuous SLA techniques. However, the minimal exploration into the monomer space in photoROMP and ROMP SLA hinders the utility of ROMP polymers as the DCPD-based resins are generally non-processable, non-degradable, and lack other useful functionalities that have previously been imbued in polymeric materials. By examining the strained olefin monomer space for their photopolymerization kinetics, material properties, and print fidelity, we have identified potential routes to rapid SLA of functional polymers using photoROMP.

**Additively Manufactured Ceramic Combustor for Power-Plant Scale Electricity Generation** [Shomik Verma](#), Mehdi Pishahang, Kyle Buznitsky, Alina LaPotin, Santosh Shanbogue and Asegun Henry; Massachusetts Institute of Technology, United States

Existing power plants have many downsides, as they have low efficiency, emit  $\text{CO}_2$ , and include high-temperature rotating machinery requiring frequency maintenance. However, they are dispatchable, which provides a direct benefit over variable renewable energy resources such as solar. The ideal technology would be both dispatchable and solid-state. A recent alternative is fuel cells, which can directly extract the chemical energy in fuels into electricity with electrochemistry, but they require expensive catalysts and have low power density.

Combustion-powered thermophotovoltaics is a promising alternative for power generation. In this system, a combustor is designed that preheats air above the auto-ignition point of a fuel, such that the mixture combusts upon contact. The heat from combustion is used to heat up an emitter to ultra-hot temperatures, and the emitter radiates heat to the TPV cell. The TPV cell converts the emitted light to electricity. If hydrogen is used as the fuel source, the electricity produced is clean, creating a solid-state, catalyst-free method of generating electricity.

When combined with high-efficiency, high-power density TPV cells, this combustion-TPV system has the potential to be high-performing. However, there are many challenges in the system design, for example that high temperatures (2000C) are required, hefty insulation is needed to prevent heat loss, and cost may be high.

Thus, this study addresses three key challenges in the combustor design: materials identification, scalable design, and fabrication with additive

manufacturing.

For materials identification, the objective of the material is to limit thermal stresses when a thermal gradient is applied, meaning the product of Young's modulus and coefficient of thermal expansion must be low. The material's yield strength must also be high, so that it does not fracture when a thermal stress is present. Due to the extreme environments present, the material should also be oxidation resistant and have high service temperature. Thus, oxides are the best option, and yttria-stabilized zirconia (YSZ) is identified as the candidate material due to its reduction resistance in the presence of high-temperature hydrogen.

Next, we design a high-efficiency combustor with 93% combustion efficiency using YSZ, enabled by milli-scale channels and a large surface area to volume ratio. The combustor also features a near-isothermal emitter wall at approximately 2000C. It is also modular, enabling vertical and horizontal stacking to reach the large length scales required for cheap insulation and grid-scale power generation.

However, the intricate internal geometries enabling the effective heat transfer within the device necessitate additive manufacturing. Because this technique can be expensive, two techniques are used to ensure cost-competitiveness. One is maximizing the power output per volume of the device, which is enabled by a large emitter surface area surrounded by high-power density TPV cells. Another is design for manufacturing, in which the device is 3D printed in 3 sections which are joined together in post-processing. This enables parallel processing and easier access to the internal channels, which would otherwise be difficult to clear. One challenge of this stacking method is how to properly join the slices, and a leak-proof joining methodology is developed to solve this.

Based on these improvements, we achieve a predicted cost per power of \$0.30/W, which is significantly less than the cost of a natural gas turbine at \$1/W, and leaves room for balance-of-plant costs such as pollution control, TPV cooling, and electronics.

Overall, in this work we push the boundaries of ceramic additive manufacturing to develop a next-generation power plant based on hydrogen combustion coupled with thermophotovoltaics.

#### 8:00 PM SF01.06.17

**Maximizing Photosynthetic Current Density of 3D Printable Thylakoid-PEDOT:PSS Composite Inks Through Bayesian Optimization** JongHyun Kim, JaeHyounng Yun and WonHyounng Ryu; Yonsei University, Korea (the Republic of)

Thylakoid membranes (TM) isolated from living plants can produce high energy electrons through photosynthesis under sunlight. If placed near an electrode, the high energy electrons can be harvested and put to practical use, creating an eco-friendly power cell. Recently our group has demonstrated TM-embedded 3D printable ink based on a conductive polymer, poly(3,4-ethylenedioxythiophene):polystyrene sulfonate (PEDOT:PSS) [1]. Compared to the conventional post-electrode-deposition methods, the pre-embedment method allowed drastic increase in TM-electrode contact. While this previous study has focused on optimizing electrode geometry, in this work, we seek to optimize the electrode material itself to reach maximum current density. However, in achieving high current density, the two key parameters: the electron production rate and electrode conductivity, are always in tradeoff. Denser TM embedment surely increases photosynthesis but decreases electrode conductivity as it interrupts the conductive networks of PEDOT, responsible for charge flow. Addition of secondary dopants, such as dimethyl sulfoxide (DMSO), boosts conductivity by facilitating phase separation between PEDOT and PSS chains, but such organic solvents are prone to damage TMs. Post treatments of dry-annealing in PEDOT:PSS electrodes are considered essential in formulating and crystallizing PEDOT-rich domains [2], but heat treatments can damage the protein structures in TM. As multiple correlated factors in the material and manufacturing process account for the overall current density of the power cell, it is not only laborious but also very difficult to optimize each parameters. Therefore, we implemented Bayesian optimization, a technique used widely in Machine Learning, to simultaneously fine tune the concentrations of TM, PEDOT:PSS, and DMSO, along with dry-annealing time and temperature. To stay within 3D printable boundaries, we conducted rheological studies of the ink composites and set their lower boundaries to where their storage modulus is just above the loss modulus. Their upper boundaries were set at a nozzle clogging point referenced from the previous work on 3D printing PEDOT:PSS [3]. Additionally, we conducted a parametric study of gradual heating of drop casted TM on ITO glass. The upper boundary of the temperature parameter was set as 150°C, where no current was longer measured from TM. In each iteration step of the Bayesian optimization, the ink was mixed thoroughly, screen printed with fixed volume on an ITO glass substrate, and dry-annealed in oven. The current density value, measured through cyclic amperometry, was fed into the Bayesian optimizer and the experimenter received back the next sampling point. As the experiment prolonged, the Bayesian optimizer attempted to find the global maxima of the surrogate model built from these current density values.

#### 8:00 PM SF01.06.18

**Digital Light Processing 3D Printed Thermochromic and Thermoresistive Sensors Based on Soybean Oil and Ionic Liquids** Cristian Mendes-Felipe<sup>1,2</sup>, Daniela Correia<sup>3</sup>, Mohammad Tariq<sup>4</sup>, José Esperança<sup>4</sup>, Marco Sangermano<sup>2</sup> and Senentxu Lanceros-Mendez<sup>1</sup>; <sup>1</sup>BCMaterials - Basque Center for Materials, Applications and Nanostructures, Spain; <sup>2</sup>Politecnico di Torino, Italy; <sup>3</sup>University of Minho, Portugal; <sup>4</sup>Universidade Nova de Lisboa, Portugal

Additive Manufacturing (AM) has revolutionized the field of manufacturing by enabling the fabrication of complex three-dimensional structures with unprecedented design freedom. This work focuses on Digital Light Processing (DLP), for the processing of soybean oil-based materials. The use of reactive solvents and the study of suitable inks for printing purposes are explored, allowing or enhance the performance, sustainability and versatility of AM processes.

Soybean oil-based materials have gained significant attention due to their renewable nature, biodegradability, and potential for sustainable manufacturing. By formulating soybean oil-based resins and optimizing the processing parameters, digital light processing techniques can effectively harness the advantages of these materials. The incorporation of reactive solvents in the formulation allows for controlled material properties, including viscosity, curing kinetics, and mechanical strength, facilitating precise material design for specific applications.

To achieve successful printing of soybean oil-based resins, it is essential to develop compatible and stable inks. The study delves into the investigation of suitable ink formulations for DLP-based AM, considering factors such as ink rheology, surface tension, and photocuring behaviour. By understanding the ink characteristics, printing parameters can be optimized, ensuring high-quality prints, and expanding the range of printable materials. Thus, different reactive diluents including isobornyl acrylate or lauryl acrylate are added decreasing that the viscosity of soybean oil and reaching proper values for DLP

printing, together with enhance the photopolymerization process. Furthermore, the thermal and mechanical properties of printed materials are tested showing a wide range of both properties depending on the reactive diluent content. Also, high quality 3D printed parts are observed in all cases. Additionally, this work explores the integration of thermochromic materials, specifically ionic liquids, into the AM process to obtain functional 3D structures for sensor applications. Thermochromic materials exhibit reversible colour changes in response to temperature variations, enabling the development of smart and responsive sensors. The incorporation of ionic liquids with thermochromic properties provides an avenue to achieve enhanced sensitivity and precise control of the thermochromic response in printed sensor structures without the ascribed problems of using thermochromic nano- or microparticles. Bis(1-butyl-3-methylimidazolium) tetrachloronickelate ([Bmim]<sub>2</sub>[NiCl<sub>4</sub>]) ionic liquid is easily dispersed in quantities up to a 40 wt.% filler content. All prepared materials present humidity dependent thermochromism from colourless to blue and this colour variation is thermally activated and humidity governed, being 55% the minimum value of the relative humidity for colour change to occur. Further, the electrical conductivity increases with increasing IL content and decreases with increasing temperature, demonstrating also the applicability of the materials as thermoresistive sensors. The proposed research contributes thus to the advancement of AM techniques by expanding the materials palette to include soybean oil-based resins, optimizing ink formulations for DLP printing, and exploring the functional integration of thermochromic ionic liquids in sensor applications. The findings from this study hold great potential for the development of sustainable, customizable, and intelligent 3D-printed structures with broad applications in fields such as sensing, robotics, and biomedical engineering.

**3D-Printed Fused Silica Glass Hollow Microneedle Arrays – From Fabrication to Transdermal Applications** Yanwen Jia and Ziyong Li; City University of Hong Kong, Hong Kong

Microneedle arrays (MNAs), a micron-scale device that recently emerged, are being recognized for their significant potential in enhancing transdermal delivery and extracting interstitial tissue fluid (ISF). Advanced 3D printing techniques have been utilized to fabricate MNAs with enhanced functionality, improved performance, and increased structural flexibility; however, the current 3D-printed MNAs are primarily composed of polymers that suffer from high costs, low durability, and poor robustness. To overcome the constraint, we integrate fused silica glass with projection micro-stereolithography (PμSL) 3D printing technology for the fabrication of transparent and high-quality fused silica glass MNAs with micron resolution, high stiffness, and excellent optical properties for the first time. The *in vitro* penetration test suggests that the 3D-printed fused silica glass MNAs are capable of piercing skin safely and smoothly. ISF extraction test demonstrates its ability to extract sufficient model biomarkers-contained fluid in a short time under capillary force. We confirmed its potential in further transdermal applications. In the future, 3D-printed fused silica glass MNAs, coupled with technology like microfluid, could be applied in precise drug delivery, intelligent transdermal biosensing, real-time monitoring, etc.

#### 8:00 PM SF01.06.20

**Ink Optimization and Pattern Design for Fast Charge Electrode Through R2R Printing** Hongli Zhu and Ying Wang; Northeastern University, United States

Reducing the tortuosity of electrodes through vertical channels establishing is a recognized method to improve the ion transfer kinetics and enhance the fast chargeability of electrodes. Concurrently, investigating the relationship between channel structure on the electrochemical performance of electrodes is meaningful for optimizing the structure of fast-charging electrodes. In order to realize these demands, screen printing is a promising technology to fabricate low-tortuosity electrodes with precisely optimized structures on a large scale. However, the lack of suitable screen printable electrode inks slows the development of screen printing structural designable electrodes. An ideal industrial screen printing electrode ink should be high solid content, outstanding printability, and well particle dispersion to satisfy the demands on industrial cost reduction, printing quality improvement, and battery performance guarantee.

Herein, printing quality evaluation, rheological properties analysis, X-ray computed tomography characterization, coarse-grained molecular dynamics simulation, and electrochemical properties comparison were applied to reveal the underlying relationship among the status of molecular chains, screen printability of inks, and electrochemical performance of electrodes. In particular, the twisted molecular chains function as additional networks that pull certain particles within the electrode ink onto the mesh, reducing its screen-printability. Furthermore, the internal architectural integrity of electrodes and sufficiently uniform dispersion of electrode components renders screen-printed electrodes with superior electrochemical performances. Based on recognizing and illustrating the relevance of the molecular chain state in high-solid-content ink for screen printability, we recommended a unique two-step approach for opening the twisted molecular chains of 60 % solid content LiN<sub>10.6</sub>Mn<sub>0.2</sub>Co<sub>0.2</sub>O<sub>2</sub> cathode ink and printed the corresponding electrodes. At the current rate of 6C, screen-printed electrodes using optimized ink exhibited a 33% larger charge capacity with a mass loading of 6.5 mg/cm<sup>2</sup> than that produced with chains-twisted ink. Additionally, according to the mechanisms of the two-step approach, we disclosed an optimization strategy for modifying inks for various printing conditions. This concept facilitates the integration of screen printing with the production of functional electrodes and can be applied to other purposes.

Further, we have successfully printed a series of high-precision vertical channels using our developed inks, systematically and comprehensively investigating the effects of the structure of vertical channels on rate performance enhancement for fast-charging electrodes. Through electrochemical evaluation, we demonstrated that 1) the staggered configuration of vertical channels improves the high-rate charge capabilities of electrodes, and 2) the decreasing channel diameter and edge distances improve the electrodes' rate performances. Specifically, the optimized electrode performed a charge capacity that is two- and seven-times greater than the conventional bar-coated electrodes at 4 and 6 C, respectively. Additionally, neutron computed tomography was applied to reveal that the Li<sup>+</sup> was homogeneously spread along the printed channels during the charging and discharging, which enhanced the average ion transfer kinetic of whole electrodes. The optimized channels can facilitate ion diffusion in the horizontal direction and ion transfer in the vertical direction for screen-printed electrodes, thereby maximizing the overall charge transfer kinetics of electrodes. Although more developments in screen printing technology are required to refine the resolution and further structural design for screen-printed electrodes, our researches suggest a reasonable method for optimization, industrialization, and commercialization of low-tortuosity electrodes for fast-charging LIBs.

#### 8:00 PM SF01.06.21

**In-Situ Analysis of Photobase Initiated Networks for Two-Photon Polymerization** Madelyn P. Jeske<sup>1,2</sup>, David R. Harding<sup>2</sup>, Mitchell J. Anthamatten<sup>1</sup>, Aofei Mao<sup>3</sup>, Xi Huang<sup>3</sup> and Yongfeng Lu<sup>3</sup>; <sup>1</sup>University of Rochester, United States; <sup>2</sup>Laboratory for Laser Energetics, United States; <sup>3</sup>University of Nebraska–Lincoln, United States

Two-photon-polymerization (TPP) performance is demonstrated in resins that polymerize via “click” chemistry – a process that has no unreacted component. Additionally, for the first time, a photobase (PBG) initiator was used in place of a free-radical photo-initiator to facilitate the reaction; a change that produced a more ordered and stiffer polymer network structure with an elastic moduli of 30 MPa and 2-10 MPa at 70°C, respectively. Structures with shape-memory behavior, and capable of surviving 12% strain at the ultimate tensile stress, were printed with sub-micrometer resolution and were robust enough to withstand several shape-memory cycles.

The click chemistry is based on thiol-ene Michael Addition chemistry and works with either a base or free radical initiators. Raman spectroscopy data from TPP samples show that networks formed with the PBG initiator have a higher selectivity for thiol-ene coupling than do networks formed with a free-radical initiator, which results in increased crosslinking density. Using Coherent Anti-Stokes Raman Spectroscopy to probe the location of the photo-initiators

during the polymerization process (with ~0.4 mm spatial resolution) provides insight into the diffusion kinetics that affects the print-resolution.

#### 8:00 PM SF01.06.22

**Additive Manufacturing of Amorphous Soft Magnetic Composites** [Anna Langham](#)<sup>1</sup>, Mitra L. Taheri<sup>1,2</sup>, Georgia Leigh<sup>1</sup>, Caleb Andrews<sup>1</sup> and Sebastian Lech<sup>1</sup>; <sup>1</sup>Johns Hopkins University, United States; <sup>2</sup>Pacific Northwest National Laboratory, United States

Electric motors play a vital role in various industries ranging from aerospace to the energy sectors. Enhancing the efficiency and power density of electric motors has become a critical objective, currently limited by high losses in the motor's magnetic core. State of the art commercial cores use steel laminates for their soft magnetic performance, relative ease of manufacture, and low cost of production. High eddy current loss in steel laminates necessitates research and development effort into other materials, such as amorphous soft magnetic composites (ASMCs), which have excellent soft magnetic characteristics like high magnetic saturation, and high relative permeability while also offering reduced losses. To date, the integration of ASMCs have been limited by the manufacturing challenges posed by traditional manufacturing methods. The goal of this work is to use Directed Energy Deposition additive manufacturing (DED) to obtain an amorphous microstructure suitable. Metglas 2605HB1M flake, a commercially available metallic glass known for its incredible relative permeability values and low losses, is explored as a potential material system. The microstructure and magnetic properties of DED printed Metglas flake, high purity Iron (Ancorsteel 1000b) and a 50/50 compositional blend of the Metglas and Ancorsteel are compared.

#### 8:00 PM SF01.06.24

**3D Printed Resins with Photo-Polymerization-Induced Phase Separation: Structure and Mechanical Properties** [Lauren Zakrzewski](#), Kanta Purkayasta, Chulsung Bae and Catalin R. Picu; Rensselaer Polytechnic Institute, United States

In this work we develop heterogeneous acrylic-based photosensitive resins with superior strength and toughness for 3D printing applications. The enhanced toughness is obtained by exploiting the polymerization-induced phase separation of linear polymer (polypropylene glycol) which creates soft domains of sub-micron dimensions. The development of these materials has three steps: (i) development of the base photo-curable resin composition, (ii) gaining control on phase separation in cast samples, and (iii) 3D printing (using SLA) with phase separation. The talk will outline the chemistry and technology developed, and the effect of process parameters on the multiscale structure and mechanical properties of the 3D printed samples. Heterogeneous thermosets are an emerging class of materials whose properties may be tailored to exceed those of the commercial, nominally homogeneous thermosets.

#### 8:00 PM SF01.06.25

**In-Situ Piezoelectricity Enhancement in 3D Printed MoS<sub>2</sub> PVDF Nanocomposites** [Rifat Hasan Rupom](#)<sup>1</sup>, Md Nurul Islam<sup>1</sup>, Pashupati R. Adhikari<sup>1</sup>, Zoriana Demchuk<sup>2</sup>, Ivan Popov<sup>2</sup>, Alexei Sokolov<sup>2</sup>, H. Felix Wu<sup>2</sup>, Rigoberto C. Advincula<sup>3</sup>, Narendra B. Dahotre<sup>1</sup>, Yijie Jiang<sup>1</sup> and Wobong Choi<sup>1</sup>; <sup>1</sup>University of North Texas, United States; <sup>2</sup>Oak Ridge National Laboratory, United States; <sup>3</sup>University of Tennessee Knoxville, United States

For sensing and energy harvesting of 3D conformal structures, flexible and high-performance piezoelectric devices are extremely desirable. Here, we demonstrate dramatically improved piezoelectricity in polyvinylidene fluoride (PVDF) due to in-situ dipole alignment of PVDF within PVDF-two dimensional molybdenum disulfide (2D MoS<sub>2</sub>) composite via 3D printing. We take use of the shear stress-induced dipole poling of PVDF and 2D MoS<sub>2</sub> alignment during 3D printing to increase piezoelectricity without any post-poling procedure. The results demonstrate an impressive increase of more than eight times in the piezoelectric coefficient ( $d_{33}$ ) for 3D printed PVDF-8wt% MoS<sub>2</sub> composite over cast pristine PVDF. According to microstructural analysis and finite element simulation, the increased volume fraction of the phase in PVDF, filler fraction, heterogeneous strain distribution around PVDF-MoS<sub>2</sub> interfaces, and strain transfer to the nanofillers are all responsible for the enhancement of piezoelectric property. Our findings offer a promising way to develop and create high-performance 3D piezoelectric devices for mechanical-electronic conformal devices and next-generation sensors using 3D printing.

#### 8:00 PM SF01.06.26

**3D-Printed Polymer-Based Conformal Space Radiation Shield with Heat Dissipation** [Yue Xiao](#)<sup>1</sup>, An Zou<sup>1</sup>, David Carlson<sup>1</sup>, Robert Hayes<sup>2</sup> and Pu Zhang<sup>3</sup>; <sup>1</sup>Advanced Cooling Technologies, Inc., United States; <sup>2</sup>North Carolina State University, United States; <sup>3</sup>Binghamton University, The State University of New York, United States

With the rapid development of SmallSats/CubeSats and space computing, the current aluminum (Al) bulk shielding technology poses challenges in Size, Weight, and Power (SWaP) requirements. The bulk shielding thickness is determined by the electronics with the least radiation resistance, which prohibits wider adoption of Commercial-off-the-shelf (COTS) electronics and results in increased system weight. In addition, the absence of advanced thermal management technologies for SmallSats/CubeSats largely limits the adoption of high-power, low-price, and readily available COTS electronics. To address these challenges, we developed an innovative 3D-printed, lightweight polymer composite radiation shield comprising of a Metal Oxide Polymer Composite (MOPC) layer and a Fiber Reinforced Polymer Composite (FRPC) layer. Specifically, the MOPC utilizes high-atomic-number metal oxides that are infused into the base polymer to achieve superior radiation attenuation performance than Al. FRPC utilizes aligned carbon fibers in the same base polymer to achieve high in-plane thermal conductivity for electronics heat dissipation. In addition, such a shield is manufactured by the advanced five-axis Direct Ink Writing (DIW) 3D printer for further improved thermal transport and structural strength. Further, the 3D-printed shield enables locally enhanced spot shielding to provide additional radiation shielding for sensitive electronics without increasing the overall shield thickness. For MOPC, we have achieved an up to 7.4x increase in photon mass attenuation coefficient compared with Al and 18%–26% weight reduction for electron attenuation compared with Al at GEO. For FRPC, we achieved 2.55 W/m-K in-plane thermal conductivity, which is ~4x higher than the base polymer. Overall, the shield prototype can achieve 7 °C reduction in CPU temperature or a 22.5% increase in CPU power, and if spot shielding is utilized, an estimated 62% weight reduction for 1U CubeSat systems can be achieved.

#### 8:00 PM SF01.06.27

**Advancing the Performance of Zinc Ion Battery (ZIB) Through Additive Manufacturing of Tailored Structured Electrode Design with Hierarchical Porosity and Microchannel** [Md Nurul Islam](#)<sup>1</sup>, Nishat S. Sayor<sup>2</sup>, Rifat Hasan Rupom<sup>2</sup>, Pashupati R. Adhikari<sup>2</sup>, Rigoberto C. Advincula<sup>3</sup>, Narendra B. Dahotre<sup>2</sup>, Yijie Jiang<sup>2</sup> and Wobong Choi<sup>2,2</sup>; <sup>1</sup>The University of Oklahoma, United States; <sup>2</sup>University of North Texas, United States; <sup>3</sup>The University of Tennessee, Knoxville, United States

Due to its abundant, high volumetric capacity, and stable redox potential in water, Zn holds significant potential as an anode material for revitalizing rechargeable batteries beyond lithium-ion battery systems. Nevertheless, the use of alkaline Zn anodes is hindered by issues such as limited cycling durability and the growth of Zn dendrites, which result in short circuits and compromise both the performance and safety of the batteries. In recent years, additive manufacturing has emerged as a viable solution to address dendrite formation in zinc-ion batteries. This approach involves fabricating tailored electrode structures using the direct ink writing (DIW) 3D printing technique. By controlling pore sizes, distribution, and connectivity, 3D-printed Zn structures can provide a highly interconnected high surface area, allowing for improved electrolyte accessibility to electrode surfaces while accommodating its volume change.

In this study, we present a fully 3D-printed flexible zinc-ion battery (ZIB) with an engineered pore structure and surface area. First, we developed a Zn-based ink for the anode and a V2O5 ink for the cathode using high-power vacuum mixing, ensuring suitable rheological properties for direct ink writing (DIW) 3D printing. We conducted a comprehensive analysis of the ink formulation, rheological characteristics, and device performance to describe formulation-rheology-printability-functional properties relationships. A remarkable 6-fold improvement in areal capacity is achieved in 3D printed Zn-V2O5 battery with control samples. Additionally, printing-induced directional channels into the electrodes provide high Zn ion diffusion towards the cathode resulting in the high specific capacity of 190 mAh/g at 1 mA/cm<sup>2</sup> and long-term cyclic stability. In this presentation, we will discuss the tailored structured electrode design with hierarchical porosity and microchannel, ink formulation-rheology-3D printability relationship, and the electrochemical performance of the additively manufactured zinc ion battery.

#### 8:00 PM SF01.06.29

**Alteration of Melt Pool Flows Depending on the Surfactants on Ceramic Coatings Built by Laser Cladding** Sumin Song<sup>1</sup>, Yeonghwan Song<sup>1</sup>, Taebum Kim<sup>1</sup>, Jeongho Han<sup>2</sup> and Kyuntaek Cho<sup>1</sup>; <sup>1</sup>Korea Institute of Industrial Technology, Korea (the Republic of); <sup>2</sup>Hanyang University, Korea (the Republic of)

As qualities of ceramic coatings manufactured by laser cladding are superior due to few pores and cracks compared to that of thermal sprayed ceramic coatings, it has been spotlighted as one of the appropriate methods for building ceramic layers. Although understanding melt pool flows is important to build high-quality ceramic layers, studies on melt pool of ceramic layers which consist of metal intermediate layers and its flow alteration depending on the existence of surfactants (e.g., sulfur, oxygen, etc.) are insufficient. In this study, experimental studies were conducted to find out the effect of surfactant on melt pool flows of intermediate layers and extent of defects in ceramic layers.

In order to identify penetrated depth of coating layers and extent of coating defects, Ni intermediate layer and Al<sub>2</sub>O<sub>3</sub> ceramic layer were manufactured under same process conditions using N<sub>2</sub> or mixture of Ar and O<sub>2</sub> gas, which were observed by OM and SEM. In addition, Vickers hardness tests and Ball-on-disk tests were performed to compare mechanical and wear properties depending on the surfactant. As oxygen was added in the shielding gas, penetration and diluted area became deeper and larger due to alteration of convection flows from outward to inward. Decrease of defects was observed at the metal intermediate layer manufactured under surfactant atmosphere, which resulted in building stable ceramic coatings with high hardness. As a result, wear resistance of ceramic layer built under surfactant atmosphere could be improved, which could be attributed to the surfactant effect on the melt pool flows.

#### 8:00 PM SF01.06.30

**Development of Study Protocol Frameworks for Data-Driven Digital Twin Development for Direct Ink Write** Hein Htet Aung<sup>1,1</sup>, Brian Au<sup>2</sup>, Alex Caviness<sup>2</sup>, Robert William Cerda<sup>2</sup>, Jayvic Cristian Jimenez<sup>1,2</sup>, Kristen J. Hernandez<sup>1,1</sup>, Thomas Ciardi<sup>1,1</sup>, Pawan K. Tripathi<sup>1,1</sup>, Brian Giera<sup>2</sup>, Roger H. French<sup>1,1,1</sup> and Laura Bruckman<sup>1,1</sup>; <sup>1</sup>Case Western Reserve University, United States; <sup>2</sup>Lawrence Livermore National Laboratory, United States

Direct Ink Write (DIW) is an advanced manufacturing technique that allows 3D printing of complex parts. DIW 'ink' is a multi-material combination of a polymer base and a filler that shear thins upon extrusion and then hardens upon lay down.<sup>1</sup> DIW process parameters and optimization of machine operations are being investigated to ensure large-scale and rapid production of high-fidelity parts. A study protocol for DIW scientific investigations is developed to identify a standardized workflow to investigate DIW process-space parameters and the resulting part characteristics. The data streams generated during DIW part fabrication are massive and rich with information, yet could be overwhelming, becoming a bottleneck for extracting research insights due to the terabyte sizes. Therefore, we use automated analysis pipelines on FAIRified datasets, implemented in our CRADLE™ Distributed and High Performance Computing Cluster, where we can ingest, perform exploratory data analysis to identify parameter correlations and develop numerous data-driven models to identify useful inferential and predictive modeling approaches to this challenging problem.

Inferential models with trained model parameters, quantified variances and confidence intervals enable us to identify the mechatronic factors leading to both desirable and undesirable part properties. These models serve as a platform to build data-driven Digital Twins (ddDTs) for a virtual representation of the physical printed part, including its historical variances and defects. With continuous two-way communication between the real-world DIW system and the ddDT, the data obtained from the real-world system can update the ddDT and the simulations from ddDT can be used to update and drive the process parameters of the real-world system to obtain desired and improved part properties over production runs. The work herein demonstrates how our materials data science and data-driven digital twin approach using rigorous study protocols, establishes standardized data collection, FAIRified dataset management and model generation that allow us to integrate both historical and current data, across multiple DIW tools and production runs to quantify printed parts characteristics and variances.

This material is based upon research in the Materials Data Science for Stockpile Stewardship Center of Excellence (MDS3-COE), and supported by the Department of Energy's National Nuclear Security Administration under Award Number(s) DE-NA0004104.

**Multi-Material Nanoscale 3D Fabrication Based on Femtosecond Light Sheets** Shih-Chi Chen; Chinese University of Hong Kong, Hong Kong

A major challenge in nanotechnology is to fabricate complex 3D structures with desired materials. Despite the many great efforts, the material choices are still largely limited to polymeric materials or metals. A fabrication solution for a wider class of materials without compromising the existing structural complexity, nanoscale feature sizes, and material functions remains a critical challenge. In this seminar, I will present our recent works on the parallelization of ultrafast lasers for 3D nanofabrication, achieving a record setting resolution (20 nm), laser patterning rate (300 mm<sup>3</sup>/hr), and wide material library. Specifically, an arbitrarily programmable femtosecond light sheet is generated based on the principle of spatial and temporal focusing to perform parallel material processing. We first demonstrate the use of the femtosecond light sheet to perform micro-laser machining on different materials, and next to fabricate complex 3D structures via two-photon polymerization. Lastly, by combining the femtosecond light sheets and swellable hydrogels, we further demonstrate a greatly expanded material library to include metals, metal oxides, semiconductors, dielectric materials etc. This has enabled the

fabrication of nanometer-scale 3D functional devices. Our new methods provide an effective and low-cost solution to scale-up the fabrication of functional micro- and nano-structures ( $\sim 1.5/\text{mm}^3$ ). This means our technology may play a large role in fields such as healthcare, clean energy and water, computing, and telecommunications.

#### 8:30 AM \*SF01.07.02

**Additive Manufacturing of Multi-Material Architectures: From Structural to Electronic and Robotic Materials** Xiaoyu (Rayne) Zheng; University of California, Berkeley, United States

**Abstract** Additive manufacturing has shown the promise of freedom of designs, enabling parts customization and tailorable properties where superior structural performances can be achieved by a fraction of weight density compared to bulk material. However, it is presently difficult to directly print different materials (structural, dielectric, conducting and ferroelectrics) to create a complex device with multiple functionalities that responds to multiple stimuli. Unlike biological systems where functions, including sensing, actuation, and control, are closely integrated, few materials have comparable system complexity.

In this talk, I will present a suite of new multi-material additive manufacturing processes and design methodologies to create materials with prescribed structural and functional behaviors. The structural materials consist of a network of micro-unit cells which collectively influence new mechanical behaviors (from high-strength, lightweight to toughening) not seen in their native counterpart. When combined with an electronic and functional phase, these materials turn themselves into a robot and is capable of motions with multiple degrees of freedom and amplification of displacement in a prescribed direction in response to an electric field (and vice versa), and thus, programmed motions with self-sensing and feedback control. I will present the manufacturing and synthesis of these materials, as well as their mechanics and design methods underpinning their novel behaviors.

#### 9:00 AM SF01.07.03

**One-Photon Three-Dimensional Printed Fused Silica Glass with Sub-Micron Features** Ziyong Li<sup>1</sup> and Yang Lu<sup>2</sup>; <sup>1</sup>City University of Hong Kong, Hong Kong; <sup>2</sup>The University of Hong Kong, Hong Kong

Glass made from silica has a history of thousands of years, and its applications have accompanied the evolution of human civilization. From everyday life to cutting-edge industries, such as micro-optics, micro-electronics, and micro-fluidics, necessitates the high-precision manufacturing of three-dimensional (3D) fused silica glass objects. Advanced 3D printing technologies have emerged as a powerful tool for fabricating arbitrary glass objects with ultimate freedom and precision. Stereolithography and femtosecond direct writing showed their capability in shaping 3D glass objects with  $\sim 50 \mu\text{m}$  and  $\sim 100 \text{nm}$  features, respectively, however, to efficiently fabricating glass structures with centimeter size and sub-micron features still remains challenge. Presented here, our study demonstrates that the gap can be effectively bridged by engineering of appropriate materials, 3D printing based on one-photon micro-stereolithography (O $\mu$ SL), allows the flexible creation of transparent and high-performance fused silica glass components with sophisticated, 3D sub-micron architectures. The methodology facilitates the construction of fused silica glass components with arbitrary 3D-specific geometries featuring fine details as small as 900 nm, while also enabling rapid prototyping of structures of several millimeters. This offers unprecedented possibilities across a range of applications, including micro-optics, microfluidics, mechanical metamaterials, and engineered surfaces.

#### 9:15 AM \*SF01.07.04

**Nanoparticle Enabled Additive Manufacturing** Wendy Gu, John Kulikowski, David Doan, Qi Li, Mingqi Shuai, Luis Delfin Manriquez and Andrew Lee; Stanford University, United States

Nanoparticles have unique optical, thermal, chemical reactivity and phase transitions that can be used to enhance additive manufacturing processes. This can be used to fabricate nanoscale architected materials with superior mechanical properties due to material size effects. First, I will present a novel two-photon lithography resin that is used to print nanocomposites, nanoporous carbon and nanostructured silk. The key ingredients in the resin are metallic nanoclusters that serve as both photoinitiators and inorganic precursors, and have pressure-dependent optical properties. Nanocomposite honeycomb, octet and shell-based lattices are fabricated that have a combination of high strength per weight, energy absorption and recoverability beyond other nano and micro-lattices due to a unique strain hardening behavior. Then, I will present our development of a particle ink laser melting (PILM) additive manufacturing system, in which a colloidal nanoparticle ink is combined with a laser-powder bed fusion machine to enable low power printing of metals and ceramics. This is used to print conductive copper electrodes and piezoelectric elements directly on printed circuit boards (PCB).

**Probing Material Transformation Volumetrically in Computed Axial Lithography** Hayden Taylor, Sui Man Luk, Chi Chung Li and Joseph Toombs; University of California, Berkeley, United States

Volumetric additive manufacturing processes such as computed axial lithography (CAL) are promising for the rapid production of 3D geometries in a wide range of photopolymer and nanocomposite materials. In CAL, light dose is reconstructed tomographically by projecting a video image into a rotating volume of precursor material. Practically, this reconstruction approach exposes the bulk of the precursor (and not just the target geometry) to background illumination. The reconstructed dose distribution is also not perfectly sharp at the boundary of the component. Consequently, there is a range of degrees of conversion throughout the volume at any given moment, and it is very important to terminate the printing process accurately to be able to recover the desired geometry. In-process volumetric monitoring of refractive index can be valuable for this purpose, because most precursor materials exhibit refractive index increases during conversion to the solid state. We will review a set of Schlieren-based techniques we previously introduced for real-time material conversion observations. We will also discuss recent work developing a volumetric temperature monitoring technique based on fluorescence imaging. The evolution of temperature within a CAL volume can serve as an indicator of material conversion dynamics and can influence the quality of printed components.

#### 10:45 AM SF01.07.06

**A New Family of 3D Auxetic Mechanical Metamaterials with High Resilience and Elastic Hysteresis** Tiantian Li and Yaning Li; Northeastern University, United States

A new family of high resilient 3D auxetic mechanical metamaterials are designed. The new designs show remarkable resilience under large deformation together with significant hysteresis under cyclic compressive loading-unloading. Both isotropic and anisotropic designs are created. The 3D isotropic design shows ideal isotropy with negative Poisson's ratio close to -1 in all loading directions, as rarely seen in existing mechanical metamaterials. Also, the anisotropic mechanical properties including the effective stiffness and effective Poisson's ratio can be tuned in a wide range. In addition, new designs can also show a unique simultaneous twisting and shrinking behavior under uni-axial compression. An integrated experimental, analytical and numerical

approach is applied to quantify the effective mechanical properties of the new designs. Systematic FE simulations and analytical analyses are performed. The new designs are also fabricated, and mechanical experiments were performed on selected designs. These novel properties make 3D keyed-brick mechanical metamaterials be a potential candidate as engineering material with unique properties beneficial from negative Poisson's ratio, damping material for energy absorption, impact resistant material under special loading conditions.

#### 11:00 AM SF01.07.07

**Additive Manufacturing of Iron and Iron-Alloy Lattices for Magnetic Nanoparticle Capture** Sammy Shaker<sup>1</sup>, Andrii Syrota<sup>2</sup>, Colin Yee<sup>3</sup>, Vitaliy L. Rayz<sup>4</sup>, Steven Hetts<sup>3</sup> and Julia R. Greer<sup>1,4</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>Université Paris-Saclay, France; <sup>3</sup>University of California, San Francisco, United States; <sup>4</sup>Purdue University, United States

Magnetic nanoparticles are of widespread interest for medical therapies ranging from internal thermal treatments to vector agents for genetic modification to MRI contrast agents.<sup>1</sup> One of the standout applications for magnetic nanoparticles in medical therapies involves the capture of small molecule chemotherapeutics, particularly doxorubicin, via surface functionalization. While rapid capture of doxorubicin by functionalized nanoparticles has been demonstrated *in vitro*, sequestration of the nanoparticles, especially *in vivo*, has proven a more complicated task.<sup>2</sup> Sequestration of nanoparticles in a biological flow such as that found in a blood vessel will require a device that can maximize capture while minimizing flow disruptions and pressure drop across the device. Device designs consisting of solid cylindrical magnets mounted on catheters inevitably obstruct and disrupt the flow as it passes through the blood vessel. Synthesizing microarchitected magnets could allow for favorable flow properties while also allowing for magnetic nanoparticle sequestration; such architected magnetic materials are underexplored in the literature.<sup>3,4</sup> Traditional subtractive methods of manufacturing often obstruct these explorations due to difficulties in attaining desired feature resolutions as well as rapid modification of alloy composition; on the other hand, additive manufacturing allows for flexibility in design and composition. Hydrogel infusion additive manufacturing (HIAM) is capable of synthesizing architected metal lattices. We demonstrate HIAM derived magnetic monolithic microarchitected lattices composed of iron, iron-nickel, and copper-iron-nickel alloys in the shape of a twisted honeycomb prism with a major face diameter of 3-4 mm and a beam thickness of 40-50  $\mu\text{m}$  optimized to minimize *in vivo* flow disruption.<sup>4,5</sup> We perform multiphysics simulations of the process of magnetite nanoparticle capture and compare the resulting capture efficiency to *in vitro* magnetite nanoparticle capture experiments that demonstrated a preliminary capture efficiency of 10-20%. In addition, we apply vibrating sample magnetometry (VSM) to demonstrate coercivities in the range of 10-100 Oe and remnant magnetizations of 100 Gauss in the synthesized lattices. Powder X-ray diffraction (pXRD) shows a bulk metallic phase with body-centered cubic symmetry for the iron lattice and face-centered cubic symmetry for the iron-nickel and copper-nickel-iron lattices; internal microstructures are characterized by electron backscattered diffraction (EBSD). Finally, we determine the final phase composition via energy dispersive X-ray spectroscopy (EDS).

**Controlling Solidification Microstructure of Aluminum Alloys using Eutectic/Peritectic Reactions in Laser Powder Bed Fusion Process** Naoki Takata<sup>1</sup>, Takanobu Miyawaki<sup>1</sup>, Yue Cheng<sup>1</sup>, Asuka Suzuki<sup>1</sup>, Makoto Kobashi<sup>1</sup> and Masaki Kato<sup>2</sup>; <sup>1</sup>Nagoya University, Japan; <sup>2</sup>Aichi Center for Industry and Science Technology, Japan

In recent, laser powder bed fusion (L-PBF) has emerged as one of the most representative metal additive manufacturing techniques capable of producing metallic components by using a scanning laser beam to melt consecutive bedded-powder layers selectively. The L-PBF process enables the fabrication of aluminum (Al) alloys with superior and anomalous mechanical properties. Such unique properties were responsible for the formation of non-equilibrium microstructure and metastable phases in rapid solidification (at an extremely high cooling rate of  $10^2$ - $10^7$  K/s) during the L-PBF process. It has been reported that the L-PBF processed Al-Fe alloys with a near eutectic composition exhibited significantly refined solidification microstructures, contributing to high mechanical performance. In the eutectic reaction in rapid solidification, alloy elements could be partitioned into a liquid phase rather than a primary solidified phase, resulting in the enhanced formation of the second solid phase ( $\text{Al}_6\text{Fe}$  phase in an Al-Fe system). It is assumed that alloy elements might be partitioned into the primary solidified  $\alpha$ -Al phase (rather than the liquid phase) through a peritectic reaction in rapid solidification. The partitioned solute elements in the  $\alpha$ -Al supersaturated solid solutions would play a significant role in solid-solution strengthening (or strengthening by atomistic clusters in the  $\alpha$ -Al matrix). These insights can open an opportunity for controlling refined microstructures of Al alloys by elemental partitioning via solidification paths of eutectic or peritectic reactions in the L-PBF process. In this concept, we have selected alloy elements exhibiting different solidification paths in Al-X binary phase diagrams. Cu and Ti elements were used as third alloy elements for the Al-Fe-X ternary system in the present study. Cu element exhibits a eutectic reaction in an Al-Cu binary system (partition coefficient,  $k_{\text{Cu}}^{\text{SL}} < 1$ ) and forms  $(\text{Al,Cu})_6\text{Fe}$  phase in an Al-Fe-Cu ternary system. In contrast, Ti element exhibits a peritectic reaction in an Al-Ti binary system (partition coefficient,  $k_{\text{Ti}}^{\text{SL}} > 1$ ) and independently forms the  $\text{Al}_3\text{Ti}$  phase (no partitioning into the  $\text{Al}_6\text{Fe}$  phase). Based on the alloy element selections, we designed two ternary alloy compositions of Al-2.5Fe-2Cu and Al-2.5Fe-1.5Ti (mass%) available to the L-PBF process utilizing the thermodynamic calculations.

In this study, L-PBF processing was performed using gas-atomized ternary alloy powders with an average particle size of about 20  $\mu\text{m}$ . Rectangular alloy samples were fabricated using a ProX DMP 200 machine (3D Systems, USA) under a wide range of laser scan speeds (0.6 ~ 1.4 m/s) and laser power (102 ~ 204 W). The results of measuring the sample density provided the optimum laser parameter sets for the manufacturing of both alloy samples with high relative densities above 99 %, indicating high L-PBF processability for the Al-Fe-Cu and Al-Fe-Ti ternary alloy powders. The L-PBF processed both alloys exhibited microstructure consisting of a number of melt pools in which regions locally melted and rapidly solidified due to scanning laser irradiation. The added Cu element was partitioned into the refined  $\text{Al}_6\text{Fe}$  phase, resulting in the formation of  $(\text{Al,Cu})_6\text{Fe}$  phase with an orthorhombic structure (*oC24*). A certain amount of solute Cu (approximately 0.6 %) was detected in the  $\alpha$ -Al matrix. A higher solute Ti content above 1 % was detected in the  $\alpha$ -Al matrix of the L-PBF processed Al-Fe-Ti ternary alloy. Such a trend appeared more significantly in relatively coarsened cellular microstructures along melt-pool boundaries. These results indicate that the elemental distribution could be controlled via different solidification paths in the L-PBF process. Mechanical properties of the L-PBF processed ternary alloys will be presented and discussed in terms of Cu or Ti elemental distribution in the refined solidification microstructures.

**Effect of Scanning Strategies and Alloying Elements on Microstructure and Mechanical Properties of Tungsten Fabricated by Laser Powder-Bed Fusion** Hyeji Im, Samuel Price and Ian D. McCue; Northwestern University, United States

Laser-powder bed fusion (L-PBF), one of the metal additive manufacturing (AM) techniques, of fusion-facing materials can help overcome the challenges associated with poor machinability and difficulties in casting for complex-shaped and/or thin-walled components. Additive manufacturing experience large thermal strain during cooling and passing through its ductile-to-brittle transition. This leads to high number of cracks of additively manufactured tungsten.

Here, we report on the enhanced microstructure and mechanical properties for tungsten-based alloys by alloying titanium and iron through L-PBF. Prototype alloys were selected using CALPHAD-based thermodynamic predictions. Various scanning strategies were employed to minimize the thermal strain during printing. The addition of titanium and iron increased density as well as increased strength and ductility.

**11:45 AM SF01.03.44**

**Strengthen Composite with 3D Aligned Carbon Fiber via Embedded 3D Printing** Qiyi Chen and Rayne Zheng; University of California, Berkeley, United States

The orientation of fibrous fillers, induced by shear forces during extrusion, has been demonstrated to significantly enhance mechanical properties, electrical/thermal conductivity, microwave attenuation etc., albeit primarily in a two-dimensional (2D) x-y plane. In this study, we present a novel approach for achieving fiber alignment in a three-dimensional (3D) context, with an emphasis on the Z-direction, by utilizing embedded 3D printing techniques. This process involves the extrusion and suspension of composite inks within a viscoelastic gel medium, during which the alignment of the fiber can be controlled *via* velocity ratio, nozzle size, fiber dispersion etc. By selectively align the fiber in a 3D pattern, the mechanical properties, and conductivity can be largely improved and tuned.

SESSION SF01.08: Session VI

Session Chairs: Christian Leinenbach and Ottman Tertuliano

**How Does Nanostructural Engineering via Additive Manufacturing Open New Opportunities in Materials Design?** Rebecca A. Gallivan, Mirco Nydegger, Nikolaus Porenta, Maxence Men trety and Ralph Spolenak; ETH Z rich, Switzerland

Architecting microstructural features like grain size, porosity, and phase, pushes the limits of material properties – even breaking away from traditional property tradeoffs as exemplified by nanotwinned nanocrystalline copper which shows improved strength without the loss in ductility. Additive manufacturing has enabled new pathways for spatial control of microstructures, promising enhanced capabilities for materials design through microstructural engineering. However, these benefits are most pronounced in nanostructured materials where features of interest lie in the submicron length scales. Leveraging the nanoscale multi-material resolution of the electrohydrodynamic redox printing (EHD-RP) technique, we demonstrate new methods for nanostructuring materials in 3D geometries and explore new opportunities for nanocomposite design. Focusing on Cu, Zn, and Ag-based compositions, we will discuss the role of nanostructured features like nanoporosity, phase segregation, and oxide nanoparticle dispersion on micromechanical properties such as strength, ductility, and failure behavior in order to more fully understand the engineering opportunities afforded through complex spatial control of microstructure. As a key tool in the materials design afforded by additive manufacturing, insights into nanostructural engineering lay the foundation for fully utilizing the promise of design flexibility for advanced materials.

**1:45 PM SF01.08.02**

**Hf-Driven Microstructural Changes and Hot Cracking Prevention of Ni-Based Superalloy During Laser-Based Direct Energy Deposition** KenHee Ryou<sup>1</sup>, Hyeji Im<sup>1,2</sup>, Jiwon Park<sup>3</sup> and Pyuck-Pa Choi<sup>1</sup>; <sup>1</sup>Korea Advanced Institute of Science and Technology, Korea (the Republic of); <sup>2</sup>Northwestern University, United States; <sup>3</sup>Korea Institute of Materials Science, Korea (the Republic of)

The Ni-based superalloy for high-temperature, such as Inconel 738 is an improper alloy for additive manufacturing because of frequent hot cracking resulting from high amounts of Al and Ti. As a solution to hot cracking, the Hf has been proposed as the alloying element of Ni-based superalloy for the improvement of castability and printability. However, the detailed microstructural changes and the hot cracking prevention mechanisms were not clarified yet. The hot cracking was not observed above a certain amount of added Hf at the laser-based direct energy deposition of Inconel 738 alloy. To investigate the microstructure of Hf-added Inconel 738 and the effect of Hf on hot cracking prevention, multi-scale characterizations were conducted including various electron microscopy and atom probe tomography besides phase-field modeling. Therefore, much more active side-branching in secondary dendrite arms was observed. It is considered that it results in the easy interconnection between the dendrites. Consequently, we attributed that the prevention of hot cracking could be possible by decreasing cracking susceptibility by changing solidification sequences.

**2:00 PM \*SF01.08.03**

**Microstructural Evolution in Metallic Alloys under Additive Manufacturing Conditions** Amy Clarke<sup>1,2</sup>; <sup>1</sup>Colorado School of Mines, United States; <sup>2</sup>Los Alamos National Laboratory, United States

In metal additive manufacturing (AM), an alloy (in powder or wire form) is melted by a rapidly moving heat source. A solid layer forms upon cooling, and successive layers are built by melting and solidification to form a three-dimensional part. AM processes typically produce large temperature gradients, high solidification rates, and repeated cycles of heating and cooling. The local processing conditions experienced during AM (e.g., thermal gradients and solid-liquid interface velocities during solidification) dictate microscopic structure (i.e., microstructure) evolution. Here we visualize melt pool dynamics and solidification during simulated AM by real-time imaging (e.g., synchrotron x-ray and dynamic transmission electron microscopy) and computational modeling to link local processing conditions to microstructural evolution. We also highlight novel microstructures produced by solid-state phase transformations. A deeper understanding of solidification and solid-state phase transformations under AM conditions is needed to optimize processing parameters across AM technologies, control microstructural evolution and resulting properties, and design metallic alloys for AM.

**2:30 PM BREAK**

**3:30 PM \*SF01.08.04**

**Deciphering the Strength and Ductility of Additively Manufactured Materials** Yinmin (Morris) Wang; University of California Los Angeles, United States

Additive manufacturing (AM, aka 3D printing) involves unique processing conditions and thus offers opportunities to produce materials with tailored strength and ductility. However, the highly nonconventional microstructural features created by AM techniques impose tremendous challenges to decipher the strength scaling law and other materials properties. This talk will describe our recent effort to investigate and understand the strength and ductility of

several model materials systems including pure copper, 316L stainless steel, and medium entropy alloys. All these materials were fabricated by laser powder-bed-fusion. In all these cases, we observe a hierarchical microstructure and multiple length scales that render a myriad of strengthening mechanisms. These interesting microstructures include solidification enabled cellular structures, low-angle grain boundaries, and dense dislocations. High uniform tensile elongation is also observed in many cases due to the progressive work-hardening mechanisms triggered by these hierarchically heterogeneous microstructures. We will further elaborate the influence of residual stresses on mechanical behavior and conclude with some outstanding issues that call for future research.

#### 4:00 PM \*SF01.08.05

**From Complex Geometries to Complex Microstructures: New Opportunities for Materials Design** Matteo Seita<sup>1</sup>, Shubo Gao<sup>2</sup> and Karl Sofinowski<sup>2</sup>; <sup>1</sup>University of Cambridge, United Kingdom; <sup>2</sup>Nanyang Technological University, United States

One of the main drivers for the adoption of additive manufacturing (AM) in industry is the ability to build parts with complex—and previously unattainable—geometries. This paradigm has enabled the production of high-performance components with optimized strength-to-weight ratio, or with internal features for enhanced functionality. The disruptive potential of AM, however, goes beyond complexity of shape. Because materials are formed at the microscopic scale following a bottom-up manufacturing approach, AM offers the opportunity to make parts with complex—and previously unattainable—microstructures. Since the relationships between these complex microstructures and the resulting materials properties are difficult to unveil, this unique feature has yet to be capitalized on in current industrial applications. However, it may be the key to design the materials which will enable the applications of tomorrow. In this talk, I will present a few examples of the microstructure complexity offered by AM, including chiral crystals and alloys with controlled defect patterns. I will discuss the mechanisms that drive the formation of such complex microstructures and propose possible applications which these materials may enable.

#### 4:30 PM SF01.08.06

**Developing a Framework to Qualify Additively Manufactured Ceramics: Effect of Sintering Temperature on Feature Resolution, Shrinkage, and Flexural Properties** Lindsey Bezek and Kwan-Soo Lee; Los Alamos National Laboratory, United States

Functional applications for additively manufactured ceramic parts are currently limited by both material constraints and knowledge of process-structure-property relationships. One challenge for developing new ceramics for additive manufacturing (AM) is determining a post-process debinding and sintering strategy that yields parts with sufficient mechanical strength while mitigating defects and unpredictable shrinkage. This work investigates how maximum sintering temperature (varied between 900°C and 1300°C) affects material and mechanical properties of parts fabricated using a commercial silica-based resin and the vat photopolymerization AM process. A custom test artifact was designed to probe dimensional accuracy and survivability of features of different sizes, shapes, and orientations. The shrinkage of cubes with 1 cm sides was generally proportional to sintering temperature and did not exceed 18% in any dimension. The shrinkage was more isotropic up to 1100°C, but at higher temperatures, Z shrinkage was typically ~30% higher than X and Y shrinkage. Parts with higher maximum sintering temperatures experienced higher flexural strength and lower strain at break in three point bend testing. Regardless of maximum sintering temperature, most parts exhibited some degree of cracking or delamination. X-ray computed tomography was used to probe internal porosity, and several voids were observed even when sintered to 1300°C. Fundamental understanding of how sintering affects parts' structure and properties will enable development of a framework to qualify ceramic AM materials and processes. This knowledge will facilitate predictable part performance, helping to ensure reliability of future parts for functional applications.

#### 4:45 PM SF01.08.07

**Design of Alloys for Green Body Printing and Sintering** Yannick Naunheim and Christopher A. Schuh; Massachusetts Institute of Technology, United States

Additive manufacturing is an emerging pathway to produce metallic materials, usually by processing a well-established commercial alloy via a powder-based approach. In this talk, we invert this approach: we selectively tailor and adjust the chemical composition of an alloy powder to make it suitable for rapid low-temperature solid-state consolidation. Acceleration of the consolidation process is based on two mechanisms: Nanocrystallinity achieved by high energy ball-milling accelerates diffusion at low temperatures, while phase evolution through diffusional demixing and remixing of a second solute-rich phase can encourage the formation and growth of interparticle necks upon heating. Computational thermodynamics provide the basis for the alloy design process to take maximum advantage of these effects. Sintered and heat treated microstructures and their mechanical properties are presented and discussed for the case of nickel-rich alloys.

SESSION SF01.09: Session VII  
Session Chairs: Zachary Cordero and Wendy Gu  
Thursday Morning, November 30, 2023  
Sheraton, Second Floor, Republic B

#### 8:00 AM \*SF01.09.01

**Merging the Computational and Experimental Gravity Poles of the Alloy Development Process: From Alloy Design to *In-Situ* Alloying of Custom Al Alloys for Laser Powder Bed Fusion** Federico Bosio<sup>1</sup>, Giuseppe Del Guercio<sup>1</sup>, Chinmay Phutela<sup>1</sup>, Marco Simonelli<sup>2</sup> and Nesma Aboulkhair<sup>1,2</sup>; <sup>1</sup>Technology Innovation Institute, United Arab Emirates; <sup>2</sup>The University of Nottingham, United Kingdom

Recent progress in metal additive manufacturing (AM) emphasised the need to develop next-generation alloys leveraging the non-equilibrium dynamics of rapid cooling processes. This raised the awareness among the leading industrial players of the AM scene that boosting the material palette for AM is the way to unlock the full potential of additive manufacturing in vital application sectors, such as aerospace, energy, and defence. In fact, functional parts with enhanced strength, good electrical and thermal resistance, and low density are often targeted for these critical applications, and the current alloys in the market might not meet these requirements. Therefore, driven by these motivations, novel aluminium alloy grades for use in Laser Powder Bed Fusion (LPBF) are currently sought.

An industrially relevant commercial Al alloy system used in targeted industrial sectors was selected in the alloy design stage. The chemical composition of such alloy was tweaked by adding a reinforcing transition metal (TM) element that enhanced the master alloy's strength by multiple strengthening mechanisms. Computational design tools based on the CALPHAD approach enabled the chemical process window's fast selection for the new aluminium grades. The solidification trajectories of various TM-dosed Al grades were assessed for conditions deviating from the equilibrium using the Scheil-Gulliver

assumptions to predict the alloy's precipitation sequence, crack sensitivity, and printability.

The computational predictions were empirically corroborated with targeted experiments involving arc-melted buttons' production in generating the corresponding Al-TM master alloys. The microstructure resulting from the fast-cooling rates of the PBF-LB process was simulated by surface remelting in an industrial printer. Hierarchical microstructure investigations conducted at all length scales from macro- to nano showed a satisfactory level of correlation with computational predictions, and the final transition metal element amount was eventually established based on considerations involving strengthening mechanisms, hot crack sensitivity, PBF-LB processability, and heat-treatment design strategies.

The developed Al-TM alloy was then manufactured by laser powder bed fusion in-situ alloying achieving near fully dense samples. At this stage, nano-particles were introduced in the newly developed metal matrix to further enhance strength and its thermal stability at temperatures higher than 300 degrees celsius. The process-structure-performance relationships of the Al-xTM alloy with and without nanoparticle additions were deeply studied at the possible environmental working conditions (RT and elevated temperatures).

The outcomes of this research prove that new high-strength Al alloy compositions can be established by exploring unconventional design spaces enabled by the fast-cooling rates of additive processes. The combined computational-experimental method utilised in this study provided a fast and robust guidance towards the development of printable high-strength Al alloys for Laser Powder Bed Fusion.

### 8:30 AM \*SF01.09.02

**Directional Recrystallization of Additively Manufactured Superalloys** Zachary C. Cordero; Massachusetts Institute of Technology, United States

Metal additive manufacturing processes can create intricate components that are difficult to form with conventional processing methods; however, the as-printed materials often have fine grain structures that result in poor high-temperature creep properties, especially compared to directionally solidified materials. Here, we address this limitation in an exemplary additively manufactured Ni-base superalloy by converting the fine as-printed grain structure to a coarse columnar one via directional recrystallization. The present results demonstrate how directional recrystallization of additively manufactured Ni-base superalloys can achieve large columnar grains with enhanced creep resistance, manipulate crystallographic texture to minimize thermal stresses expected in service, and functionally grade the grain structure in net-shaped parts to selectively enhance fatigue or creep performance.

### 9:00 AM SF01.09.03

**A Process-Structure Correlation Between the Beam Crossing Interval and the Size of Meltpool in the Laser Powder Bed Fusion Process** Chang-Eun Kim<sup>1</sup>, Clara L. Druzgalski<sup>1</sup>, Alexandra Loaiza<sup>2</sup>, David F. Bahr<sup>2</sup>, Gabe Guss<sup>1</sup>, Vincenzo Lordi<sup>1</sup>, Patrick G. Allen<sup>1</sup>, Rebecca J. Dylla-Spears<sup>1</sup> and Manyalibo Matthews<sup>1</sup>; <sup>1</sup>Lawrence Livermore National Laboratory, United States; <sup>2</sup>Purdue University, United States

The laser powder bed fusion process creates a unique microstructure that impacts the property of printed parts. We asked whether the time interval between neighboring meltpool track was a critical parameter that dictates the process-structure relationship. We used metallography, machine learning, and laser toolpath trajectory analyses to collect the data needed to establish a correlation. We found a clear negative correlation between the size of meltpools and the proposed timing descriptor, as 'beam crossing interval (BCI)'. The observed correlation paves a way to enable a data-driven model to control the microstructure of metal part printed by the laser powder bed fusion. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344.

### 9:15 AM SF01.09.04

**Predicting Defect Formation in Additive Manufacturing using Inferences and Statistical Modeling** Erika I. Barcelos, Mohommad Redad Mehdi, Kristen J. Hernandez, Pawan K. Tripathi, Hein Htet Aung, Laura Bruckman, Anirban Mondal and Roger H. French; Case Western Reserve University, United States

Datasets originated from experimental research tend to be small. Performing experiments is expensive, time consuming and often the available resources are limited. Therefore, developing a framework to design, plan and optimize experiments is essential for a more efficient, reliable and cost-effective for experimental research. Statistical Learning approaches represent a promising alternative to address the challenges associated with limited and sparse experimental datasets. It consists of applying modeling approaches to explore and understand the data and relationships via statistical and exploratory data analysis. Laser Powder Bed Fusion (LPBF) is one of the most common Additive Manufacturing methods used in the fabrication of metal parts. The process can generate highly customizable parts having complex shapes and geometries with the generation of minimum waste, which represents an important benefit over traditional subtractive technologies. Nonetheless, it is highly susceptible to defect formation due to the complexity of the printing process and non optimal process parameters. In this work, we explore different statistical learning approaches and evaluate their capabilities in predicting defects in a LPBF experiment. In-situ and ex-situ data from pyrometry, radiography and machine parameters were integrated, FAIRified and ingested into our CRADE/HPC distributed environment. Feature selection and importance ranking were performed using correlation analysis and network structural Modeling (netSEM). Different Statistical Learning approaches were evaluated including Robust Regression based methods and Generalized Additive Modeling (GAM). These techniques were applied for predictions and inference, i.e. understanding and quantifying relationships between variables. This work brings a new perspective to experimental research that generates small datasets. It shows that even when there is a limited number of available data points, statistical analysis can be applied for an accurate and reliable data analysis and statistical modeling can be successfully used to estimate and predict future outcomes.

### 9:30 AM BREAK

### 10:00 AM \*SF01.09.05

**3D Nanoprinting of Functional Crystalline Materials** Ji Tae Kim; The University of Hong Kong, Hong Kong

Can 3D printing become an innovative strategy for manufacturing electronic and photonic integrated circuits? A key prerequisite is to acquire high-quality crystalline functional materials that are 3D printable at the nanoscale. Here, we present our solvent-engineering-assisted 3D printing method that enables freeform, nanoscale structuring of diverse crystalline materials. The method exploits a femtoliter ink meniscus to guide material crystallization in three dimensions with the aid of in-situ solvent engineering, fabricating freestanding nanostructures with programmed shape, composition, and crystallinity. This scheme has pioneered new 3D printing materials that can be used for integrating electronic and photonic circuits, including metal halide perovskites [1-3], peptides [4,5], metal-organic frameworks [6], and nanoparticle clusters [7]. Successful demonstrations of 3D-printed real devices such as bright nano-displays [8], lasers, anticounterfeiting labels [2,3], biosensors [7], and micro-thermometers [9] have proven the practicality of our method. In this talk, I will discuss our experimental/theoretical studies on how to develop the nanoscale 3D printing method, and the prospects of our work for potential applications in IC (integrated circuit) manufacturing.

**3D Printed Schwarzites: From Pure Mathematics to Macroscale Applications** Levi C. Felix<sup>1</sup>, Raphael Tromer<sup>1</sup>, Cristiano F. Woellner<sup>2</sup>, Varlei Rodrigues<sup>1</sup>, Pulickel Ajayan<sup>3</sup>, Chandra S. Tiwary<sup>4</sup> and Douglas S. Galvao<sup>1</sup>; <sup>1</sup>State University of Campinas, Brazil; <sup>2</sup>Federal University of Parana, Brazil; <sup>3</sup>Rice University, United States; <sup>4</sup>Indian Institute of Technology, India

Additive manufacturing, sometimes called 3D Printing, can create structures of great complexity. It has been exploited in many areas, in particular, in materials science.

In this work, we present a comprehensive multi-scale (from atomic to macroscale 3D Printed models) study of the structural and mechanical properties of some Schwarzites families. Schwarzites are crystalline porous carbon structures with negative Gaussian curvatures. They were proposed by Mackay and Terrones [1] and name Schwarzites after the German mathematician Hermann Schwarz and his works on triple periodic minimum surfaces (TPMS).

We have carried out DFT and molecular dynamics simulations of atomic models. These geometrically optimized models were used to create corresponding macroscale models that were 3D Printed using fused deposition modeling (FDM). We have used different polymers (acrylonitrile butadiene styrene (ABS) and polylactic acid (PLA)).

The MD and 3D Printed results for the profiles of the stress-strain curves are quite similar, showing that the deformation mechanisms are scale independent and are dominated by topological features.

The 3D Printed models were successfully tested for macroscale applications, such as large deformations sensors and filters for water remediations of micro and nano plastics [4,5]

**Sustainable Graphene-Based Inks for Screen Printable Piezoresistive and Thermoresistive Sensing** Miguel Franco<sup>1</sup>, A Motealleh<sup>2</sup>, Carlos Costa<sup>1</sup>, L Hilliou<sup>1</sup>, Nikola Perinka<sup>3</sup>, Clarisse Ribeiro<sup>1</sup>, Julio Viana<sup>1</sup>, Pedro Costa<sup>1</sup> and Senentxu Lanceros-Mendez<sup>3,4,1</sup>; <sup>1</sup>University of Minho, Portugal; <sup>2</sup>LayerOne AS, Norway; <sup>3</sup>BCMaterials, Basque Center for Materials, Applications and Nanostructures, Spain; <sup>4</sup>Ikerbasque, Basque Foundation for Science, Spain

Graphene-based conductive inks are increasingly being used for printed and conformable electronics. In the present work, rGO has been used both in pristine form and doped with nitrogen (N-rGO), the latter allowing to increase the electrical conductivity.

Based on the aforementioned graphene types, polymer-based conductive inks have been developed based on cellulose or polyvinylpyrrolidone (PVP) as polymer binders and water or dihydrolevoglucosenone (Cyrene) as green solvents, respectively.

Screen-printable inks have been optimized in terms of viscosity and adhesion properties, leading to printed films with sheet resistance up to 1 kΩ sq<sup>-1</sup>. Further, graphene:PVP composite inks are also biocompatible and nontoxic, being suitable for biomedical applications.<sup>1</sup>

The developed graphene-based inks have been applied by screen-printing for the development of both conductive track and sensing elements. For the latter, thermoresistive temperature and piezoresistive force and deformation sensors have been developed, as well as multitouch capacitive sensing devices.<sup>2,3</sup>

**Site- and Shape-Selective Synthesis of Nanocale Heterostructures Based on Combinations of Direct-Writing and Nano-Micro-CVD** Sven Barth, Fabrizio Porrati and Michael Huth; Goethe University Frankfurt, Germany

Recent advancements in additive manufacturing enable the fabrication of free-shaped 3D objects with very high accuracy using focused electron beam- and focused ion beam-induced deposition (FEBID and FIBID).[1] We demonstrate the formation of 3D core-shell heterostructures by combination of direct-written 3D FEBID scaffolds and the successive site-selective chemical vapor deposition (CVD). In particular, conductive 3D nanobridges are printed by FEBID and used as resistors allowing deposition induced by Joule heating. The successful combination of both approaches is demonstrated using two material systems of specific physical properties.[2] The fabrication of complex 3D core-shell heterostructures promises to add new functionalities by combining free-shaped 3D nanostructure writing with thin film deposition of materials with different properties. Specifically, shape-dependent and topological physical properties can be investigated by this highly adaptable approach.

**3D Printing of Nanomaterial-Based Devices with Metamaterial-Inspired Near-Field Electromagnetic Structure** Samuel Hales<sup>1</sup>, Jared Anklam<sup>1</sup>, Yang Xin<sup>2</sup>, Cordelia Latham<sup>1</sup>, Tian Xi<sup>2</sup>, Derrick Wong<sup>1</sup>, LeiBin Li<sup>1</sup>, John Ho<sup>2</sup> and Yong Lin Kong<sup>1</sup>; <sup>1</sup>University of Utah, United States; <sup>2</sup>National University of Singapore, Singapore

The ability to 3D print nanomaterials enables the creation of freeform architecture and devices with an unprecedented level of functional integration. However, the possible material integration and geometrical configuration remain limited by the inability to selectively anneal printed nanomaterials, especially on temperature-sensitive substrates. Indeed, thermal annealing is a critical process that dictates 3D printed device performance by (1) merging otherwise disconnected nanomaterials, (2) reducing defects and interfaces, (3) removing polymeric additives, and (4) improving contact between printed layers. Here we demonstrate the ability to selectively and locally anneal 3D printed nanomaterials *in situ* on a broad range of temperature-sensitive substrates by focusing near-field electromagnetic waves to submillimeter resolution using a metamaterial-inspired near-field electromagnetic structure (Meta-NFS). This near-field electromagnetic wave printing (NFP) enables exceptional control of printed nanomaterial annealing parameters, allowing the creation of spatially freeform microstructure where the electronic and mechanical properties can be locally programmed. We envision that NFP significantly broadens the possible class of materials compatible with an additive manufacturing process, enabling the creation of hybrid multi-functional constructs and the printing of functional electronics even on temperature-sensitive substrates.

**3D Printing with a 3D Printed Digital Material Filament for Programming Functional Gradients** Sang-Joon Ahn, Howon Lee and KyuJin Cho; Seoul National University, Korea (the Republic of)

Three-dimensional (3D) printing attracts growing attention as a promising method for manufacturing functionally graded materials (FGMs). Fused deposition modeling (FDM) 3D printing is widely available, but due to its simple process, creating spatial gradation of diverse properties using FDM is challenging. Here, we present a 3D printed digital material (DM) filament that is structured towards 3D printing of FGMs, utilizing only a readily available FDM printer and filaments. The DM filament consists of multiple base materials combined with specific concentrations and distributions, which are 3D printed using FDM process. When the DM filament is supplied to the same printer, its constituent materials are homogeneously blended during extrusion, resulting in the desired properties in the final structure. This blended FDM (b-FDM) printing enables spatial programming of material properties in extreme variations, including mechanical strength, electrical conductivity, and color. The b-FDM with DM filaments can be readily adopted to any standard FDM printer, enabling low-cost production of FGMs.

**Thermoformable All-Ceramics Through AM and Particle Assembly** Randall M. Erb, Jason Bice and Echo St. Germain; Northeastern University, United States

Thermoforming processing, traditionally reserved for thermoplastic polymers and sheet metals, has been extended here to boron-based all-ceramics. Specifically, sintered boron nitride composite sheets manufactured via a combined vibration and tape-casting photopolymerization process exhibited highly oriented microstructure which allowed these preform sheets to flow as viscous Bingham pseudoplastics during compression molding. These sintered all-ceramic preforms are thermoformed into thin, complex parts with features down to 200  $\mu\text{m}$ . Further, a new workflow is leveraged to generate bespoke all-ceramic heat spreaders that can be press-fit onto printed circuit boards and outperform metal heat sinks as a low-profile thermal management solution. This work offers a route for other all-ceramics that may be thermoformed through first fabricating pre-forms with highly-ordered anisotropic microstructures.

**Photo-Polymerizing Heterogeneities to Self-Shape Ceramics** Zizhen Ding<sup>1</sup>, Hala Zreiqat<sup>2</sup> and Mohammad Mirkhalaf<sup>1</sup>; <sup>1</sup>Queensland University of Technology, Australia; <sup>2</sup>The University of Sydney, Australia

Ceramics with complex shapes are desired in many applications, including architectural design and construction, protective systems, molds for gas turbines, and biomaterials. 3D printing through photopolymerization is amongst the most powerful approaches to make ceramics with complex shapes. However, these procedures are usually difficult to implement, are time-consuming, require further processing, and result in material waste. To address these challenges, we developed a simple, fast, and low-waste self-shaping procedure to make ceramics with complex shapes. The approach draws on a principle that the amount of shrinkage a ceramic undergoes during sintering is a function of the concentration of particles in the ceramic resin: the higher the concentration, the less the shrinkage. By printing components with inhomogeneous concentrations of particles, the parts with higher concentrations shrink less during sintering, resulting in well-controlled shape changes. This approach does not require extensive instrumentation and can be used for a wide range of ceramics. We then developed a material- and scale-independent mechanical model, which predicted the shape changes accurately. The model can be used as a tool to design the self-shaping experiments, potentially for a large variety of ceramics and glasses.

**2:15 PM \*SF01.10.03**

**High-Throughput Printing of Combinatorial Materials from Aerosols** Yanliang Zhang; University of Notre Dame, United States

The development of new materials and their compositional and microstructural optimizations are essential to next-generation technologies such as clean energy and environmental sustainability. However, materials discovery and optimization have been a frustratingly slow process. The Edisonian trial-and-error process is time-consuming and resource-inefficient, particularly when contrasted to vast materials design spaces. While traditional combinatorial

deposition methods can generate material libraries, it suffers from limited material options and inability to leverage immense breakthroughs in nanomaterials synthesis. Here we present a high-throughput combinatorial printing (HTCP) method capable of fabricating materials with compositional gradients with microscale spatial resolution. The *in situ* "mix and print" in the aerosol phase allows instantaneous tuning of the mixing ratio of a broad range of materials on the fly, which is an important feature unobtainable in conventional multi-materials printing using feedstocks in liquid/liquid or solid/solid phases. We demonstrate a variety of high-throughput printing strategies and applications in combinatorial materials discovery, functional grading, and chemical reaction, enabling materials explorations of doped chalcogenides and compositionally graded materials with gradient properties. The versatile aerosol based HTCP enables universal printing and integration of a broad range of materials including metals, semiconductors, dielectrics, as well as polymers and biomaterials, leading to facile fabrication of multifunctional and flexible/wearable devices for energy conversion/storage, sensing, and health monitoring. The ability to combine the top-down design freedom of additive manufacturing with bottom-up control over the local material compositions promises compositionally complex materials inaccessible via conventional manufacturing approaches. The fabrication freedom and data-rich nature of HTCP along with machine learning and artificial intelligence guided design strategies is expected to accelerate the discovery and development of a broad range of materials with intriguing and unprecedented properties for emerging applications.

#### 2:45 PM SF01.10.04

**High-Throughput Printing and Post-Processing Approaches for Realization of Novel Flexible Magnetoresistive Sensors** Mykola Vinnichenko<sup>1</sup>, Clemens Voigt<sup>1</sup>, Eduardo Sergio Oliveros Mata<sup>2</sup>, Sindy Mosch<sup>1</sup>, Yevhen Zabala<sup>2</sup>, Morris Ott<sup>3</sup>, Marco Fritsch<sup>1</sup>, Thomas Preussner<sup>3</sup> and Denys Makarov<sup>2</sup>; <sup>1</sup>Fraunhofer IKTS, Germany; <sup>2</sup>Helmholtz-Zentrum Dresden-Rossendorf, Germany; <sup>3</sup>Fraunhofer FEP, Germany

The research in the field of additive manufacturing is increasingly focusing on realization of electrically conductive interconnects, passive and active components such as resistors, capacitors, inductors, and application-specific electronic devices [1]. The additive manufacturing technologies are offering high design flexibility and high throughput, are material saving and have a great potential of the production cost reduction. The flexible printed magnetoresistive (MR) sensors based on various physical principles are novel components in printed electronics demonstrated in recent years using additive manufacturing methods [2]. However, the large-scale manufacturing of these sensors and their industrial uptake are hampered by the lack of commercially available magneto-resistive inks and scalable post-printing processing methods to enable optimal functionality of the components. Our work is focused on establishing a fully additive approach for realization of flexible MR-sensors and their arrays. We address the complete process chain from MR-material particles selection/preparation, through the ink formulation, printing and post processing of the structures, their characterization and demonstration of defined use cases. Two types of materials were used to formulate MR-inks: i) commercially available  $\mu\text{m}$ -size spherical Bi particles showing non-saturating large magnetoresistance (LMR), and (ii) permalloy (Py) flakes of own development showing anisotropic magnetoresistance (AMR). In the latter case, a method was developed to ensure a production of the particles with 100 nm thickness and in-plane dimensions of a few micrometers with a yield of approx. 2.7 g/day which can be further upscaled. It is based upon large-area PVD deposition of the corresponding materials as thin films onto glass substrates coated with a special sacrificial layer, following lift-off process of the thin films, and their ultrasonic milling. Based on these powder materials, screen-printing compatible inks were formulated with solid fraction as high as 82-90 wt.% (Bi particles) and 21 wt.% (Py flakes). Electrical contacts were realized either using commercially available or IKTS-proprietary Ag inks. Different layouts of LMR and AMR sensors were created and printed on flexible polymer foils (PET, PI).

The core of our approach is a combination of scalable printing methods (screen-, dispenser-, inkjet-printing) with high power diode laser post-processing. The line-shaped laser beam was generated by microoptically optimized high-power diode laser array operating in the near-infrared spectral range using continuous wave mode. In contrast to standard furnace heating this approach enables treatment on the millisecond time scale, preventing temperature-induced damages of sensitive substrates and permitting selective sintering of printed films in air. The laser beam was swept along the printed structures to remove the organic phase and sinter particles of the magnetoresistive material. Depending on the type of material, the dwell time was varied from 3 to 20 ms and the laser intensity from 0.8 to 2.0 kW/cm<sup>2</sup>. In case of Bi-based LMR material, the sensors with a strong linear response within a broad magnetic field range 100 mT - 7 T were achieved. The resulting magnetic field sensors based on Py flakes showed a very promising AMR effect in the range of 0.5% at much lower magnetic fields of 2-3 mT. The applicability of the sensors and their arrays for contactless switching and flexible human-machine interfaces is demonstrated. The relationship between the sensor manufacturing parameters and the resulting structure and properties is analyzed to define pathways to further improvement of their performance.

**Towards Inline Property Prediction in Material Extrusion-Fabricated Structures with Limited Information** Amy Peterson, David Kazmer, Ahmed Adisa and Austin Colon; University of Massachusetts Lowell, United States

Modeling polymer material extrusion additive manufacturing (AM) for prediction of mechanical properties requires substantial training data, and many modeling approaches are computationally intensive. This work investigates measurement and modeling approaches to enable inline property prediction in filament-fed material extrusion AM, commonly referred to as fused filament fabrication (FFF). We explore what kinds and how much information is necessary to create an acceptably accurate model, and to output accurate predictions. We also performed detailed analysis of the types of fracture that occurred across a range of processing conditions and relate this mechanical behavior to print conditions. This work contributes to efforts towards higher reliability, higher performance additively manufactured parts.

#### 4:00 PM SF01.10.08

**3D Printed BioPE Textile for Low Temperature Applications** Volodymyr Korolovych, Duo Xu, Amy Huynh and Svetlana V. Boriskina; Massachusetts Institute of Technology, United States

The developments in polymer material synthesis and manufacturing processes are re-shaping the textile industry, ushering in a new textile manufacturing paradigm, namely implementation of digital and sustainable manufacturing approaches, such as fused deposition modelling (FDM) 3D printing. In recent years, 3D printing of polymers on textiles has shown a lot of potential to optimize complex designs, automate manufacturing as well as to develop new textile functionalities and aesthetic elements. Most popular polymers printed on textiles include polylactic acid, acrylonitrile butadiene styrene, nylon, polycarbonate, glycol modified poly-ethylene terephthalate, and thermoplastic polyurethane. They are usually printed on a dissimilar textile material, which leads to poor adhesion between the printed parts and the fabric. In addition, poly-material nature of the state-of-the-art 3D printed textiles often makes it impossible to separate and reclaim their ingredients at the end of the product lifecycle. Furthermore, conventional 3D printable polymers are typically stiff and have poor thermal management properties, which may cause thermo-physiological wear discomfort of 3D printed textiles. Overcoming these challenges will significantly improve wear comfort, sustainability of 3D printed textile and drastically expand their functionality.

This work aims to develop bioderived, low-carbon-footprint monomaterial 3D printed textile platform for low temperature applications in defense and

aerospace industries. We explore the role of the nanostructure of bioderived polyethylene (bioPE) 3D printed structures in engineering their tensile and elastic performance at extremely low temperatures (down to  $-70\text{ }^{\circ}\text{C}$ ). A range of bioPE yarns and textile with various 3D printed patterns and different nano-scale structure has been fabricated via a combination of a scalable fiber melt-extrusion method and fused deposition modelling. These yarns and textiles have been characterized by their tensile and viscoelastic performance, as well as classified according to their meso- and nanoscale structure. Wide angle (WAXS) and small angle (SAXS) X-ray scattering techniques confirmed that by precise engineering of bioPE material nanostructure, we can tune the material crystallinity degree from  $\sim 60\%$  to  $\sim 80\%$  and to achieve high degree of crystalline domain orientation along the fiber axis. This tunability of the fiber nanostructure translates into tunable elongation at break (up to  $\sim 100\%$ ) and tensile strength (up to  $\sim 180\text{ MPa}$ ) values of the bioPE yarns at  $-70\text{ }^{\circ}\text{C}$ . We further show that mono-material bioPE 3D printed textiles exhibit great adhesion between the printed parts and the fabric, together with high flexibility and durability. In addition, bioPE 3D printed textiles are fully recyclable into a high-value and utility material stock. Overall, our work provides novel route towards development of lightweight, multifunctional bioPE 3D printed textiles with potential applications from uniforms and wearables to aerospace suits, while offering lower environmental footprint in production and full mechanical recyclability.

This work was supported by the Advanced Functional Fabrics of America (AFFOA) and the US Army Research Office. We thank Brandon Henry, Michael Lampkin, Tony DeLaHoz and Jeff Haggard from Hills Inc. for help with the PE yarns fabrication and Braskem for providing bio-derived PE resins. A.H. was supported by NSF GRFP. Useful discussions with Leslie Yan, Michael Rein, and Michelle Farrington are gratefully acknowledged. We also thank Steven Kooi for his help with equipment installation.

#### 4:15 PM SF01.10.09

**Infrared Scanning Near-Field Spectroscopic Studies of Self-Assembled Nanostructures Based on Photo-Crosslinkable Block Copolymers** Nadine von Coelln, Britta Weidinger, Christian Huck, Irene U. Wacker, Rasmus Schroeder, Eva Blasco and Petra Tegeger; Heidelberg University, Germany

Block copolymers, i.e., chemically distinct polymer blocks which are covalently bond, are known for their ability to self-assemble into a variety of morphologies on the nanometer scale.<sup>[1]</sup> The self-assembly of block copolymers has been extensively investigated for 2D films,<sup>[2,3]</sup> however, less attention has been paid to 3D bulk morphologies as well as light-based 3D printed microstructures. To achieve long-range ordered samples in thermodynamic equilibrium, in this work, 3D bulk morphologies were prepared via solvent annealing and 3D printed microstructures were fabricated from pre-self-assembled block copolymer inks.

Infrared scanning near-field optical microscopy (IR-SNOM) offers the unique possibility of infrared chemical imaging and spectroscopy with a spatial resolution down to  $\sim 20\text{ nm}$ .<sup>[4]</sup> When irradiating a well-defined diblock copolymer consisting of polystyrene and a methacrylate-based copolymer decorated with photo-crosslinkable units at an independently addressable absorption band of a polymer block, chemical imaging of the blocks' nano-ordered spatial arrangement is possible.

Here, the internal nanostructure of self-assembled 3D bulk morphologies with lamellar nanostructures is studied by means of IR-SNOM. When selectively exciting each polymer block, a switch of the relative optical phase, related to the local absorption, is observed, revealing a strong phase segregation via spectroscopic contrast. A successful correlation with scanning electron microscopy (SEM) measurements, performed after post-staining with ruthenium tetroxide, furthermore demonstrates, that ruthenium tetroxide creates a specific metal stain for polystyrene. These studies are extended to cylindrical nanostructures as well as two-photon laser printed microstructures exhibiting complex geometry and hierarchically nano-ordered structures.

#### 8:15 AM SF01.11.01

**Influence of Diffusion on Print Fidelity in Vat Polymerization 3D Printing—Acrylate-Chain vs Thiolene-Step Growth Chemistry** Bhavana Deore<sup>1</sup>, Chantal Paquet<sup>1</sup>, Hendrick deHaan<sup>2</sup>, Thomas Lacelle<sup>1</sup>, Laura Dickson<sup>1</sup>, Katie Sampson<sup>1</sup> and Yujie Zhang<sup>1</sup>; <sup>1</sup>National Research Council Canada, Canada; <sup>2</sup>Ontario Tech University, Canada

3D printing is an emerging additive manufacturing technology poised to transform both design and manufacturing due to its ability to customize design and generate structural complexity not possible using traditional manufacturing processes. Light-based 3D printing techniques, such as SLA, DLP or tomographic printing, use patterned light to trigger polymerizations within a volume of a photorein and thus producing 3D objects. The process of printing in a vat of resin using light that varies temporally and spatially creates dynamics within the resin that ultimately influences properties of the printed part. In this work, we present how concentration gradients and changes in miscibilities during printing causes phase separation and diffusion of species that effect the printing process. The dynamics created by 3D printing are complex with factors governing the extent of the diffusion of inhibiting and reactive species include the geometry and dimensions of the printed features, the viscosity of the resin, rates of polymerization and gelation point. These factors are in turn governed by the formulation and on the type of polymerization i.e., step growth vs. chain growth. By tuning the formulations, changes in diffusivity, viscosity and gelation rates can be control and therefore allow control over phase separation or deviations from nominal print dimensions. The results are supported by modeling allowing us to identify the underlying mechanism behind each.

#### 8:30 AM SF01.11.02

**On-Demand Printing of Metallic Polymer Composite Microstructures via Hybrid 3D Printing** Yeowon Yoon, Youngwoo Lee, Yang Xu and Yong Chen; University of Southern California, United States

On-demand printing of microstructures using polymer composites can enhance the materials' functionality with tailored properties. Especially metallic polymer composites have been used in a wide range of applications, including electronics, energy solutions, soft robotics, and four-dimensional printing

due to their mechanical strength, high electrical/thermal conductivity, and ferromagnetic behavior. However, current manufacturing challenges limit the concentration of the filler materials in these metallic polymer composites to be low so low viscous slurry can be used in printing. In this study, a novel hybrid additive manufacturing (AM) process is developed to print a highly concentrated metallic polymer composite with over 80% metal particles within the polymer matrix. In this hybrid AM process, highly viscous slurry (~400,000 mPa·s) is printed using DDW, and metal (Iron)-polymer composites are fabricated at designed locations in both discrete and continuous manner so functional material portions can be well defined. In addition, DLP-based VPP is used to print bulk matrix portions using photopolymers to build intricate matrix structures at a fast building speed. An extensive range of composite inks including various photopolymers can be employed in this hybrid 3D printing process to fabricate functional structures with adjustable mechanical properties and multifunctional characteristics. The printing parameters of this hybrid process have been studied, including nozzle height, dispensing speed, and different surface conditions. Using ferromagnetic particles (44 μm) with soft and elastic photopolymer resins, magnetic-actuated grippers were fabricated to demonstrate design functions. The developed 3D printing approach offers a promising route to manufacture metallic polymer composites with tunable magnetic and mechanical properties, which could have potential applications in soft-form sensors, actuators, and biomedical devices.

#### 8:45 AM SF01.11.03

**Strategies for Integrating Metal Nanoparticles with Two Photon Polymerization Process** Jisun Im<sup>1</sup>, Liu Yaan<sup>2,3</sup>, Qin Hu<sup>2</sup>, Gustavo Trindade<sup>4,2</sup>, Ricky Wildman<sup>2</sup>, Richard Hague<sup>2</sup>, Lyudmila Turyanska<sup>2</sup> and Christopher Tuck<sup>2</sup>; <sup>1</sup>University of Warwick, United Kingdom; <sup>2</sup>University of Nottingham, United Kingdom; <sup>3</sup>University of Exeter, United Kingdom; <sup>4</sup>National Physical Laboratory, United Kingdom

A femtosecond laser-induced two photon polymerization (2PP) is a high-resolution additive manufacturing technology that allows for the creation of highly precise and complex microstructures with submicron resolution. This technology has revolutionised the creation of micro- and nano-scale structures, leading to the emergence of new products and technologies. However, the limited availability of functional materials, especially metal nanoparticles that are suitable for use in this process, hinders the technology's full exploitation. Here we propose three complementary strategies for the integration of metal nanoparticles (MeNPs) with 2PP processes to fabricate nanoparticle-polymer composites and metal nanoparticle-decorated surface patterns in microscale: 1) in-situ formation of MeNPs through a single-step photoreduction process; 2) integration of pre-formed MeNPs into 2PP resin, and 3) site-selective MeNPs decoration of 3D 2PP structures. We demonstrate successful fabrication of high-fidelity structures with incorporated MeNPs and provide detailed morphological and compositional analysis including advanced time-of-flight secondary ion mass spectrometry (ToF-SIMS) mapping results. These complementary strategies open up a broad range of prospective applications from metamaterials and nano/micro-photonics to optoelectronics and biomedicine.

#### 9:00 AM SF01.11.05

**Interpenetrating Networks with Tuned Thermal and Mechanical Properties by Multiphoton Lithography** Paulina Szymoniak<sup>1</sup>, Dorothee Silbernagl<sup>1</sup>, Zeynab Tavasolyzadeh<sup>1</sup>, Heinz Sturm<sup>1,2</sup> and Ievgeniia Topolniak<sup>1</sup>; <sup>1</sup>Federal Institute for Materials Research and Testing (BAM), Germany; <sup>2</sup>Technical University of Berlin, Germany

Multiphoton lithography (MPL) has recently attracted significant research interest as a versatile tool capable of fabricating 2D and 3D micro- and nanoscopic features with high spatial resolution. The integrity of MPL microstructures, or their ability to respond to external stimuli, is of critical importance. Often, the mechanically flexible micro-objects are expected to be capable of shape morphing, bending, or other motion to ensure their functionality. However, achieving the desired properties of MPL-manufactured micro components for a specific application still remains challenging. In this work, we present new MPL materials based on epoxy-acrylate interpenetrating networks (IPNs). We aim at fabrication 3D microstructures, whose properties can be easily tuned by varying the ratio of the IPN components and fabrication parameters. The studied mixtures consist of polyethylene glycol diacrylate (PEGDA) and cycloaliphatic epoxide functional groups. Consequently, tryarylsulfonium salt and cyclopentanone photoinitiator tailored for MPL were used to ensure cationic and radical polymerization, respectively. The resulting library of 3D microstructures was investigated for their thermal and mechanical properties using highly sensitive space-resolved methods. For the first time, we were able to evaluate the glass transition behavior of 3D MPL microstructures using fast scanning calorimetry. The influence of both IPN composition and fabrication parameters on glass transition temperature and material fragility was demonstrated. AFM force-distance curve and intermodulation methods were used to characterize the micromechanical properties with lateral resolution of the techniques in the range of 1 micron and 4 nm, respectively. The elastic-plastic behavior of the microarchitectures was evaluated and explained in terms of IPN morphology and thermal properties. The fabricated 3D IPN microstructures exhibit higher structural strength and integrity compared to PEGDA. In addition, IPNs exhibit high to full elastic recovery (up to 100%) with bulk modulus in the range of 4 to 6 MPa. This makes IPNs a good base material for modeling microstructures with intricate 3D designs for biomimetics and scaffold engineering. The effects of composition and MPL microfabrication parameters on the resulting IPN properties give us a better understanding of the underlying mechanisms and microfabrication-structure-property relationships. Moreover, our funding supports the further development of IPN systems as versatile and easily tunable MPL materials.

#### 9:15 AM SF01.11.06

**4D Printing of Free-Standing Carbon Fiber-Reinforced Shape Memory Polymer Composites via Frontal Polymerization** Hyeon-Ju Jang and Woong-Ryeol Yu; Seoul National University, Korea (the Republic of)

Continuous carbon fiber-reinforced polymer composites have been used in various industries, such as automobiles and aerospace, due to their high strength performance and lightweight. With the emergence of 3D printing technology, there has been a growing interest in utilizing this technique to fabricate continuous carbon fiber-reinforced plastics, particularly thermoplastic composites. In this study, we developed a 3D printing process for fabricating free-standing continuous carbon fiber-reinforced shape memory polymer composites without supports using frontal polymerization. Frontal polymerization is a self-catalytic exothermic reaction that converts monomers into polymers without external energy supply. One of the key challenges in printing continuous carbon fiber-reinforced shape memory polymer is to achieve a high degree of resin impregnation of carbon fibers to ensure optimal physical properties. We enhanced the degree of impregnation by developing an *in situ* pin-assisted printing head. Subsequently, we investigated the printability of frontal polymer with continuous carbon fibers with a focus on the degree of impregnation. Finally, the newly developed 3D printing system was evaluated characterizing the mechanical properties of the printed composites including their shape memory performance.

#### 9:30 AM SF01.11.07

**Embedded 3D Printing of Mechanically Robust Ionogel Composites** Alexander Q. Kane, EunBi Oh and Ryan L. Truby; Northwestern University, United States

Multifunctional materials with programmable mechanical properties and electronic/ionic conductivities are required for many emerging applications, including soft electronics, robotics, structural batteries, and more. Additive manufacturing has revolutionized our ability to fabricate these materials, which often require complex 3D forms. Poly(ionic liquid) composites are an emerging structural electrolyte that provide a wide electrochemical window and high ionic conductivity. However, poor intrinsic mechanical properties (e.g. Young's modulus) limit the printability of precise functional poly(ionic liquid) architectures, hindering their potential utility as materials for the aforementioned applications. Moreover, existing light-based 3D printing methods are

often incompatible with filler particles that can enhance the mechanical properties of poly(ionic liquids) or provide additional functionalities. In this work, we present a method for overcoming the challenges of 3D printing poly(ionic liquids) via embedded 3D (EMB3D) printing. Our integrated material design and manufacturing process produces free-form, lightweight, and flexible poly(ionic liquid) composites that are mechanically robust under cyclic compression. We demonstrate the modularity of our methods by showcasing multimaterial printing with various particle fillers (e.g., carbon black, hexagonal boron nitride, and fumed silica) and poly(ionic liquids). We anticipate our contributions will open new avenues for fabricating complex, architected solid electrolytes for soft sensors and robots, wearable devices, solid-state batteries, and more.

#### 9:45 AM SF01.11.08

**Discovery of New Strengthening Law in Nanocomposite Reinforced by Ceramic Nanoarchitected Materials** Gwangmin Bae<sup>1</sup>, Dong Gyu Kang<sup>2</sup>, Changui Ahn<sup>3</sup>, Daeho Kim<sup>2</sup>, Hyeon Gyun Nam<sup>2</sup>, Gayea Hyun<sup>2</sup>, Dongchan Jang<sup>2</sup>, Seung Min Han<sup>2</sup> and Seokwoo Jeon<sup>1</sup>; <sup>1</sup>Korea University, Korea (the Republic of); <sup>2</sup>Korea Advanced Institute of Science and Technology, Korea (the Republic of); <sup>3</sup>Korea Institute of Ceramic Engineering and Technology, Korea (the Republic of)

Engineers have long sought to utilize the exceptional mechanical properties achieved by size effect at the macroscopic level, as the strengthening effect derived from size is exclusive to the nanoscale realm. In this work, we present a novel approach to harness the size-induced strengthening effect and apply it on a macroscopic scale in a three-dimensional (3D) metal/ceramic/metal (MCM) nanocomposite. 3D Ni matrix nanocomposites embedding nanoscale Al<sub>2</sub>O<sub>3</sub> nanoarchitectures were produced in a large area (~1 inch) using Proximity-field nanopatterning (PnP) and material conversion techniques. Ceramic thin-shell nanoarchitected materials (t < 100 nm), utilized by a reinforcement of metal nanocomposite, perfectly separate 1<sup>st</sup> and 2<sup>nd</sup> metal layers. 1<sup>st</sup> and 2<sup>nd</sup> metals are densely infiltrated in and out of the ceramic nanoarchitected materials without defects. The 3D Ni/Al<sub>2</sub>O<sub>3</sub>/Ni nanocomposite exhibits a significantly higher compressive strength, surpassing the upper bounds predicted by conventional rule of mixture by approximately 30%. This remarkable strength is attributed to the extrinsic size effect of the ceramic nanoarchitected materials. By integrating the size-induced strengthening of ceramics into the traditional strengthening models of composites, a new strengthening model is derived and experimentally validated using the 3D Ni/Al<sub>2</sub>O<sub>3</sub>/Ni nanocomposite system. The utilization of size-induced strengthening in nanomaterials allows the 3D MCM nanocomposite system to offer a novel approach for enhancing the mechanical properties of bulk materials.

**3D-Printed Microarray Biosensor for Real-Time Monitoring in Interstitial Fluid** Jean Won Kwak, Tuan Trinh, Alexander D. White, Yue Xu, H. Tom Soh and Joseph M. DeSimone; Stanford University, United States

Real-time tracking of biochemical biomarkers in the body can provide personalized healthcare information. Microneedles, as a promising platform, enable continuous access to interstitial fluid in the dermal region through a minimally invasive and painless approach. However, wearable microneedle-based sensors face limitations, including the lack of reagent loading capacity due to conventional fabrication processes (e.g., microfabrication, molding) and deficiencies in continuous sensing capabilities caused by restricted biorecognition elements. Here we present a microarray biosensor (MAB) that integrates 3D-printing technology with biochemical sensing techniques for continuous and real-time monitoring of small molecules, such as cortisol and lactate. The MAB leverages the Continuous Liquid Interface Production (CLIP) to achieve tunable geometries, enabling utilization of the void volume of each microarray projection. These voids facilitate loading of hydrogel membranes, where optical molecular switches are immobilized within the network, enhancing signal detection and providing biochemical protection. Additionally, the MAB allows omnidirectional diffusion of targeted analytes while offering mechanical support during insertion. Ex vivo and in vivo evaluations are underway to validate the performance of the MAB in an effort to demonstrate its potential to provide comprehensive information about our bodies for precise prognosis and diagnosis of our health.

#### 10:45 AM SF01.11.10

**Towards a 3D Solid-State Na-Ion Battery using a Direct Ink Writing-Infiltration Approach** Shreyas Pathreker<sup>1</sup>, Shahryar Moaraj<sup>2</sup>, Selina Liu<sup>1</sup>, William R. Fullerton<sup>3</sup>, Hyeonjun Koh<sup>1</sup>, Wen Chen<sup>2</sup>, Russell J. Composto<sup>1</sup>, Eric A. Stach<sup>1</sup>, Christopher Y. Li<sup>3</sup> and Eric Detsi<sup>1</sup>; <sup>1</sup>University of Pennsylvania, United States; <sup>2</sup>University of Massachusetts Amherst, United States; <sup>3</sup>Drexel University, United States

3D solid-state batteries based on porous materials offer significant advantages over conventional 2D batteries, namely, high areal energy and high power density due to their increased surface area and intimate contact between cell components. They can also exhibit enhanced safety due to the high modulus of the solid electrolyte, which is known to suppress dendrite growth. The fabrication of 3D batteries calls for innovative, sustainable, non-roll-to-roll manufacturing approaches. We describe a three-step fabrication approach comprising direct ink writing, Capillary Rise Infiltration (CaRI), and vacuum-assisted infiltration for the development of a 3D solid-state battery. Pre-alloyed NiMn<sub>2</sub> powder mixed with a porogen is 3D printed into lattices, and sintering time and temperature are optimized to create a porous NiMn<sub>2</sub> 3D lattice comprising two different pore sizes in the range of 5 μm–10 μm and 150 μm–200 μm, respectively. Partial oxidation of the porous lattice generates a Na<sub>2/3</sub>[Ni<sub>1/3</sub>Mn<sub>2/3</sub>]O<sub>2</sub> (NNMO) layer, which serves as the cathode. Following this step, capillary-rise infiltration (CaRI) of an optimized poly(glycidyl methacrylate)-poly(ethylene glycol) (PGMA-PEG6k) electrolyte solution is used to deposit the polymer electrolyte within the small pores of the lattice. Thermal crosslinking between the epoxide groups on the PGMA backbone and amine end groups of the PEG within the pores yields a dense composite of solid polymer electrolyte in conformal contact with the pore surfaces. To deposit the anode in the large pores of the 3D lattice, vacuum-assisted infiltration of Na<sub>80</sub>K<sub>20</sub> metal is carried out, thereby completing the battery. Notably, this sequential fabrication approach uses zero solvent and polymer binder during either cathode (NNMO) or anode (Na<sub>80</sub>K<sub>20</sub>) deposition, which is in remarkable contrast to conventional slurry-casting methods that require the use of both N-methyl-pyrrolidone (NMP) and a polymer binder such as polyvinylidene fluoride (PVDF). Focused ion beam (FIB) milling, scanning electron microscopy (SEM), and energy dispersive x-ray spectroscopy (EDS) on the 3D matrix reveal excellent scaffold-polymer-anode contact, confirming the formation of robust interfaces that are necessary for battery application, which is currently being investigated. This work underscores the importance of cross-cutting collaborative research in materials science for emerging energy applications.

#### 11:00 AM SF01.11.11

**End-To-End Performance Analysis of 3D Printed Luminescent Devices for Energy Conversion Applications** Shomik Verma<sup>1</sup> and Rachel Evans<sup>2</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>University of Cambridge, United Kingdom

In recent years, there has been increasing urgency to develop cheap, efficient solar devices. However, most solar modules are large, bulky, and rectangular, making integration into the built environment non-trivial. A promising technological solution that may help solve this problem is the luminescent solar concentrator (LSC). A typical LSC is a plastic slab that absorbs sunlight and re-emits light of a tailored wavelength towards its edges, where solar cells can

be installed. Because LSCs are colorful, semi-transparent, and modular, they hold great potential in reducing the cost and barrier to entry of solar technologies. However, they suffer from significant optical losses limiting their efficiency. Many novel device shapes have been proposed to improve light transport pathways in LSCs, but these often rely on expensive or wasteful fabrication techniques.

A potential solution to this is 3D printing, which has gained immense traction as an alternative manufacturing technology. 3D printing has many benefits including accessibility, rapid prototyping, and fabrication of completely new designs. This study presents an end-to-end performance analysis methodology to evaluate new LSC designs that can take advantage of this novel manufacturing technology. This methodology is applied to some preliminary 3D printed parts as a proof of concept that can be applied to a wider variety of designs.

This study consists of 3 distinct steps: simulating the optical efficiency of the printed part, 3D printing the part with luminescent filament, and characterizing its optical efficiency experimentally.

Simulation of LSCs using ray tracing has been extensively investigated in the past; however, this has been limited to conventional, rectangular LSCs. Analyzing the performance of alternative LSC geometries requires developing a novel methodology for evaluating device efficiency, as well as implementing parallelization techniques to reduce computation time for complex geometries.

Among the 3D printing technologies, fused deposition modeling (FDM) is the most accessible and widely used, but it is not known for producing transparent parts usable for optical applications. This thesis aims to solve some of the complications of FDM to develop a cheap, rapid, and accessible methodology for printing efficient LSCs.

Similar to modeling, device characterization has been limited to rectangular LSCs, so a standardized methodology for evaluating device efficiency has been developed, allowing for comparison between different device shapes.

The simulated results of this study indicate 3D printed devices have the potential to offer a twofold increase in efficiency over conventionally manufactured bulk devices. Actual 3D printed devices were measured to have similar efficiency to bulk devices (within 1%), but extrapolating the results to parts made with higher quality material also suggests some parts would have twice the efficiency of their bulk counterparts. 3D printed parts may have additional benefits in improving directionality of edge-emitted light, but this will have to be confirmed in future work.

Overall, 3D printing provides major benefits over conventional manufacturing techniques, as it introduces rapid prototyping by allowing experimental iteration and model validation, allows custom-built designs for easier integration into the built environment, and increases the optical efficiency of devices by improving light transport pathways. With further development, this technology can help make widespread solar adoption a reality.

#### 11:15 AM SF01.11.12

**Unique Mechanical Behaviors of Mechanical Metamaterials with Engineered Imperfections** [Siyao Liu](#) and Yaning Li; Northeastern University, United States

Traditionally, imperfections are undesired in the materials and structures, because they often reduce the load-bearing capacity and cause premature failure. However, if imperfections are designed and engineered, they could generate unique new mechanical properties. In this investigation, we introduce patterned and hierarchical imperfections to lattice structures and find that the new designs show dramatically different mechanical properties under loads at different locations. Also, by utilizing the concept of tensegrity, the mechanical properties can be further controlled and tuned. In this investigation, new hybrid lattices are designed, which are composed of hard cells connected via engineering soft connections. Upon external mechanical or thermal loads, the hard cells will either keep the orientation or rotate due to the chiral arrangement or the soft components. Both deformation mechanisms will contribute to the overall volume change of the material and are related to the loading type and location. Therefore, the pattern transformation will lead to a change in both mechanical properties and functionality related to the material structure. To further prove the concept, prototypes of selected designs are fabricated in both macro- and micro- scales. Quasi-static uniaxial compression experiments were conducted in both room temperature and elevated temperatures. Finite element simulations are performed to further quantify the mechanical behaviors.

#### 11:30 AM SF01.03.32

**Investigation of Structure-Processing Relationships in Metal Additive Manufacturing Through Featurization of Microstructural Images** [Dipayan Sanpuji](#)<sup>1,2</sup>, [Anirban Chandra](#)<sup>1,2</sup>, [Sukriti Manna](#)<sup>1,2</sup>, [Partha Sarathi Dutta](#)<sup>1,2</sup>, [Maria K. Chan](#)<sup>1</sup>, [Henry Chan](#)<sup>1,2</sup> and [Subramanian Sankaranarayanan](#)<sup>1,2</sup>; <sup>1</sup>Argonne National Laboratory, United States; <sup>2</sup>University of Illinois at Chicago, United States

The understanding and prediction of accurate property-structure-processing relationships is essential in designing robust, reliable parts and assemblies, both forward and inverse. The direct mapping of process parameters to property values can be plausible in some cases, but it is often hampered by poor microstructural control. Therefore exploring a straightforward relationship between processing conditions and microstructural features can offer important physical insights and assist the overall design procedure. In this work, we present an automated high-throughput approach towards simulating an AM process that is uncertainty-aware, can characterize microstructural images, and extract appropriate features and descriptors. We used a kinetic Monte Carlo (KMC) based model of the AM process to simulate microstructural evolution for a variety of processing conditions, having utmost relevance with the experimental conditions. We perform a parametric study by selecting four input processing parameters in KMC simulations (velocity, hatch spacing, melt-pool width, and tail length) to explore the relationship between microstructural features and processing conditions. As a first step towards the exploration of microstructural features and processing conditions, we performed a parametric study by selecting the four input processing parameters in KMC simulations (velocity, hatch spacing, melt-pool width, and tail length). With systematic variations of the process parameters, a large number of simulations were performed for obtaining a diverse set of microstructural images. Subsequently we performed thorough analysis of the simulated images and extracted meaningful descriptors using conventional algorithms and an off-the-rack image processing tool, the Watershed algorithm. Finally, we present an approach towards discussion of the ability of various quantitative microstructural features to differentiate between the obtained microstructures. For accurate featurization of microstructural images, we focus on a set of six most relevant microstructural descriptors: Orientation, Aspect ratio, Perimeter-Area ratio, Equivalent diameter, Two-point statistics and chord length distribution (CLD) in two dimensions. As byproducts of our featurization algorithm, we realize many-to-one mapping is a necessity for representation of microstructural images unambiguously, multiple descriptors are therefore required to unambiguously map processing conditions to typical descriptors. Depending on the differentiability of the distributions of the microstructural features, a unique score can be allotted to a particular grain profile. This unique value of the metric or score can be further utilized to propel the inverse design problems. Defining a unique score is impossible if the four dominant microstructural features do not differ across the chosen processing conditions. Hence our research work provides very important information, in both qualitative and quantitative aspects, that would help in the proper understanding of microstructural representations. Appropriately characterized microstructural representations can then be utilized for development of data-driven models for predictive control of grain profiles, resulting in tailored mechanical or thermal properties of additively manufactured parts.

SESSION SF01.12: Session X

### 1:30 PM SF01.12.01

**Materials Design for Charge-Programmed Additive Manufacturing of Antennas** Zhen Wang<sup>1</sup>, Junbo Wang<sup>2</sup>, Zhenpeng Xu<sup>1</sup>, Ryan Hensleigh<sup>2</sup>, Yahya Rahmat-Samii<sup>2</sup> and Rayne Zheng<sup>1</sup>; <sup>1</sup>University of California, Berkeley, United States; <sup>2</sup>University of California, Los Angeles, United States

Additive manufacturing (AM) is emerging as a powerful tool for fabricating antennas particularly in the capability of creating arbitrary complex geometries without incorporating excessive materials owing to its unique materials build-up mechanism. Taking such benefits, 3D printed antennas, including horns, waveguides, and dielectric antennas, have been reported with enhanced performances in different aspects. These examples, however, are constructed mainly by single materials (either all-dielectric or all-metal). While multi-process AM can potentially perform conductive coating on 3D printed dielectric structure, the lack of selectivity and limited access to complex 3D geometries exclude a considerable amount of antennas from current AM approaches. The charge-programmed multi-material 3D printing technique integrates multiple materials and functionalities into 3D devices, which is achieved by programmed volumetric deposition of one (or multiple) materials into arbitrary 3D micro-architectures. The printed structures had programmed surface charge regions, enabling the selective deposition of functional materials into complex 3D architectures based on localized electrostatic interactions. For antenna applications, charge-programmed AM can achieve sophisticated 3D architected lattice materials with interpenetrating dielectrics and metals, allowing free space for designing antennas being ultra-light and yet mechanically robust. In this paper, we present the materials design principles enabling charge-programmed multi-material printing of lightweight antennas with unique mechanical properties and competitive antenna performances.

#### CHARGE-PROGRAMMED SELECTIVE DEPOSITION

Charge-programmed selective deposition for the fabrication of antennas is based on a multi-material printing system. Resins with positive, negative, or neutral charge polarity were alternately solidified and bound to the previously built layer of the printed parts. The process was repeated layer by layer, pin-pointing multiple materials with different polarities into their designated coordination in 3D space. The charged surfaces immobilize the oppositely charged catalyst species, which in-situ catalyze the subsequent deposition of functional materials. In such a way, the printed objects obtained patterned structures that selectively integrated different functionalities in designated locations with a resolution as high as the 3D printer could achieve.

#### MATERIALS DESIGN FOR ANTENNA APPLICATION

Charge-programmed selective deposition allows a wide range of space for materials design. Particularly for antenna applications, a variety of combinations of conductivity and dielectric constant, the most crucial parameters, can be achieved, suggesting the versatility of the charge-programmed selective deposition for custom tailored antenna applications.

The composition of the negative resin directly influences the antenna performances which relies on the quality of the plated Cu layer as well as antenna's mechanical robustness. Based on the molecular configurations of the polymerized photo-monomers, the negative resins were formulated to deliver either stiffness or flexibility for the printed antennas. By tuning the composition of the resins, we achieved a balance between the cross-link density and charge density. This enabled a uniform catalyst distribution on the stiff and tough negative resins and consequently grew a crack-free conformal Cu coating on the surface, serving excellent electrical properties for a K-band horn antenna. By introducing flexible monomers, we fabricated transmitarray with considerable flexibility, which promises potential for deployable antennas.

### 1:45 PM SF01.12.02

**Additive Manufacturing of Micro-Architected Metals via Hydrogel Infusion** Max A. Saccone<sup>1,2</sup>, Rebecca A. Gallivan<sup>1,3</sup>, Kai Narita<sup>1</sup>, Daryl W. Yee<sup>1,4</sup> and Julia R. Greer<sup>1</sup>; <sup>1</sup>California Institute of Technology, United States; <sup>2</sup>Stanford University, United States; <sup>3</sup>ETH Zürich, Switzerland; <sup>4</sup>École Polytechnique Fédérale de Lausanne, Switzerland

Metal additive manufacturing (AM) has emerged as a uniquely powerful tool to produce complex and high-performance parts with applications from the aerospace to biomedical fields. Most existing metal AM techniques use heat to define part shape via thermally initiated melting or sintering. In contrast, we report a polymer-based AM technique, coined hydrogel infusion additive manufacturing (HIAM), that produces metals and alloys with microscale resolution via vat photopolymerization (VP). To fabricate micro-architected metal structures, we infuse 3D-architected hydrogels with aqueous metal precursors, then calcine and reduce the infused hydrogel scaffolds to create miniaturized metal replicas. Unlike previous VP strategies, which incorporate target materials or precursors into the photoresin during printing, HIAM does not require re-optimization of resins and curing parameters for different materials, enabling quick iteration, compositional tuning, and the ability to fabricate multimaterials. We demonstrate HIAM of micro-architected metals including copper, nickel, silver, cobalt, cupronickel alloys, high entropy alloys, and tungsten with critical dimensions of ~50 μm. This work shows how single architected gel scaffold can respond to a variety of chemical and thermal stimuli to transform into a vast array of metals, providing a pathway to create advanced micro-architected metals.

### 2:00 PM SF01.12.03

**3D Printing and Processing of High-Performance Piezoelectrics for Ultrasound Transducer Applications** Haotian Lu<sup>1,2</sup>, Victor Couedel<sup>1</sup> and Rayne Zheng<sup>1</sup>; <sup>1</sup>University of California, Berkeley, United States; <sup>2</sup>University of California, Los Angeles, United States

The performance of ultrasonic transducers is largely determined by the piezoelectric properties and geometries of their active elements. Due to the brittle nature of piezoceramics, existing processing tools for piezoelectric elements only achieve simple geometries, including flat disks, cylinders, cubes and rings. While advances in additive manufacturing give rise to the free-form fabrication of piezoceramics, the resultant transducers suffer from high porosity, weak piezoelectric responses, and limited geometrical flexibility. We introduce optimized piezoceramic printing and processing strategies to produce highly responsive piezoelectric micro transducers that operate at ultrasonic frequencies. The 3D-printed dense piezoelectric elements achieve high piezoelectric coefficients and complex architectures. The resulting piezoelectric charge constant,  $d_{33}$ , and coupling factor,  $k_t$ , of the 3D printed piezoceramic reach 583 pC/N and 0.57, approaching the properties of pristine ceramics. The integrated printing of transducer packaging materials and 3D printed piezoceramics with microarchitectures create opportunities for miniaturized piezoelectric ultrasound transducers capable of acoustic focusing and localized cavitation within millimeter-sized channels, leading to miniaturized ultrasonic devices that enable a wide range of biomedical applications.

### 2:15 PM SF01.12.04

**Three-Dimensional Printing of High-Sensitivity Micro-Architected Piezoelectric Hydrophones with Designed Beam Patterns** Victor Couedel<sup>1</sup>, Haotian Lu<sup>1,2</sup> and Rayne Zheng<sup>1</sup>; <sup>1</sup>University of California, Berkeley, United States; <sup>2</sup>University of California, Los Angeles, United States

Piezoelectric hydrophones are crucial for underwater applications such as communication and seafloor mapping. Limited by the brittleness of piezoelectric ceramics, conventional manufacturing methods restrict hydrophones' shapes to simple geometries such as disks, cylinders, or spheres, which limits the sensitivity, directivity pattern, and working frequency bandwidth of the device.

Here, we present a new class of high-performance 3D printed piezoelectric hydrophones consisting of rationally designed micro-architectures. Using a high-resolution light-based printing process, and thanks to a liquid sealing sintering process, the piezoelectric coefficients and electromagnetic coupling factor can reach respectively 92% and 85% of the pristine material's values, the highest values among all existing 3D printing work.

We have developed a framework to artificially manipulate the piezoelectric coefficients of an architected material by modifying the spatial arrangement of unit cell struts. This can be harnessed to develop a new class of metamaterial hydrophones whose sensitivity can be locally manipulated. We take advantage of this framework to generate hydrophones with sensitivities ~10 dB higher than the commercial ones, and whose directivity patterns can be inversely designed.

This work holds great promises for high frequency sound localization without the need of hydrophone arrays, and for low frequency sound monitoring thanks to a hydrostatic figure of merit five times higher than the one of commercial transversely isotropic piezoelectric hydrophones.

### 2:30 PM SF01.12.05

**The Role of Particle Microstructure and Polymer Configuration in 3D Printed Thermal Composites** [Daniel Braconnier](#)<sup>1</sup>, Eric Wetzel<sup>2</sup>, Ryan Dunn<sup>2</sup> and Randall M. Erb<sup>1</sup>; <sup>1</sup>Northeastern University, United States; <sup>2</sup>U.S. Army Research Laboratory, United States

While everyday device sizes continue to shrink, the power being packed into them increases drastically, driving internal heat generation to the point of overwhelming current thermal management solutions and limiting system-level performance. New thermal management materials and solutions are required to support higher energy density electronics; incumbent materials including metals like copper and aluminum satisfy many applications, however they are heavy and cannot be placed adjacent to electronics or in the proximity of radio frequency components. Additive manufacturing and fine-tuned composite creation can enable lightweight and geometrically complex thermal management solutions that provide a distinct advantage over current solutions. Here we present a collection of new understandings around process-structure-property relationships that will help enable higher performing thermal parts via additive manufacturing. This work focuses on the interplay between the filament composition, the processing conditions of fused filament fabrication (FFF), and the post-processing of printed parts (annealing). The goal of this research is to enable emergent properties in FFF printed composites through material interface and interphase engineering, flow-induced self-assembly of mesostructure, and temperature-induced self-assembly of polymeric nanostructure. The ability to locally control the thermal conductivity of FFF parts would enable a new class of advanced thermal management materials.

### 2:45 PM SF01.12.06

**Radiation Shielding of Microelectronics via Additive Manufacturing** [Avery Rosh](#)<sup>1</sup>, Austin Coon<sup>1</sup>, Devon Beck<sup>1</sup>, Rich D'Onofrio<sup>1</sup>, Ethan Cascio<sup>2</sup>, Ksenofono Konomi<sup>3</sup>, Andrea Barney<sup>1</sup>, Robert Longton<sup>1</sup>, Pascale Gouker<sup>1</sup>, Melissa Smith<sup>1</sup> and Bradley Duncan<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology Lincoln Laboratory, United States; <sup>2</sup>Massachusetts General Hospital, United States; <sup>3</sup>University of Massachusetts Lowell, United States

The miniaturization of satellite systems has compounded the need to protect microelectronic components from damaging radiation. Current approaches to mitigate this damage, such as indiscriminate mass shielding, built-in redundancies, and radiation hardened electronics, introduce high SWaP-C (Size, Weight, and Power-Cost) penalties that reduce the overall performance of the satellite. Additive manufacturing provides an appealing strategy to print radiation shielding only on susceptible components within an electronic assembly. Utilizing direct ink writing, we are able to conformally print customized inks at room temperatures directly and selectively onto COTS (commercial-of-the-shelf) electronics. The suite of inks uses a flexible styrene-isoprene-styrene block copolymer binder that can be filled with particles of varying atomic densities for varying radiation shielding capabilities. Additionally, blended composites of both high and low Z fillers were created to investigate the performance in radiation attenuation depending on composition. We anticipate this low SWaP-C alternative to traditional shielding methods will enable the development of novel complex and compact satellite designs.

### 3:00 PM BREAK

### 3:30 PM SF01.12.07

**High-Speed Fabrication of Intrinsically Flexible Perovskite Optoelectronic Devices on Diverse Substrates (Elastomer, Paper, Textiles, etc.) Using Printing and Direct Writing** [Junyi Zhao](#) and Chuan Wang; Washington University in St. Louis, United States

Flexible optoelectronic devices built on thin elastomer substrates may find a wide range of applications in wearable electronics, soft robots, deformable displays, and more. While considerable efforts have been made to explore the potential of halide perovskites in high-performance light-emitting diodes (LEDs), existing fabrication techniques using rigid substrates cannot meet the growing demand for large-area flexible devices. In this work, we report a high-speed fabrication approach for intrinsically flexible perovskite LEDs (PeLEDs) directly printed on elastomer thin films. Using a highly scalable inkjet printing approach, each layer in the device, from the bottom anode to the top cathode, is patterned. In addition to elastomer, paper, and textiles commonly used in our daily lives also hold great potential as platforms for next-generation flexible and wearable electronics. Therefore, we have developed a versatile, scalable, and eco-friendly direct writing approach that enables multicolor PeLEDs (covering the entire visible spectrum) and perovskite photodetectors (PePDs) (both vertical-photodiode configuration and planar-photoconductor configuration) to be directly drawn onto various unconventional substrates (paper, textiles, plastic, rubber, metal, and common three-dimensional objects) in an ultrafast and mask-free manner. This is achieved by daily used ballpoint pens filled with our uniquely formulated inks of conductive polymers, metal nanowires, and perovskite/polymer composite for photoactive layers. The addition of an ionic polymer in the inks helps address the challenge of rough surface morphology on yarn and fiber networks, ensuring uniform printed film thickness and minimizing leakage current. Just like drawing with multicolor pens, by writing the above functional inks layer-by-layer, high-performance perovskite optoelectronic devices can be customized on almost any target substrate within minutes even by untrained individuals. Notably, the entire manufacturing was conducted in ambient conditions without the need for specific moisture and temperature control. The simplified device architecture and fabrication strategy significantly reduce the fabrication time compared to the hours or days required by conventional microfabrication processes. The written PeLEDs exhibit a brightness as high as 15,225 cd/m<sup>2</sup>, a current efficiency of 6.65 cd/A, and a turn-on voltage of 2.4 V. The PePDs exhibit an on/off ratio over 10<sup>4</sup>, and a response time of less than 15 ms. Owing to the extraordinary flexibility of each functional layer, the written LEDs on the paper substrate could be bent to a 1 mm extreme curvature radius for over 5000 cycles without decay in performance. Overall, this work paves the way for the practical application of perovskite optoelectronics in cost-effective and large-area scenarios, such as E-textile, E-paper, smart packaging, disposable electronics, and wearables.

### 3:45 PM DISCUSSION TIME

### 4:00 PM SF01.12.09

**Direct Photopatterning of Metals on Polymer Surfaces at Ambient Conditions** [Ivan B. Dimov](#)<sup>1</sup>, Antonio Domínguez Alfaro<sup>1,2</sup>, Tobias Naegele<sup>1</sup> and George G. Malliaras<sup>1</sup>; <sup>1</sup>University of Cambridge, Department of Engineering, Electrical Division, United Kingdom; <sup>2</sup>University of Basque Country, Spain

Metal interconnects on polymer substrates are an integral part of many stretchable and flexible electronic devices. However, metal deposition typically involves harsh conditions, such as high vacuum and temperature. These requirements limit compatibility with many substrates and impede rapid prototyping and increases energy requirements. Solution-phase depositing such metal features is an attractive alternative to conventional processes, especially when combined with a rapid additive manufacturing technique.

Here we present an aqueous gold ink, comprised of  $\text{H[AuCl}_4]$  as a metal source, a reducing agent and a benign, nontoxic dye as an initiator, that allowed us to deposit gold onto silicone surfaces upon UV illumination at ambient conditions. Altering the reaction time and ink composition, we could tune the morphology of the deposited metal, between isolated nanoparticles and a continuous film. Using this ink, we deposit stretchable gold interconnects on pre-strained silicone, using solely UV illumination, achieving conductivity of 40% of bulk gold. We additionally used a commercial stereolithographic printer without any modifications as a maskless lithography system, allowing us to pattern conductive features of 300  $\mu\text{m}$ . Investigating different substrates suggests a preference for polymers with reducible species on the surface. Lastly, we have successfully performed the reaction with  $\text{AgNO}_3$  as a metal source, depositing silver on silicone. We are working towards 2-photon illumination, in order to increase resolution and expand to 3D metal structures.

#### 4:15 PM SF01.12.11

**Chemically Coalescing Liquid Metal Emulsions as 3D Printed Soft Conductors** [Stephanie F. Zopf](#), Chloe Kekedjian, Ramon E. Sanchez, Lu Ping and John W. Boley; Boston University, United States

Patterning room temperature liquid metals as soft conductors requires nontrivial solutions due to its complex rheology. To facilitate material handling, liquid metals are often transformed into an emulsion by dispersing it as droplets within a continuous liquid. Oxides present on liquid metal droplets, however, render liquid metal emulsions nonconductive, which must be "activated" through droplet coalescence for the ink to be conductive. Although liquid metal droplet coalescence in emulsion inks has been shown by using mechanical ([1], [2]), laser [3], and extreme thermal ([4], [5]) means, these modes of activation make it challenging to integrate with other materials and device components. This work presents a liquid metal emulsion ink that is 3D printable through direct ink writing (DIW), and can be activated chemically through the use of an active ingredient. It requires a low thermal stimulus ( $\sim 80^\circ\text{C}$ ), which is compatible with commercial off the shelf electronic components. The ink developed in this work is able to retain its printed structure after being thermally activated. Coalescence through chemical etching of the oxides on the liquid metal droplets is evident through electrical conductivity measurements, scanning electron microscopy, nuclear magnetic resonance, and x-ray photoelectron spectroscopy characterization. Conductivities of formulated emulsions are precisely calculated using measured resistances combined with micron-level 3D scans with the maximum conductivity obtained of attempted formulations being  $3.54 \times 10^3 \text{ S/cm}$ . Printability outcomes of emulsion inks with respect to formulated chemistries will be presented. Rheology for the most printable formulation with the highest conductivity shows that the ink is shear thinning and shear yielding and exhibits a high plateau modulus and high yield stress, giving it the ability to print features that span long distances. Lastly, an automated 3D print and electronic device assembly process will be shown to demonstrate the utility of this ink as a soft conductor for manufacturing integrated electronic systems.

#### 4:30 PM SF01.12.12

**Computational Discovery of Microstructured Composites with Optimal Strength-Toughness Trade-Offs** [Bolei Deng](#)<sup>1,2</sup>, Beichen Li<sup>1</sup>, Wan Shou<sup>3</sup> and Wojciech Matusik<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Georgia Institute of Technology, United States; <sup>3</sup>University of Arkansas, Fayetteville, United States

The conflict between strength and toughness is a fundamental problem in engineering materials design. However, systematic discovery of microstructured composites with optimal strength-toughness trade-offs has never been demonstrated due to the discrepancies between simulation and reality and the lack of data-efficient exploration of the entire Pareto front. Here, we report a widely applicable pipeline harnessing physical experiments, numerical simulations and artificial neural networks to efficiently discover microstructured designs that are simultaneously tough and strong. Using a physics-based simulator with moderate complexity, our strategy runs a data-driven proposal-validation workflow in a nested-loop fashion to bridge the gap between simulation and reality in high sample efficiency. Without any prescribed expert knowledge of materials design, our approach automatically identifies existing toughness enhancement mechanisms that were traditionally discovered through trial-and-error or biomimicry. We provide a blueprint for the computational discovery of optimal designs, which inverts traditional scientific approaches, and is applicable to a wide range of research problems beyond composites, including polymer chemistry, fluid dynamics, meteorology, and robotics.

**Additive Manufacturing of Carbon Nanotubes Reinforced Metal Matrix Composites** [Li Cao](#); University of Dayton, United States

High-performance components are always highly demanded for modern aerospace applications due to their critical role in ensuring safety and efficiency. Developing metal matrix composites (MMCs) reinforced with nanomaterials is an effective strategy to enhance the properties of such functional components. Among the various reinforcements, 1D nanomaterials such as carbon nanotubes (CNTs) have attracted much attention due to their exceptional mechanical, thermal, and electrical properties. Meanwhile, Additive manufacturing (AM) offers innovative manufacturing techniques that can be used to construct complex and intricate structural components. Integrating advanced material development and AM techniques has drawn significant attention as it overcomes the limitations and challenges of conventional fabrication approaches. This research focuses on the development of CNTs reinforced nickel-based alloys using laser powder bed fusion, a popular AM technique. The result showed significant improvements in the yield strength, ultimate tensile strength, and elastic modulus of the 3D printed specimens when 2.5vol.% CNTs were incorporated, demonstrating the remarkable impact of CNTs on enhancing the performance of the metal-based alloys.

**8:30 AM SF01.13.02**

**High-Fidelity Beetle-Inspired 3D-Printed Wings for Miniature Flapping Drones** Bar-El Pinchasik, Or Filc, Hagit Gilon, Shmuel Gershon and Gal Ribak; Tel Aviv University, Israel

Miniature flapping drones equipped with lightweight membranous wings have shown great potential for operating effectively in small spaces. Achieving optimal flight performance in these drones heavily relies on the appropriate design of their flexible wings. In this study, we explore the utilization of 3D-printing technology to fabricate high-fidelity, bioinspired wings and expedite the design process for miniature flapping drones.

Drawing inspiration from the wings of the rose chafer beetle, we employ a bioinspired approach to develop 3D-printed wings. By modulating the wing structure, we create twelve distinct wing models that feature variations in vein cross-section shape, tapering geometry, and membrane thickness. Through a comprehensive comparison of their mechanical and aerodynamic properties, we establish guidelines to correlate wing form and function.

Our findings reveal the following key insights: first, manipulating the cross-section shape of the veins provides a powerful tool for engineering in-plane and out-of-plane deformations. Second, tapering veins enhance the wings' mechanical stability, improving their overall performance.

Experimental results demonstrate that the optimized wings exhibit a 16% increase in lift and a 27% improvement in lift production efficiency (N/Watts) when tested in a revolving wing setup. The successful design of lightweight, flexible, robust, and aerodynamically efficient wings poses a formidable engineering challenge that we aim to address through our bioinspired methodology. By reverse engineering these intricate structures, we contribute empirical knowledge to the field of wing design for miniature flapping drones.

Our work highlights the potential of bioinspiration and 3D-printing techniques to advance the development of miniature flapping drones with enhanced flight performance. The insights gained from this study provide valuable guidance for future advancements in the field of bioinspired wing design and optimization.

**FAIRification of Additive Manufacturing Process Through Ontology Development and Linked Data** Kristen J. Hernandez, Hein Htet Aung, Xuanji Yu, Pawan K. Tripathi, Erika I. Barcelos, Roger H. French and Laura Bruckman; Case Western Reserve University, United States

In order to improve current knowledge on Additive Manufacturing process the use of computer science principles is of interest. In order to optimize datasets for data analysis is a difficult process, due in part to the multiple data sources and the different output formats from each data source. The FAIRification process represents an attractive alternative to overcome the challenges associated with the storage, integration and reusability of these datasets. FAIR principles describe a set of guidelines applied to data and metadata to ensure a proper and efficient data management system. When applied correctly, it ensures that data is properly stored, organized, accessible and reusable. A fundamental component in the development of a successful FAIR framework and the integration of datasets is the development of ontologies. Domain ontologies are standardized representations of properties and relationships in a field and provide a sharing and common understanding within the research community. Using FAIR principles and domain ontologies as the backbone of organizing and processing data, the use of automated extraction methods are more feasible and able to process data regardless of the original capturing method. Data from disparate sources need to be processed and extracted in a method that can capture the feature of interest as well as relate the feature in a linked manner to the original data output. Information in the Additive Manufacturing process of Laser Powder Bed Fusion is sparse and separated among multiple instrument data sources that both capture different features and represent it using different encoding methods. These different encoding methods have the same object in reference while having different material characteristics extractable from the data source. In order to process through large data spaces of disparate features, data must be organized in a machine-compatible method. Furthermore, data must be retrieved with an automated pipeline for the ability to extract measurement of specific variables in a verifiably reproducible manner. Many datasets are reliant on operator specific inputs and often unreproducible evaluation methods. By using a more data scientific approach and organization scheme of linking datasets, information on Additively Manufactured parts, in spite of its sparse data, can be used and expanded further data visualization and trend relationships through specific software development and application. Organizing and streamlining data outputs to a common data framework allows for automation of analysis, quick retrieval of digital representations of variables of interest and the framework for decision making using data driven methods as opposed to physics informed simulations.

**8:50 AM SF01.13.05**

**Engineering a Thermally and Electrically Conductive, Biodegradable, Mechanically Sustainable Nanocomposite via 3D Printing** Xuyi Zhou<sup>1</sup>, Yu-Chung Lin<sup>2</sup> and Miriam Rafailovich<sup>2</sup>; <sup>1</sup>Shanghai Pinghe School, China; <sup>2</sup>Stony Brook University, The State University of New York, United States

The electronic industry has considerable demand for materials with good electrical and thermal conductivity, and for the convenience of manufacturing, it would be beneficial for the materials to have better mechanical properties in comparison to the currently actively researched material graphene nanoplatelets (GNPs). In response to such need, we intend to engineer nanocomposites with a blend of PLA, PBAT, and GNPs H-5 (average diameter of 5 microns) through 3D printing in this research. From the properties of individual materials, PLA is the currently commercialized 3D printing filament material; PBAT, as a ductile polymer, compensates for the brittleness of GNPs; GNPs H-5 contributes to good electrical and thermal conductivity. For environmental concerns, both PLA and PBAT are biodegradable polymers. From our previous studies, it had been concluded that the optimal ratio of PLA to PBAT is 1:3, creating percolation pathway for electrical conductivity. Contact angle tests and work of adhesion calculation indicated that GNPs preferred the phase of PBAT as opposed to PLA. The addition of PLA, at low concentration, would take up space and confine GNPs in PBAT, therefore improving electrical and thermal conductivity. Nevertheless, more PLA has the risk of making PBAT phase discontinuous. Inspired by this, in our research, we altered the concentration of GNPs (including 8wt.%, 12wt.%, 16wt.%, and 20wt.%) to find the composites with optimal thermal conductivity, electrical conductivity, and mechanical properties. The ratio of PLA to PBAT is fixed as 1:3. The 3D printing nozzle shear force is expected to further orientate the H-5 platelets.

Four-point electrical conductivity tests were performed on the 3D printed electrical test samples. As expected, electrical conductivity increases as GNPs concentration increases. For horizontally infilled samples, 8wt.% GNPs and 12wt.% GNPs samples were generally not electrically conductive. The electrical conductivity increases from 0 to 1.6 S/m when 16wt.% of GNPs is added. In addition, the orientation of infill during the 3D printing process has an effect on electrical conductivity. Vertically infilled samples are less electrically conductive than horizontally infilled samples, however, the overall trend is similar. At 16wt.% GNPs, the electrical conductivity of horizontally infilled samples is approximately the value of Germanium, a classical semiconductor element. The thermal conductivity of samples were measured by a thermal camera while the samples were heated for a fixed interval of time. Thermal conductivity experiences minor increase as GNPs concentration increases. In comparison to pure PLA, 20wt.% GNPs samples are 350% as thermally conductive. Their thermal conductivity values are approximately the same as that of water at 50 Celsius degrees. This result support that an increase in the concentration of GNPs incurs an uplift in thermal conductivity. In the Instron test, the strain to stress diagram revealed the brittleness of high GNPs filling load samples. As the concentration of GNPs increases, the breaking elongation decreases, toughness decreases, and Young's Modulus increases. Such result suggests that at the microscopic level, GNPs block the entanglement between polymers in the composites, giving rise to the decrease in material ductility. We expect the ideal blend of PLA, PBAT, and GNPs H-5 to have the proportion between 12wt.% and 16wt.%. If the concentration of GNPs is above 16wt.%, the material will be too brittle according to the mechanical tests data. Otherwise, if the concentration of GNPs equals or is below 12wt.%, the electrical conductivity of the material will be comparatively low for practical use.

**8:55 AM SF01.13.06**

**Printing Electronic Circuits and Devices via Hybrid Fused Filament Deposition of a TPU/Copper Composite** [Remi Rafael](#) and Paddy K. L. Chan; Hong Kong University, Hong Kong

Printing metals and polymers together to form complex electronic devices is difficult due to the large difference in fusion temperature between those materials. In a previous article, we have introduced a hybrid printing technique based on the fused filament deposition of a copper-poly(lactic acid) composite followed by a step of laser sintering, to produce a conductive, porous copper material. This technology integrates together a conventional fused filament deposition printer and a 10-watt laser diode. The printer is used to deposit layer by layer a composite material containing a polymer matrix, copper, and copper oxide particles. After printing each layer, the laser diode is used to selectively sinter the composite. Under the effect of the laser, the polymer matrix is evaporated, and the copper oxide is reduced, forming a highly conductive, porous copper material. However, in our precedent experiments, the out-of-plane resistivity of this printed porous copper was high, and the applications were restricted to low dimensionality, 2.5D applications. More recently, we have investigated more composite materials and sintering conditions and developed a new TPU based composite. After sintering, this composite presents a resistivity as low as  $10^{-5} \Omega \cdot \text{cm}$  in the in-plane direction and  $10^{-4} \Omega \cdot \text{cm}$  in the transverse direction. As a result, we can now design and print completely embedded 3D electronic circuits and complex electronic components. We demonstrate these capabilities by making an embedded 3D circuit controlled by capacitive sensors.

**9:10 AM SF01.11.04**

**Additive Manufacturing of Anisotropic Graphene-Based Composites for Thermal Management Applications** [Shani Ligati Schleifer](#)<sup>1</sup> and Oren Regev<sup>1,2</sup>; <sup>1</sup>Ben Gurion University of the Negev, Israel; <sup>2</sup>Ben-Gurion University of the Negev, Israel

The use of additive manufacturing (AM) for the rapid, facile creation of complex structures could provide thermal management solutions in the form of heat sinks and heat exchangers with high surface areas that facilitate heat dissipation. To prepare a heat sink with high thermal conductivity (TC), we use vat photopolymerization (VPP) of a polymer-based composite material with a low TC that is enhanced by loading with a graphene-based thermally conductive filler. Phase separation of the carbon-based filler, in this case graphene nanoplatelets (GNP), in the monomer printing solution is prevented by stabilizing the GNPs by the addition of a second fiber-like clay (sepiolite) filler, which traps the GNPs. This methodology enables the AM of a composite with a relatively high GNP concentration of 2.0 wt%, yielding a TC increase of 160% vs. the pristine polymer—an impressive accomplishment for VPP 3D printing. Moreover, this printing technique yields a material with anisotropic TC with a cross-plane/in-plane ( $TC_{\perp}/TC_{\parallel}$ ) ratio of 1.6, which is beneficial for thermal management systems required to dissipate the heat vertically from a heat source. Such VPP 3D-printed composites with high and anisotropic TC could be applied in thermal management systems made of lightweight and cost-effective materials.

**Investigation of Faceted Solid-Liquid Interface Behavior During the Directional Solidification of Salol** [Anassya Raad](#), Nathalie Bergeon, Nathalie Mangelinck-Noël and Fatima L. Mota; Aix-Marseille Université, IM2NP, UMR CNRS 7334, France

During solidification of materials, a microstructure forms at the solid-liquid interface that depends on both the physical parameters of the material (in

particular the surface energy and kinetic attachment anisotropies) and the processing parameters such as thermal gradient  $G$ , growth velocity  $v$ , and composition of the sample. The microstructure plays a critical role in determining the final properties of the material. One can distinguish two different macroscopic types of interface: rough where the kinetic attachment of atoms is fast and heat and solute diffusion in the liquid is dominant; and faceted where the kinetic attachment of atoms is anisotropic and slow and considered as the dominant effect. In this last, the crystals grow with smooth surfaces at the atomic scale, and facets at macroscopic scale. Despite numerous researches, particularly for semi-conductors such as silicon, the understanding of the faceted growth is still a significant challenge.

In this work, directional solidification experiments of organic transparent materials are used to evidence and analyze mechanisms involved during the growth of faceted solid-liquid interfaces. Such transparent model materials are chosen to have similar solid-liquid interface properties as technological materials studied, and thus to form similar microstructures, with the advantages of being transparent to visible light, so that common optical techniques can be used to follow their growth. We use salol, which is orthorhombic in structure and grows from its melt with a distinct macroscopic faceted interface because of its very high degree of anisotropy. Directional solidifications are performed in the ECODIS device a Bridgman furnace designed for thin samples geometries, equipped with an optical microscope to observe solid-liquid interface dynamics *in situ* and real time.

A highly faceted solid-liquid interface appears and keeps evolving till the end of the experiment. The facet angles are characterized and it shows that they correspond mostly to  $\{1\ 1\ 1\}$  and  $\{1\ 0\ 0\}$  crystallographic planes. Velocities of the different facets are measured and they vary with facet orientation relatively to the thermal gradient. These measurements allow to establish kinetic growth laws which depend on the crystallographic nature of the facet. Facets are also studied in terms of size evolution and distribution, which are affected by facet competition and interaction with defects.

#### 10:45 AM SF02.01.02

**Growth Dynamics of Three-Dimensional Grain Boundaries in Polycrystalline Solidification using DECLIC-DSI Facility** Fatima L. Mota<sup>1</sup>, Younggil Song<sup>2</sup>, Kaihua Ji<sup>3</sup>, Damien Tourret<sup>4</sup>, Alain Karma<sup>3</sup> and Nathalie Bergeon<sup>1</sup>; <sup>1</sup>Aix-Marseille Université, IM2NP UMR CNRS, France; <sup>2</sup>Lawrence Livermore National Laboratory, United States; <sup>3</sup>Northeastern University, United States; <sup>4</sup>IMDEA Materials Institute, Spain

Polycrystalline microstructures formed by directional solidification are often polycrystalline, made up of a several large grains of different crystallographic orientations. Grain boundaries (GBs) have a crucial influence on the mechanical behavior of materials, by their peculiar interactions with dislocations, or by providing solute segregated regions prone to the formation of secondary phases. In technological alloys, GBs typically evolve in the solid state through a series of complex thermomechanical post-processes. However, their initial shape and existence goes back to the initial stage of solidification from the liquid phase. The importance of GBs is well-acknowledged at the macroscopic scale, and grain growth competition is already used in the design of technological components (e.g. grain selectors in single-crystal turbine blades). However, our understanding of GB selection during polycrystalline solidification remains qualitative at best, and a number of unanswered questions remain.

Until now, grains have been assumed to occupy distinct compact regions of 3D space separated by smooth borders on a scale larger than the cellular/dendritic array spacing. In this presentation, we report experimental observations revealing for the first time that cells from one grain can invade a nearby grain during polycrystalline growth. This unexpected invasion process causes grains to interpenetrate each other on the fine scale of the array spacing, and hence grain borders to become highly irregular. By computational modeling, we further reveal the ubiquitous nature of this invasion process by showing that it occurs for a wide range of grain misorientations beyond those studied experimentally. Those results fundamentally alter the traditional view that cellular/dendritic grains are distinct regions embedded in three-dimensional space.

Those unique observations are made possible by *in situ* visualization of the spatiotemporal evolution of the solid-liquid interface during directional solidification of a transparent organic alloy (Succinonitrile-0.24wt% Camphor) using the DECLIC-DSI experimental device installed onboard the International Space Station. Transparent alloys have similar solid-liquid interface properties as metallic alloys and thus form similar microstructures. The microgravity environment of the space station eliminates buoyancy-driven fluid convection and the associated large scale inhomogeneities of alloy composition, thereby facilitating quantitative comparisons with computational modeling in a purely diffusive regime.

#### 11:00 AM SF02.01.03

**Disorder to Order in Interface Patterns: Thermal Noise to Limit Cycle Transition in Dendrite Sidebranch Formation** Trevor D. Lyons<sup>1</sup>, Louise S. Littles<sup>2</sup> and Rohit Trivedi<sup>3</sup>; <sup>1</sup>Northeastern University, United States; <sup>2</sup>NASA, United States; <sup>3</sup>Iowa State University of Science and Technology, United States

Thin sample directional solidification experiments have been carried out in the model succinonitrile-camphor system to examine the origin of secondary branches in dendrite morphologies. Thermal noise at the dendrite tip creates interface instabilities which amplify to form sidebranches. This is accepted as the primary mode of sidebranching in dendritic growth from an undercooled melt and occurs in directional solidification of dendrites. The proposed limit cycle couples the growth of the tip with the initiation of the sidebranch. Directional solidification of curved interfaces is a driven dissipative system with the potential to form a limit cycle. Two sets of experiments were performed, the first holding velocity constant and evolving the gradient and the second imposing oscillating velocities around the natural period of sidebranching. Both experimental methods were found to characterize a transition from disordered sidebranching induced by thermal noise to ordered sidebranching produced by the limit cycle mechanisms. This is the first quantitative measurement of previously hypothesized limit cycle growth.

These experiment sets have been quantitatively analyzed for dynamic behavior seen in limit cycles. High-quality data sets of the tip and instability enable the measurement of the FFT and analysis through a power spectrum. At low gradients, the sidebranches are found to be excited by thermal noise far away from the tip. As the gradient increases and velocity is held constant, the distance between the instability and tip decreases until limit cycle growth is found between the tip of the primary dendrite and the first forming sidebranch. An alternative to the deterministic limit cycles seen in experiments of gradient evolution is a limit cycle actively driven through the square wave oscillation of velocity. Crucial observations of the solidified microstructure conclude that this produced periodic interconnected bridges between the primary dendrites. This is a finding with potentially significant implications for commercial applications.

**Direct Observation of Growth and Interfacial Dynamics of Ice Nanocrystals with Cryo-Electron Microscopy** Minyoung Lee and Jungwon Park; Seoul National University, Korea (the Republic of)

Ice at low temperatures exhibit structural polymorphs including hexagonal ice, cubic ice, or a hetero-crystalline mixture of the two phases. These polymorphs coexist at a broad range of temperatures, but exhibit distinct growth kinetics. While numerous studies, mainly based on spatially-averaged techniques, have investigated the structural properties of ice formed at low temperatures, mechanisms behind the growths of coexisting polymorphs and their interfacial properties have been difficult to probe individually. Here, we use *in-situ* cryo-electron microscopy and computational ice-dynamics simulations to directly observe ice formation and growth amidst amorphous ice. We reveal that nanoscale ice crystals exhibit polymorph-dependent growth kinetics, with hetero-crystalline ice exhibiting anisotropic growth based on accelerated growth of the prismatic planes. Fast-growing facets are associated with low-density interfaces that possess high surface energy, driving tetrahedral ordering of interfacial water molecules and accelerating growth. Our approach in observing ice crystallization, based on nanoscale techniques, improve our understanding on early stages of ice formation and the mechanistic

roles of ice interfaces, providing important insight into various fields such as ice physics, cloud physics, or designing cryoprotective molecules.

### 11:30 AM SF02.01.05

**Phase-Field Modeling of Ice-Templated Hierarchical Structures** Kaihua Ji<sup>1</sup>, Mingwang Zhong<sup>1</sup>, Kaiyang Yin<sup>2</sup>, Louise S. Littles<sup>3</sup>, Rohit Trivedi<sup>4</sup>, Ulrike G. K. Wegst<sup>1</sup> and Alain Karma<sup>1</sup>; <sup>1</sup>Northeastern University, United States; <sup>2</sup>University of Freiburg, Germany; <sup>3</sup>NASA Marshall Space Flight Center, United States; <sup>4</sup>Iowa State University, United States

Directional solidification of aqueous solutions and slurries in a temperature gradient has emerged as a promising method to produce cellular materials through a phase separation of solutes or suspended particles between growing ice lamellae. Those ice-templated cellular materials are hierarchically organized into a honeycomb-like porous structure on the largest scale, lamellar cell walls at an intermediate scale, and different unilateral surface features including ridges and other more complex shapes reminiscent of living forms that decorate the cell walls on a yet smaller scale. While the strong anisotropy of ice-crystal growth has been hypothesized to play a role in shaping those structures, the mechanism by which they form has remained elusive. We report the results of a detailed phase-field simulation study of ice templating of binary mixtures that reproduces the salient features of those cellular materials and that sheds light on the mechanism by which anisotropic ice crystal growth shapes their hierarchical structure. The simulation results reveal that the flat side of lamellae forms because of slow faceted ice-crystal growth along the c-axis, while weakly anisotropic fast growth in other directions, including the basal plane, is responsible for the unilateral features. Diffusion-controlled morphological primary instabilities on the solid-liquid interface form a cellular structure on the atomically rough side of the lamellae, which template regularly spaced ridges while secondary instabilities of this structure are responsible for the more complex features. The simulation results are compared with experimentally obtained results by directional freezing of binary water mixtures containing small solutes. Good quantitative agreement is found for the lamellar spacing that is shown to obey the scaling law  $\lambda \sim (VG)^{-1/2}$ , where V and G are the local growth rate and temperature gradient, respectively. Preliminary simulation results are presented that address the basic question of how other solvents such as DMSO, which exhibit different anisotropic crystal growth properties than ice, can produce a rich variety of hierarchical structures.

### 11:45 AM SF02.01.06

**Ice Crystal Growth and the Dynamics of Ice Templating by X-Ray Tomoscopy** Paul H. Kamm<sup>1,2</sup>, Kaiyang Yin<sup>3</sup>, Tillmann R. Neu<sup>1,2</sup>, Christian M. Schlepütz<sup>4</sup>, Francisco Garcia-Moreno<sup>1,2</sup> and Ulrike G. K. Wegst<sup>5,2</sup>; <sup>1</sup>Helmholtz-Zentrum Berlin für Materialien und Energie, Germany; <sup>2</sup>Technische Universität Berlin, Germany; <sup>3</sup>University of Freiburg, Germany; <sup>4</sup>Swiss Light Source, Switzerland; <sup>5</sup>Northeastern University, United States

The physics of ice-crystal growth from the liquid phase and the complex dynamics of microstructure formation by ice-templating during the directional solidification of aqueous solutions and slurries, also termed freeze casting, has to date received comparatively little research attention. Recent advances in synchrotron-based X-ray tomography, which is time-resolved X-ray tomography, enable us now to investigate in situ under well-defined experimental conditions the formation of the hierarchical architecture of freeze-cast materials. We can quantify in 3D ice crystal growth at high spatial and temporal resolution and observe the ice-templating mechanisms, which determine the morphology of the freeze-cast material. The performance-defining morphology is defined by a honeycomb-like material structure with lamellar cell walls that frequently are decorated with a range of unilateral surface features. Analyzing the tomography data, we can determine, which features of the freeze-cast materials are templated by the slow faceted growth along the c-axis of the hexagonal ice-crystal, and which are templated by the slightly anisotropic fast crystal growth along the preferred a- and t-axes, both of which are characterized by atomically rough ice-water interfaces. Additionally, we can observe, which role secondary instabilities play in the formation of cell wall surface features. Important advantages, which in situ X-ray tomography offers over post-mortem imaging and state-of-the-art simulation techniques, are that the dynamics of the structural evolution can be monitored over several minutes in a sample volume of several cubic millimeters so that also transient phenomena are captured.

**Dodecahedral Silica Cages and Their Assembly at Liquid-Liquid Interfaces and in Inks for 3D Printing** Ulrich Wiesner; Cornell University, United States

Crystallization and assembly at interfaces are hallmarks of biological systems and have provided inspiration for researchers world-wide to understand and control materials formation from the atomic scale all the way to the macroscale. This presentation will focus on the formation of silica nanocage structures with dodecahedral symmetry around spherical micelles (zero-dimensional, 0D) as well as their assembly at liquid-liquid interfaces (two-dimensional, 2D) and in inks for direct and internal three-dimensional (3D) printing. Detection of silica nanocage structures with dodecahedral symmetry and diameters around 10 nm has been enabled by the first application of machine learning enabled single-particle reconstruction of tens of thousands of cryo-electron microscopy images to materials discovery.<sup>1</sup> Synthesis of mesoporous silica at an interface between two immiscible solvents under conditions favoring the formation of 2D superstructures of silica nanocages leads to the thinnest mesoporous silica films synthesized to date.<sup>2</sup> It will be demonstrated how orientational correlations between nanocage units increases with increasing layer number controlled via pH, while swelling with oil and mixed surfactants increase micelle size dispersity, leading to complex clathrate type structures in multilayer superstructures. Mesoporous 2D superstructures can be fabricated over macroscopic film dimensions and stacked on top of each other to generate mesoporous heterostructures enabling potential separation and catalytic properties not achievable via conventional bulk syntheses. Finally, ultrasmall silica nanocages are combined with digital light processing (DLP) technique for the direct 3D printing of hierarchically porous parts with arbitrary shapes, as well as tunable internal structures and high surface area. Via versatile and orthogonal cage surface modifications, it will be shown how this approach can be applied for the implementation and positioning of functionalities throughout 3D printed objects. Taking advantage of the internal porosity of the printed parts, an internal printing approach is demonstrated for the localized deposition of a guest material within a host matrix, enabling complex 3D material designs.

**The Effect of Flame Temperature on Structure of Ceria-Supported Pt Nanoparticles in Flame-Assisted Spray Pyrolysis** Naoya Minegishi, Peizhou Li, Tsuyoshi Nagasawa and Hidenori Kosaka; Tokyo Institute of Technology, Japan

Supported metal catalysts are used in many applications such as combustion gas purification catalysts, gas reforming systems, and chemical product synthesis processes. Supported metal catalysts generally have a structure with high specific surface area and high dispersion of precious metal to improve catalytic activity and economic efficiency. One of the big challenges in these catalysts is to prevent deterioration of catalytic activity caused by thermal aging and following aggregation of precious metal nanoparticles in high-temperature environment. To achieve both high thermal stability and high catalytic activity, it is necessary to properly control the oxide and metal particle sizes and metal/oxide interface structure. However, in the case of wet processes such as the impregnation method, precise structural control requires complex multi-step processes, which can be disadvantage toward practical application. The aim of this study is to synthesize supported metal catalysts with high catalytic activity and thermal stability in a simple process. For this purpose, we synthesized Pt/CeO<sub>2</sub> nanoparticles by flame-assisted spray pyrolysis using a burner diffusion flame, and the effects of material precursor concentration and flame conditions on the structure of the synthesized particles were investigated. In addition, the CO oxidation properties and thermal stability of the particles synthesized by flame-assisted spray pyrolysis were evaluated and compared with those of particles prepared by the impregnation method. A coaxial flow diffusion flame burner with a double-tube structure was used for the particle synthesis experiments. A mixture of oxygen and nitrogen is supplied to the outer tube, and a mixture of nitrogen and methane containing a precursor solution atomized by an ultrasonic transducer (2.4 MHz) is supplied to the inner tube. The synthesized Pt/CeO<sub>2</sub> particles consisted of submicron-scale CeO<sub>2</sub> with 10 nm-scale Pt and aggregation of fine CeO<sub>2</sub> less than 10 nm with highly dispersed Pt (1 nm or less) [1]. When the flame temperature was varied by changing the ratio of oxygen and nitrogen supplied to the burner outer tube, more fine particles were produced at higher flame temperatures. Submicron-level particles may have formed by the droplet-to-particle route, in which the precursor droplets do not evaporate completely and nucleation occurs within the droplet. On the other hand, fine nanoparticles may have formed by the gas-to-particle route, in which the droplets completely evaporate and nucleation occurs in the gas phase. The evaporation of precursor droplets is enhanced at higher flame temperature, resulting in the shift of particle formation route from droplet-to-particle to gas-to-particle. The fine Pt/CeO<sub>2</sub> nanoparticles synthesized by the high-temperature flame showed CO catalytic activity comparable to that of particles prepared by the impregnation method. Moreover, the thermal stability of the Pt particles on CeO<sub>2</sub> by flame synthesis was better than that of the impregnation method.

**Colloidal Metal-Halide Epitaxial Heterostructures: From Serendipity to Rational Design** Stefano Toso<sup>1</sup>, Muhammad Imran<sup>1,2</sup>, Derek Dardzinsky<sup>3</sup>, Noa Marom<sup>3</sup> and Liberato Manna<sup>1</sup>; <sup>1</sup>Istituto Italiano di Tecnologia, Italy; <sup>2</sup>University of Toronto, Canada; <sup>3</sup>Carnegie Mellon University, United States

Colloidal epitaxial heterostructures are nanoparticles made of two crystalline materials connected at an interface. These architectures profitably combine the properties of their components, and can express unique ones stemming from their interactions. Historically, heterostructures have produced major breakthroughs in the field of colloidal nanomaterials, with core/shell quantum dots being the most renowned examples. Indeed, heterostructures are often grown from isostructural materials like CdSe/CdS, where the only requirements are similar lattice parameters. However, the increasing number of heterostructures reported between non-isostructural materials points to the limits of this design strategy. In this talk, we will take the serendipitous discovery of heterostructures between lead halide perovskites (CsPbX<sub>3</sub>) and lead sulfohalides (Pb<sub>4</sub>S<sub>3</sub>X<sub>2</sub>) as a case study.[1,2] We will first identify empirical criteria behind the formation of these heterostructures by comparing them with other interfaces formed by lead halides.[3] Then, we will exploit in-situ spectroscopies performed directly in the liquid reaction medium to gain insight into the growth mechanism of these composite nanomaterials. As a next step, we will take advantage of such knowledge to master the synthesis of two competing nanomaterials (Pb<sub>4</sub>S<sub>3</sub>Cl<sub>2</sub> vs Pb<sub>3</sub>S<sub>2</sub>Cl<sub>2</sub>) by exploiting heterostructures as phase-selective reaction intermediates.[4] This approach is inspired by the retrosynthetic strategies typical of organic chemistry, and provides advanced control over the product of colloidal syntheses. Finally, we will rationalize these results with the help of a novel computational tool, which we designed specifically for predicting the formation of stable colloidal epitaxial heterostructures. By providing fundamental insights into the growth mechanism and stability of colloidal nanocrystal heterostructures, we hope to lower the barrier that separates the widely appealing properties of these fascinating composite nanomaterials from real-world applications.

**Visualizing Interfacial Processes and Surface Instabilities in Nanoparticle Systems Through *In Situ* TEM and Artificial Intelligence** Piyush Haluai<sup>1</sup>, Adria M. Morales<sup>2</sup>, Matan Leibovich<sup>2</sup>, Mai Tan<sup>1</sup>, Sreyas Mohan<sup>2</sup>, Yifan Wang<sup>1</sup>, Carlos Fernandez-Granda<sup>2</sup> and Peter A. Crozier<sup>1</sup>; <sup>1</sup>Arizona State University, United States; <sup>2</sup>New York University, United States

Interfacial processes control not only crystal growth but also crystal dissolution. For example, during classic nucleation and growth, nuclei are forming and dissolving in solution and only when a seed crystal grows above the critical size, can a larger crystal evolve. The structural evolution of a crystal surface may be strongly influenced by the ambient environment. In small nanoparticles (<5 nm) in the presence of a surface stimuli, such as gas or liquid ambient, the thermodynamic driving force to minimize surface energy is continuously perturbed due to the adsorption and desorption associated with molecular exchange processes. This leads to an evolving interfacial energy landscape with the system constantly “chasing” an elusive energy minimum. The nanoparticle surface is far from equilibrium, but local energy minima give rise to a variety of short-lived metastable states. There is considerable interest in exploring the system evolution as it transitions between stable and less stable surface configurations. Not only is this of fundamental interest to materials science, but it may impact applications in fields where surface reactivity is important such as catalysis and corrosion. The recent development of direct electron detectors with high sensitivity and fast readout rates together with advances in AI based denoisers [1] now makes it possible to perform atomic

resolution exploration of nanoparticle surface processes with time resolutions ultimately limited by detector readout speeds (0.0001 – 0.001 s is now common). We are investigating the surface dynamics of Pt nanoparticles with temporal resolutions of ~0.01 s under different ambient conditions. Typical kinetic pathways are observed to follow elementary surface transformation steps including atom column activity (e.g., adatom migration, adatom fluxionality, surface layer growth, surface layer fluxionality, surface layer removal), shearing (e.g., surface shear, subsurface shear creating or annihilating stacking faults). Since there is a tight connection between the surface and subsurface structure in small particles, instabilities in the surface structure can trigger instabilities in the entire nanoparticle crystal. The relationship between these different metastable states and kinetic pathway will be discussed in the presentation.

**Observing Crystal Nucleation on Graphene via High-Speed Atomic-Resolution TEM** Won Chul Lee<sup>1</sup>, Jungwon Park<sup>2</sup> and Peter Ercius<sup>3</sup>; <sup>1</sup>Hanyang University, Korea (the Republic of); <sup>2</sup>Seoul National University, Korea (the Republic of); <sup>3</sup>Lawrence Berkeley National Laboratory, United States

Nucleation in atomic crystallization remains poorly understood despite advances in classical nucleation theory. The nucleation process has been described to involve a non-classical mechanism including a spontaneous transition from disordered to crystalline states, but a detailed understanding of dynamics requires further investigation. Here, using in-situ transmission electron microscopy of heterogeneous nucleation of individual gold nanocrystals with millisecond temporal resolution, we show that the early stage of atomic crystallization proceeds through dynamic structural fluctuations between disordered and crystalline states, rather than through a single irreversible transition. Our experimental and theoretical analyses support that structural fluctuations originate from size-dependent thermodynamic stability of the two states in atomic clusters. These findings, based on dynamics in a real atomic system, reshape and improve our understanding of nucleation mechanisms in atomic crystallization.

#### 4:00 PM SF02.02.06

**The Onset of Crystallization of Aerosol Au Nanoparticles** Yi Wang<sup>1</sup>, Sotiris E. Pratsinis<sup>1</sup> and Eirini Goudeli<sup>2</sup>; <sup>1</sup>ETH Zürich, Switzerland; <sup>2</sup>The University of Melbourne, Australia

Gold nanoparticles have versatile applications in catalysis, chemical and biological sensing, medicine (drug carrier, therapeutic agents and gene delivery), nanolithography and microelectronics [1]. The performance of these nanoparticles is heavily influenced by their crystalline characteristics. Even though Au nanoparticles are routinely made in the liquid phase, their gas-phase (aerosol) synthesis is most attractive for its proven scalability (25 t/h) and high-purity products (i.e. optical fibers) [2]. During aerosol synthesis, the formation of particles occurs at high temperatures, steep cooling rates and short residence times that affect considerably nanoparticle characteristics, including their crystallinity, size, and morphology [3].

Here, the gas-phase crystallization of Au nanoparticles is investigated by molecular dynamics (MD) using the embedded atom method (EAM) that is most relevant to their synthesis by aerosol processes (flame, plasma, laser, etc.). We elucidate the onset of crystallization and growth dynamics of 2.5 – 11 nm Au nanoparticles under isothermal conditions.

The relationship between Au melting point and particle size is used to validate the method. A metastable region of 200 - 300 K wide between the melting point and super-cooled solidifying temperature of Au is revealed as a function of particle size. The crystalline disorder parameters and potential energy are used to elucidate the isothermal crystallization dynamics of Au nanoparticles in three distinct stages at 500 – 800 K (subcritical cluster dynamics, onset of crystallization and crystal growth). The degree of crystallization (predominantly face-centered cubic (FCC) with some hexagonal close-packing (HCP)), is quantified from the local crystalline disorder. In the first stage, before the onset of crystallization, subcritical Au cluster form and deform continuously similar to the subcritical nucleation dynamics of liquid (i.e. water) droplets in the atmosphere. The onset of crystallization is detected by the steep rise of the retained atoms fraction (RAF) of the largest subcritical cluster. This increase is accompanied by a sharp drop of the amorphous fraction of the Au nanoparticle.

In the second stage, crystallization usually starts from the nanoparticle surface as a result of lower kinetic energy barriers there. 3D-snapshots of the Au particle reveal two crystallization nucleation pathways: (A) Catastrophic nucleation when crystallization takes place well below the Au supercooled solidifying temperature resulting in many small crystal domains within the nanoparticle; and (B) Accretion nucleation when crystallization takes place at temperatures near the super-cooled solidifying temperature where fewer nanocrystals are formed that gradually coalesce into larger crystal domains.

In the third stage, after the onset of crystallization, crystals grow via both accretion and cluster merging, with crystal domain reorganization after the crystalline transformation is completed. X-ray diffraction (XRD) patterns are generated, from which the dynamics of crystal growth are elucidated and compared to direct tracing of crystal sizes. The product crystal size is influenced largely by crystallization temperature, with the largest crystal size obtained when crystallization takes place near the supercooled solidifying temperature consistent with the literature [4].

The results of this study can facilitate the process design for aerosol synthesis of Au as well as other metal nanoparticles for optical, electronic, catalytic and biomedical applications.

**Ni Nanostructures Formed via pH-Dependent Corrosion-Redeposition of Thin Nickel Films in Glycine-Based Solutions** Ayrton A. Lima<sup>1</sup>, Duber M. Murillo<sup>1</sup>, Antonio Augusto G. von Zuben<sup>1</sup>, Douglas S. de Oliveira<sup>2</sup> and Monica A. Cotta<sup>1</sup>; <sup>1</sup>University of Campinas, Brazil; <sup>2</sup>Federal University of Parana, Brazil

Nickel (Ni) is an interesting material for several applications, due to qualities including resistance to high temperature, oxidation, and corrosion, which are also present at the nanoscale. In particular, Ni nanowires show many applications in biology, optical devices, solar cells, and sensors, among others. Ni nanostructures have been created so far using a variety of methods, including hydrothermal, laser ablation, and chemical vapor deposition techniques. In this study, we investigate the fabrication of Ni nanostructures via local corrosion of thin Ni films deposited by physical vapor deposition. Slow Ni corrosion is achieved using water, glycine, and calcium chloride static solutions with various pH levels. After a considerable amount of time (24-48 hours) of contact between the Ni film and the solution, micron-sized, roughly circular isotropic corrosion patterns are observed. Scanning Electron Microscopy (SEM) images show that nanostructures form inside the corrosion patterns. Typically, a nanowire-like structure extends vertically from the center of most patterns; for those with larger diameters, very thin planar nanowires extend from this central structure. SEM-based Energy Dispersive Spectroscopy measurements reveal that the central nanostructure is made of Ni, while the composition of the thinner, planar nanowires cannot be resolved using this technique. Our findings via simulations suggest a process of corrosion starting at specific locations such as film defects, with subsequent Ni redeposition due to a radial Ni concentration gradient at the metal film-solution interface. Further studies should determine if this process can be made controllable as a new synthesis process of Ni nanostructures.

**Operando Catalysis Studies from Model Systems to Real Catalysts** [Andreas Stierle](#)<sup>1,2</sup>; <sup>1</sup>DESY, Germany; <sup>2</sup>University of Hamburg, Germany

The atomic structure determination of nano-objects with dimensions in the sub-100 nm regime is a formidable task for today's diffraction, imaging and scanning probe techniques. A detailed structural and compositional analysis is mandatory for a correlation with the nano-object's functionality e.g. as heterogeneous catalysts, magnetic storage material or light emitting device. In conventional x-ray diffraction experiments on powder samples the structural analysis is hampered by a random nanoparticle orientation and often by background scattering from the supporting material. We have therefore focused on the development of model systems based on epitaxial metal nanoparticles on single crystal oxide supports, which can be studied under ambient pressure catalytic reaction conditions. In the first part of my talk I will present different ensemble averaging synchrotron radiation based x-ray diffraction schemes. They deliver quantitative information on the nanoparticle size, shape and facet surface structures under operando reaction conditions for CO oxidation using high resolution reciprocal space mapping and high energy x-ray diffraction [1-4]. In the second part I will focus on experiments overcoming the ensemble average by single nanoparticle imaging and I will discuss future possibilities exploiting the high coherence of high energy photons available at fourth generation synchrotron radiation sources [5].

**An *In Situ* Look at Interfacial Controls on Crystal Nucleation and Assembly** [James J. De Yoreo](#)<sup>1,2</sup>; <sup>1</sup>Pacific Northwest National Laboratory, United States; <sup>2</sup>University of Washington, United States

Interfaces play a critical role in solution-based phenomena, such as ion segregation, mineral nucleation, and biomolecular and colloidal self-assembly. The interface alters the distribution of water and ions from that of the bulk, introduces an interfacial free energy that largely determines the free energy barrier for nucleation, and creates an entropic repulsion that acts like a volume exclusion force to drive colloidal assembly. The origin and characteristic length scales of these phenomena are inherently atomic-to-molecular but are manifest in ensemble dynamics and outcomes. Moreover, processes like nucleation and self-assembly arise from fluctuations, making the events that must be probed transient in nature. Consequently, *in situ* imaging techniques that can capture structure and its evolution, particularly at high speed and atomic-to-nm resolution, are required to build a quantitative picture of such processes. Here I use examples from and *in situ* TEM, high-speed AFM, and fast force mapping studies of interfacial structure, nucleation, and nanoparticle assembly to elucidate the mechanisms by which interfaces direct these processes, leading to unique pathways, materials and morphologies. The results reveal the importance of surface charge, organic ligands, chemical gradients, and solvent organization near interfaces in determining how ordered solids emerge from the solution.

#### 9:00 AM SF02.03.02

**Solvation Directed Dimensionality and Hierarchy Control in Solution Synthesis of Nanomaterials** [Maria Sushko](#), Lili Liu and Duo Song; Pacific Northwest National Laboratory, United States

The development of structural hierarchy on various length scales during crystallization process is ubiquitous in biological systems and is common in synthetic nanomaterials. The driving forces for the formations of complex architectures range from local interfacial interactions, that modify interfacial speciation, local supersaturation, and nucleation barriers, to macroscopic interparticle forces. Although it is enticing to interpret the formation of hierarchical architectures as the assembly of independently nucleated building blocks, often crystallization pathways follow monomer-by-monomer addition with structural complexity arising from interfacial chemical coupling and strongly correlated fluctuation dynamics in the electric double layers. Here, we show that the development of structural hierarchy through heterogeneous nucleation is driven by dipolar and solvation forces. Specifically, coupled simulations and experimental studies revealed that dipole build up along the slow growth direction can trigger twinning and the development of branched architectures. Enthalpic solvation interactions were shown to either enhance or reduce the dipole moment of the nanoparticles and, thereby, control crystal morphology and architecture. The systematic studies of chemical coupling between different solvents and undercoordinated surface atoms of the growing nanocrystals revealed the mechanism of dimensionality control and the development of structural hierarchy in the absence of ligands or

structure-directing agents.

**4D Structures of Colloidal Nanoparticles using Graphene Liquid Cell TEM and Self-Supervised Machine Learning Analysis** Jungwon Park; Seoul National University, Korea (the Republic of)

Colloidal nanocrystals containing a few tens to hundreds of atoms have applications in a range of areas, from electronics to catalysis and biological sensors. This versatility stems from the high sensitivity of nanocrystal properties to size, chemical composition, and shape, which are largely determined by the synthesis route by which they are produced. However, structure characterization based on bulk-originating methods is usually not enough because of the unique structural characteristics emerging at the nanoscale. Exposed surfaces, defects, dislocations, and quantum effects are dominant in nanocrystals of finite size. In addition, the ensemble of nanocrystals produced from conventional colloidal synthesis displays a large degree of heterogeneity in the atomic structures and has the effects of organic ligands and solvent molecules. Thus, understanding the structures of nanocrystals at a level where fundamental structure-property relationships can be linked requires new analysis methods that allow precise and reproducible determination of the positions of the constituent atoms of single nanocrystals directly from the solution phase. We developed a “one-particle Brownian 3D reconstruction method” for the analysis of the three-dimensional (3D) structures of colloidal nanocrystals based on graphene liquid cell electron microscopy. “One-particle Brownian 3D reconstruction” can be applied to not only uni-component metallic nanoparticles but also multi-component nanoparticles such as CdSe, PbSe, and FePt. We further extend 3D structure characterization approach to time-resolved domain such that colloidal nanoparticles undergoing structural transition in solution can be captured in time-resolved 3D resolution. To enable 3D and 4D reconstruction of colloidal nanoparticles directly from liquid phase TEM imaging, a series of large image data processing, a part of which is potentially enhanced by machine-learning based data analysis, is developed.

**Observation of Amorphous-To-Crystalline Transition at the Single-Atom Level** Jianwei (John) Miao; University of California Los Angeles, United States

The amorphous-to-crystalline transition is fundamental to many physical, chemical and biological phenomena, but is a challenging process to study at the atomic scale. An approach to overcome this challenge is atomic electron tomography (AET) (1). AET combines high-resolution tomographic tilt series with advanced computational algorithms to resolve the three-dimensional (3D) atomic structure of materials without assuming crystallinity (2). We have recently advanced AET to determine the 3D atomic structure of amorphous materials and characterize the short- and medium-range order of the 3D atomic arrangement (3,4). In this talk, I will present our most recent results on the application of AET to observe the amorphous-to-crystalline transition in 3D at the atomic resolution. By using a carbothermal shock method (5), we trapped high entropy alloy nanoparticles at different stages of crystallization. We then used AET to determine the 3D atomic structure of the high entropy alloy nanoparticles as a function of crystallization. By quantitatively characterize the 3D atomic arrangement inside a large number of nuclei, we observed crystal nucleation pathways at the single-atom level. We expect that these experimental results not only open the door to study the amorphous-to-crystalline transition at the atomic scale, but also could transform our fundamental understanding of nucleation and crystal growth.

**10:45 AM SF02.03.06**

**Probing the Mass Transport in Iron-Air Batteries using Operando Electrochemical Transmission Electron Microscopy** Hanglong Wu<sup>1</sup>, Joseph S. Manser<sup>2</sup>, Maria Ronchi<sup>2</sup>, Jeff Poirier<sup>2</sup>, Yet-Ming Chiang<sup>1,2</sup> and Frances M. Ross<sup>1</sup>; <sup>1</sup>Massachusetts Institute of Technology, United States; <sup>2</sup>Form Energy, United States

In a rechargeable battery, the transport of ions between the electrode and the electrolyte plays a crucial role in governing electrochemical kinetics and can strongly influence the battery performance. Studying the diffusion of metal ions during battery operation is therefore important in developing new battery designs aimed at mitigating existing technical challenges associated with mass transport, such as dendrite growth. To date, a wide range of techniques, including X-ray/neutron imaging, NMR spectroscopy, and electrochemical impedance spectroscopy, have been developed to study the diffusion phenomena of metal ions under operando conditions. Nevertheless, the experimental determination of the nanoscale spatial distribution of ionic concentration gradients remains a challenge.

Rechargeable alkaline iron-air batteries have recently emerged as the leading candidate for long-duration energy storage due to their environmental friendliness, low cost, safety, and scalability. Although the reverse rusting of iron in alkaline electrolytes has been extensively investigated over the last five decades, the transformation pathways of iron species during this process are still under debate. Specifically, the role of diffusion gradients of the initially formed soluble  $\text{HFeO}_2^-$  species in governing the precipitation of amorphous  $\text{Fe}(\text{OH})_2$  passivation layers during anodic reactions remains poorly understood.

Here we present the use of operando electrochemical transmission electron microscopy (EC-TEM) as a probing technique to investigate the diffusion gradient during battery operation. Using the iron-air battery as a case study, we focus on studying the concentration gradient of the soluble iron ions, i.e.,  $\text{HFeO}_2^-$ , formed during the anodic dissolution of body-centered cubic (BCC) iron at pH 14. We first discuss the importance of electrolyte volume in mitigating the ion diffusion limitations within the confined cell to achieve reproducible cyclic voltammograms. Subsequently, by manipulating the positioning of one or multiple counter electrodes (CE) relative to the iron anode along the electrolyte flow channel, we observe that iron dendrites can grow on these CE electrodes during battery discharge. The concentration gradient of  $\text{HFeO}_2^-$  can therefore be estimated by quantifying the size/mass of these dendrites as a function of the distance from the anode. Our findings suggest that EC-TEM could serve as a useful tool for comprehending the effects of local ion concentration on the morphological evolution of the electrodes in the various battery systems during charge and discharge processes.

**Cinematographic Recording and Analysis of the Whole Process of Crystal Nucleation/Growth at Millisecond Sub-Angstrom Resolution** Eiichi Nakamura; The University of Tokyo, Japan

Chemical phenomena are complex events where a variety of molecules stochastically appear on time scales ranging from nanoseconds to hours. Studying the stochastic behavior of individual molecules requires unconventional methods that differ from the traditional ensemble- and time-averaged experimental techniques. Crystal nucleation/growth is no exception. Since 2004, we have spent considerable effort on developing the SMART-EM technique (Single Molecule Atomic Resolution Time-resolved Electron Microscopy, ref 1, 2). In this talk, I will discuss the cinematographic recording of the whole process of the nucleation and growth of NaCl crystal (ref 3, 4) and of the PAN carbon fiber formation by pyrolysis of polyacrylonitrile (ref 5). We are transforming chemistry from the macroscopic paradigm of thermodynamics to the microscopic statistical mechanical paradigm.

**8:00 PM SF02.05.01**

**Dynamic DNA Nanodevices with Switchable Optical Properties** Soojung Lee<sup>1</sup>, Jason Kahn<sup>2</sup>, Daniel McKeen<sup>1</sup> and Oleg Gang<sup>1,2</sup>; <sup>1</sup>Columbia University, United States; <sup>2</sup>Brookhaven National Laboratory, United States

Advancements in DNA nanotechnology have opened up the ability to fabricate nanomaterials with dynamic properties for applications in optics, medicine, and electronics. Such properties are defined by precisely controlled arrangements of functional nanocomponents. However, there remains a continual challenge in gaining dynamic control of nanoscale materials. DNA-based self-assembly offers a promising approach to form switchable three-dimensional (3D) clusters and large-scale ordered nanostructures that can encapsulate, organize and manipulate various types of nanoscale objects through programmable interactions.

Here we study the assembly, reconfiguration and optical response of a nanoscale device with stimuli-responsive and switchable properties. We utilized a 3D polyhedral DNA frame to establish a system that can switch between different conformations that allow for the manipulation of nanoparticles. Our previous studies have demonstrated that the optical output of a binary self-assembled system composed of gold nanoparticles (AuNP) and quantum dots depends on the interparticle separation distance. With this as a reference, we designed a structurally switchable 3D DNA frame for nanoparticle repositioning. By utilizing a DNA motif that acts as a manipulator, we show an ability to pass molecular information over a distance of tens of nanometers on a frame. We used this principle to investigate how this DNA device is able to direct nanoparticle reconfigurations and induce different optical responses. Interactions between the plasmonic and fluorescent particles were explored by testing various system designs. The structural reconfiguration of the system was examined by electron microscopy and small-angle X-ray scattering (SAXS), while spectroscopic measurements were applied to correlated optical responses with structural switching.

**8:00 PM SF02.05.02**

**Enhancing Biosensor Performance by Optimizing Surface Coverage of the Self-Assembled Monolayer** Jaehyun Kim, Honglin Piao, Daerl Park and Heon-Jin Choi; Yonsei University, Korea (the Republic of)

Self-assembled monolayers (SAMs) are widely used in various fields such as nanotechnology, electronics, and biomedical applications. SAMs are a crucial component in the fabrication of biosensors, as they provide functional surfaces for the immobilization of biological recognition elements. However, non-uniform SAM coverage on biosensor substrates can lead to variability in detection and quantification, which can severely hamper the biosensor's performance. The method proposed in this research includes experimental SAM analysis and prediction of SAM formation results through fitted function. After fixing several deposition parameters such as concentration, temperature, we applied logistic functions to create a function for the deposition rate of SAMs. Using this function, deposition has clearly improved the uniformity of SAMs. This outcome, confirmed through various characterization techniques including atomic force microscopy (AFM), and X-ray photoelectron spectroscopy (XPS), leads to an enhanced biosensor performance in terms of sensitivity and selectivity. To validate the accuracy of our developed function, we employed a comparative approach using machine learning techniques. These techniques, known for their ability to predict complex patterns and interactions, served as a benchmark for our optimization function. Preliminary results indicate that the proposed function holds significant promise in optimizing SAM surface coverage, with performance comparable to or exceeding that of the machine learning models. The proposed methodology not only provides a more stable and predictable biosensor response but also contributes to the advancement in the broader field of biosensing technology. This new approach offers significant implications for the development of high-performance biosensors, enabling more precise and consistent biomedical diagnostics, environmental monitoring, and other related applications. We will show experimental evidences on our proposed approach from glucose monitoring system (GMS).

**8:00 PM SF02.05.03**

**Temperature Measurements During Laser-Induced Graphitization of Polydimethylsiloxane** Masato Kai, Shuichiro Hayashi, Ken Kashikawa and Mitsuhiro Terakawa; Keio University, Japan

Laser-induced graphitization of polymers has attracted attention as a technique to simultaneously form and pattern graphitic carbon on and/or inside polymers. Depending on the laser parameters, the morphology and the crystallinity of the formed graphitic carbon vary with photochemical and photothermal effects. However, the mechanism of laser-induced graphitization of polymers has not been revealed in detail. In this study, we measure the

temperature of a polymer's surface during laser-induced graphitization to investigate the relationship between the laser parameter and the characteristics of the formed structure with regard to photothermal effects. An organosilicon polymer, polydimethylsiloxane (PDMS), was irradiated with high-repetition-rate femtosecond laser pulses at different laser scanning speeds. The temperature of the PDMS surface was measured using a thermography camera. Plano-convex lenses were located between the irradiated surface and the thermography camera for micro-thermographic measurements with a spatial resolution of  $\sim 40 \mu\text{m}$ . The morphology of the formed structure was observed using scanning electron microscopy (SEM), and the crystallinity of the structure was analyzed using Raman spectroscopy, respectively. SEM observations showed that the cross-sectional area of the formed structure increased with the decrease in scanning speed, suggesting that the amount of the energy absorbed by PDMS was positively correlated with the number of irradiated pulses per spot. Furthermore, for significantly low scanning speeds, the formation of cracks was observed in the formed structures, which may be attributable to the laser ablation induced by the excessive amount of energy absorbed by PDMS. Raman spectra showed peaks at  $\sim 1350$ ,  $\sim 1600$ , and  $\sim 2700 \text{ cm}^{-1}$  that corresponds to the D, G, and 2D bands, respectively, indicating the formation of graphitic carbon. Also, a peak at  $\sim 520 \text{ cm}^{-1}$  was observed in the obtained Raman spectra in the case of significantly low scanning speeds, indicating the formation of crystalline silicon. Taking the results of SEM observations into account, it can be assumed that crystalline silicon was formed owing to the high temperature induced by the excessive amount of energy absorbed by PDMS. It was confirmed in temperature measurements that the measured temperature increased with the decrease in the scanning speed, suggesting the increase in the amount of energy absorbed by PDMS with the increase in the number of irradiated pulses per spot. However, in the case of significantly low scanning speeds, the measured temperatures kept constant regardless of the scanning speed, indicating the saturation of the temperature of the laser-irradiated area. The saturation of the temperature at significantly low scanning speeds cannot be explained solely by the change in the amount of the energy absorbed by PDMS. One possible explanation for the saturation is the change in the energy diffusion property of the laser-irradiated area with the change in the morphology and the material composition. It can be suggested from the obtained SEM images that the bulk density of the laser-irradiated area may be changed with the formation of cracks, changing the energy diffusion property of the laser-irradiated area. Moreover, considering the obtained Raman spectra, the formation of crystalline silicon in addition to the graphitic carbon may change the energy diffusion property of the laser-irradiated area.

**Assembly of Short-Sequence Amphiphilic Peptoids into Helical Nanostructures with Controllable Supramolecular Chirality** [Renyu Zheng](#)<sup>1,2</sup>, Mingfei Zhao<sup>3</sup>, Jingshan Du<sup>2</sup>, Yicheng Zhou<sup>2</sup>, Shuai Zhang<sup>1</sup>, Wenhao Zhou<sup>1</sup>, Andrew Ferguson<sup>4</sup> and Chun-Long Chen<sup>2</sup>; <sup>1</sup>University of Washington, United States; <sup>2</sup>Pacific Northwest National Laboratory, United States; <sup>3</sup>Los Alamos National Laboratory, United States; <sup>4</sup>The University of Chicago, United States

A long-standing challenge in biomimetic research is to create sophisticated hierarchical nanostructures that mimic the biomaterials found in living organisms. Self-assembly is a crucial process for creating these nanostructures, but the forces and dynamics governing the self-assembly of biomacromolecules, such as proteins and peptides, are complex. Developing sequence-defined synthetic polymers with simplified molecular interactions is a promising approach to synthesizing information-rich nanostructures and understanding their self-assembly mechanisms. Peptoid is a peptidomimetic molecule that moves the side group from  $\alpha$ -carbon to nitrogen to keep the sequence programmability while simplifying the structure without backbone hydrogen donors and no backbone chirality. Previous studies have shown that amphiphilic peptoids can crystallize into highly ordered nanostructures, including nanoribbons, nanosheets, nanotubes, and nanohelices, by controlling peptoid-peptoid and peptoid-substrate interactions. However, achieving the predictable self-assembly of peptoids into designed nanostructures remains a significant challenge. In this study, we report a system of short tetramer peptoids to form crystalline peptoid helices. Due to the reduced hydrophobic interactions compared to those with six hydrophobic side chains, we showed that the self-assembly of these peptoids into nanohelices and other nanostructures are highly sensitive to the solution ionic strength and solvent condition, resulting in the formation of various nanostructures including nanohelices, nanohelix bundles, as well as nanotubes. We also demonstrate the control of supramolecular chirality of self-assembled peptoid nanohelices by using chiral polar groups with D- or L-configuration. By combining the synchrotron XRD results with molecular dynamic simulation studies, we showed the twisted form of bi-layer structures of these amphiphilic peptoids are the most stable form for those polar side chains to hide hydrophobic domains in the aqueous environment. We further demonstrated that the organic cosolvent in the self-assembly could also affect the self-assembly morphology from nanohelices to nanotubes, which provides additional information on peptoid-solvent interactions as well as the self-assembly kinetics and thermodynamics. Our findings provide a facile system for controlling the twisting and stacking of peptoid amphiphiles into helical and tubular structures and suggest an approach for the precisely controlled synthesis of biomaterials.

**Molecular Dynamics Characterization of Gas Diffusivity of CO<sub>2</sub>-CH<sub>4</sub> in sI Clathrate Hydrates** [Ali Beydoun](#), Alejandro D. Rey and Phillip Servio; McGill University, Canada

Clathrate hydrates are cage-like water structures entrapping a gaseous guest molecule in their cavities. The need for alternative fuel sources has spurred an interest in methane hydrates as estimates predict that they account for two thirds of the fossil fuel global reserves. However, their exploitation is not without fault as methane hydrates occupy a crucial role in stabilizing the soil as well as being a potential major source of greenhouse gases. Fortunately, methane found in clathrate hydrates can be swapped with carbon dioxide (CO<sub>2</sub>), thus allowing for carbon sequestration, and rendering the production of methane effectively carbon neutral. The process has been shown to be feasible and resulting in the formation of stable CO<sub>2</sub> hydrates, but the mechanism surrounding the exchange remains to be elucidated.

This presentation focuses on a system where pure methane sI hydrates are exposed to a front of CO<sub>2</sub> dissolved in water. The system conditions are set to be favorable to the melting of methane hydrates and to the formation of CO<sub>2</sub> hydrates. As the system evolves with time, methane escapes the lattice and CO<sub>2</sub> diffuses into the latter, replacing methane in partially melted cages as well as forming new cages at the interface in a phenomenon known as co-growth. An analysis of the impact of temperature, pressure, and CO<sub>2</sub> concentration on the diffusivity of CO<sub>2</sub> and methane is conducted. It is followed by an analysis on how co-growth at the interface hinders diffusion and prohibits CO<sub>2</sub> from diffusing deeper in the lattice. Previous work found in the literature has quantitatively described the impact of such impediment on the ultimate replacement ratio, but the presented research is the first quantify the effect on mass diffusivity. This work will also discuss the impact of water vacancies and of gas occupancy on mass diffusivity. To understand the effects of vacancies and gas occupancy on the thermodynamics of the system, the Gibbs free energy, the enthalpy, and the entropy are calculated. Our previous work quantified diffusivity in a CO<sub>2</sub> filled hydrate system and the impact of such vacancies and serves as a basis for comparison. The investigation also looks into how diffusion evolves from a non-Fickian process to a Fickian one. Finally, this work also tackles how the swapping mechanism between methane and CO<sub>2</sub> differs near the interface from deeper strata with the hole-in-cage model dominating the latter.

The methodology is based on molecular dynamics. The Large-scale Atomic/Molecular Massively Parallel Simulator (LAMMPS) is used to perform simulations on a 3x3x3 methane hydrate lattice juxtaposing a CO<sub>2</sub> front dissolved in water. The force fields used for methane, carbon dioxide, and water are OPLS-AA, EPM2, and TIP4P/ICE respectively. The LAMMPS software allows to quantify the mean squared displacement (MSD) which can be correlated to the mass diffusivity. Furthermore, LAMMPS computes primordial thermodynamics parameters such as the Free Gibbs energy, the entropy, and the enthalpy.

#### 8:00 PM SF02.05.06

**Investigation of the Amorphization Threshold by Ion Implantation as a Function of Energy and Implant Temperature in Silicon Substrates** [Arianna Rivera](#)<sup>1</sup>, Noel Kennedy<sup>2</sup>, Christopher Hatem<sup>2</sup> and Kevin S. Jones<sup>1</sup>; <sup>1</sup>University of Florida, United States; <sup>2</sup>Applied Materials, Inc., United States

As semiconductor devices continue to scale, ion implantation processes must follow suit to confine fabrication to nanosized structures. One such process is ion-beam induced amorphization, namely in silicon devices. Pre-amorphizing implants are known to increase dopant solid solubility once post-annealed, increasing the active carrier concentration within the recrystallized layer. Because of this, they are often incorporated during the processing of top-off implants, used to decrease contact resistance. The mechanism of silicon-substrate amorphization mechanism varies with ion mass but for heavier ions, it is associated with the overlap of damage cascades induced by nuclear stopping. As such, it should show little dependence on the surface. However, if the point defect accumulation mechanism associated with light ions is active, then the surface may play a role. To better understand the amorphization mechanism at ultra-low energies, the critical threshold for amorphization is investigated for different implant temperatures and energies. Silicon substrates were implanted with  $\text{Si}^+$  ions at low energies between 1 keV to 10 keV and implant temperature was varied ranging between 25°C to 150°C. The dose is kept constant at  $3 \times 10^{14}$  ions/cm<sup>2</sup> at a dose rate of 0.95 mA. The amorphous layer was studied by high resolution cross-sectional TEM and to SRIM simulations to determine the threshold damage density for amorphization. By studying the amorphization extent at varying energies and implant temperatures, it was possible to observe how the amorphization layer thickness produced by the implant differs as the damage becomes closer to the surface. It was found that as the implant energy decreased, the threshold damage density for amorphization increased, suggesting a shift in the amorphization mechanism possibly induced by an increasing role of the surface. The role of implant temperature will also be presented.

**Enhancing the Self-Assembly of Binary Colloidal Crystals with Confinement** [Nathan Huang](#), Rachael S. Skye and Julia Dshemuchadse; Cornell University, United States

Photonic crystals with a bandgap in the visible-light range have been theorized to self-assemble from a binary colloidal dispersion but difficulties remain in robustly assembling high-quality crystals in quantities sufficient for large-scale applications. Computational methods give insight into the conditions under which photonic crystals can self-assemble. In this study, we performed hard-particle Monte Carlo simulations of tetrahedral and octahedral nanoparticles in spherical and flat-wall geometries to determine the influence of confinement on the process and products of crystallization compared to the bulk. Confinement was found to improve crystallization at non-ideal stoichiometries but did not lower the minimal packing fraction at which crystallization occurred throughout the system. Crystals formed under confinement exhibited higher crystallinity and lower quantities of secondary phase defects. These findings demonstrate the potential for enhanced control over the synthesis of novel materials with tailored structures and properties for photonic applications.

**Bimetallic ZnCo Metal-Organic Framework at NiCo-Layered Double Hydroxides for Multiple Storage and Capability Synergy All-Solid-State Supercapacitors** [Nageh K. Allam](#); American University in Cairo, Egypt

Rational design and structural regulation of hybrid nanomaterials with superior electrochemical performance are crucial for developing sustainable energy storage platforms. Among these materials, NiCo-layered double hydroxides (NiCo-LDHs) demonstrate an exceptional charge storage capabilities owing to their tunable 2D lamellar structure, large interlayer spacing, and rich redox electrochemically active sites. However, NiCo-LDHs still suffer from severe agglomeration of their particles with limited charge transfer rates, resulting in an inadequate rate capability. In this study, bimetallic ZnCo-metal organic framework (MOF) tripods were grown on the surface of NiCo-LDH nanowires, which significantly reduced the self-agglomeration and stacking of the NiCo-LDH nanowire arrays, offering more accessible active sites for charge transfer and shortening the path for ion diffusion. The fabricated hybrid ZnCo-MOF@NiCo-LDH and its individual counterparts were tested as supercapacitor electrodes. The ZnCo-MOF@NiCo-LDH electrode demonstrated a remarkable specific capacitance of 1611 F g<sup>-1</sup> at 2 A g<sup>-1</sup> with an enhanced rate capability of 66% from 2 to 20 A g<sup>-1</sup>. Moreover, an asymmetric all solid-state supercapacitor device was constructed using ZnCo-MOF@NiCo-LDH and palm tree-derived activated carbon (P-AC) as positive and negative poles, respectively. The constructed device can store a high specific energy of 44.5 Wh Kg<sup>-1</sup> and deliver a specific power of 876.7 W Kg<sup>-1</sup> with outstanding Columbic efficiency over 10,000 charging/discharging cycles at 15 A g<sup>-1</sup>.

#### 8:00 PM SF02.05.13

**Effect of Sulfate Regioisomerism on Ca<sup>2+</sup>-Heparin Binding Thermodynamics and Implications for Nucleation of Sparingly Soluble Salts** [Brenna M. Knight](#), Connor M. Gallagher, Michael D. Schulz, Kevin J. Edgar, Louis A. Madsen and Patricia M. Dove; Virginia Tech, United States

Heparin is a sulfated glycomaterial of long-standing importance as an anticoagulant in biomedicine due to its antithrombin binding sequence. Many more protein binding sequences are identified in heparin and other glycosaminoglycans (GAGs) but are understudied relative to antithrombin. Heparin and sulfate-rich macromolecules are also widely associated with biological crystallization in diverse animals. However, the lack of systematic and quantitative studies is impeding the potential of furthering heparin applications as well as a mechanistic understanding of how functional groups modulate biomaterialization. Using heparin as a model for understanding the role of sulfate groups associated with macromolecules in biological and synthetic settings, we test the hypothesis that the position of these groups influences Ca<sup>2+</sup> binding to regulate calcite nucleation.

This experimental study employs isothermal titration calorimetry (ITC) to quantify the binding thermodynamics of Ca<sup>2+</sup>-heparin interactions for a group of characterized heparin materials that differ by sulfate regioisomerism. Previous studies indicate Ca<sup>2+</sup>-heparin interactions involve water molecule(s) and are independent of electrostatic interactions. Our preliminary ITC findings show the binding is entropically driven, supporting this model. We further observe sulfate position moderates  $K_{\text{Ca}^{2+}}$  and dramatically alters binding stoichiometry.

In parallel experiments that measure the rate of nucleation of the sparingly soluble salt, CaCO<sub>3</sub>, onto the corresponding heparin materials, we are determining the relationship between sulfate position and the interfacial energy barrier to calcite crystallization ( $\gamma_{\text{calc}}$ ). Initial results suggest materials that more efficiently bind Ca<sup>2+</sup> (i.e., require fewer repeat units per ion) present a higher barrier to nucleation. To better understand this interaction, we are also determining the dependence of NMR relaxation time and chemical shifts on Ca<sup>2+</sup> concentration. This study highlights the potential for using sulfate position to tune and optimize the design of heparin-based materials for advanced material design and biomedical applications.

**DNA-Programmable Assembly in Bulk and at Liquid-Air and Liquid-Solid Interfaces** [Oleg Gang](#)<sup>1,2</sup>; <sup>1</sup>Columbia University, United States;

<sup>2</sup>Brookhaven National Laboratory, United States

Organizing diverse types of functional nanocomponents into the designed 3D architectures promises to enable new functions with a broad range of applications, from engineered biomaterials to photonic devices and energy materials. However, current methods are limited in their ability to create such 3D nanomaterials with prescribed structures and integration of different types of nanocomponents. Using sequence-specific interactions and structural plasticity of DNA we established a self-assembly platform for assembly of designed large-scale and finite-size nano-architectures from diverse inorganic and biomolecular nanocomponents. We applied in-situ and ex-situ methods to reveal the lattice formation processes in bulk and at the interfaces for DNA-programmable systems. By combining designed nanoscale anisotropic bonds and their DNA encoding, we developed assembly approaches that allow for the creation of periodic and hierarchical organizations from inorganic nanoparticles and proteins. The formed nanostructures were further transformed into inorganic 3D replicas via several nano-templating methods. The novel DNA-assembled nanomaterials were investigated for nano-optical, mechanical, electrical and biochemical functions. Furthermore, approaches for integration with surface-based devices were established.

#### 9:00 AM SF02.06.02

**Programmable Colloidal Kagome Superlattices for Anisotropic Light Emission** [Zhiwei Li](#) and Chad A. Mirkin; Northwestern University, United States

DNA-mediated programmable assembly of nanomaterials has given rise to a diverse library of colloidal superlattices and crystals with precise phase and symmetry control. Design rules for colloidal crystallization have been extensively studied but most of them, regardless of structural complexity and phase diversity, are driven by thermodynamically favored processes that lead to maximum DNA hybridization and complete particle surface overlap. Here, we show that the assembly of non-space-filling bipyramids results in partial DNA surface matching and yields colloidal Kagome superlattices. In short, Au pentagonal bipyramids of different sizes are used as building blocks and modified with single-stranded DNA as programmable atom equivalents (PAEs). Driven by DNA hybridization, the bipyramids assemble into distorted Kagome lattices through partial surface matching, featuring shield-like lattices, lattice distortion, bipyramid twisting, and rhombohedral super unit cells. Characterization of these low-symmetry Kagome lattices reveals diverse lattice plasmon resonance modes, which are dependent on the light incident direction and polarization. We take advantage of the Kagome lattice plasmon resonance and report facet-dependent anisotropic light emission enabled by doping dyes into the Kagome lattices. Taken together, this work opens up new avenues towards designing and accessing exotic colloidal superlattices and thus new materials for anisotropic light emission, which has implications for emerging optical platforms such as coupled optics and sensing.

#### 9:15 AM SF02.06.03

**Mapping The Spatial Dependence of Surface Ligand Binding in Individual Nanoparticles** [Zhi Yang](#)<sup>1</sup>, Duaa Ansari<sup>1,2</sup>, Manuel Pichardo<sup>1</sup> and Matthew Jones<sup>1,1</sup>; <sup>1</sup>Rice University, United States; <sup>2</sup>The University of Texas at Austin, United States

While it is well-appreciated that surface ligands bind preferentially to certain locations on an inorganic nanoparticle (e.g. tips vs. flat facets), a quantitative understanding of this phenomenon is lacking. In this work, ligands are “tagged” with small gold nanoparticles so that their spatially-resolved binding positions can be measured in Cryogenic Transmission Electron Microscopy (CryoEM) images. Labeled thiol ligands were then exposed to hexadecyltrimethylammonium bromide (CTAB) modified gold triangular nanoprisms particles, which present energetically distinct face, edge, and tip regions that we hypothesized would reveal different binding properties. By recording the relative positions of ~700 ligand binding events, a 3D energetic map of thiol chemisorption to gold nanoprisms could be generated, revealing a strong preference for edge and tip sites compared to {111} triangular faces. Interpreting these data as a thermodynamic measure of binding probability allows for the use of the Boltzmann distribution to calculate the Gibbs free energy differences between tips or edges relative to faces of -8.01 and -6.81 kJ/mol, respectively, from which relative binding constants can be calculated. This work establishes an experimental platform for quantifying the spatial preferences of ligand binding that, because of the superior resolution of modern TEM instruments, is limited in accuracy only by the effective size of the tag-ligand conjugate.

#### 9:30 AM SF02.06.04

**Interfacial Assembly of Ligand-Functionalized Nanoparticles into Low-Dimensional Architectures** Yilong Zhou<sup>1</sup>, Brian H. Lee<sup>1</sup>, Tsung-Yeh Tang<sup>2</sup> and [Gaurav Arya](#)<sup>1</sup>; <sup>1</sup>Duke University, United States; <sup>2</sup>University of California, San Diego, United States

Self-assembly of nanoparticles (NPs) is a powerful approach for fabricating materials with unique architectures and properties. This is especially important for plasmonic, optical, and electronic applications where nanostructures need to be arranged in non-close packed clusters or periodic arrays to take advantage of the unique electromagnetic couplings that emerge from such arrangements. However, achieving unique and complex assemblies remains a challenging task. In this talk, I will demonstrate how fluid-fluid interfaces can be used to self-assemble ligand-functionalized NPs into exotic 1D and 2D architectures by harnessing the three-way competition between particle-particle interactions, particle-fluid surface energy, and fluid-fluid surface tension. I will begin by demonstrating via molecular dynamics simulations the interfacial assembly of binary systems of spherical NPs into open clusters, quasi-linear strings and networks, and layered structures [1]. Next, I will show how Monte Carlo optimization combined with analytical modeling of interfacial and interparticle interactions can be used to quickly map out the full repertoire of 2D NP superlattices achievable through this interfacial assembly approach [2]. I will also show how this approach can be extended to shaped NPs, where a range of periodic porous superlattices may be assembled from polymer-grafted nanocubes by controlling their orientation at the interface [3]. Lastly, I will discuss the development of multibody potential via a machine learning approach to elucidate the role of multibody effects in the self-assembly of polymer-grafted NPs [4]. Overall, our results suggest that the interfacial assembly approach could be a versatile platform for fabricating 1D and 2D colloidal assemblies of tunable structure and properties.

**Growth Habits and Phonon Modes of Nanoparticle Superlattices** [Qian Chen](#); University of Illinois at Urbana-Champaign, United States

Growth habits of nanoparticle superlattices dictate major design parameters (for example, symmetry, morphology and surface structure) of crystalline materials and consequently their applications. Using liquid-phase TEM, we show that nanoparticles can follow four different growth habits during self-

assembly as governed by nanoparticle interaction and mass transport, leading to distinct surface morphologies. Meanwhile, lattice relaxations at equilibrium are originated from nanoscopic springs and phonon vibrations, which we are able to map and quantify for the first time using single particle tracking and lattice dynamics theory for topologically-engineered nanoparticle superlattices. Our work paves the way for engineering geometries for applications of mechanical metamaterials.

#### 10:45 AM SF02.06.06

**Controlling Coulomb Interactions Among Nanoparticles to Achieve Novel Assembly and Crystallization** Binay P. Nayak<sup>1,2</sup>, Honghu Zhang<sup>3</sup>, Wei Bu<sup>4</sup>, Benjamin M. Ocko<sup>3</sup>, Alex Travesset<sup>1,2</sup>, David Vaknin<sup>1,2</sup>, Surya K. Mallapragada<sup>1,2</sup> and Wenjie Wang<sup>2</sup>; <sup>1</sup>Iowa State University of Science and Technology, United States; <sup>2</sup>Ames National Laboratory, United States; <sup>3</sup>Brookhaven National Laboratory, United States; <sup>4</sup>The University of Chicago, United States

Controlling interactions among nanoparticles is paramount to achieving assemblies vital to technologies seeking to exploit their novel collective properties. Although various techniques have been advanced, robust ones are necessary for upscaling nanoparticle assembly and crystallization. Here, we explore the self-assembly of binary nanoparticle superlattices (BNSLs) at a vapor/liquid interface by grafting gold nanoparticles (AuNPs) with end-charge-polyethylene glycol (PEG). The grafting PEG terminates with either COOH (negatively charged) or NH<sub>2</sub> (positively charged) end groups. Lowering the pH increases the positive charge of NH<sub>2</sub> (to form NH<sub>3</sub><sup>+</sup>) and decreases the negative charge of COO<sup>-</sup> (to form COOH). Such control facilitates the formation of various two- and three-dimensional ionic-like superstructures of oppositely charged binary constituents either at the vapor/liquid interfaces or in bulk. Unlike traditional ionic crystals, this approach enables manipulation of the relative surface charge between the two constituents. We demonstrate this approach by using surface-sensitive synchrotron-based X-ray diffraction at grazing angles of incidence (GISAXS), X-ray reflectivity (XR), and SAXS, and establish the formation of distinct checker-board square and hexagonal lattice structures also by varying the molar ratios of the constituents. The main results of our study are summarized as follows: 1) For 1:1, 2:1, and 1:4 mixing ratios (-COOH: NH<sub>2</sub> terminated-PEG), a checker-board square lattice structure is formed at various pH values. 2) For the 2:1 mixing ratio, lowering the pH transforms the structure from a checker-board structure to a hexagonal superstructure. 3) In the case of extremely low pH, whereas the NH<sub>2</sub> terminated nanoparticles are water soluble, the -COOH terminated forms a single-particle hexagonal structure similar to neutral PEG-grafted AuNPs at the vapor/liquid interface. Our results confront zeta-potential measurements that determine the total charge of each particle. This qualitatively allows for a quick prediction of outcome structures based on pH and the molar mixing ratios. SAXS measurements show executive super-ionic structures in bulk consistent with interfacial observations.

#### 11:00 AM SF02.06.07

**Self-Assembly of Atomically Aligned Nanoparticle Superlattices from Pt-Fe<sub>3</sub>O<sub>4</sub> Heterodimer Nanoparticles** Shengsong Yang<sup>1</sup>, R. A. LaCour<sup>2</sup>, Yi-Yu Cai<sup>1</sup>, Yugang Zhang<sup>3</sup>, Cherie R. Kagan<sup>1</sup>, Sharon Glotzer<sup>2</sup> and Christopher B. Murray<sup>1</sup>; <sup>1</sup>University of Pennsylvania, United States; <sup>2</sup>University of Michigan-Ann Arbor, United States; <sup>3</sup>Brookhaven National Laboratory, United States

Multicomponent nanoparticle superlattices (SLs) promise the integration of nanoparticles (NPs) with remarkable electronic, magnetic, and optical properties into a single structure. Here, we demonstrate that heterodimers consisting of two conjoined NPs can self-assemble into novel multicomponent SLs with a high degree of alignment between the atomic lattices of individual NPs, which has been theorized to lead to a wide variety of remarkable properties. Specifically, by using simulations and experiments, we show that heterodimers composed of larger Fe<sub>3</sub>O<sub>4</sub> domains decorated with a Pt domain at one vertex can self-assemble into an SL with long-range atomic alignment between the Fe<sub>3</sub>O<sub>4</sub> domains of different NPs across the SL. The SLs show an unanticipated decreased coercivity relative to nonassembled NPs. In situ scattering of the self-assembly reveals a two-stage mechanism of self-assembly: translational ordering between NPs develops before atomic alignment. Our experiments and simulation indicate that atomic alignment requires selective epitaxial growth of the smaller domain during heterodimer synthesis and specific size ratios of the heterodimer domains as opposed to specific chemical composition. This composition independence makes the self-assembly principles elucidated here applicable to the future preparation of multicomponent materials with fine structural control.

#### SESSION SF02.07: Macromolecular Crystallization and Assembly

#### 1:30 PM \*SF02.07.01

**Directed Self-Assembly of Diblock, Multiblock, Bottlebrush and Rod-Coil Copolymers** Caroline A. Ross; Massachusetts Institute of Technology, United States

Block copolymer microphase separation, driven by the chemical incompatibility between the blocks, leads to periodic patterns of spheres, cylinders, gyroids, lamellae and other structures with periods of a few nm and above. The microphase separation of thin films of block copolymers can be directed by topographical or chemical substrate features, leading to well-ordered patterns with long range order and/or non-bulk morphologies. This directed self-assembly (DSA) process offers compelling opportunities for the generation of dense patterns with small period which are useful in nanofabrication and nanolithography. The utility of DSA can be enhanced by expanding the range of possible microdomain geometries available, and by developing methods to direct their self-assembly in the out-of-plane direction to make three dimensional structures.

We will describe morphologies created by Si-containing triblock terpolymers, rod-coil copolymers, and bottlebrush copolymers, including zigzags, bends, junctions, tiling patterns and hierarchical structures with two independently tunable periods. As an example, a Janus bottlebrush triblock terpolymer yields layers made up of meshes of one block in a matrix of a second block, separated by layers of a third block. The meshes have sub-20 nm period and various angles, and can be aligned in topographical substrate features. Sequential self-assembly can produce three dimensional structures, including orthogonal mesh patterns, by assembling one block copolymer on another. We also describe metal infiltration of block copolymers by immersion in an acid solution of a metal salt, which locks the self-assembled structure, and reversibility of the metallization by immersion in a solution of a complexing agent, unlocking the structure so that it can evolve in response to annealing. We use in situ grazing incidence small angle x-ray scattering to reveal details of the self-assembly process during thermal or solvent vapor annealing. Combinations of novel polymers, templating approaches, and processing techniques yield an extensive array of rectilinear and 3D pattern geometries that can expand current nanofabrication capabilities.

**2:00 PM SF02.07.02****Mapping the Phase Behavior of Block Copolymer Supramolecular Thin Films using Solvent Vapor Absorption – Desorption Isotherms**

Nayanathara Hendeniya, Caden Chittick, Kaitlyn Hillery, Shaghayegh Abtahi and Boyce Chang; Iowa State University of Science and Technology, United States

The self-assembly of block copolymers has been widely studied over decades as a potential platform in a plethora of nanotechnological applications. Recently, significant attention has been drawn to the self-assembly of BCP-based supramolecules rather than traditional BCPs, as a more efficient method of tuning the morphologies. While the self-assembly of supramolecules is governed by the competition between minimizing the enthalpy of mixing between the blocks and maximizing the conformational entropy, tuning of morphologies and kinetic behavior are heavily influenced by molecular architecture and processing. Solvent vapor annealing is a versatile processive pathway to obtain heavily periodic self-assemblies from high  $\chi$  block copolymers and supramolecules. However, little evidence is found regarding the kinetic behavior of the order-disorder transition of such assemblies during controlled solvent vapor annealing. Adsorption-desorption isotherm is a method of characterizing host-guest interactions in porous materials. A similar approach can be used to understand the interactions between polymer chains and solvent vapor molecules. The present study is focused on understanding the kinetic factors that influence the morphological evolution using characteristic absorption-desorption behavior of cylinder-forming polystyrene – block – poly(4-vinyl pyridine) block copolymer combined with pentadecylphenol (PS – b – P4VP(PDP)) during solvent vapor annealing. We identify the transition points from kinetically trapped initial phase segregation to periodic horizontal cylindrical structures with long-range order using absorption-desorption isotherms. We further investigate the tunability of grain coarsening and macroscopic film dewetting under continuous flow solvent vapor annealing. Atomic Force Microscopy (AFM) is used to characterize surface morphological evolution. Using Grazing Incidence Small Angle X-ray Scattering (GISAXS), the periodicity (D0) and grain size are quantitatively analyzed.

**2:15 PM SF02.07.03****Surface Crystallization of Molecular Crystals by Exsolution from Poly(ethylene)** Bryan Erriah<sup>1</sup>, Alexander Shtukenberg<sup>1</sup>, Reese Aronin<sup>1</sup>, Derik McCarthy<sup>1</sup>, Leilani Smith<sup>1</sup>, Petr Brazda<sup>2</sup>, Michael D. Ward<sup>1</sup> and Bart Kahr<sup>1</sup>; <sup>1</sup>New York University, United States; <sup>2</sup>The Czech Academy of Sciences, Czechia

The properties of synthetic polymers are often tuned with additives. Whilst most additives, like plasticizers, are non-migratory, some are migratory, like lubricants. Blooming and/or bleeding refers to phenomena in which additives in a polymer migrate to its surface; this is a common phenomenon that is important for several industries including food packaging and pharmaceuticals, medicine, art, and the production of long-lasting insecticidal bed nets. Many long-lasting insecticidal bed nets for protection against disease vectors are made of poly(ethylene) fibers in which the insecticide is embedded at the time of manufacture. Insecticide molecules diffuse from within the supersaturated polymers to surfaces and become bioavailable to insects, in most cases eventually crystallizing. Recent studies have revealed that contact insecticides can be highly polymorphic. Moreover, insecticidal activity is polymorph dependent, with forms having higher crystal free energy yielding faster insect knockdown and mortality. Consequently, the crystallographic characterization of insecticide crystals that emerge from fibers is critical to understanding net function and improving net performance. Structural characterization of insecticide crystals on bed net fiber surfaces, let alone their polymorphs, has been elusive owing to the minute size of the crystals that by necessity grow in and on threads, however.

Here we describe surface crystallization of several molecules by phase separation from extruded poly(ethylene) fibers including ROY, paracetamol, flufenamic acid, benzamide, benzil, deltamethrin, alpha-cypermethrin, lambda-cyhalothrin and chlorfenapyr. In general, solutes diffuse from the polymer matrix and form amorphous droplets on the surface. With time the system may undergo substantial evolution from droplet coalescence to metastable crystalline growth, to recrystallizing as more thermodynamically stable forms, a demonstration of Ostwald's Rule of Stages. In general, crystallization on the surface of poly(ethylene) resembles growth from vapor phase and is often limited by diffusion mass transport. With the highly polymorphous compound ROY (5-methyl-2-[(2-nitrophenyl)-amino]thiophene-3-carbonitrile) as a proxy for insecticide crystallization, we investigated blooming kinetics and crystallization on the surface of melt-extruded, and cold-drawn poly(ethylene) fibers that had been impregnated with ROY. The blooming rates, tracked from the time of extrusion, were determined by UV-vis spectroscopy after successive washes. Six crystalline polymorphs (of the 14 known) were observed on poly(ethylene) fiber surfaces, and they were identified and characterized by Raman microscopy, scanning electron microscopy, and 3D electron diffraction (3D ED). We show both polymorph control and particle size/morphology control. These observations reveal that the crystallization and phase behavior of polymorphs emerging from poly(ethylene) fibers is complex, dynamic, and tuneable. Furthermore, the demonstration that 3D ED can characterize the minute crystals grown on fibers promises a pathway to bed net crystallography and subsequent optimization of bed net performance.

**2:30 PM BREAK****3:30 PM \*SF02.07.04****High Throughput Platform to Meet Covarying Materials Manufacturing Design Criteria for Block Copolymer Nanolithography** Paul F. Nealey; University of Chicago, United States

Methodologies and tools for the accelerated discovery and design of materials for use in manufacturing have been transformed over the past decade through the combination and integration of experiment, theory, and computation. Here we build on the integration of experiment and molecular simulation to specify design rules for block copolymer (BCP) materials, for use in the directed self-assembly (DSA) of ultra-high resolution lithographic patterns for semiconductor manufacturing, and report on a high throughput synthesis and characterization platform for discovery and subsequent optimization of BCP materials for this application over a range of pattern dimensions. The design rules are agnostic to specific polymer chemistries and are derived from equilibrium (thermodynamic) and non-equilibrium (dynamic) predictive physics-based models that were validated by comparison to one of a kind quantitative experiments using the only BCP material and DSA process that have been successfully implemented in an industry-relevant format, at one serendipitously-found pattern dimension, and interrogated by state-of-the-art inspection tools so as to be known to satisfy manufacturing constraints. In a departure from conventional materials development, multiple co-varying properties must be simultaneously optimized in the BCP materials, and materials of different chemistry and composition must be developed for each pattern dimension over the desired range. A key advance to develop a family of different materials to realize these objectives is the design and implementation of a high throughput discovery-oriented synthesis and characterization platform using interchangeable polymer components to explore a large and complex parameter space to find possible combinations of components that satisfy the design rules at different pattern dimensions. The large data sets acquired from the high throughput methodologies then allow rapid convergence on the synthesis of BCP materials for specific objectives in the application space.

**4:00 PM SF02.07.05****Assembly of Sequence-Defined Peptoids into Crystalline Nanomaterials as Biomimetic Catalysts** Chun-Long Chen<sup>1,2</sup>; <sup>1</sup>Pacific Northwest National Laboratory, United States; <sup>2</sup>University of Washington, United States

While natural enzymes, including lignin peroxidase, phosphotriesterase, and carbonic anhydrase, are promising for various applications, such as lignin

depolymerization, degradation of toxic organophosphates, and accelerated CO<sub>2</sub> precipitation, there are numerous key technical barriers to prevent their practical applications, because they often suffer from low stability and high cost. To circumvent these barriers, researchers have started to develop synthetic materials as enzyme mimetics with enhanced stability for various purposes. Despite tremendous efforts made in this area, constructing highly efficient and robust enzyme mimetics with natural enzyme-like flexibility in tuning active sites and microenvironments remains a grand challenge.

In this presentation, we will report our recent progress in developing peptoid-based crystalline nanomaterials as highly robust and programmable catalysts for a variety of applications. Peptoids are one of the most advanced classes of sequence-defined synthetic foldamers that bridge the properties of proteins and polymers.<sup>1-4</sup> While exhibiting protein- and peptide-like molecular recognition, peptoids offer unique opportunities for controlled synthesis of hierarchically-structured crystalline nanomaterials<sup>1,5-7</sup> exclusively through side-chain chemistry due to the lack of backbone hydrogen bond donors. Because of highly tunable features and robustness of these peptoid-based crystalline nanomaterials, they provide an ideal platform to mimic nature enzymes by offering high surface area, programmable microenvironments, and other unique advantages. For example, comparing to a typical lignin peroxidase which contains one active site per enzyme molecule, peptoid-based crystalline nanotube catalysts can accommodate a high-density of active sites to achieve a significantly enhanced catalytic activity in lignin depolymerization.<sup>8</sup> Moreover, due to their high chemical and thermal stability, these peptoid-based catalysts can be operated at a variety of conditions, such as at elevated reaction temperature and broad pH range which nature enzymes denature.

##### **Reconfigurable Multi-Component Assemblies Built from DNA Origami Voxels** Minh Tri Luu<sup>1</sup>, Jonathan Berengut<sup>2</sup> and Shelley Wickham<sup>1</sup>:

<sup>1</sup>University of Sydney, Australia; <sup>2</sup>University of New South Wales, Australia

DNA origami is a robust nanofabrication method that enables the biomimetic self-assembly of diverse nanostructures with nanoscale addressability and reconfiguration. Hierarchical assembly of DNA origami components into larger assemblies offers a pathway to create larger or more complex structures. However, challenges remain in achieving structural diversity, rigidity, and programmable reconfiguration. Here we present a universal and robust DNA origami building block to support 2D and 3D hierarchical assembly that combines rigid DNA barrel monomers with rigid connections. The building block is modular and contains 14 directional binding interfaces in 3D, each with multiple DNA strands that can hybridise with connector strands to create rigid connections within hierarchical assemblies.

We demonstrate the use of DNA barrel monomers as modular voxels to build diverse multi-component assemblies with intricate custom features and addressable components for potential materials patterning. DNA strand displacement reactions are used to switch connections between flexible and rigid states, enabling rapid and reversible shape transformations of assemblies with high yield. Additionally, we explore strategies to improve the yield of hierarchical assembly of DNA origami. Inspired by protein assembly, we investigate multi-step folding pathways. Initially, we assemble individual DNA origami building blocks into a flexible linear chain of linked DNA origami. We then fold these chains into more compact structures in several steps, resulting in improved yields for certain pathways. We envision that DNA origami chains could be integrated with scalable assembly methods to build new materials with rapid and high-yield reconfiguration.

SESSION SF02.08: Poster Session II

#### 8:00 PM SF02.08.01

##### **Bio-Inspired Physical Unclonable Function Labels Fabricated by Self-Assembly Processes** Su Eon Lee<sup>1</sup>, Junhyun Park<sup>1</sup>, Jang Hwan Kim<sup>2</sup> and Bong Hoon Kim<sup>1</sup>; <sup>1</sup>Daegu Gyeongbuk Institute of Science and Technology, Korea (the Republic of); <sup>2</sup>LG Chem Ltd., Korea (the Republic of)

The demand for robust verification and recognition techniques is increasing because of the evolution of Internet of Things (IoT) and wireless data storage systems. Although authentications with software systems are prevalent, they are susceptible to external threats like hacking and electronic interference. For these reasons, verification methods with hardware systems using physical unclonable functions (PUFs) have been interested in applying wireless interconnection devices and network-based data servers. The validation process using PUFs relies on the electrical and optical signals generated from micropatterns or randomly oscillating signals in electronic devices, and the verification of these encrypted signatures typically depends on complex and time-consuming measurement instruments.

In this poster, we introduce bio-inspired PUF labels fabricated by self-assembly processes. BCP self-assembly forms randomly oriented nanopatterns (i.e., fingerprint-like lamellar structures) as small as 5 nm across the broad area because of the thermodynamical microphase separation. We fabricate the multi-layered nanopatterns from the randomly oriented BCP templates by stacking a thin layer of the metallic lamella structures *via* the transfer printing process on non-planar and flexible surfaces for wearable or soft electronic devices. As the purpose of the verification systems, we produce multiple independent keys, utilizing electrical resistance, optical dichroism, or Raman signals for high-security rates and fast scan speeds.

The multiple-layered fingerprint-like nanoscale PUF labels respond to the electrical potentials and polarized visible light, which can generate non-deterministic keys by physically measuring the electrical resistance, optical dichroism, and Raman scattering. We decrypt the respective or integrated signal according to the purpose with scan speeds of ~10 μs (resistance), ~1 μs (birefringence), ~100 ms (Raman scattering), and ~1 ms (Integrated methods). Moreover, we can form PUF labels on paper bills, deformable transparent polymer substrates, human wrists, human hair, ant bodies, and microbacteria by a transfer printing process, which provides ultra-high security rates, simultaneously rapid validation speeds, and universal application to the PUF labels.

In conclusion, we show randomly oriented BCP nanopatterns applied to the PUF labels with robust and secure properties and meaningful encoding abilities, which offer unpredictable signals for identification, utilizing electrical and optical response with fast scan time. Our approach reduces the critical

dimensions of PUF labels, has the potential to be a versatile platform for advanced authentication systems, and can be used for discreet miniature identifiers on various surfaces or integrated multikey authentication systems. Integrating PUFs seamlessly with essential validation tools is the next valuable step, enabling versatile applications, including hardware-based on-demand cryptographic key generation.

#### 8:00 PM SF02.08.03

**Effects of Crystallization on Micromechanical Behavior of Polyethylene Nanocomposites** Mason Martell, Linda S. Schadler, David Punihaole and Frederic Sansoz; University of Vermont, United States

The addition of small amounts of nanofillers to a polymer matrix has been shown to impart significant changes in mechanical, dielectric, and optical properties. A common challenge in creating these polymer nanocomposites (PNCs) is controlling the dispersion of the nanofillers. Recent work has demonstrated methods to control dispersion and organization of spherical nanoparticles (NPs) in compatible matrices. At sufficiently slow crystallization rates in semicrystalline polymers, the NPs organize in the amorphous regions of the growing spherulites. PNCs with organized NPs have been shown to exhibit improved bulk mechanical properties, but the micromechanical behavior underpinning these has not been fully explored. In this study, in-situ Raman spectroscopy was performed on polyethylene samples under tensile load to explore differences in micromechanical behavior between neat, filled but unorganized PNCs, and PNCs with crystallization-induced particle organization. Crystallization of each sample was characterized in DSC, and organization of PNC samples confirmed by SAXS and TEM. Results show that the addition of fillers leads to a significant change in the distribution of load between the crystalline and amorphous phase. Shift is only apparent in samples that undergo necking (high strain), consistent with previous work on neat polyethylene.

#### 8:00 PM SF02.08.04

**Self-Assembled Tetrapod Molecules on Graphite Form Nanopockets with Attractive Force Distribution Studied by 3D Scanning AFM** Moe Ogasawara, Masayuki Morimoto and Hitoshi Asakawa; Kanazawa University, Japan

The precise design of molecular architectures through molecular self-assembly on solid substrates is a promising approach for developing next-generation materials and their functions. The molecular architecture having nanopockets that can capture target molecules with high selectivity and affinity has immense potential for use in sensing devices and separation materials with molecular recognition functions. Toward the design and construction of molecular architecture with nanopockets, we have been exploring molecular building blocks having three-dimensional (3D) extended structures. Furthermore, we have developed a molecular-scale analytical technique based on atomic-resolution atomic force microscopy in liquid.

For the applications of molecular nanopockets, not only nanoscale surface structures such as molecular orientation, but also the recognition mechanism of how guest molecules and host nanospaces interact is an important research topic. However, the lack of a measurement method for interaction forces in 3D nanospace has made it difficult to improve the understanding of the recognition mechanism. We have developed a 3D scanning atomic force microscope (3D-AFM) that can visualize hydration structures and surface fluctuation structures at the solid-liquid interface with sub-nanometer resolution. Conventional AFMs scan the tip only in the XY direction, but 3D-AFM scans the tip in the Z direction in addition to the XY direction, making it possible to obtain 3D force distribution information. Combined with the frequency shift detection method, 3D-AFM can also detect the interaction force acting on the tip at the piconewton (pN) level. Based on this principle and performance, we believe that 3D-AFM technology can be applied as an analysis tool for "interaction force measurement" as well as "structural measurement."

We have performed direct visualization with 3D-AFM of the characteristic interaction force in 3D nanospaces at the self-assembled molecules/water interface. Two types of tetrakis(4-ethynylphenyl)methane (TEPM) derivatives with oligo(ethyleneglycol) (EG<sub>n</sub>) chain (EG<sub>2</sub>-TEPM, EG<sub>4</sub>-TEPM) were used as the building blocks and these TEPM derivatives form self-assembled monolayers on graphite. In the monolayers, there are hydrophobic nanopockets (diameter: approx. 1.7 nm) surrounded by the aromatic structure of the TEPM derivatives. We performed 3D-AFM measurement at the self-assembled monolayers/water interface. As a result, characteristic localized attractive interaction was visualized only at the EG<sub>2</sub>-TEPM monolayer/water interface, and analysis of the 3D-AFM images suggests that the attractive interaction forces originate from the nanopockets and that the nanopockets of EG<sub>2</sub>-TEPM are slightly smaller than those of EG<sub>4</sub>-TEPM. The number of hydrogen bonds forming the water molecule network and the water molecule density are reduced in restricted spaces, such as inside the EG<sub>2</sub>-TEPM nanopockets, compared to the bulk water. The visualized attractive interaction forces seem to originate from the water molecule behavior in the nanopockets. Our results demonstrate that the 3D-AFM technique has the capability of visualizing the characteristic interaction forces at the single molecule level, suggesting future contributions to the elucidation of the molecular recognition mechanisms and the design of novel nanodevices.

**Low Temp Heterogeneous Integration of Ultra-Thin-Silicon Interposer via Transfer Printing and Laser Bonding** Uhyeon Kim, Seungbeom Kim, Junhyung Kim, Agha A. Jan and Seok Kim; Pohang University of Science and Technology, Korea (the Republic of)

Interposer-based 2.5D heterogeneous integration packaging is being used as a key technology for next-generation semiconductor miniaturization that will lead "Beyond Moore." However, traditional wafer bonding techniques and flip chip processes have limitations in handling very thin silicon interposers (<30µm) that can be easily deformed. In this study, we developed a process of stably transferring and bonding ultra-thin silicon interposer with high accuracy using transfer printing technology through Shape Memory Polymer (SMP) stamp and laser heating.

The ultra-thin silicon interposer is designed as a transferable ink of Micro-Lego technology. Copper TSV (Through-Silicon Via) and Cu-Sn solder bump were formed on silicon on insulation (SOI) wafers with predefined thickness, and an independent ultra-thin interposer with a thickness of 15µm was prepared by separating the Box Layer. The interposer was accurately and stably transferred to the receiver substrate by and Shape Memory Polymer (SMP) stamp. At this time, the stamp is made by Shape Memory Polymer that can selectively transfer through heat deformation. Thereafter, the laser was irradiated to the interposer and coupled using a low-temperature bonding (~230°C) method suitable for the Cu-Sn eutectic condition. The interposer bonding was successful after finding the low-temperature bonding conditions according to the variables of laser power, time, and metal layer thickness to be used in the semiconductor post-process. The bonded interposer was characterized by FIB, IV curves, etc... This ultra-thin integration technology has advantages such as low-temperature bonding, low signal loss in channels, and low heat generation, so high-performance low-power packaging can be expected.

#### 8:00 PM SF02.08.08

**Tuning Semi-Crystalline Polymer Thin Film Structure via Substrate Nano-Geometry Modulation** Roberta Ruffino, Giovanni Li Destri and Giovanni Marletta; University of Catania, Italy

The ability to create ultra-thin functional polymer films with controlled nano-crystallinity structure for large-scale integration is at the focus of numerous experimental and theoretical works. [1-3] The main goal is to control and manipulate the assembly of building blocks to obtain structures with desired

characteristics and unique properties. The geometric constraints imposed by the nanometric thickness and interfacial interactions affect the self-assembly process and, in turn, their behaviour. [4,5] In addition, non-planar substrates, such as nano-curved substrates, can further complicate the resultant structure as already observed for block copolymer thin films. [6,7] The combination of geometric effects, i.e. surface curvature, with surface free energy (SFE) may allow more finely controlled self-assemblies. To this end, we have developed a novel approach to prepare substrates with controlled nano-curvature and surface-free-energy (SFE), to be used to investigate how geometric and energetic factors affect the self-assembly of polymeric thin films. [8,9] In particular, by employing a semi-crystalline model polymer, namely poly-3-hexylthiophene (P3HT), it was observed that the crystals follow the surface curvature only in the presence of an energetic gain.[8]

Here, from the structural characterization via synchrotron radiation grazing incidence X-ray diffraction (GIXRD) and the morphological characterization via atomic force microscopy (AFM), we will demonstrate a non-conformal coverage, after the polymer equilibration, showing that the crystallization strongly depends on the surface curvature. The results suggest the polymer accumulation in the interstices between the particles for the lowest curvature, leading to an in-plane crystal growth. The increase in curvature improves the nucleation probability, leading to shorter crystals on both interstices and curved portions. Moreover, we demonstrate that the crystalline fraction is strongly curvature-dependent, as the crystallization only occurs when the distance between two neighbour particles is higher than the lamellar folding period. Finally, the in-situ structural characterization during thermal cooling shows a variation in the crystallization temperature ( $T_c$ ) as a function of the substrate geometry, with a decrease in the onset of the crystallization with respect to the flat substrate. These results highlight the role played by the substrate in the crystallization process, suggesting that the geometric factors affect the crystalline structure itself, with the formation of distorted crystals following the surface curvature. The reported work provides a novel and easy method to modulate the structure of polymer films by exploiting geometric distortion and interfacial interactions with possible effects on the functional properties of the polymer film. This correlation sheds more light on how these factors influence the polymer film crystallization and could allow the determination of the crystallization enthalpy and its related loss when a nanometric strain is applied. A deeper understanding of this behaviour could pave the way for the development of finely tailored crystalline structures via control of the substrate geometry and energy.

**Spray Deposited Block Copolymer Thin Films with Solvent Evaporation Controlled Domain Orientation** Semih Cetindag, Beatrice Bellini, Ruipeng Li, Esther Tsai and Gregory Doerk; Brookhaven National Laboratory, United States

With their ability to self-assemble spontaneously into well-defined nanoscale morphologies, block copolymer (BCP) thin films are a versatile platform to fabricate functional nanomaterials such as lithographic nanopatterns, nanoporous membranes and optical metasurfaces. An important yet unsolved challenge to wider deployment of BCPs in nanofabrication, however, is combining the desired precise control of BCP assembly with scalable deposition techniques that are applicable to large-area, curved and flexible substrates for high-volume manufacturing. Ultrasonic spraying is a scalable, non-batch casting method with minimal wasted polymer, yet its use in thin film BCP assembly has not been investigated.

Here, we show that the latent orientation (vertical vs. horizontal) of well-ordered cylindrical domains in spray-deposited, optically-smooth thin films of polystyrene-block-poly(4-vinylpyridine) (PS-*b*-P4VP) can be controlled by regulating solvent evaporation kinetics. Faster evaporation during deposition facilitates assembly of vertically oriented cylinders spanning the entire film thickness (100-300 nm) upon subsequent solvent vapor annealing. In comparison, slow solvent evaporation induces assembly of horizontal cylinders, imposing an additional energy barrier for reorientation to vertical cylinders during solvent vapor annealing. Using in-situ characterization by synchrotron grazing-incidence small-angle X-ray scattering (GISAXS), we identify the relevant timescale for polymer vitrification which determines latent cylinder orientation. This dependency on solvent evaporation kinetics is exploited to control cylinder orientation in multiple ways, including substrate heating, forced convection, and solvent formulation. To highlight the scalability and utility of the spray casting technique, an exemplar application using spray deposited self-assembled patterns on curved surfaces will also be described.

*Funding: This research was conducted at the Center for Functional Nanomaterials (CFN) and the National Synchrotron Light Source II (NSLS-II), which are U.S. Department of Energy (DOE) Office of Science User Facilities, at Brookhaven National Laboratory under Contract No. DE-SC0012704. S.C., B.B., and G.S.D. were supported by a DOE Early Career Research Program grant.*

**Controlling Structural Changes in 2D Magnets using In Situ Microscopy and Machine Learning Techniques** Julian Klein and Frances M. Ross; Massachusetts Institute of Technology, United States

Electron beam patterning raises exciting prospects for modifying the crystal structure and hence physical properties of 2D materials, and has been explored for several 2D materials in single or few-layer form. Here we examine the opportunities arising from patterning thicker, more robust crystals of 2D semiconducting magnets, intriguing materials in which the local ordering of spins determines both the magnetic properties and the optical response. CrSBr is one such material, having layers with alternating magnetic moment and a structure in which Cr atoms located in their own columns are separated by columns of mixed S and Br atoms. For 10-50nm thick multilayer crystals, we find that broad-area irradiation by electrons reorganizes CrSBr into a new structure, which is also van der Waals-bonded but with a layer orientation and calculated magnetization that are rotated by 90° from the initial direction. Further structural changes can be generated if we irradiate the structure along rows of Cr atoms to open local gaps, changing the calculated interaction

between magnetic atoms. Extending to the ultimate objective of controlling the position of individual Cr columns requires the use of machine learning techniques to track column positions, direct the beam and evaluate whether the desired modification has been achieved. We will describe strategies for achieving this goal and for understanding the process by which the Cr atoms are rearranged. We conclude by discussing correlative techniques to measure the optical and magnetic properties of the modified material, and the more general opportunities arising from patterned recrystallization of multilayer van der Waals bonded magnetic materials for spin-based and optical quantum devices.

#### 9:00 AM SF02.09.02

**Mechanism and Kinetics of Topochemical Etching for Synthesis of 2D MXenes from Layered MAX Phases** Mark Anayee, Ruocun (John) Wang, Stefano Ippolito, Mikhail Shekhirev and Yuri Gogotsi; Drexel University, United States

MXenes represent a rapidly growing family of 2D transition metal carbides and/or nitrides, which exhibit unique combinations of properties, including metallic conductivity, hydrophilic surface chemistry, redox-active surface, and plasmonic behavior that make them attractive as electrodes for pseudocapacitive energy storage to coatings for electromagnetic interference shielding, transparent conducting displays for optoelectronics, conductive yarns for functional textiles, implantable electrodes for medicine, and many other applications.

MXenes are typically derived via selective etching of atomically thick 'A' layers from precursor layered MAX phases using HF-based aqueous etchants. However, the chemical etching process is only somewhat optimized for one composition, and is nonetheless often slow, with low-yield, and results in defects in the materials. Thus, understanding the fundamental mechanism and kinetics of the etching reaction is needed to rationally explore etching of yet-to-be synthesized MXene compositions and optimize etching of existing MXene compositions. Despite their importance, such studies have been challenging because of the atomic thickness of the A-element layers being etched and the aggressive etchants that hinder in situ studies.

Here, we spatially track the etching front in 3D (using analytical setups for tracking byproduct gas evolution), 2D (using cross-sectional imaging of partially etched particles), and 1D (using in situ optical microscopy and profilometry of single particles). Thus, we show the role of surface oxide and binary carbide impurities on the nucleation of etching, and we discovered a layer-by-layer growth process for the etching front. From kinetic modeling, we show that etching varies from reaction-limited to diffusion-limited for various MAX compositions. Overall, our work enables rational high-throughput optimization of synthesis for all MXene compositions, scaling up synthesis towards industrial levels, and tailored synthesis for specific applications.

#### 9:15 AM \*SF02.09.03

**Dynamics of Advanced Low-Dimensional Materials by Low-Voltage Atomic-Scale TEM Experiments** Ute A. Kaiser; University of Ulm, Germany

To create next generation functional low-dimensional materials, it is a growing demand in materials sciences to understand their formation mechanisms as well as their structural and electronic properties at the atomic or molecular scale. Some of the most challenging tasks nowadays are related to energy storage, nano-catalysts or battery materials.

A unique type of transmission electron microscopes operating at electron energies between 80keV and 20keV was developed, which allows to undercut most of the materials knock-on damage thresholds and enables sub-Angstrom resolution in an 4000x4000 pixels sized image, single-shoot image down to 40keV by correcting not only geometrical but also the chromatic aberration of the imaging lens [1-3]. This instrument is used for the in-situ studies presented here. Before we discuss several in-situ TEM experiments, we develop a detailed understanding of the electron beam - 2D specimen interactions: By density functional theory molecular dynamics we show that excitations in the electronic system can form vacancies through ballistic energy transfer at electron energies, which are much lower than the knock-on threshold for the ground state. We propose a two-step vacancy formation process as combination of elastic and inelastic events, evaluated also by an U-net-based fully convolution neural network (FCN) [4].

Based on this knowledge, we discuss the dynamics of properties of point, line and extended defects in various transition metal - dichalcogenides and -phosphor dichalcogenides [5-8]. Optical measurements are performed independent of the TEM experiment. To relate optical and TEM results we demonstrate proof-of-principle experiments in which we transfer electron-exposed defect-characterized TMD flakes from a TEM grid to arbitrary substrates and relate the subsequently performed photoluminescence and transport signals to the defect structure [9].

Furthermore, we present in-situ studies of a miniaturized electrochemical cell, where reversibly single-crystalline bilayer graphene is lithiated and delithiated in controlled manner using an electrochemical gate confined to a device protrusion [10] and report on the Li crystal nucleation and growth during lithiation and Li-O formation and amorphization during delithiation. We generate further encapsulated metal-atom-dimers within single-walled carbon nanotubes and observe the dynamics of single metallic bond formation by exact measurements of the interatomic distance [11].

At the end we show that the approaches of graphene encapsulation and lowering the electron accelerating voltage (here from 300kV to 120kV) can be successfully applied for imaging 2D organic materials at the molecular level [12-14].

**Surface Dynamics of Atomically Controlled Electrodes for Clean Energy** Magali Lingenfelder; EPFL, Switzerland

Our society faces a critical challenge in shifting from a reliance on carbon-based energy to sustainable renewable sources. A key step towards achieving clean energy lies in developing efficient catalysts that can convert chemical energy into electricity or use electrons to generate chemical energy.

In our research group, we tackle these challenges by creating customized materials that draw inspiration from nature (biomimicry) and combine principles from interfacial chemistry and surface physics. For this presentation, I focus on the process of photosynthesis as inspiration for the design, characterization,

and dynamic nature of functional interfaces that drive energy conversion processes such as CO<sub>2</sub> electroreduction and water splitting on the surface of Earth-abundant materials.

I will also discuss the application of cutting-edge scanning probe microscopy and Raman spectroscopy under electrochemical conditions, which allows us to visualize dynamic processes at the nanoscale (*operando* imaging). Additionally, I will highlight our use of unconventional strategies that leverage the assembly of chiral molecular layers and two-dimensional materials to enhance electrocatalytic conversion processes. (References : Nanoletters, 2021, 21, 2059; Nature Comm., 2022, 13, 3356, IJC 62, 11, 2022).

#### 10:45 AM \*SF02.09.05

**Interfacial Liquid Water on Graphite, Graphene and 2D Materials** Ricardo Garcia; Consejo Superior de Investigaciones Científicas, Spain

Solid-water interfaces have a prominent role in a variety of fields such as surface science, geochemistry, electrochemistry, energy storage or molecular and cell biology. Liquids near a solid surface form an interfacial layer where the molecular structure is different from that of the bulk. Yet the molecular-scale understanding of the interactions of liquid water with solid interfaces is unsatisfactory for the lack of high-spatial resolution methods. Here I will present an AFM-based method that provides atomic-scale resolution images of solid-liquid interfaces.

The presentation is divided in three sections. The first section is an introduction to the relevance of solid-liquid interfaces. The second section, presents the features and capabilities of 3D-AFM [1-3] to image with atomic resolution the **three-dimensional** interfacial structure of surfaces immersed in aqueous solutions. The third section reports the structure of interfacial water layers on different **2D materials** from graphene to a few layer MoS<sub>2</sub>; from hexagonal boron nitride to a few layer WSe<sub>2</sub>. Those interfaces are characterized by the existence of a 2 nm thick region above the solid surface where the liquid density oscillates [4-8]. The distances between adjacent layers for graphene, few-layer MoS<sub>2</sub>, h-BN and pentacene are ~0.50 nm. This value is larger than the one predicted and measured for water density oscillations (~0.30 nm). The experiments demonstrate that on extended **hydrophobic surfaces water** molecules are **expelled** from the vicinity of the surface and replaced by several molecular-size hydrophobic layers.

**Modeling and Experimental Analysis of Vertical and Lateral Growth of 2D Mo<sub>2</sub>C Crystals via Chemical Vapor Deposition** Goknur Cambaz Buke<sup>1</sup>, Omer Caylan<sup>2</sup> and Tarik Ogurtani<sup>3</sup>; <sup>1</sup>TOBB ETU, Turkey; <sup>2</sup>Massachusetts Institute of Technology, United States; <sup>3</sup>Middle East Technical University, Turkey

This study investigates the growth of Mo<sub>2</sub>C crystals through Chemical Vapor Deposition (CVD) on Cu substrates. The research combines theoretical and experimental approaches to examine both the vertical and lateral growth of Mo<sub>2</sub>C crystals. A physico-mathematical model is developed, incorporating bulk and surface diffusivities, as well as solubility gradients for Mo<sub>2</sub>C crystal growth. Nonlinear flow equations are used to predict Mo<sub>2</sub>C crystal growth rates in vertical and lateral directions within the Mo-, Cu-, Mo<sub>2</sub>C layer framework. The model correlates the height and diameter of the Mo<sub>2</sub>C crystals with the thickness of the copper layer and time, which is then validated through experiments and imaging techniques such as SEM and AFM. The results highlight the significant influence of the copper layer thickness on the height of Mo<sub>2</sub>C crystals, while its impact on the lateral dimensions is less critical. The study goes beyond enhancing Mo<sub>2</sub>C crystal growth and explores the synthesis of tailored Mo<sub>2</sub>C crystals for specific applications. The developed forward model provides a platform for further advancements and exploration of related material analogs.

**Interface and Interlayer Dynamics in 2-D MnO<sub>2</sub> via *In-Situ* Characterization** Scott T. Misture; Alfred University, United States

Supercapacitor electrodes can be prepared from MnO<sub>2</sub> nanosheets exfoliated from highly crystalline powder particles and subsequently flocculated to form porous solid electrodes. Restacking of the 2-D nanosheets in packets of ~5 layers affords high surface area electrodes with highly flexible interlayer spaces for electrochemical activity. The talk centers on the application in-situ and in-operando studies using high energy X-ray diffraction, X-ray pair distribution functions, EXAFS/XANES and Raman spectroscopy. We show that linking electrochemical measurements to local structure characterization results enables us to understand the mechanisms by which charging occurs in supercapacitor electrodes. The data show that the re-stacked 2-D nanosheets go through a phase transition during charge/discharge wherein the interlayer chemistry alters the interlayer stacking in a subtle but detectable manner. The presence vs. absence of interlayer water and electrochemically active ions including Na, K or Rb define the interlayer stacking. Using a combined approach that tracks the Mn oxidation state, the local structures (via PDF and Raman) and charge/discharge electron exchange forms a clear picture of the physical mechanisms at play, including mechanisms of capacity fade.

SESSION SF02.10: Materials Surfaces II  
Session Chairs: Goknur Cambaz Buke and Mohsin Qazi  
Thursday Afternoon, November 30, 2023  
Sheraton, Second Floor, Republic A
